The Effect of Health Education Based on the Health Belief Model about Pap Smear Test on Women in Rural District Indonesia

Ernawati¹, Dina Oktaviana¹, Mantasia¹, Rezky Aulia Yusuf², Sumarmi¹

¹Nursing College, STIKes Tanawali Takalar; ²Faculty of Public Health, Universitas Muslim Indonesia

Abstract

Background: The aim of this study was to evaluate the effectiveness of educational interventions based on Health Belief Models (HBM) on the adoption of cervical cancer screening and prevention behaviours in Indonesian women in a rural district.

Method: This is a quasi-experimental study with pre-test and post-test design. The convenience sampling was used and a total of 100 women participated in this study. One hour educational intervention based on a health belief model including lectures, question and answer, group discussions and booklets on cervical cancer and cervical cancer screening provided to participants. The content of the session included basic information regarding cervical cancer facts, important early detection, recommended screening method, guidelines for Pap smear screening and the role of pap smears in early diagnosis of cervical cancer. As well as, pamphlets distributed to participants. Post-test test hold within six months after the end of the intervention.

Results: The findings showed that the mean difference of the scores before and after health educational intervention about Pap smear and cervical cancer for all constructs (except; perceived susceptibility and severity were no changes) has increased significantly with P-value <0.001.

Conclusion: Providing rigorous information to women about the risk of cervical cancer the benefits of early detection of cervical cancer and having regular Pap smear tests are crucial to increase the intention to undergo cervical cancer screening among women in a rural area.

Keywords: Health education, health beliefs model, Pap smear.

Introduction

Cervical cancer is the main cancer in women, and the leading cause of death in women around the world including in Indonesia¹,². According to WHO data in 2012, in Indonesia cervical cancer is the second leading cause of death on women with cancer, with an incidence of 20,928 cases and 9,498 deaths, cases per 100,000 women. In addition, the burden of cervical cancer is very high (> 80%) in developing countries³.

Early detection of cervical cancer can prevent or delay the progression of cervical abnormalities to become invasive⁴. Pap smear screening is effective in reducing the incidence and mortality of cervical cancer cases⁵-⁷. In fact, when cervical cancer is found early, it is possible to treat it. Starting June 2014, the Indonesian government has offered free Pap smear screening to married women over the age of 30 to reduce the incidence of cervical cancer. In Indonesia, women with low socioeconomic status generally seek healthcare only when they experience the symptoms, and it is strenuous to treat the advanced stage of cervical cancer⁸.

DOI Number: 10.37506/mlu.v21i2.2636
According to the health belief model (HBM), women are quicker to seek health services if their perceptions of vulnerability and seriousness related to certain health conditions are high, barriers to carrying out such behavior are low, and the benefits of engaging in health behaviors are very important. Similarly, health beliefs about cervical cancer screening have been shown to be important in determining behaviors associated with cancer prevention. Knowledge has an important role in influencing women’s decisions to undergo cervical cancer screening. Research shows that having sufficient knowledge of cervical cancer and a screening program increases the acceptance and use of available screening services. Designing efficient educational programs by selecting suitable and influential theories or models for behavior change. Health education is the main basis for all cancer prevention interventions in women. The aim of this study was to evaluate the effectiveness of educational interventions based on health belief models on screening behavior and prevention of cervical cancer in women in Indonesia.

Method

A quasi-experimental study with pre-test and post-test designs was used to evaluate the effectiveness of educational interventions based on a health belief model in preventing cervical cancer among Indonesian women in Takalar district. Post-test hold within six months after the end of the intervention. Convenience sampling was applied to recruit a sufficiently representative sample of the target population in Takalar District, a rural area with an estimate of around 66,000 women (Central Bureau of Statistics, Takalar District, 2012).

The inclusion criteria for study participants were married women, aged ≥18 years, able to communicate using Indonesian (national language), regardless of whether they could read or not. The exclusion criteria were women with a history of cervical cancer or hysterectomy. G*Power version 3.1.9.2 was used to perform sample size assuming α = 0.05, power level = 0.8, and an effect size of 0.36. The minimum sample size is estimated to be 59. Given the 10% reduction rate, a total of 70 participants will be recruited into this study.

Measurements: All variables were measured using a questionnaire. Health Beliefs Model Scale for Cervical Cancer and Pap The Smear test (HBMSCCPS) was used to assess the health confidence of cervical cancer screening. The scale was modified from the Champion Health Beliefs Model (CHBM) scale and the HBMSCCPS consisted of 35 items (5 subscales) with a five-point Likert scale from strongly disagree (score 1) to strongly agree (score 5). HBMSCCPS retest tests ranged from 0.79 to 0.87 and Cronbach’s alpha ranged from 0.62 to 0.86. The questionnaire consisted with five subscales; “benefits of pap smear test” consisted 8 questions, “barriers to pap smear test” for 14 questions, “perceived seriousness of cervical cancer” for 7 questions, and “health motivation” consisted of 3 questions. The mean of the item-Content Validity Index (I-CVI) was 0.99 and the mean -CVI score was 0.97 for Indonesian questionnaire. As well as, the internal consistency of HBMSCCPS with Cronbach’s alpha = 0.69 for the total score.

Data Collection Procedure: The principal investigator (PI) and one research assistant collected and analyzed the data. After obtaining IRB approval from Muhammadiyah Jogyakarta University, PI will seek permission from the head of the community health center, and also visit community health cadres in each district to identify potential subjects that meet all the inclusion criteria. Women who met the inclusion criteria and agreed to participate were provided with informed consent to be read and signed, and then asked to complete a pre-test questionnaire, including demographic data, intention to take cervical cancer screening, Health Belief Model Scale for Cervical Cancer and Pap Smear Test.

One-hour educational intervention based on a health belief model including basic information regarding cervical cancer facts (e.g. epidemiology, signs/symptoms and risk factors for cervical cancer development), important early detection, recommended screening method, guidelines for Pap smear screening and the role of Pap smears in early diagnosis of cervical cancer. Pamphlets were also be distributed to all participants. The post-test will measure after the end of the intervention.

Statistical Analysis: The analysis was carried out using SPSS version 26.0. Descriptive statistics of proportion used to analyze the demographics data and for Health Model Belief data used a paired sample t-test to provide further description and evaluation of the intervention with a statistical significance of 0.05.
## Result

The table showed that the characteristic of the total 100 respondents participated in this study. The results showed that the average age of the participants was 39.66±1.25. The majority of the participants were Muslims (99%), Makassarnese (97%), married (92%), worked as housewife (76%), history of partum (86%) and income <1.5 million per month (74%). In addition, 60% of total participants had received cervical cancer and Pap smear information. Most of participants reported never did Pap smear (91%), as well as most of them did not have family and friends with the history of cervical cancer respectively 97-98%.

Table 2 reported that the mean scores of the construct of the benefits of Pap smear test in pre-test were 3.8±0.78 and after the intervention increase to 4.2±0.79 with the statistically significant (P<0.001). Related on the construct of barriers to Pap smear showed the mean scores before intervention were 3.1±0.63 and 3.4±0.81 after interventions with the p value 0.001. In addition, the construct of perceived seriousness of cervical cancer and susceptibility to cervical cancer revealed no change in the mean scores before and after intervention. While, related the construct of health motivation showed the mean scores increased from 3.9±0.93 to 4.2±0.90 respectively before and after intervention with p value<0.001.

Table 3 showed the mean difference before and after intervention for the construct of benefits of Papsmear test were increased 0.4, while the construct of barriers to Papsmear and health motivation were increased 0.3.

Discussion

The major focus of this study is to investigate the effect of health educational intervention based on health belief model scale in improving the health confidence of cervical cancer screening among adult women in Takalar, a rural district in South Sulawesi Indonesia. Of total 100 respondents received 40-60 minutes health educational intervention.

This study revealed that there was a significant increase of the confidence on participants based on the perceived benefits of Pap smear test subscales. This findings is similar with the result of another study among 70 women in Iran, this study found that women were more sensible of the advantages from doing pap smear after the education. Further, this finding were also proved by other studies. The highlight on perceived benefits has been emphasized in some studies about the persuasion of adults’ women to undertake the Pap smear test. Considering to the impact of knowledge on practice, lack of knowledge about the advantages and the functions of the pap smear might be as the caused for poor practice of pap smear. Consistent with our results, another study also knew the lack of knowledge as one of the primary reasons of low participation on the cervical cancer screening test. After the intervention of health education, the level of knowledge was improved notably that was emphasized on the effect of the health education on participants’ knowledge. This study findings validated by other similar studies. Another study has also confirmed the impact of educational intervention on increasing women’s knowledge and participation in cervical cancer screening program. However, there was appositive relationships for designing educational interventions for changing the knowledge levels and women beliefs.

Furthermore, this study also found that there was a significant decreased of the perceived barriers to undergo Pap smear test among the women after the intervention. Designing and implementing educational program based on health belief model can promote women’s
awareness and reduce their perceived barriers and as well as enhance their practice regarding Pap smear test\textsuperscript{15,18}. This findings may refers to the effectiveness of educational intervention based on the Health Belief Model that has caused the women in the intervention group able to overcome the barriers\textsuperscript{15}. This findings is contrast with other studies which reported that educational intervention increased the perceived barriers in intervention group\textsuperscript{13,14}. Psychological barriers for instance fear and embarrassment have been the most crucial barriers among women.

With regards to perceived susceptibility and severity in intervention group showed no effect on the confidence of taking cervical cancer screening program. It might be due to insufficient intervention time for influencing the attitudes of the adult’s women\textsuperscript{13}. In contrast with other study that reported the increasing in the mean scores after receiving education about cervical cancer\textsuperscript{14,16}. Moreover, regarding the health motivation subscales showed that there was a significant increased on women motivation to do Pap smear test. This result also supports by the study among 106 women in Iran that showed the mean difference of the scores before and immediately after educational intervention was significant higher than score before intervention\textsuperscript{19}.

This study has some limitations; the sample limited to women who referred to the healthcare centers and only include small sample group. Further, it is suggested that future research should recruit participants from variety groups of women, increasing the total number of participants would also allow for a more robust results and analysis. As well as, this research had pre- and post-intervention measurements at two times, which showed only the short-term effects of the health educational intervention.

**Conclusion**

Generally, the results of this research suggested that health education based on Health Belief Model guide to encourage women to do Pap smear test. By considering the advantages of taking Pap smear as a helpful screening tools, health educational intervention based on Health Belief Model is highly advocated in healthcare centers.

Abstract

Introduction: Healthcare waste are considered infectious and hazardous. It requires specific handling prior to its disposal and poses a stern dangers to ecological, occupational and public health if not managed with caution. Hazardous waste management is a concern for every health care organization and for every healthcare professional.

Objective: The objective of the study was to know association demographic social determinants, working status, knowledge and attitude with practice of disposal infectious waste among health personal in hospital Province of Bengkulu

Methodology: A quantitative descriptive cross-sectional Study design was used. The research was carried for the period of five months from February 2019 to August 2019 and the sample size is estimate base on the multiple logistic regressions.

Result: In this study, most of the respondents (42.06%) not good practice of disposal infectious waste. The multivariate analysis reported age (Adjusted OR: 1.44, 95% CI: 1.04 to 2.01) with p-value: <0.030, education (Adjusted OR: 1.40, 95% CI: 1.04 to 1.90) with p-value: <0.028, management system (Adjusted OR: 5.24, 95% CI: 3.04 to 9.03) with p-value: <0.001, knowledge (Adjusted OR: 1.85, 95% CI: 1.30 to 2.63 with p-value: <0.001, attitude (Adjusted OR: 5.21, 95% CI: 3.06 to 8.86) with p-value: <0.001.

Conclusion: Almost half of hospital health personal had poor practice of disposal handling infectious waste in Bengkulu Province, Indonesia. Infectious waste management system was strongly influence on practice disposal waste.

Keywords: Infectious Waste, Social Determinants, Working Status, Knowledge, Attitude, Hospital Bengkulu.

Introduction

The hospital is not only a place of patient care but also can be a place of disease spread. Hospital waste may be dangerous to risk to patients but also to other health workers. Medical waste is very dangerous and then they need special care and management before the final disposal. Every countries have regulatory systems on medical waste depending on their own country’s finances, regulations and political capacity as well. Generally, Indonesia have universal waste transfers and transport vehicles that it used to transfer health waste from the point of activities to the care and disposal facilities. Indonesia is the country with the most results from health-care waste across the country.[1,2,3]

A research in 2004 indicated that around half of the hospitals surveyed carried out waste separation.
However, most of Health-Centers activities used to mix their waste at landfills along with domestic waste or burned them in their backyard. Generally overcoming hospital waste has been using incinerators as the most common medical waste handling technology. However, the specifications of their standard operating tools and procedures have not been good yet. The level of knowledge about hospital waste hazards is also very low at all levels of health facility personnel.\(^{[4,5]}\)

The absolute number of clinical waste made in Indonesia is around 225 tons every day and the normal/quiet/bed/day of creation squander - 0.68 kg/bed/day.\(^{[6]}\)

The Management of emergency clinics must oblige data about the threats of irresistible waste and report pretty much the entirety of the means, not simply the isolation cycle. \(^{[7]}\)

The population of Bengkulu province in 2015 is 1,874,944 million people, consists of 10 residences have 22 hospitals that do not perform hospital standard medical waste management. Thus, about health care waste information in Bengkulu province still lack off details information. This study will focus on quantity of infectious waste in hospital, the implementation to integrate it according to regulation and the knowledge and attitude of hospital workers about health care waste at public and private hospitals in Bengkulu Province.\(^{[8]}\)

The right actions and less of knowledge on the management of handling waste infection will be result to happen of nosocomial infection. Furthermore, several studies have concluded that the advent of pathogenic bacteria in various types of general waste, clinically sharp waste and another waste. The results of research show that clinical solid waste contains various types of nosocomial and practical bacterial pathogens like *Staphylococcus aureus* and *Pseudomonas aeruginosa*.\(^{[9]}\)

Clinical waste ought to be taken care of appropriately, including irresistible, obsessive, sharps, drug, genotoxic, synthetic squanders, hardcore hefty squanders pressurized compartments and radioactive waste. Good system of waste management can reduce incidence of healthcare workers. The system can reduce the incidence of injection of syringes and nosocomial infections also. It is crucial to create a condition of safe working good atmosphere for health workers.\(^{[10]}\)

This paper is an attempt to provide with a review of hospital waste management practices of among workers, who are considered as the integral part of health care and are the focal members of health care team dealing with health care waste.

### Methodology

This studied design with cross sectional study, collect general data for descriptive and after that researcher will conduct with quantitative method and calculated, to know about Practice Infectious Waste Management System (segregation to transportation process) of Socio Demographic factors (age and education attainment), Working Status (occupation, position, work experience, working day/week, working hour/day, average personal income), Management system infectious waste, Knowledge of disposal infectious waste and Attitude infectious waste of health personal at small hospital of Bengkulu Province, Indonesia. The method included questionnaire adopted by government policy in Indonesia.

The sample in this study was taken as many as 825 respondents from 7 hospitals (type B and C) hospitals province of Bengkulu. The research sample consisted of 590 nurses, 129 midwives, 16 sanitation workers and 20 doctors.

The type of dependent variable is a dichotomous outcome and the statistics that use to answer the research question is multiple logistic regressions and the sample size is estimate base on the multiple logistic regressions formula (Hsieh, Bloch, & Larsen, 1998) and is calculate by software STATA version 14.

**Ethical Consideration:** Written Consent from participants was taken before including them in study. The data collected from the correspondents has been kept purely confidential and only used for statistical analysis about study.

### Results and Discussion

The finding of a 40% not good practice of disposal waste, therefore the future studies might with largest of hospitals. The socio economic characteristics of respondents were showed mean age was 35.79±6.48 SD years old consist of male (26.42%) and female (73.58%). They were married (79.03%) and (20.97%) single. Almost all of the respondents were Diploma degree (51.03%) followed by bachelor degree (43.88%), high school (4.48%) and Master degree (0.61%).
The working status characteristics of respondents were showed in Table 4. Half of them have working in inpatient unit (64.61%) have outpatient unit (19.39) and other (16%). They occupation have nurse (71.52%) have midwife (15.64%) and other (12.84%). Type position respondent were permanent staff (61.45%) and temporary staff (38.55%) and almost of the respondent have work experience less than 10 years. Most of respondents working more than 6 days per week (82.42%) and working more than 8 hours per days (62.30%). Monthly per capita income of respondents ranged from 850,000.- to 5,000,000 Indonesia Rupiah with the mean 2,399,000 and SD 893,092.

Table 1. Associated with demographic factors in Bengkulu Sumatra is used simple logistic regression.

</table>

The results showed that nurses who had low knowledge about treatment process 41.02% of the total nurses were 686 respondents, midwife had low knowledge about treatment of 37.98% of the total midwife of 135 respondent, sanitarian officer had low knowledge about treatment and transportation 50% of the total sanitarian account of 23 respondent and doctors had low knowledge of transportation 30% of the total doctors of 15 respondent.
Multiple logistic regression was performed for multivariate analysis which including variable that reported statistical effect on practice in bivariate analysis. The multivariate analysis reported age (Adjusted OR: 1.44, 95% CI: 1.04 to 2.01) with p-value: <0.030, education (Adjusted OR: 1.40, 95% CI: 1.04 to 1.90) with p-value: <0.028, management system (Adjusted OR: 5.24, 95% CI: 3.04 to 9.03) with p-value: <0.001, knowledge (Adjusted OR: 1.85, 95% CI: 1.30 to 2.63 with p-value: <0.001, attitude (Adjusted OR: 5.21, 95% CI: 3.06 to 8.86) with p-value: <0.001 and level of finding information literacy (Adjusted OR: 2.31, 95% CI: 1.48 to 3.59) with p-value: <0.001.

In this study, most of the respondents (42.06%) not good practice of disposal infectious waste, it means that personal health have good practice (57.94%), age > 35 years old (44.12%), high school and diploma (45.63%). Based on the results of research study conducted in the metropolitan city of Pakistan found that out of 275 including doctors, nurses, paramedics and sanitary workers were interviewed that only 28% had good practice following the proper guidelines and WHO rules, > 35 years old 36% and high school and diploma (51.6%) \[11\]. Furthermore, the practice of officers in the management of medical waste carried out in hospital of Kebumen Indonesia, it was find that (22.2%) had poor practice while respondents who had good practices obtained results (77.8%). \[12\]

In line with the findings with present study the research by Hence, Sahiledengle, B.\[13\] that reported of four hundred and nine healthcare workers cooperated in the study, for a response rate of 97.4% were factors that associated with self-reported healthcare waste segregation practice. The differences in the results of this study are due to differences in the number of study samples, locations and research questions. This research is an action that is observe is an active process of activities from segregation to infectious waste disposal of infectious waste.

In light of the outcome, got ordinary and powerful preparing of clinical understudies is significant. Regular mindfulness missions and classes ought to improve the information about safe dealing with and removal of biomedical waste among clinical understudies for future pragmatic application. \[14\]

**Conclusion**

Almost half of hospital health personal had poor practice of disposal handling infectious waste in Bengkulu Province, Indonesia. Infectious waste management system was strongly influence on practice disposal waste. Therefore, hospital should be doing promotion about impact of practice infectious waste. The target of promotion should be all of personal health and the promotion could be using mass media and community in hospital.

Management of Hospital should be provided some poster or brochure which explained about danger of infectious waste and how to prevent. Health care professional should improve their knowledge about infectious waste. Besides, they should discover if poor waste management practices have a bearing on the health of hospital staff.

Future study might be conducted with qualitative studies it can be providing better understanding and knowledge in practice disposal infectious waste.

Abstract

The development of prenatal diagnosis has developed very rapidly over decades. Prenatal screening is applied to a mother with high-risk pregnancy (threatening the life of the fetus), such as a too-old mother or a too-young mother and having a certain disease in her medical history. Up until now, the curative method to treat genetic disorder is still developed and perfected. Therefore, a preventative action during pregnancy is important to do, such as Noninvasive Prenatal Testing (NIPT). NIPT method that is widely developed is the circulating cell-free fetal DNA (cffDNA) testing that can be useful for determining the fetal gender, the identification of specific single-gene disorders, blood type, paternity determination, and the potency of regular use for testing chromosomal abnormalities. The detection of cell-free fetal DNA in the maternal blood circulation provides a new expectation for NIPT, especially preventing the severity of genetic disorders.

Keywords: Cell-free fetal DNA, Prenatal diagnosis, Genetic disorder.

Introduction

The development of prenatal diagnosis has developed very rapidly over decades. Firstly, amniocentesis was developed at the beginning of 1970 and chorionic villus sampling (CVS) was developed at the beginning of 1980. Invasive prenatal diagnosis (CVS and amniocentesis) is not a low-risk option for all mothers, because there are many limitations that need to be improved. The invention of cell-free DNA (cf DNA) began from a study conducted by Mandel and Metals in 1948 showing the availability of nucleic acid (DNA) circulating in the peripheral blood. Furthermore, a further study was conducted by Bianchi et al., in 1997 to identify fetal cells in maternal blood report the method to isolating the cells. Dennis Lo, in his research findings, also reported the existence of cell-free fetal DNA (cffDNA) circulation in the plasma of pregnant women. These findings paved the way for developing Noninvasive Prenatal Testing (NIPT). The discovery of cell-free fetal DNA in maternal plasma in 1997 triggered the scientists to develop a reliable method, namely noninvasive prenatal diagnosis.

Cell-Free Fetal (cff) during Pregnancy: In 1953, Peter Brian Medawar, in his publication, explained the immunological tolerance during pregnancy. Peter suggested that there was anatomy that became a barrier between a mother and the fetus. For his finding, he was awarded a Nobel prize in 1960. However, as time went by, his finding was proven wrong. During pregnancy,
fetal cells flow across the placenta to the maternal circulation and vice versa, and the fetal cells can be identified as stem cells. Cell free fetal (cff) DNA is from trophoblast cells. Hence, the fragment of fetal DNA is released to the maternal circulation after the degradation of trophoblasts, the apoptotic fetal cells circulating in maternal blood can be the minor source of cffDNA. In the maternal blood circulation during early and late pregnancy, there are around 3 to 6% of the total cffDNA.

In the current development by using microfluidic digital polymerase chain reaction (PCR), it shows a higher concentration of fetal DNA than expected of around 10 to 12% from the total DNA in the maternal plasma. The size of circulating cffDNA mostly in the form of a short fragment of DNA; its length is around 193 bp (base pair) and it can be detected since week 4 of pregnancy, even though it can be definitely known since week 7 of pregnancy, and the concentration is significantly increased during the last 8 weeks of pregnancy. The half-life of cffDNA is around 16 minutes and is undetectable 2 hours after giving birth.

The Potency of Genetic Materials in Maternal Plasma as Biomarkers for Fetal Abnormalities: A study on genetic materials in maternal plasma during pregnancy as biomarkers had a special challenge. It is due to a high number of fetal components that can pass through the placenta or are directly released from the placenta, and it is important to note that the fetal components can be isolated and distinguished according to maternal biofluids.

(1) **Protein:** Human plasma proteome is an invaluable resource to assess health status and since it reflects the physiological status of an individual. Protein as biomarkers in prenatal diagnosis for congenital malformation has not been widely investigated and understood. Clinically, the application of maternal plasma proteins is an analysis of alpha-fetoprotein (AFP) analysis for neural tube defects (NTD).

(2) **Micro RNA:** MicroRNA (miR) is a series of short RNAs with a length of around 22 nucleotides and it is functional for gene expression. A unique microRNA profile can also be used as biomarkers for congenital malformation. Congenital diseases like congenital diaphragmatic hernia (CDH) and congenital heart disease (CHD) can be associated with the failure of miR gene expression.

In the development, the miR profile, besides being a new diagnostic instrument in certain diseases, potentially can be biomarkers for fetal health.

(3) **Long Non-Coding RNAs:** Long RNA non-coding (lncRNA) is a DNA transcription with a length of more than ~200 nucleotides and has no protein code. Gu et al., identified five lncRNAs (ENST00000436681, ENST00000422826, AA584040, AA709223, dan BX478947) from maternal plasma to detect fetal congenital heart disease. LncRNA has a big potency as prenatal biomarkers yet it still needs further investigation.

(4) **Circular RNAs:** Circular RNAs (CircRNA) are circular RNA particles resulted from the ligation of pre-mRNA (‘back-splicing’). CircRNA has a circular structure and remarkably high stability in biological matrices, such as plasma and saliva. A study by Peng et al., showed that circ-ZNF609 was detected in the tissue of a patient with Hirschsprung (HD) disease. Since the stability of circRNA is high and it plays a role in cell differentiation, it fulfills the requirements as biomarkers for fetal abnormalities.

(5) **Circulating Fetal DNA:** Circulating Fetal DNA (cfDNA) is produced from the placenta to maternal circulation during pregnancy; cfDNA is from cytotrophoblast and apoptosis in the syncytiotrophoblast or syncytiotrophoblast fusion in the physiological condition. cfDNA as biomarkers can provide information to patients for medical decision-making without increasing the risk of pregnancy loss and providing additional diagnostic information, treatment planning, the strategy, and the management of counseling.
using the target sequence; this method uses a different fraction of coding sequence and is detected in all chromosomes, however, the target sequence amplifies either non-polymorphic or polymorphic regions.1,2,7 The NIPT method refers to circulating cfDNA testing and it can be used for fetal gender, the identification of specific single-gene disorders, blood type, paternity determination, and the potency of routine use for testing Down Syndrome (DS) in all pregnancies.8 Several latest studies showed that the screening method is the most effective way for trisomy 21, with a detection level of more than 99% and a false positive rate of around 0.1%, coming from cfDNA testing.2

Conclusion

Non-Invasive Prenatal can be used as an initial health screening test and enhanced by fetal examination to see abnormalities either through diagnostic tools or maternal serum biomarkers. One such serum biomarker is using cfDNA for fetal and genetic diagnosis the chromosomal conditions of this examination have a major influence on the development of fetal medicine practice around the world.

Measurement the Levels of Catalase Activity, Malondialdehyde and Ferritin in Beta-thalassemia Major Patient

Abdalaziz Ali Shakir¹, Alaa Mohammad Hasson Al-Husseini²

¹Research, ²Assit. Prof., University of Al-Qadisiyah, College of Science, Department of Biology, Iraq

Abstract

The present study has been carried out at the Women’s and Educational Children’s Hospital in the city of Samawa to determine the level of oxidative stress indicators and level ferritin. 66 samples of a patient with beta-thalassemia major were collected and observation of some clinical signs was followed, the group of a patient was divided into two subgroups according to the splenectomy, Group One (G1)) Included 52 samples from beta-thalassemia major patients, type non-splenectomy, (G2) included 14 samples from thalassemia patients splenectomy and 34 samples were collected from healthy males as control samples (C) to measure the level the activity of Catalase enzyme (CAT) and concentration levels of malondialdehyde MDA as oxidative stress indicators by using the Spectrophotometer and level ferritin using vidas. The results showed a significant decrease (p<0.05) in the efficacy of catalase and a significant increase (p<0.05) in the level of the MDA and level ferritin in beta-thalassemia major patients compared to control group.

Keywords: Beta-thalassemia, splenectomy, MDA, CAT.

Introduction

Thalassemia: It is a genetic disorder in the synthesis of haemoglobin widespread in the world. The distinguishing feature of thalassemia is the synthesis of unbalanced globin chains, as the synthesis of the α-chain takes place at a normal rate, in contrast, a decrease in the production of the β-chain, which leads to deposits A large intracellular basis leads to ineffective erythrocyte production and a set of subsequent pathophysiological mechanisms(1). Oxidative stress is a disturbance in the balance between oxidants and antioxidant enzymes present in the body. Oxidative stress occurs in patients with beta-thalassemia major as a result of increased levels of lipid peroxides and intermediate free radicals, as well as a decrease in the total capacity of antioxidants caused by repeated blood transfusions due to severe anemia. The use of iron chelation agents with antioxidants material can be useful in regulating antioxidant status in patients with beta-thalassemia major(2) Perform frequent blood transfusions in patients with beta-thalassemia major, iron levels are increased, making the red blood cells vulnerable to oxidative stress(3) Due to increased generation of free radicals and lipid peroxidation, and a decrease in total antioxidant capacity, lead to an imbalance between oxidants and antioxidants that results in oxidative stress(4) Patients with beta-thalassemia major receive regular blood transfusions monthly to prevent severe anemia and allow the normal growth and development of the body(5). Each unit of donor blood contains 420ml of blood and about 200mg of iron(6) While blood transfusions prevent many complications of severe anemia, the body is unable to get rid of the iron overload that accompanies every blood transfusion, so it is deposited in the tissues and organs, leading to damage and failure of the body’s systems(7). By stimulating the formation of reactive oxygen species (ROS) causing chronic oxidative stress the excess quantities of iron convert oxidants into high-energy radicals represented by hydroxyl radicals from ROS through the Fenton/Haber-Weiss reaction(8). Which leads to oxidative stress, as ROS acts on lipid peroxidation of free cell membranes to form lipid hydroperoxides, which upon their dissolution form cell-toxic secondary compounds such as alkanes and aldehydes (such as MDA), which is a by product of the lipid peroxidation process, which reflects cases of increased generation of free radicals and Oxidative stress(9). MDA is a biomarker of oxidative damage(10). Also, it is considered one of the indicators of iron concentration in the liver, and chronic blood transfusion in thalassemia patients is associated with the cumulative damage of iron in the tissues(11). The level of MDA in the blood plasma of beta-type thalassemia major patients
increases (1-8) times compared to healthy subjects\(^{(12)}\). Also, the levels of cellular antioxidant vitamins such as vitamins A, C and E, and enzymatic antioxidants such as catalase, glutathione peroxide and glutathione in patients with beta-thalassemia major, compared to the normal level for healthy people, indicates the effect of disease on antioxidant systems\(^{(13)}\). The presence of the catalase enzyme as an antioxidant system in all cells and at high concentrations in red blood cells works to remove hydrogen peroxide by analyzing it into molecular oxygen and water\(^{(14)}\). It is one of the most abundant antioxidants that work to reduce the types of reactive oxygen (ROS) that accompany many diseases such as thalassemia, aging, cataract, atherosclerosis, diabetes and nutritional deficiencies\(^{(15)}\).

**Materials and Method**

This study was conducted at the College of Science/Al-Qadisiyah University for the period from 1/10/2019 to 1/10/2020, as 66 samples of males with Thalassemia were collected in the Thalassemia Center in Samawah, and they were previously diagnosed, and they were divided into two groups: Group One (G1)) Included 52 samples from beta-thalassemia major patients, type non-splenectomy, and the second group (G2) included 14 samples from Thalassemia patients splenectomy, and 34 samples were collected from non-infected males as control samples (C), with ages ranging from 18 to 40 years for all samples.

**Sample collection:** About 4 ml of venous blood was drawn by syringe from the current study samples, then transferred to gel tubes without anticoagulant and then left for 20 minutes at room temperature for blood to coagulate, and then transferred to a centrifuge for ten minutes at 3000 rpm. Then, collecting and transfer into 3 test tubes to use in measuring the level of ferritin,MDA and CAT.

**Measuring the level of ferritin:** The serum concentration of ferritin was measured by automated equipment (Vidas). The assay principle combines an enzyme immunoassay competition method with a final fluorescent detection (ELFA). The solid phase receptacle (SRP) serves as the solid phase as well as the pipetting device for the assay. Dispensed in the sealed reagent strips. All assay steps are performed automatically by the instrument. The reaction medium is cycled in and out of the SRP several times. The sample is taken and transferred into the well containing the antigen labelled with alkaline phosphate (conjugate). Competition occurs between the antigen present in the sample and the labelled antigen for specific anti-ferritin antibody coated on the interior of the SRP. During the final detection step, the substrate (4-Methyl-umbelliferyl phosphate) is cycled in and out of the SRP. The conjugated enzyme catalyzes the hydrolysis of this substrate into a fluorescent product (4-Methyl-umbelliferyl) the fluorescence of which is measured at 450nm.

**Measurement of catalase activity:** The method (Aebi, 1974) was followed to investigate the level of activity of the enzyme catalase in the blood serum, which depends on the activity of the enzyme in breaking down hydrogen peroxide, and its effectiveness is measured by the lack of absorption of consumed hydrogen peroxide, and the absorbance reading of samples is recorded at a wavelength of 240 nm.

**Measurement of the Malondialdehyde level:** The level of MDA in the serum was measured using the method used by researchers (Guidet and Shah, 1989). The level of MDA was measured in the serum, and it represents one of the main products of lipid peroxide. The method depends on the interaction between lipid peroxides, mainly the Malondialdehyde, and thiobarbituric acid (TBA) This reaction takes place in an acidic medium and forms a coloured product, as the absorption intensity was measured at 532 nm.

**Statistical Analysis:** To analyze the results, Graph Prism 7 was used to know the significant differences in the studied criteria included in the current study using one-way analysis of variance (ANOVA). Tukey’s multiple comparisons test was used with a probability level of 0.05 to compare the significant differences between the averages of the current study groups.

**Results and Discussion**

The catalase activity recorded a significant decrease of \( p < 0.05 \) in the G1 patient group compared to the G2 patient group and the control group, while the last two groups did not record a significant difference between them, \( p > 0.05 \) (Table 1 and Fig. 1A).

The results recorded a significant increase, \( p < 0.05 \), in the MDA concentration level in the two groups of patients, G1 and G2, compared to the control group, but when the two groups of patients were compared with each other, they did not show a significant difference \( p > 0.05 \) Table (1) and Figure (1B).
Table (1) and Figure (1C) show the level of ferritin in the two groups of beta-thalassemia patients without splenectomy (G1) and patients with splenectomy (G2) compared to the control group. The results recorded a significant difference of p <0.05 in the level of Ferritin at probability level p <0.05 in the G1 and G2 patient groups compared to the control group.

Figure (1) Shows the level of efficacy CAT enzyme (A), MDA concentration (B) and level Ferritin in beta-thalassemia major.

The decrease in the level of catalase may reflect the extent of oxidative damage that may arise in thalassemia patients, which may be one of the reasons that lead to complications of the disease, as patients suffer from impaired function of the liver, heart, endocrine glands and other clinical complications, as catalase is one of the enzymes of the system Defensive antioxidant in the cells of the body and at a high level in red blood cells. Therefore, the oxidative damage increases when the antioxidant activity decreases against the high
The decrease in catalase enzyme activity was associated with an increase in the patients’ MDA levels. The oxidation of lipids resulting from MDA leads to the generation of collateral bonds that act on some antioxidants and weaken their link with cell membranes, leading to their lack of activity and imbalance of the oxidation-antioxidant system. Also, thalassemia patients have a low level of expression of the FOXO3 gene, which encodes for antioxidant enzymes, including catalase, and this gene is found spread on red cell membranes, and that the defect and degradation occurring in the patients’ blood cells and early stages leads to a decrease in the level of the FOXO3 gene, which is negatively reflected on the antioxidant system and thus inhibition of reactive oxygen species and increase oxidative damage to red blood cells and their membranes and this was confirmed by the Al-Athari (2019) study, as it was observed that low levels of catalase activity were associated with decreased expression of the FOXO3 gene.

The amounts of iron released as a result of the decomposition of hemoglobin in thalassemia patients stimulate the production of reactive oxygen species, in addition to the negative effect resulting from the accumulated iron as a result of periodic blood transfusions to compensate for the decrease in the hemoglobin level, as repeated blood transfusions contribute to increasing iron absorption and thus generating high levels from the reactive oxygen species ROS and superoxide resulting from the increase of free radicals in red blood cells leading to oxidative damage. These products increase the lipid peroxidation, which results in high levels of MDA, in addition to that the state of oxidative stress can affect all cells and tissues of the body, and consequently, high levels of MDA in the tissues leak into the blood causing this noticeable increase in thalassemia patients. This was confirmed by Walter et al. (2006) in his study, as they observed an increase in the level of MDA in beta-thalassemia major patients about (1-8) times compared to healthy subjects. As noted by Vichinsky et al. 2005. To the fact that the increase in the level of MDA is one of the indicators of iron concentration in the liver, and the process of chronic blood transfusion in thalassemia patients is associated with the cumulative damage to iron in the tissues, and accordingly, the increased levels of MDA were associated with increased levels of ferritin in patients and these results were consistent with the findings of the current study.

Ferritin binds to iron, transports and stores it in a non-toxic, soluble form. The reason for the increase in ferritin levels may be due to the increase in iron levels caused by thalassemia, or due to frequent blood transfusions in thalassemia patients that lead to rapid iron loading. Because each unit of blood contains 200-250 mg of iron (1 ml of red blood cells contains 1 mg of iron) that cannot be excreted. Excess iron stimulates lipid oxidation and the generation of oxidants that affect the red blood cells and thus reduce antioxidants, especially catalase, according to what Aziz and others (2017), as he mentioned in his study that iron overload comes from continuous blood transfusions for patients as free iron ions accumulate That leads to an increase in oxidative stress that depletes antioxidants in the cells and thus increased oxidants that cause damage to the membranes and organelles of the cells of the body. Iron also increases in the body as a result of iron absorption in food through the intestine or from continuous blood transfusions, which leads to an accumulation of iron that may exceed the ability to detoxify ferritin. One of the secondary causes of iron overload is the inefficiency of the treatments used to iron chelation, accumulated which is one of the main reasons for the increase in oxidants that break down the red blood cells’ membranes in their formation stages.

The Proteomic Expression of Nuclear Apoptosis-Inducing Factor1 (NAIF1) in Colorectal Tissues

Ahmed Arnaoty1, Yves Bigot2, Thierry Lecomte3

1Assistant Professor at Medenat AL-Elem University College Department of Nursing/Baghdad/Iraq, 2Director of research at UMR INRA-CNRS 7247, INRA Val de Loire-France, 3Professor at Tours university, Department of Hepato-Gastro-Enterology; Tours/France

Abstract

The neogenic recombinases are potentially a source of genetic variability possibly implicated in the mechanisms of genetic instability involved in the processes of carcinogenesis. One of these neogenic recombinases is the nuclear apoptosis-inducing factor 1 (NAIF1), which codes the protein NAIF1 that induces apoptosis in various human cancers.

The aim of this work is to study the expression of NAIF1 neogene in cancerous and non-cancerous colorectal tissues.

The protein expression of NAIF1 gene has been studied by western blot method in the samples of protein extracted from 29 patients with colorectal cancer.

The result of this study showed that the protein expression of NAIF1 was found in both cancerous and non-cancerous colorectal tissues, but it is highly expressed in non-cancerous tissues adjacent to cancerous one. Its expression is higher in non-metastatic cancerous tissues compared with metastatic one. Also this expression is higher in microsatellite instable (MSI) group of cancer compared with microsatellite stable (MSS) group.

It can be concluded that NAIF1 protein expression inversely related with more advanced stage or grade of colorectal cancer and it may have a role in inhibition of proliferation, migration and invasion of colorectal cancer by inducing apoptosis.

Keywords: DNA transposons, Domestication, Neogene, NAIF1, microsatellite instable, microsatellite stable, colorectal cancer.

Introduction

Colorectal cancers are solid tumors whose somatic genetic and epigenetic alterations are best documented[1]. They are relatively homogeneous tumors in terms of their anatomopathological characteristics as they are in more than 90% of cases of adenocarcinomas[1]. Two main groups of colorectal cancers characterized by different somatic genetic alterations were presents[1-3]. The most frequent group is characterized by a chromosomal instability resulting in the recurrent loss of chromosomal segments[4,5], called LOH for Loss of heterozygoty and represents 85% of colorectal adenocarcinomas[2]. The other colorectal cancer group is characterized by microsatellite instability (MSI) due to a mismatch repair of DNA (MMR repair system)[2].

However, a phenomenon called molecular domestication has been reported for some DNA transposons resulting in the formation of neogenes[6]. Most of these neogenes domesticated from DNA transpon encode proteins for the most part still poorly characterized and whose biological functions are poorly
known. These proteins are involved in various biological processes that contribute directly or indirectly to genome stability (cell proliferation, cell cycle progression, chromatin modification, transcription...) [6,7]. Analysis of the human genome made it possible to identify 47 genes derived from transposable elements among which 43 genes are derived from domesticated DNA transposons [8]. One of these neogenes, which is selected in this study, is the neogenic recombinase nuclear apoptosis-inducing factor 1 (NAIF1) code the protein NAIF1 that derived from the DNA transposon by molecular domestication. NAIF1 is a nuclear protein that contains a Myb-like domain at its N-terminal region [9].

The human gene encoding nuclear apoptosis inducing factor 1 (NAIF1) is located on chromosome 9q34.11, and reported to repress the progression of several human cancers [9,10-14].

In gastric cancer [10,12], prostate carcinoma [11], in osteosarcoma cells [13], in non-small-cell lung cancer [14]. NAIF1 inhibit the progression of cancer by inducing apoptosis and it plays an important role in control of the expression of some pivotal anti-cancer or apoptosis-related genes in physiological level [10,12]. These findings may indicate that it is very likely that NAIF1 may predominantly act as a tumor-suppressive gene, possibly through the activation of apoptotic pathways, in various types of cancers [10-14]. In the present study the model retained for the study of the expression of NAIF1 neogenic protein by the western blot method was an in vitro model of human colorectal cancerous and non-cancerous tissues, using the protein extracted from these tissues and by the antibodies synthesized by Arnaoty et al [15], that allow the study of the expression and the analysis of neogenic recombinase corresponding to NAIF1 protein.

The aim of this study is to show the protein expression of NAIF1 in these colorectal tissues.

Materials and Method

The tumor samples and their Characteristics: Frozen samples of colorectal tumors (tumor tissue and adjacent non-tumoral colonic tissue) from 29 patients operated with colorectal cancer in 2007 or 2008 and stored in a tumor bank were selected for this study. The main characteristics of the included colorectal tumors are summarized in Table 1.

### Protein extractions from tumoral and non-tumoral samples:

Sections with a thickness of 10 μm of the samples of tumor and non-tumor tissues preserved at -80°C, were made by using a cryostat in the department of histopathology/Trousseau hospital/Tours/France. From these tissue sections, protein lysates were prepared using an ice-cold RIPA buffer (20 mM Tris-HCl (pH 7.2), 150 mM NaCl, 1 mM EDTA, 10% glycerol, 1% Triton X-100, 0.5% deoxycholate, 0.1% SDS, 1 mM DTT, 16 complete protease cocktail (Roche)). The protein extracts were assayed by the Bradford method and preserved at -20°C.

### Analysis of proteins by acrylamide gel electrophoresis:

The electrophoresis technique under denaturing conditions SDS-PAGE was used. The total protein extracts were mixed with lysis buffer (20% SDS, 100 mM NaCl, 10 mM beta-mercaptoethanol, cocktail of protease inhibitors (Roche Diagnostics GmbH, Mannheim, Germany)), and then denatured for 5 min at 95°C.

Fifty micrograms of protein extracts from cancerous and non-cancerous tissues were deposited in each well of a polyacrylamide gel.

### Western Blot:

After electrophoresis, the proteins were transferred to a polyvinylidene difluoride (PVDF) membrane (Bio-Rad, Richmond, USA) using “Trans-Blot® SD Semi-DryTransfer Cell” (BIO-RAD) in transfer buffer (40 mM Tris-base, 0.1M Glycine, 20% ethanol).

The membranes were then incubated with the anti-NAIF1 primary antibody (In Cell Art, Nantes/France) at a dilution of 1: 250 for two hours at room temperature. After three successive 10-minute washes then incubated with a secondary antibody coupled to Goat anti-Mouse IgG-HRP (Amersham, GE Healthcare) for 1 hour at room temperature. After three successive 10-minute washes the membranes were analyzed by means of a chemiluminescence reaction (Amersham ECL Advance Western Blotting Detection Kit, GE Healthcare) the images were collected using the FUGI LAS4000 imager.

The membranes were then dehybridized and then re-hybridized with a polyclonal anti-chicken actin antibody (Abcam, USA).

### Analysis of the data obtained by western blot:

For each patient, expression of the NAIF1 protein in cancerous colorectal tissue was compared to that observed in adjacent non-cancerous tissue. The expression results were then analysed according to different clinical and molecular parameters. The results were calculated by taking into account on the migration gels the band corresponding to the 35-kDa isoform of NAIF1 expression. The Western blot signals were analysed with the Multi Gauge software (which determines the optical density of the bands obtained in Western Blot and corresponding to the protein expression and their contents of housekeeping protein, actin).

### Statistical Analysis:

We have performed statistical analyses to compare the two types of samples (cancerous...
(T) and non-cancerous (N)), this is an adjustment of protein expression parameters as a function of stromal cell percentage over sample T or N for each selected patient. The Kolmogorov-Smirnov and Shapiro-Wilk test were used to test a difference in NAIF1 expression in these two types of samples [non-cancerous (N) versus cancerous (T)], and for cancerous samples (T) differentiate between non-metastatic/metastatic; MSI/MSS; mutated KRAS, BRAF/non-mutated, A result is considered significant if p≤0.05.

**Results**

**Expression of the NAIF1 protein in colorectal tissues (cancerous & non-cancerous):** Results highlighted a unique product of expression of NAIF1 in all samples of colorectal tissues cancerous (T) and non-cancerous (N) by western blot, corresponding to 35 kDa molecular weight equal to that of the NAIF1 transposase (figure 1,2) using the anti-NAIF1 antibody (In Cell Art, Nantes/France).

![Figure 1](image1.png)

**Figure 1:** NAIF1 expression by western blot for 8 patients with antisera anti NAIF1. Lanes 1 to 16 correspond to protein extracts colorectal tissues (N,T) in 8 patients respectively. Hybridizing the membranes with a specific monoclonal antibody actin, in each lane. Molecular weights are indicated in the left margins. Molecular weight of NAIF1 is indicated in the right margin.

![Figure 2](image2.png)

**Figure 2:** NAIF1 expression by western blot represented by Histogram for protein extracts of 8 samples with anti NAIF1.

The protein expression of the NAIF1 gene was analysed according to different parameters figures 3:

We compared the expression of NAIF1 between the two types of samples non-cancerous tissues (N) versus cancerous tissues (T) by adjusting them according to the percentage of stromal cell on the N and T sample. This comparison showed that the level of expression of NAIF1 in N is significantly higher than that observed in T (p-value = 0.0001).

![Figure 3](image3.png)

**Figure 3:** NAIF1 expression by western blot represented by Histogram for protein extracts of 8 samples with anti NAIF1.

Also we compared the expression of NAIF1 for the cancerous samples (T) according to the status of phenotype microsatellite instable (MSI) or microsatellite stable (MSS).

We observed that NAIF1 expression of T in MSI tumors was significantly greater than that observed in MSS tumors (p-value = 0.0001).

Then we compared the expression of NAIF1 for cancerous samples (T) according to the metastatic or non-metastatic stage of cancer. There is a significant difference observed in NAIF1 expression in the metastatic (low expression) versus non-metastatic (high expression) stage of cancer, high expression in non-
metastatic compared with metastatic one (p-value = 0.0001).

Finally, we compared the expression of NAIF1 for cancerous samples (T) according to KRAS and BRAF mutated versus non-mutated cancers. There is no significant association was observed between the level of NAIF1 expression for cancerous samples (T) according to KRAS and BRAF mutated versus non-mutated cancers.

Figure 3: NAIF1 expression according to comparison between 3 parameters where P=0.0001. A: comparison between (N, T). B: comparison between (non-metastatic, metastatic). C: comparison between (MSI, MSS).

Discussion

Several studies have described the proteomic expression of NAIF1 gene [10-14]. Our results are consistent with the previous studies were done on NAIF1 gene expression showed that, NAIF1 is expressed in both cancer tissue or cancer cell lines and in non-cancerous or normal tissue[10,12], this expression was strong or high in non-cancerous or normal tissue compared with weak or little seen in cancerous one. This finding may be interpreted by a possible relationship between gene expression and stage or grade of tumor (inversely related) and inturn possible role for this gene in the regression or inhibition in this type of cancer. Our results here in colorectal tissue cancerous and non-cancerous are in coherence with Luo’s finding in tissues, they demonstrated NAIF1 protein is highly expressed in human normal gastric tissue and down-regulated or lost in gastric cancer tissue [10]. These findings may indicate that it is very likely that NAIF1 may predominantly act as a tumor-suppressive gene, possibly through the activation of apoptotic pathways, in various types of cancers [10-14]. On the other hand, the high level of expression of NAIF1 in normal areas might suggest a role of NAIF1 in the control of genes with anti-tumor activity.

NAIF1 is significantly highly expressed in the tumor tissues of the colon with molecular phenotype of microsatellite instable (MSI) than in those of microsatellite stable (MSS) molecular phenotype. These results tend to suggest that NAIF1 could be associated with the mechanism of carcinogenesis of colorectal cancers of MSI molecular phenotype. Unfortunately, no information available in the bibliography tried to reveal this possible link between the genetic phenotype of cancer wether microsatellite instable (MSI) or microsatellite stable (MSS) status at the level of nucleotide and NAIF1 gene expression. To confirm the correlation, further research is required.

NAIF1 expression in the metastatic (low expression) versus non-metastatic (high expression) stage of colorectal cancer, is in coherence Luo’s finding in tissues [10]. This may be assumed by either the gene has a role in inhibition the progression of cancer by inducing apoptosis or the highly progressed cancer express this gene little. Further investigation will be required to clarify this relationship.

Conclusion

The higher expression of NAIF1 protein in non-cancerous colorectal tissues and lower expression in cancerous one, with higher expression in non-metastatic than metastatic one may indicates a relationship between cancer inhibition and regression with gene expression. There is a role of NAIF1 in colorectal carcinogenesis especially for cancers of microsatellite instable (MSI) phenotype. Therefore, NAIF1 may provide new clues for developing anti-cancer drugs.

Acknowledgments: We thank E. Goudeau (INSERM UMR 1087, Nantes) for her technical expertise in molecular biology, B. Pitard (Nantes university) for providing antibodies.

Source of Funding: This work was funded by the C.N.R.S, the I.N.R.A., the Groupement de Recherche CNRS 2157, and the Ministère de l’Education Nationale, de la Recherche et de la Technologie. It also received funding from a research program grant from the Cancéropôle Grand-Ouestand grants from Amgen and the French National Society of Gastroenterology.

Ethical Clearance: Samples were taken from the department of histopathology/Trousseau hospital/ Tours/France. Patients had been informed of using their samples for research purposes and their consents to participation in this type of research had been collected.

Studying and Evaluating the Effect of Laser on Bacterial Species, (A Vetro Study)

Aedah Z. Alkaisy¹, Hydar Saadi Hassan Al-Wasti²

¹Asst Prof., ²Lecturer, College of Medicine, University of Baghdad, Iraq

Abstract

Background: Candida species are part of the normal oral microbiota being Candida albicans.

Objective: This study was designed and carried out to find the effect of laser on Candida albicans bacterial cell line.

Materials and Method: 16 mice 2 months ages which divided into 4 groups each one consist of 4 mice, while additional 4 mice (group E) were not exposed to the laser beam and considered as a control while the other groups were irradiated with laser beam after anaesthetized and swapped by the species on the tongue of target animal with range of 250 clinical isolates of Candida species, the groups were exposed for different time 10, 15, 20, and 25 seconds (groups A, B, C, and D respectively) with a duration of 2 hours.

Results: The no. of colony/2cm² were calculated for four times and there mean was calculated, the means were 10⁹, 10⁷, 10⁴, and 10² for groups A, B, C, and D respectively, while it was 10¹⁵ in control group.

Conclusions: Laser beam reached the tissue of the cervical lymph nodules that treated with laser, the electromagnetic oscillations gradually “swing and excite “single cells, this thought to eventually intensify the bionomical process that ultimately regulate the performance of various vital organs.

Keywords: Candida albicans, laser, bacterial species, vetro study.

Introduction

Candida species are part of the normal oral microbiota being Candida albicans the most common species associated with clinical manifestations, which range from superficial mucocutaneous lesions, such as oropharyngeal candidiasis (OPC), to disseminated forms of the infection (¹-³). OPC is the result of adhesion and penetration of fungal species into the oral tissues⁴ and it has a high incidence in patients that use immunosuppressive drugs, broad-spectrum antibiotics, anti-diabetic mediations, anticancer therapies, and in patients with the acquired immunodeficiency syndrome (AIDS)⁵.

This study evaluated the effectiveness of antimicrobial Low Level Laser Therapy (LLT) in the treatment of oral candidiasis by using diode laser to reduce the activity of fungi(Candida) in the tongue. This model of oral candidiasis was developed to allow the monitoring of the infection and the establishment of the laser treatment. Three-weeks-old female and male mice were immunosuppressed and inoculated with C. albicans to induce oral candidiasis. After the appearance of white coated tongue the subject were ready for study.

Materials and Method

Twenty white mice were randomly ascending taken 2 months of age; 100gm of weight were prepared for this study. The animals were grouped for six groups, each of 4 mice, treated and not treated mice. One group were taken as a control, the other were treated by laser, all the animals tangs were swapped by the Candida that cultured in the agar, after preparing the culture. A range of 250 clinical isolates of Candida species were streaked
onto chocolate agar and incubated for 48 hours at 37°C in the presence of an atmosphere of 6% CO₂. All cultures were grown in 90 mm diameter plastic petri dishes with 25 ml of chocolate agar.

Group A, B, C, D were treated with laser by irradiated the cervical lymph nodules of the target animal by different duration times 10, 15, 20, and 25 min respectively and repeated the same for four days, while group E was considered as control and were not treated with laser beam. The animal anaesthetized and swapped by the species on the tongue of target animal, after the success appearing of the white coated spots on the tongue we take a swapped from each tongue of irradiated animal as follows:

- **Group A:** Continuous irradiated by laser for 10 sec twice daily with duration time of two hours
- **Group B:** Continuous irradiated by laser for 15 sec twice daily with duration time of two hours.
- Same procedure was applied on the groups C, and D with time of irradiation of 20, and 25 min respectively. After three days we swapped the tongue of the animals of each groups and cultured them in chocolate agar incubated for 24 hours. Each petridish were examined under microscope and bay using mesh lens we count the colony of each petri.

- **Group E:** remain as a control after swapped all the animals of his group with candida, and exam the swap of each animal (not treated) at the day four after the appearance of the white spot appearance.

### Results and Discussions

The results that were collected are shown in table 1, and 2.

Many theories have been postulated about the mechanism of action for low level laser especially about the exact mechanism of action and the physiological changes occurring at the cellular level(5,6).

The increasing in the diameter of diseased mice that swapped with *Candida* is a result of laser that laser beam carries electromagnetic oscillations of definite frequency. When it reaches the tissue of the cervical lymph nodules that treated with laser, the electromagnetic oscillations gradually “swing and excite “single cells, this thought to eventually intensify the bionomical process that ultimately regulate the performance of various vital organs, and then the cell itself begins to emit light similar to the rays of the laser and that let to stimulate the salivary gland secretion(3).

The salivary glands connective tissue contains many plasma cells and lymphocytes that plasma cells secrete $\text{IgA}$, which form a complex with secretory component synthesized by the serous acinar, the $\text{IgA}$-rich secretory complex released into the saliva is resistant to enzymatic digestion and constitutes an immunologic defense mechanism against pathogens in the oral cavity(3), so the laser beam main job was to cause activation in the cell which in turn leads to an intensification of the bionomical processes shown in table 2.

The biological law states that weak stimuli excite physiological activity and moderately strong ones favor it, strong ones retard it and very strong ones arrest it from all laser irradiation of tissue show that units of light energy (photons) are absorbed by enzymes which react to light within the cell(6,7).

Infrared light that used in this study absorbed at the cell membrane, this results in a change in membrane permeability, increased ATP levels and increased DNA production(8). The photons picked up by the cell membrane result in improved membrane stability and increased activity of the ATP-dependent Na/K pump, because cell metabolism is influenced by Na/K movement.
across the membrane, increasing the gradient will affect the flow of ions and hence the overall metabolism of the cell\(^9\).

**Ethic Statement:** The researchers already have ethical clearance from all required institution and laboratories.

Knowledge and Practices of Nurses Regarding Corona Virus (COVID-19): An Educational Intervention

Amira Refaat Said

Associate Professor of Obstetrics & Women’s Health Nursing, Farasan University College, Jazan University

Abstract

Background: COVID-19 it is the new coronavirus and most cases appeared in the Chinese city, Wuhan at the end of December 2019 in the form of acute pneumonia. It was identified through genetic sequences. It is believed that the COVID-19 originated in animals and most cases appeared in the seafood and animal market in Wuhan. The virus can spread from the infected person to another person through close contact without protection. Aim was to evaluate the effect of an educational intervention nurses’ knowledge and practices regarding Corona virus (COVID-19). Quasi-experimental design (pre and post intervention) was utilized. A total sample of (70) staff nurses were recruited in the study. The study was conducted at General Farasan Hospital. Data were collected through two main tools: A structured self-administered questionnaire, and nurses’ practices toward COVID-19.

Results: Revealed that 55.7% of nurses had poor knowledge before intervention. However, 88.6% of them had good knowledge after intervention. As well as, only 7.1% of the studied nurses had competent practices toward covid 19 before training. Meanwhile, after training the competent practices changed to 94.3%.

Conclusion: The implementation of an educational intervention was effective and significantly improved nurses’ knowledge and practices towards covid 19.

Keywords: Corona virus (COVID-19), Nurses practices, Educational Intervention.

Introduction

COVID-19 It is the new coronavirus and most cases appeared in the Chinese city, Wuhan at the end of December 2019 in the form of acute pneumonia. The virus was identified through genetic sequences. It is believed that the COVID-19 originated in animals and most cases appeared in the seafood and animal market in Wuhan. The virus can spread from the infected person to another person through close contact without protection. The common symptoms of COVID-19 include: fever, cough, shortness of breath and sometimes develops into pneumonia. It may cause severe complications in persons with immunodeficiency, the elderly and persons with chronic diseases such as cancer, diabetes and lung diseases.[1]

The novel coronavirus infection (COVID-19), also termed SARS-CoV-2, which emerged in December 2019 has become a global public health emergency and was declared a pandemic by the World Health Organisation on the 11th March 2020. Symptoms of COVID-19 are nonspecific although most typically involve cough, shortness of breath and fever, and the disease presentation can range from no symptoms (asymptomatic) to severe pneumonia and death. Most people infected with COVID-19 virus have mild disease and recover. Approximately 80% of those infected have mild to moderate disease, 13-14% has severe disease and around 6% develop critical disease. Individuals at highest risk for severe disease and death include people aged over 60 years and those with underlying conditions such as hypertension diabetes and cardiovascular disease; mortality rates increase with age and disease in children seems to be both rare and mild .[2]
A comprehensive understanding of infection prevention and control is mandatory for nurses while seeking to protect themselves, patients, colleagues and community. So taking it after the hand hygiene, understanding the key component of the proper use of PPE is when and how to put it on (don) and how to take it off (doff) again comes under lead responsibilities. The nurses should select the appropriate personal protective equipment like before undertaking any clinical intervention according to the provision of ministry of health.\[26\] Preventing the spread of infection to and from nurses and patients depends totally on your prompt actions by the effective and proper use of personal protective equipment’s such as cover all gowns or plastic aprons, Triple layer medical mask or N-95 Respirator mask, goggles, face shields and gloves, head and shoe cover.\[3\]

Nurses play a vital role in health care system and health team. All health care providers especially nurses are on the frontline battling against this pandemic and providing services to patients which is helpful to prevent and control COVID-19 pandemic. Nurses should properly arrange critically ill patients with COVID-19; complete the evaluation in the shortest time possible. In the meanwhile, urgent care, such as wheelchair/flatbed transfer, oxygen inhalation, electrocardiogram monitoring, sputum suction, and establishment of venous access, should be completed. The evaluation should include three components: general condition assessment should include age, present history illness, past medical history, allergic history, vital signs, oxygen saturation, breath, consciousness state, and systemic symptoms, such as fever, cough, expectoration, chest congestion, hypodynamia, muscle soreness, and diarrhoea., self-care ability assessment, and specialized assessment. The evaluation’s specific content should be reasonably selected according to the nursing human resources available and the critical degree of the patient’s condition.\[4\]

Specialized assessment should include cognitive functional assessment, nutritional status assessment, and venous thromboembolism (VTE) risk assessment. The Mini-Cog Test (Milian M et al 2012) is recommended for the evaluation of cognitive function as it is brief, minimally influenced by language and education level, and easily accepted by patients. The Nutrition Risk in Critically Ill (NUTRIC) Scale may be used to evaluate the nutritional status of critically ill elderly patients. However, considering elderly patients are prone to suffering from malnutrition, nutritional support should be provided immediately after admission in the case of insufficient medical staff. VTE risk assessment varies depending on different clinical situations: For medical patients, the Padua Scale is recommended, while for surgical patients, the Cabrini Risk Assessment Model is recommended.\[5\]

Critically ill patients with COVID-19 are more likely to have psychological panic and anxiety due to insufficient knowledge of the disease and lack of access to information. The following measures should be considered in these cases. First, evaluate the patient’s cognitive changes, emotional responses, and behavior changes, and provide appropriate emotional support. For patients with anxious and depressed tendencies, self-rating scales, such as an anxiety self-rating scale and a depression self-rating scale, can be used for assessment, and professional psychological personnel can be asked to help patients according to the situation. Second, various means, such as cognitive behavioral therapy, positive psychology, explaining COVID-19 in simple and understandable language, and providing continuous information support, may help elderly patients to a timely transition to the psychological stage of treatment, and to build up the confidence to overcome the disease. Third, relaxation training, such as meditation, hypnosis, music therapy, and other ways to relieve patients’ anxiety and depression, should be provided if possible.\[6\]

Discharge instructions should consist of the following: Select appropriate breathing rehabilitation exercises and teach them to patients, such as airway clearance training, breathing exercises, pursed-lip breathing, and abdominal breathing, advise patients to strengthen nutritional support, eat more high-protein, high-vitamin, high-calorie food, and more fresh vegetables, fruits, milk, and so on. Likewise, instruct patients to work and rest regularly and to get adequate sleep, it is recommended that patients continue to be monitored for 14 days after discharge and continue to wear masks. If possible, it is recommended to live in a single room with good ventilation, reduce close contact with others, eat separately, carry out hand hygiene thoroughly, and avoid outdoor activities. And it is recommended that patients return to the hospital for re-examination 2 and 4 weeks after discharge. During the period after discharge, if the patient has fever, dyspnoea, or the reappearance of other uncomfortable symptoms, or if a family member with close contact has a new novel
coronavirus infection or suspected infection symptoms, they should go to the hospital immediately. [7]

Significance of the Study: The novel coronavirus detected in China in 2019 is closely related genetically to the SARS-CoV-1 virus. SARS emerged at the end of 2002 in China, and it caused more than 8 000 cases in 33 countries over a period of eight months. Around one in ten of the people who developed SARS died. As of 30 March 2020, the COVID-19 outbreak had caused over 700 000 cases worldwide since the first case was reported in China in January 2020. Of these, more than 30 000 are known to have died. Elderly people above 70 years of age and those with underlying health conditions (e.g. hypertension, diabetes, cardiovascular disease, chronic respiratory disease and cancer) are considered to be more at risk of developing severe symptoms. Men in these groups also appear to be at a slightly higher risk than females. [8]

In addition, from the researchers’ clinical experiences, they found Nurses are lacking knowledge and skills required for caring of those patients. Best practices intervention protocols are not available for nurses working in the hospital. So, the current educational intervention was developed for nurses to update and upgrade their knowledge, skills and to be reference guide whenever needed, also, it should be utilized and integrated through educational modalities, in order to assist nurses to be competent in nursing care, therefore this study conducted to improve maternity nurses’ knowledge and skills regarding corona virus by applying an educational intervention.

Aim of the Research: To evaluate the effect of an educational intervention on nurses ’knowledge and practices regarding covid 19. This aim was achieved through:

1. Assessing nurses’ knowledge and practices regarding covid 19
2. Designing and implementing nursing educational intervention regarding coping with covid 19 & international standards infection control.
3. Evaluating nursing educational intervention after application it

Research Hypotheses: Nurses who received an educational intervention would have improved knowledge and practices toward covid 19 & international standards infection control than before intervention.

Materials and Method

Research Design: Quasi-experimental design (pre and post intervention) was utilized to fulfil the aim of this study.

Setting:

This study was conducted at General Farasan Hospital.

Sampling:

Sample type: A convenient sample.

Sample size and technique: All nurses working in the above mentioned setting at the time of the data collection were included in the study. The sample size was completed three days per week during four months. Total number was 70 staff nurses.

Tools of data collection:

Two main tools were used for data collection:

I- A structured self-administered questionnaire: It was designed by the researcher after reviewing related literature. It was written in an Arabic language in the form of close and open-ended questions. It encompassed two major parts:

First part included personal and socio demographic data such as (age, educational qualifications, occupation, residence and years of experience in the hospital).

Second part included nurses’ knowledge about corona virus (covid 19). It consisted of;

(Definition, aetiology, incubation period, signs symptoms, mode of transmission, most dangerous groups vulnerable for covid 19,self-assessment tool, signs of recovery from covid 19 complications, methods of personal protective for preventing spreading the virus, precautions of infection control, priorities of nursing care for this infection and healthy life style following during covid 19).

Knowledge Scoring: Each item was assigned a score of (2) given when the answer was correct and a score (0) was given when the answer was incorrect or do not know. Nurses total knowledge score was 24 and classified as the following; poor when total score was < 60%, average when total score was 60% < 75% and good when total score was ≥ 75%.
II- Nurses practices towards corona virus (covid 19): This tool was developed by the researcher after reviewing related literatures to assess nurses skills pertaining corona virus (covid 19) and consisted of (20) items such as (Placing patients with potential or confirmed infection with the emerging coronaviruses (Covid 19) in well-ventilated individual rooms or in rooms equipped with airborne infection reserves, reducing the number of health care workers, family members and visitors who come into contact with a patient with a potential or confirmed infection with coronavirus, Applying the “Five Times” approach in which the hands should be cleaned: Before touching the patient; Before any cleaning or disinfection procedure; And after exposure to the risks of body fluids; After touching the patient; After touching the patient’s surroundings, including contaminated objects or surfaces, wash hands with soap and water, or use an alcoholic solution to scrub hands, using of personal protective equipment for hand hygiene is not necessary. Hand hygiene is essential when placing these equipment, especially when taking it off etc………;).

**Scoring:** The items were judged according to a three point. Not done took (1) score, incompetent done took (2) score and competent done took (3) score. The total practice were divided into competent if the total score above 75 and incompetent if less than 75.

**Tools validity and reliability:** Tools were reviewed by a panel of three experts in the field of nursing to test its content validity. Modifications were done accordingly based on their judgment. Reliability was done by Cronbach’s Alpha coefficient test which revealed that each of the two tools consisted of relatively homogenous items as indicated by the moderate to high reliability (internal consistency) of each tool (knowledge = 0.92 and practices = 0.87).

**Ethical Considerations:** An official permission was granted from the directors of the pre mentioned setting with reference number (REC41/5/105). Each nurse was informed about the purpose of the study then an oral consent was obtained before starting the data collection. Confidentiality was ensured throughout the research study process, and the nurses were assured that all data was used only for research purpose. Each nurse was informed that participation is voluntary and free to withdraw from the study at any time.

**Pilot Study:** The pilot study was carried out on 8 nurses (about 10% percent of the total sample) to test the clarity and applicability of the study tools as well as estimation of the time needed to fill the questionnaire. Required modifications were done in the form of added of some questions. Nurses involved in the pilot were excluded from the study.

**Procedure:** The following phases were adopted to fulfil the aim of the current study; assessment, planning, implementation, and evaluation phases. These phases were carried out from the beginning of June 2020 to the end of September 2020 covering 4 months. Official approvals and letters to conduct this research were obtained from Dean of researcher Faculty to Directors of the previous mentioned sitting.

**Assessment Phase:** This phase encompassed interviewing the nurses to collect baseline data, at the beginning of interview the researcher greeted each nurse, explained the purpose, duration, and activities of the study and taken oral consent. Pre-test was done to assess nurses’ knowledge and practices regarding corona virus (covid 19). The data obtained during this phase constituted the base line for further comparison to evaluate the effect of an educational intervention. Average time for the completion of each nurse interview was around (25-30 minutes).

**Planning Phase:** Based on baseline data obtained from pre-test assessment and relevant review of literature, the educational intervention was developed by the researcher in a form of printed Arabic booklet to satisfy the studied nurses’ deficit knowledge, and practices regarding corona virus (covid 19).

**General objective of the educational intervention** was to improve nurses’ knowledge and practices about corona virus (covid 19).

**Implementation Phase:** Implementation of an educational intervention took (16) weeks period. The researcher visited the previous mentioned setting, three days/week. The educational intervention involved (4) scheduled sessions and were implemented according to working circumstances. These sessions were repeated to each subgroup of (3-5) nurses. The duration of each session lasted from half an hour to one hour including periods of discussion according to their achievement, progress and feedback. The researcher followed all
precautionary measures during the training of the nurses, as well as the nurses, they were committed to wearing masks, social distancing, safety and sterilization. At the beginning of the first session an orientation to the educational intervention and its aims took place, Arabic and English language was used to suit the nurses’ level of understanding. Feedback was given in the beginning of each session about the previous one. Different methods of teaching were used such as modified lecture, group discussion, power point and brainstorming. Suitable teaching media were included an educational booklet that distributed to all nurses in the first day of the educational intervention as well as audio-visual aids and videos were used.

**Evaluation Phase:** After the implementation of the educational intervention, the follow up test for nurses’ knowledge and practices were done by the same format of the pre test to evaluate the effect of the implemented educational intervention.

**Statistical Design:** Data were verified prior to computerized entry. The Statistical Package for Social Sciences (SPSS version 20.0) was used. Descriptive statistics were applied (e.g., mean, standard deviation, frequency and percentages). Test of significance (chi square and paired t test) was applied to test the study hypothesis. Correlation coefficient was calculated between knowledge, and attitude scores. A statistically significant difference was considered at p-value p<0.05, and a highly statistically significant difference was considered at p-value p ≤ 0.001.

**Results**

**Table (1)** shows personnel characteristics of the studied nurses. It was found that more half of nurses (74.3%) were aged from 20-30 years, with a mean of age 27, 34 ± 5.44 years. As far as nurses’ qualification, more than half of them (60.0 %) had bachelor of nursing as well as half of them (50.0 %) was nursing specialist. Regarding experience years at the hospital, about half of nurses (51.4%), their experience ranged from 5-10 years, with a mean of 6.36 ± 2.75 years. And (64.3%) of nurses were lived in rural area.

**Table (2)** represents that total mean scores of studied nurses’ knowledge regarding covid 19, indicated that more than half (55.7%) of them had poor level of knowledge before implementation. The mean of the total score of nurses’ knowledge was 14.1 ± 3.25 to evaluate the knowledge retention among nurses after implementation the same table proved that 88.6% of the nurses had good knowledge and the mean of total score was 22.52 ± 1.09.. The same table illustrated that the total nurses’ practice, indicated that 7.1% have competent practices before implantation. While after implementation 94.3% have competent practices.

**Figure 1** shows that, there was statistically significant difference between pre and after implementation regarding knowledge about covid 19 (p=<0.001)

**Figure 2** represent that, there was statistically significant difference between pre and after implementation regarding practices about covid 19 (p=<0.001)

**Table (3)** reflects that, distribution of the studied nurses total knowledge score in relation to their personnel characteristics, there was a general improvement in all items of knowledge about covid 19 after educational intervention as compared to before educational intervention with highly statistically significant difference between studied nurses total knowledge score, and their personnel characteristics pre and post intervention.

**Table (4)** demonstrates distribution of the studied nurses total practices score in relation to their personnel characteristics, there was a highly statistically significant difference between studied nurses total performance score, and their personnel characteristics pre and post training, with highly statistically significant difference before, and after implementing educational intervention.

**Table (5)** clears that correlation between studied nurse’s total knowledge and practices score pre and post intervention, there was there was highly statistically significant correlation between knowledge after teaching and practice after training.

**Discussion**

Nowadays, COVID-19 is a life-threatening agent with the worldwide spread and it has become an international concern. This disease was first reported on 12 December 2019 from Wuhan (1). Health workers, especially nurses, have close contact with infected patients and have a decisive role in infection control. The health care providers are at the front line of the outbreak response of current pandemic of COVID19 and exposed to hazards that put them at risk of infection. Rapid spread of the COVID-19 pandemic has become a major cause of concern for the healthcare profession in all over the world. All health care professional must stay aware of the latest information on the COVID-19 outbreak.[10]

This study was carried out to evaluate the effect of educational intervention on nurses’ knowledge and practices regarding corona virus (covid 19). As regard characteristic of the studied sample, it was found that more half of nurses (74.3%) were aged from 20-30years, with a mean of age 27, 34 ± 5.44years. As far as nurses’ qualification, more than half of them (60.0 %) had bachelor of nursing as well as half of them (50.0 %) was nursing specialist. Regarding experience years at the hospital, about half of nurses (51.4%), their experience ranged from 5-10 years, with a mean of 6.36 ± 2.75 years. And (64.3%) of nurses were lived in rural area. In this respect Nemati , et al (2020) [11] who studied “Assessment of Iranian Nurses’ Knowledge and Anxiety Toward COVID-19 During the Current Outbreak in Iran” and found that the demographic characteristics of the participants. More than 75% of the respondents were in the group of less than 40-years-old. Concerning the education level, (56.3%) participants had a high school diploma or less, more than half of them (67%) had associate’s or bachelor’s degrees, provides data regarding work experience:, 30.6% between 5 and 15 years.

On investigating knowledge of the studied sample regarding corona virus (covid 19), the findings of the current study revealed that before the educational intervention, nurses had poor knowledge about covid 19, their low scores of knowledge may be attributed to the fact that covid 19 are new advanced emerging virus and the nurses, are still deficient in this issue. As well as after graduation, nurse’s neglect reading updating their professional knowledge, it was expected to find such low level of knowledge. The present study findings are in congruence with Joshi, et al (2020) [12] who studied “Knowledge and awareness among nursing students regarding the COVID-19: a cross sectional study”, who concluded that, the study participants showed adequate basic knowledge and awareness of COVID-19. There is a strong need to implement periodic educational interventions and training programs on infection control practices and other updates of COVID-19 across all healthcare professions including nursing students. Additional online education interventions and campaigns are also required. This would definitely improve the knowledge and confidence of nursing students to provide the right care to their patients and protect them self from COVID-19.

Furthermore, after implementing the educational intervention, there was a statistically significant improvement for knowledge scores in relation to covid 19. Such improvement might be accounted on nurses’ interest to learn and acquire knowledge about the study topic as well as the written booklet distributed to nurses used as an ongoing reference, which was helpful in nurses’ acquisition of knowledge, in addition to encouragement of questions, participation, and interactions along the intervention as well as the use of multimedia. These results are consistent with CHEN etal.,(2020) [13] who studied that Nursing Perspectives on the Impacts of COVID-19, and concluded that- Nurses are key members of healthcare teams charged to control and prevent the spread of infectious diseases. Moreover, nurses work on the front line, providing direct care to individuals infected with COVID-19. Further effort is
necessary to develop strategic recommendations and to integrate new knowledge into education. The immediate efforts to control and prevent COVID-19 and to care for those who are infected remain ongoing.

Concerning nurses’ practices towards covid 19, the findings of the current study revealed that about two thirds of the studied nurses had incompetent practices toward covid 19 before intervention. Meanwhile, after intervention the percentage changed to majority of the studied nurses had competent practices toward covid 19. This could be due to the fact that, receiving training from educational intervention and high adherence with training sessions with their active participation improving their knowledge and lead to competent practices.

These findings are in the same line with Fernandez et al., (2020)\(^\text{[14]}\) who studied “Implications for COVID-19: a systematic review of nurses’ experiences of working in acute care hospital settings during a respiratory pandemic” who concluded that nurses should receive clear, concise and current information about best practice nursing care and infection control, as well as sufficient access to appropriate PPE to optimise their safety. Adequate staffing is essential to ensure that nurses are able to take breaks during shifts, take leave when they are ill and provide appropriate skill mix. Support for nurses to manage competing family responsibilities and maintain safe contact and communication with family members can reduce personal stress and anxiety.

In general, the nurses in the present study demonstrated poor knowledge, with incompetent practices. Implementing educational intervention that met their needs proved successful in fostering their knowledge and improving their skills, thus leading to acceptance of the research hypothesis. The effectiveness of the educational intervention and its independent positive influence on nurses’ knowledge and practices towards covid 19 was apparent from the results. The findings are in congruence with the results of Chen and Lou, (2013)\(^\text{[15]}\) systematic review that revealed that such programs are beneficial as they involve multi-dimensional teaching strategies. Furthermore, Varghese (2013)\(^\text{[16]}\) added that nurses have an important role in imparting knowledge, therefore, the nursing policy protocol should include the current technologies to update the knowledge regarding recent advances to cope with infection control of covid 19 in addition to structured teaching programme is one of the effective methods to acquire & impart knowledge and practices.

Regarding integrating knowledge into practices, the present study demonstrated a positive statistically significant correlation between knowledge and practices, with improved knowledge being associated with competent practices. This finding is quite expected and is consistent with McEachan et al., (2016)\(^\text{[17]}\) who studied “Meta-analysis of the reasoned action approach (RAA) to understanding health behaviours” who reported that some health care workers have inadequate awareness of infection prevention practices. Knowledge of a disease may influence health care workers practices, and incorrect practices directly increase the risk of infection. Understanding health care workers knowledge, & practices and possible risk factors helps to predict the outcomes of planned behaviour.

Additionally, the findings of the current study illustrated that there was a highly statistically significant correlation between total knowledge, total practices scores and general characteristics. These findings are supported by Zhang et al., (2020)\(^\text{[18]}\) who studied “Knowledge, attitude, and practice regarding COVID-19 among healthcare workers in Henan, China” that emphasized that training regarding protection should be organized according to different factors (work experience, educational attainment, and so on), and medical systems should ensure that frontline workers have enough time to rest between shifts, to avoid overwork and non-conscious errors during epidemic relief efforts. Moreover, to reduce the risk of infection among healthcare professionals who are not in direct contact with patients, policy and education should be implemented to convey the importance of disclosing possible exposure to the virus.

**Conclusion**

In the light of the study findings, it can be concluded that, there was a statistically significant improvement in nurses ‘knowledge mean scores, after intervention, as well as there was a statistically significant difference in nurses’ practices scores before, and after intervention. The implementation of an educational intervention was effective and significantly improved nurses’ knowledge and practices towards covid 19. Furthermore, the above mentioned findings proved and supported the research hypothesis.

**Recommendations:**

- Adequately planned in-service training programs related to covid 19 must be established to develop
nurses' knowledge and practices in order to fit newly developed concepts in care.

- Simple guidelines regarding COVID-19 should be available and easily access in all departments of the hospital
- This study can be replicated on a larger sample in other hospitals for generalizing the findings.

Protecting Public Rights on Land Management: A Disjunction between Ideality and Reality

Agus Suprihanto¹, Farida Patittingi², Anwar Borahima³, Sri Susyanti Nur⁴

¹Doctoral Candidate at Graduate School Hasanuddin University, Indonesia, ²Professor, Department of Civil Law, Faculty of Law, Hasanuddin University, Indonesia, ³Professor, Department of Civil Law, Faculty of Law, Hasanuddin University, Indonesia, ⁴Associate Professor, Department of Civil Law, Faculty of Law, Hasanuddin University, Indonesia

Abstract

Land-use systems are characterized by complex interactions between human decision-makers and their rights environment. Mismatches between the scale of human drivers and the impacts of human decisions potentially threaten the public rights as a whole. The research is a normative legal research using a statute, case, and conceptual approaches. The results show that land for management rights can be used for the purposes of conducting their duties or business, and its use can be transferred to third parties with the approval of the holder of management right. In fact, transfer of rights and imposition of mortgage rights can occur even without the permit of the holder of management right. However, when there is default, the creditor experiences obstacles because the National Land Agency rejects to issue a Land Registration Certificate without the holder’s permit of management rights, so that collateral cannot be executed. This condition results in the failure to fulfill the principles of justice and legal certainty for creditors and debtors. This provision should be abolished because it contradicts the principle of justice and legal certainty for the parties having an interest in utilizing the management rights land.

Keywords: Civil Law; Public Rights; Land Rights; Management.

Introduction

Land is a fundamental human need (constitutional rights). More important of land for human life, everyone will always try to own and control it.¹ The population continues to grow causes the need for land to increase, it can be seen from the development of residential, industrial and tourism areas or other needs. Meanwhile, the existing land does not increase or permanent, so requires the State to regulate it so that the State’s objectives in promoting the welfare of the Indonesian people can be fulfilled for national development. Land is one of the main assets as a medium for implementing development to create a just and prosperous society. The preamble of the 1945 Constitution affirms one of the objectives of the Indonesian namely to establishes an Indonesian state government that protects the entire Indonesian nation and all Indonesian blood and to promote public welfare. It can be seen that one of the objectives of the Indonesian State is to promote the general welfare and for all Indonesian people.²

In order to ensure legal certainty for individuals and legal entities to fulfill business needs and to build anything, it is given the right of the land.³ According to Van Vollenhoven, the source of State power over natural resources (including land) is the State is given the authority to regulate everything and it is based on its position has the authority to make legal regulations.⁴ This land registration will produce registration maps, measuring documents for legal certainty including the location, boundaries and width, information and the subject concerned, right status, as well as anything concerns the land and finally issuing a certificate as a powerful evidence.⁵ Land right is a right that give the authority to use land that is given to a person or legal entity. In principle, the purpose of land utilization is to fulfill 2 (two) types of needs i.e cultivation and to build anything.

In practice, the implementation of management rights has experienced significant developments both in terms of its regulation and implementation in the field.⁶
Various regulations that regulate the management rights are all at the level of implementing regulations, the rules governing and their explanations are still separate and have not been formed in one law. Management rights which include designation, use, period and compensation provided that the granting of land rights to third parties is conducted by an authorized official based on statutory regulations. In juridical context, the position of the third party is only the “hitchhiking” party such as the holder of temporary land rights due to limited.7

Lending made by a Bank as a financing institution should receive legal protection for creditors and recipients, as well as for related parties to receive protection through a legal guarantee institution for all interested parties. In giving credit facilities, requires a sufficient credit guarantee economically and good in juridical, because the condition of debtor may unexpectedly be in a situation of being unable to pay his/her loan installments (bad credit). If this happens, then the guarantee is expected to guarantee the repayment of debtor’s credit.

As the legal phenomena as described above, it can be seen that stakeholders, including notary and the National Land Agency have not implemented procedures according to the applicable regulations in granting, transferring and binding mortgage rights to building use rights on management rights land, due to existing regulations is still unclear and not-codified, so it does not provide legal protection and legal certainty for parties, especially creditors.

Method

The research is a normative legal research using a statute, case, and conceptual approaches.8 Data were analyzed with descriptive qualitative analysis with content analysis. In this study, the authors used the qualitative research method, which (in general) generates words rather than numbers as data for analysis. The approach used is observation and interpretation, which makes these phenomena observable. This paper provides information on the latest trend in research.9

Selling and Buying a Plot of Land on Management Right Land: Insights from Indonesia: The procedure for legal actions in transferring (selling, grants, exchanging, pledging or collateralizing and others) of land located on management rights land is almost same as the procedure for buying and selling a plot of land on State land. In selling and buying transaction of land and/or buildings on State land, the parties, namely the seller and the buyer do not need to request approval or permit from any party unless otherwise stipulated by the legislation. It is different if the land are transferred or traded over the land area of management rights, stipulated by Article 34 paragraph (7) jowith Article 54 paragraph (9) Government Regulation No. 40 of 1996 concerning Business Use Rights, Building Use Rights and Land Use Rights before the selling and buying of land use rights for building on management rights land, the parties especially the seller are required to apply for a permit from the holder of the management rights concerned.

As a follow-up to the request, the holder of the management right has the right to issue or reject a permit or recommendation as a form of approval or rejection of the transfer of land and/or buildings to other parties. Permits or recommendations are addressed to the person concerned, the land-owner. However, sometimes when a management right holder gives a permit or recommendation to the Head of the National Land Agency to continue to registration of names change in the documents or certificates of land as traded.

The permits or recommendations by holder of management rights are a real reflection of the implementation of part of the authority of the State’ Controlling Rights. In the process of issuing permits or recommendations, the holders of the management rights refer to the terms and conditions set by the holder of the management rights and refer to the contents of the agreed land use surrender agreements as a basis for consideration in the framework of granting permits or recommendations.1

Each holder of management rights has its own policies, terms and conditions. They have different administrative management procedures for the land that is controlled with a management right, including the procedure for transferring land rights or assigning them. If the transfer of land will result in inconsistent with the function of land designation and use other than the stipulated provisions or policies, the holder of the management right may reject the application for a permit or recommendation for transfer of the land.

Permits or recommendations for the transfer (selling and buying) of land and/or buildings on management rights are used as tools or instruments to do supervisory (control) function which is the duty and authority of the
holder of the management rights concerned over land use by third parties. Through a permit or recommendation agency, the holder of the management right can monitor and prevent parts of management rights land that violate government provisions and policies.

One of the requirements for the transfer (selling and buying) of land and/or buildings on management rights land is to pay the management money concerned. The holders of management rights are authorized to charge administrative fees from holders of land rights on management rights land. The amount of administrative fee is determined based on the full policy by the holder of the management right concerned and notified to the applicant in the permit or recommendation or notified separately.

The Fulfillment of Prudential Banking Principles as an Ideal Model for Protecting Public Rights to Land: Based on banking principles, credit or financing as provided by banks contains an element of risk, so that in its implementation the bank must consider the principles of credible credit. These principles are to prevent or reduce the occurrence of risk, therefore the banking sector is required to implement prudent banking principles. The term prudent relates to the supervision and bank management. The principle of prudent requires banks to always be careful in conduct their business activities, meaning that they must always be consistent in implementing laws and regulations in the banking sector based on professionalism and good faith.

The principle of prudence or also known as the prudential banking principle is an important principle in the practice of banking in Indonesia so that it must be applied or implemented by banks in conduct their business activities. Also, banks are required to be able to design a good legal relationship with prospective debtors, so as to create good working synergy between creditors and debtors. If the debtor is declared in default, the bank can easily execute the collateral given by the debtor based on the design of the legal relationship that has been previously made. Thus, collateral in their credit is a powerful means of securing credit.

The process of granting credit decisions includes credit initiatives and applications, followed by credit analysis and evaluation, credit negotiations, recommendations for granting credit decisions, credit agreements, binding credit collateral, documentation and credit administration, credit disbursement approval and credit monitoring also against risks that may arise, so as to anticipate by taking measures as protection, legal aspects that strengthen the position of the bank, as well as looking for various alternatives to save credit repayments. Especially in this research regarding Building Use Rights, it is necessary to analyze the collateral that will be used as credit guarantees.

Generally, legal theory states that the act of transferring rights can only be done by legal subjects against legal objects that are privately owned as well. Because the legal relationship between the subject and the object in the management rights is more public in nature, the legal act of transferring rights (transferring rights directly to another legal subject) is legally prohibited. If there is an intention to terminate the legal relationship between management rights from the legal subject to another legal subject, that intention is only possible through waiving the right. Especially for investment needs, local governments may apply for management rights to cooperate with investors or third parties. Such management rights can be issued after a certificate is issued which states that the land or land concerned is a management right for the agency concerned.

Such management rights can be utilized by management rights holders including the private sector for or for commercial purposes. One of the forms is by granting Building Use Rights on land under management rights which according to regulations regulates the period of time and other related matters. Management rights are assets of state assets, for the guarantee of Building Use Rights on the land of the management rights that the guarantee is done by the holder of the Building Use Rights on land. The management rights are the Building Use Rights not on the land concerned, so that the provisions related to the prohibition of guaranteeing state assets can be avoided.

Get legal protection is the hope of every legal subject in an agreement. Legal protection is a protection of the rights and obligations of a person where a protection is provided to legal subjects in the form of legal instruments, both preventive and repressive in nature. As a preventive measure, creditors must also conduct credit supervision where the bank must monitor the use of credit, whether the use is in accordance with the provisions. In addition, periodic visits are also held, as well as warnings if the credit being extended has problems. Supervision must also be done over the period of guarantee for Building
Use Rights so that it does not expire before the credit period. At this stage of supervision, it can be seen that credit quality or what is commonly referred to as earning asset quality.

Conclusion

Land for management rights can be used for the purposes of conducting their duties or business, and its use can be transferred to third parties with the approval of the holder of management right. In fact, transfer of rights and imposition of mortgage rights can occur even without the permit of the holder of management right. However, when there is default, the creditor experiences obstacles because the National Land Agency rejects to issue a Land Registration Certificate without the holder’s permit of management rights, so that collateral cannot be executed. This condition results in the failure to fulfill the principles of justice and legal certainty for creditors and debtors. A judicial review is required of Government Regulation No. 40 of 1996 which stipulates that the transfer of Building Use Rights on management rights land requires prior permit. This provision should be abolished because it contradicts the principle of justice and legal certainty for the parties having an interest in utilizing the management rights land.

Effect of Lifestyle Modification Module on Patients’ Compliance Postoperative Bariatric Surgery

Ahmed Elsayed Ibrahiem¹, Salwa Samir Kamel², Asmaa Abdel Rahman Abdel Rahman³, Amr Hamed Afifi⁴

¹Assistant Lecturer, ²Professor, ³Assistant Professor, Medical Surgical Nursing Department, Faculty of Nursing, Ain Shams University, Cairo, Egypt, ⁴General Surgery Department, Faculty of Medicine, Ain Shams University, Cairo, Egypt

Abstract

Background: Obesity is a grave public health threat, more serious even than the opioid epidemic. It is associated with increased risk of several chronic diseases. Bariatric surgery is an effective and safe technique for the treatment of morbid obesity and co-morbidities related to obesity.

Objective: This study aimed to evaluate the effect of lifestyle modification module on patients’ compliance postoperative bariatric surgery.

Method: A quasi experimental design was utilized for the study. A purposive sample of 104 patients with postoperative bariatric surgery who are selected according to certain inclusion criteria.

Results: There was significant improvement in patients’ compliance post implementation of lifestyle modification module where the pre compliance mean score was 21.04±8.07 and the post mean score was 33.59±8.34.

Conclusions: Lifestyle modification module has positive effect on improving patients’ compliance postoperative bariatric surgery. This demonstrates that the module is an effective intervention for postoperative counseling to improve bariatric surgery outcomes.

Keywords: Postoperative bariatric surgery, lifestyle modification, patient’s compliance.

Introduction

Obesity has been recognized as a universal global health problem, described as an epidemic by the World Health Organization (WHO). It is a chronic, life-limiting disease, which is associated with a number of serious health conditions such as type 2 diabetes mellitus, cardiovascular disease, high blood pressure, obstructive sleep apnea, asthma, osteoarthritis, and some types of cancer¹². Bariatric surgery is increasingly recognized as the most effective treatment for individuals who are severely obese. Bariatric surgery not only helps in weight reduction, but also improves obesity-related medical conditions and consequently increases the quality of life³.

Worldwide, the total number of bariatric surgery performed in 2014 consisted of 579,517 surgical operations. Compared with 2017, the total number of metabolic and bariatric procedures performed in the united states in 2018 increased from approximately 228,000 to 252,000⁴⁵.

Patients undergoing bariatric surgery are required to adhere to the postsurgical behavioral recommendations that includes; following specific eating and drinking behaviors; exercise regularly; take medication/supplements daily; and attend follow-up medical appointments for regular monitor and evaluation of health status⁶⁷.
It is recommended that patients receive lifestyle modification instructions in the form of a discussion or seminar, booklet or through support groups, educational sessions and one-to-one discussions that provides information of recovery and lifestyle behaviors change[^8,^9].

**Method**

In the present study, quantitative and evaluative approach was used. Research design was quasi experimental: one group pre test - post test. Study was conducted in bariatric surgery outpatient clinic and bariatric surgery department at El-Demerdash Hospital which affiliated to Ain Shams University, Cairo, Egypt.

The sample of 104 postoperative patients with bariatric surgery. Type I error with significant level alpha (α) = 0.05 (confidence level 95%). The inclusion criteria were: patients’ one month postoperative bariatric surgery, age over 18 years, from both sexes, obesity related co-morbidity.

The structured questionnaire was administered.

1. Demographic characteristics and patients’ clinical data.

2. (A) Postoperative compliance assessment tool, developed by the researcher using the related literatures (American Society for Metabolic and Bariatric Surgery Surgery[^10^]; still et al[^11^] and Kumar and Gomes[^12^]). (B) Medication Adherence Rating Scale (MARS): adopted from (Thompson et al, 2000[^13^]). (C) Perceived Stress Scale (PSS): adopted from (Cohen et al., 1983[^14^]). (D) Bariatric Analysis and Reporting Outcome System (BARO) and quality of life questionnaire: adopted from (Moorehead et al., 2003[^15^]).

Data collection started by selecting patients who are met the inclusion criteria, informed consent was taken followed by the pretest and distribution of lifestyle modification module. Patients’ tools were filled in by the researchers or by the patients according to patients’ educational level.

Patients followed and evaluated after six months post sessions. Data collection process starting at December 2018 until the end of September 2019.

Statistical analysis was performed with SPSS for window, version 20.0 Armonk, NY: IBM Crop. Data analysis was done using A chi-square test $x^2$ and the values were considered statistically significant when p-value $< 0.05$.

**Results**

**Patients’ Characteristics:** Table (1) shows the mean age of all patients was 32.57±6.18 years. The study participants include 78 female (75%), 75 urban (72.1%), 51 diploma education (49%), 81 not working (77.9%) and 67 married (64.4%).

**Regarding clinical data:** Table (2) illustrates that 96 suffered from chronic disease (92.3%), 85 were obese (81.7%), 56 were between 40 kg$^2$<50 kg$^2$(53.8%) of body mass index, 100 patients followed program before to lose weight (96.2%), 52 diet regimen only (50%) and 101 gain weight (97.1%).

Table (3) demonstrates significant difference in total compliance post implementation of lifestyle modification module where mean score pre module implementation was (9.51±3.32, 3.53±3.27, 3.95±1.27, 3.50±1.51, 21.04±8.07) and post implementation of lifestyle modification module was (13.82±3.28, 9.06±3.19, 5.58±1.24, 4.48±0.85, 33.59±8.34) respectively.

Table (4) illustrates significant differences in total mean scores of patients’ compliance with medication, perceiving stress and Bariatric Analysis and Reporting Outcome System (BARO): quality of life post implementation of lifestyle modification module with 95% confidence interval 1.542-2.164, 2.063-2.349, 2.133-2.867 respectively.

Table (1): Percentage distribution of the studied patients according to their demographic characteristics (n=104).
### Table (2): Percentage distribution of the studied patients regarding clinical data (n=104).

Discussion

This study evaluates the effect of lifestyle modification module on patients’ compliance postoperative bariatric surgery and found that it produced a significant improvement in patients’ compliance. The hypothesis of the study demonstrated that the module is an effective tool to help this group of bariatric surgery patients to modify their lifestyle.

The study findings illustrates that, more than half of patients achieved good level of compliance with diet instructions post implementation of lifestyle modification module. This result may be due to the motivation and support provided by researchers and the desire of patients to achieve good outcomes of operation and appropriate weight loss. In addition to improved patients’ skills in preparing foods, selecting types and eliminating prohibited diet.

This result agree with Kalarchian et al. who found that there was statistically significance difference in weight change of the studied patients at 4 months and 6 months after surgery post eating guidelines interventions[16]. While Toussi, Fujioka and Coleman stated that the non compliance was higher after the surgery regarding diet recommendations[17].

There was statistically significance difference in patients’ compliance post implementation of lifestyle modification module. This may be due to that the researchers ensured that the successful outcomes of bariatric surgery didn’t depend only on compliance with diet or medication but it also includes physical exercises that help to achieve the desirable weight loss. This result is agreed with Coen et al. who reported that two thirds of the studied patients successfully completed the recommended physical exercise interventions at the first six months after bariatric surgery[18].

The majorities of the studied patients have good level of compliance with sleep and rest instructions after bariatric surgery. This is because patients stated that the recommended instructions about sleep and rest after bariatric surgery in the module was easy and simple to applied and followed. This enhances quality, duration of sleep and improves obstructive sleep apnea, and body posture. This result is consistent with Mello et al. who stated that bariatric surgery have demonstrated improvement in sleep disorders in people after surgery due to the impact of weight reduction[19].

The majority of the studied patients have good level of compliance with follow up after bariatric surgery. This due to that patient recognized the importance of follow up visits during the educational session of lifestyle modification where it promote health and reduce the
risk of weight regain. This finding agree with Dagan et al. who reported that most of studied people attend to follow-up visit at the first 3 months and 6 months and more than three quarters of them attend to follow-up after 12 month of bariatric surgery[20].

There was statistically significant improvement post implementation of lifestyle modification module where, more than half of the studied people achieve fair level of total compliance. This study is agree with Dagan et al. who revealed that all of the studied patients have medium to high adherence to the major lifestyle recommendations during the first year following bariatric surgery[20].

There was statistically significant improvement in patients’ compliance with medication post implementation of lifestyle modification module. This could be attributed to patients’ believes about the importance of prescribed medications and increased their awareness regarding benefits of compliance with vitamins and minerals supplements long life after surgery as a mean to compensate the essential element that have been lost due to small dietary meals intake as a result of surgery mechanism.

This result is consistent with Hood et al. who reported that medication adherence tends to be good in the early post-surgery period, 90% of patients taking supplements daily or every other day 5 months post-surgery[21].

The perceiving of stress was improved among individuals with bariatric surgery because they convinced about the bad effect of stress on health and surgery outcomes, so that they practice and adhere to the stress relieving measures that explained by the researchers. This result go in the same line with Boniecka et al. who reported that, near half of the studied individuals had a moderate level of stress[22].

Regarding Bariatric Analysis and Reporting Outcome System (BARO) and quality of life, there was a statistically significant improvement post implementation of lifestyle modification module among studied people where (pre mean score= 1.57±0.89 and post mean score= 5.00±1.47). This finding is supported by Alkassis et al. who found that there was a statistically significant improvement in people quality of life domains after surgery and no one had a very poor or poor quality of life score, where (pre mean= −0.33±0.93 and post mean= 1.68±0.62)[23].

Conclusion

Implementation of lifestyle modification module has positive effect on improving patients’ compliance post-operative bariatric surgery regarding diet, physical exercise, sleep and rest instructions, follow up visits, medication adherence, stress perceiving, and quality of life.

The Association of Serum Irisin with Vitamin D and Body Mass Index in Healthy Adults

Anwar A. Saiel1, Rashied M. Rashied2, Khalid F. AL-Rawi3

1Scholar Researcher, Department of Biology, College of Sciences, University of Anbar, Ramadi, Iraq, 2Scholar Researcher, Department of Biotechnology, College of Sciences, University of Anbar, Ramadi, Iraq, 3Scholar Researcher, Department of Chemistry, College of Sciences, University of Anbar, Ramadi, Iraq.

Abstract

Objectives: This study was designed to explore the relationship between serum irisin hormone with Vitamin D levels and investigate the association of serum Vitamin D3 concentrations and serum irisin levels with BMI of male healthy individuals in Anbar province.

Method: This study included 84 Iraqi men with the age range (20-40) year, divided into three groups depending on body mass index (BMI). The weight and height of all participants were taken to extract BMI. The ELISA method has been used to estimate levels of vitamin D and the irisin hormone in the serum. Pearson correlation coefficient was used to find the association between the studied variables.

Results: The mean and standard deviation of serum vitamin D concentrations was significantly lower in all groups. This study showed there was non-significant difference in the mean of irisin among the three groups. A negative linear correlation was found between vitamin D and BMI, while a positive correlation with irisin. A positive correlation was found between irisin with BMI.

Conclusion: People with a high BMI are deficient in Vitamin D. There was a positively relation between serum irisin levels and BMI.

Keywords: Serum, Irisin, hormone, Vitamin D, BMI.

Introduction

Vitamin D is a set of sterol hormones which have a function as a hormone and are required for the growing and conservation of bone tissue, also for the calcium and phosphorous homeostasis (1). Its levels are evaluated through the plasma 25-hydroxyvitamin D levels [25(OH)2D] (2). It is regarded as a hormone which acts through nuclear receptors called vitamin D receptor (VDR) which present in various organs such as bone, kidneys, intestine, brain, immune system, and most different body parts (3). The main source of 25(OH) D is daily sunlight exposure, numerous functions of over two hundred genes regulated by vitamin D and is vital for maturity and growth. There are two forms of vitamin D: Ergocalciferol (Vitamin D2) and Cholecalciferol (vitamin D3) (4). Vitamin D3 can be performed in two ways: firstly, by intestinal absorption, secondly, endogenously by a precursor of 17-hydroxyl cholesterol on the skin with adequate exposure to UV day time (5). Many studies have revealed that obesity, described as a BMI ≥ 30 kg/m², and low serum 25(OH)D levels are linked with many diseases (6, 7).

Irisin/FNDC5 a newly detected hormone that became a promising target for the connection between health and physical exercise in recent years (8). Irisin is a hormone similarly as polypeptide consisting of 112 amino acid and is split from the carboxyl end of a membrane-spanning protein with 196 amino acid so-called FNDC5 (9). Fibronectin type three domain-containing protein five(FNDC5) forms of an extracellular area containing the fibronectin type three (FnIII) domain, which is disunited from a slight cytoplasmic area by the helical trans membrane part and is split to irisin(10). Irisin is a myokine that expressed and secreted principally by muscle tissue, and its secretion is especially stimulated by exercise performing on white adipose tissue by
Peroxisome proliferator-activated receptor gamma (PPAR-γ) coactivator-1α (is a part of a family of transcription co-activators that acts a fundamental role in the regulation of cellular energy metabolism) (9). Irisin hormone is considered a transporter that enhances the transformation of the lipid-storing white adipose to the brown adipose tissue that catabolize the energy leading to raise thermogenesis (11). Additionally, Irisin improves oxidation of fatty acid and glucose metabolism, retard atherosclerosis (12). Pardo et al., They indicated that an increase in fat body mass about (1) kilogram could cause a double rise in irisin levels (13), Whereas two previous studies have shown that losing weight in people described as obese leads to low levels of irisin in the blood (14).

Materials and Method

The current study was done at the college of science, University of Anbar, and the General Educational Hospital in Ramadi city from August 2019 to January 2020. This study includes three groups of healthy individual men in the range of age (20-40) years. These groups have no chronic disease or infectious disease when they are tested, were chosen by depending on body mass index (Normal group (A): BMI=18.5 to 24.9 kg/m², Obese group (B): BMI≥30 kg/m², and Underweight group (C): BMI≤18.5 kg/m²). From each individual, (5 mL) of blood were obtained in the early morning after fasting (10-12) hours. This amount of blood, after serum isolation, stored in Eppendorf tubes in a freezer at -20ºC for hormonal analysis. Serum vitamin D levels and irisin hormone levels were estimated by the enzyme-linked immunosorbent assay (ELISA). Calculation of body mass index was done by “dividing the body weight in (Kilogram) by the square of the height (in meter)”(16).

Statistical Analysis: The statistical analysis was carried by using the computer program SPSS version 16 (Statistical Package for Social Sciences). All studied parameters were expressed as mean±standard deviation (SD). The significance of differences among the groups was determined by a one-way ANOVA test. The correlations between variables were confirmed by Pearson correlation analysis.

Results

The mean of BMI in group A was (24.4 ±1.48 kg/m²), which showed a significant difference with group B (36.7 ±4.52 kg/m²) and group C (18.4±0.45 kg/m²) at p ≤ 0.05, Table 1. The mean of Vitamin D in A, B and C groups (18.27±10.23 ng/mL), (17.26±8.17 ng/mL), (20.25±10.77 ng/mL) respectively showed there was non-significant difference (Table 1). In this study, there was non-significant difference in serum irisin among A, B, and C groups (Table 1). As appeared in Table 2, Pearson analysis showed a negative correlation between vitamin D and BMI (r=- 0.252) at P ≤ 0.05. While a weakly positive association was shown between vitamin D and irisin (r=0.21) at p≤ 0.05. A moderate positive correlation was showed between irisin with BMI at p<0.05 (r= 0.477).

Discussion

This result showed that the majority of the individuals who participated in this study were suffering from hypovitaminosis D. Most of those with vitamin D deficiency were in the obesity and normal groups compared with underweight group. In 2016, Wakayo T et al., (17) indicated that vitamin D deficiency was associated with metabolic syndrome. Vitamin D levels insufficient could have numerous causes, like irregular intestinal function or malabsorption, decreased intake or raised degradation of vitamin D(18). Some researches proposed that obesity improved the chance of vitamin D deficiency(19). In a study to observe the predominance of vitamin D deficiency in adult Iraqi personages including postmenopausal women, they showed that
deficiency of vitamin D happened in more than (85%) of postmenopausal women, more than (60%) of young men in age (25-49) years (20). The significant decrease in the level of vitamin D in this study is due to numerous causes, such as: eating poor meals with vitamin D, lack of exposure to sunlight, the geographic location or the lack of animal sources (milk, cheese, and egg yolks) as a similar result with the previous study (21). Underweight is considered as an abnormal condition like obesity due to its association with several cases such as mental health defect, a decline of muscle strength, osteoporosis and cardiovascular disease(22). In the current period, FNDC5/irisin became a hopeful aim for the link between physical activity and body health(23). There are some studies investigated that serum irisin is unclear in obese individuals. One previous study includes (300) obese cooperators discovered that serum irisin levels were not significant higher than those in the group of controls (24). Other investigations reported to lowering the serum irisin concentrations in obese subjects than in normal weight, but the variation was correlated with presence or absence of DM (25,26). The mechanisms that control synthesis and secretion of irisin are not perfectly known (27). In the common people, irisin levels increase with daily activities and serum irisin is correlated with the lipid profile (28).

For the correlation relationships, These results agreed with Taheri et al., (29) who have found that serum levels of 25(OH)D has a negative correlation with body mass index in adults with and without type 2 diabetes mellitus in Iran. A new meta-analysis revealed a positive linking between obesity and vitamin D deficiency in whole age groups (30). A study by Vimaleswaran et al., (31) showed high BMI cause lowering in vitamin D levels between both men and women in various age groups, presenting strong argument about role of obesity as a crucial risk agent in hypovitaminosis D. This finding corresponding with Al-Daghri et al., (32) who found a significant increase in circulating irisin level at 12 months post-vitamin D intervention. Also this result agreed with previous study in Iraqi rheumatoid arthritis males patients with diabetes mellitus type II (30). In a previous study, Irisin levels were associated with “body mass index (BMI)” and fat accumulation, and researchers revealed that the main source of irisin levels is adipose tissue in the serum of patients (13). Most studies additionally revealed a positively association between the levels of irisin hormone and body mass, mass of fats, and, infrequently, waist-hip ratio. In a health people, the greatest of the irisin concentrations in the blood comes from the muscle cells, but, in case of obesity, the rate of irisin that secreted from adipose tissue is apparently more elevate than in lean status because of the rise in fat mass totally(31). There is second clarification about the relationship between irisin levels with fat mass and BMI, might be in the resistance progression of irisin. In obesity, the secretion of Irisin increased from muscle cells, perhaps to increase using of energy and glucose homeostasis to reach a metabolic balance (32).

Conclusion
The current study showed a decrease in vitamin D levels in the study sample subjects for the three groups who are healthy. The hormone irisin has a critical correlation with BMI. People with a higher body mass index are more likely to have a vitamin D deficiency.

Efficacy of Health Belief Model-Based Intervention in Enhancing Breast Cancer Screening Behaviors among Women at Al-Najaf Al-Ashraf City

Alaa Abdul-hadi Kadhim1, ArkanBahlol Naji2

1M.Sc. N(c), Research Scholar, University of Baghdad, College of Nursing, 2Professor (PhD), University of Baghdad, College of Nursing, Community Health Nursing Department

Abstract

Background: Breast cancer is disease in which cells in breast tissue change and divide uncontrolled, resulting in a lump or mass. This study aims to determine the efficacy of health belief model-based intervention in enhancing women’s breast cancer screening behaviors.

Method: A randomized controlled trial was conducted using the Health Belief Model. The study included a systematic random sample of 110 women. Women who age 22-68-years were selected from Banks in Al-Najaf Al-Ashraf City.

Data were collected through a self-report instrument that includes women’s sociodemographic characteristics of age, marital status, and economic status, the Perceived Susceptibility Scale, the Perceived Benefits Scale, the Self-Efficacy Scale, the Health Motivation, the Perceived Severity Scale, and the Perceived Barriers Scale. Data were analyzed using the statistical package for social sciences, version 26.

The study results revealed that HBM-based intervention was efficacious in enhancing the Perceived Susceptibility, the Perceived Benefits, the Self-Efficacy, the Health Motivation, the Perceived Severity, and the Perceived Barriers for women in the study group. The researcher concluded that the HBM-based intervention was efficacious in enhancing women’s screening behaviors for breast cancer.

Conclusion: The researcher concluded that the HBM-based intervention was effective in enhancing women’s breast cancer screening behaviors.

Keywords: Health Belief Model-Based Intervention, Breast Cancer, Screening Behaviors.

Introduction

Cancer is a present of abnormal cells that spread and characterized by the uncontrolled growth and result in death. If the spread is not controlled (1). Globally, more than half new cases deaths from cancer among worldwide of men and women combined in 2018 are estimated to occur in Asia, because the region has nearly 60% of the global population (9).

Breast cancer is disease in which cells in breast tissue change and divide uncontrolled, resulting in a lump or mass. Most breast cancers begin in the lobules (milk glands) or in the ducts that connect the lobules to the nipple (1) during 2013 year 4,529 women with breast cancer were forming loss of life, and 909 ladies died from that disorder due to late analysis and insufficient administration (10). According of American Cancer Society (ACS) there are three screening method are BSE, clinical breast examination, mammography. Mammography is more effective way for early detection of breast cancer (3). Breast self-examination make women aware of their breasts so as to detect changes early (4).

In health education, the Champion Health Belief Model (CHBM) is theoretical models used to study the health behavior that can be introduced by Champion in the 1980s. This model has been widely used by researchers (5). When people find themselves at risk for the disease (Perceived Susceptibility), realize that the disease has serious potential consequences (Perceived Seriousness), believe that prevention would have positive results...
(Perceived Benefits), barriers of that behavior is fewer than obtained benefits (Perceived Barriers), and believe that they have the ability to perform health behavior activities (Self-Efficacy), it would be more probable for them to accomplish this behavior.(6)

A randomized controlled trial design was used to guide this study in Banks of Al–Raafidayn/branch Al-Amir, Al-Ghuri, Seven, and Muslim Bin Aqeel at Al-Najaf Al-Ashraf for the period from February 1th, 2020 to thirty of April, 2020 on probability randomized sampling method (systematic random samplings method) to recruit study subjects. Data were collected through a self-report instrument that includes First part: The demographic characteristics of the nursing staff (age, marital status, economic status).

The validity of the questionnaire and the educational program were verified by presenting it to (9) experts. The sample has received a pre-test, intervention based health belief model, and post-test I, Post- test II. Descriptive and inferential statistics were used to analyze the results of the study using the Statistical Package of Social Sciences (SPSS) version 26.

Table (1) The age mean for participants in the study group is 41.21±10.32; more than two-fifth age 44-55-years (n = 25; 45.4%), followed by those who age 33-43-years (n = 14; 25.5%), those who age 22-32-years (n = 11; 20.0%), and those who age 55-68-years (n = 5; 9.1%).

For the control group, the age mean is 41.76±10.17; two-fifth age 44-54-years (n = 22; 39.5%), followed by those who age 33-43-years (n = 15; 27.3%), those who age 22-32-years (n = 12; 21.8%), and those who age 55-68-years (n = 6; 10.9%).
There are significant differences in the values of the HM for BSE over time for participants both in the study and control groups (F = 186.222, df = 2, p < .05 vs. F = 9.352, df = 2, p < .05).

There are significant differences in the values of the Perceived Susceptibility for contracting breast cancer over time for participants both in the study and control groups (F = 339.015, df = 2, p < .05 vs. F = 3.723, df = 2, p < .05).

There are significant differences in the values of the Perceived Severity of breast cancer over time for participants both in the study and control groups (F = 133.393, df = 2, p < .05 vs. F = 3.879, df = 2, p < .05).

a. Design: Intercept Within Subjects Design: Perceived Benefits of BSE, b. Exact statistic

There are significant differences in the values of the Perceived Benefits of BSE over time for participants both in the study and control groups ($F = 226.598$, df = 2, $p < .05$ vs. $F = 6.868$, df = 2, $p < .05$).

**Discussion**

Concerning the values of the Health Motivation (HM) for BSE for the study group, there was a noticeably increase by time compared to the control group. Also, there was a priori significant difference in the HM for BSE over time for participants in the study group. The omnibus effect (measure of association) for this analysis is .567, which indicates that approximately 56% of the total variance in the HME for BSE values is accounted for by the variance in the administered intervention. For the control group, there was no significant difference in the HM for BSE over time. Furthermore, there was a constant difference in participants’ HM for BSE in the study group over time. These findings reflect the positive, constant effect of the administered intervention in enhancing participants’ HM for BSE. These findings are consistent with (8) with who concluded that The results of the data analysis showed a statistically significant difference between the intervention and control groups regarding the mean scores of knowledge and motivation before the intervention (P>0.05) and after intervention the mean score and standard deviation for intervention group 40.84±6.21 while control group 38±6.47.

Regarding the values of the Perceived Susceptibility for developing breast cancer for the study group, there was a noticeably increase by time compared to the control group. Also, there was a significant difference in the Perceived Susceptibility for developing breast cancer over time for participants in the study group. The omnibus effect (measure of association) for this analysis is .521, which indicates that approximately 56% of the total variance in the Perceived Susceptibility for developing breast cancer values is accounted.

For by the variance in the administered intervention. For the control group, there was no significant difference in the Perceived Susceptibility for developing breast cancer over time. Furthermore, there was a constant difference in participants’ Perceived Susceptibility for developing breast cancer in the study group over time. These findings reflect the positive, constant effect of the administered intervention in enhancing participants’ Perceived Susceptibility for developing breast cancer. These findings are consistent with (7) who concluded that mean score and standard deviation for experimental 4.33±28.14 and p-value 0.007 while in control group 4.32±14.79 and 0.23 The results of the present study indicate a significant increase in the post-test mean scores on perceived susceptibility and severity in the experimental group compared to the control.

Regarding the values of the Perceived Severity of
breast cancer for the study group, there was a noticeably increase by time compared to the control group. Also, there was a significant difference in the Perceived Severity of breast cancer over time for participants in the study group. The omnibus effect (measure of association) for this analysis is .371, which indicates that approximately 37% of the total variance in the Perceived Severity of breast cancer values is accounted for by the variance in the administered intervention. For the control group, there was no significant difference in the Perceived Severity of breast cancer over time. Furthermore, there was a constant difference in participants’ Perceived Severity of breast cancer in the study group over time. These findings reflect the positive, but not constant effect of the administered intervention in enhancing participants’ Perceived Severity of breast cancer. These findings are consistent with(7) who concluded that the mean score and standard deviation for experimental group. 4.01±26.75 and p<0.001 and control group 1.67±84.10 and p-value 0.36 after intervention with respect to the values of the Perceived Benefits of BSE for the study group, there was a noticeably increase by time compared to the control group. Also, there was a significant difference in the Perceived Benefits of BSE over time for participants in the study group. The omnibus effect (measure of association) for this analysis is .550, which indicates that approximately 55% of the total variance in the Perceived Benefits of BSE values is accounted for by the variance in the administered intervention. For the control group, there was no significant difference in the Perceived Benefits of BSE over time. Furthermore, there was a constant difference in participants’ Perceived Benefits of BSE in the study group over time. These findings reflect the positive, constant effect of the administered intervention in enhancing participants’ Perceived Benefits of BSE. These findings are consistent with (7) who concluded that the study results demonstrated a significant increase in the post-test mean score of perceived benefits in the experimental group compared to the control group. Mean±SD 1.23±22.20 for the experimental group and the control group 1.67±84.10.

Conclusion

1. The Customer Satisfaction Scale is very important to assess the quality of health services and can predict compliance and use with international standards for quality of services.

2. The study found that most primary health care centers are located in densely populated areas. Therefore, primary health care services are adequately provided.

Recommendations: The researchers recommend it is necessary to incorporate health belief model-based interventions into the curricula of graduate programs in Iraq.

Encourage graduate students to adopt intervention-based studies in their future proposed research.

Conflict of Interest: The researchers confirm that there is no any conflict of interest.

Source of Funding: This study is self-funded.

Ethical Clearance: The researchers obtained the ethical approval from the University of Baghdad, College of Nursing.

Abstract

Background: Determining the sperm quality can be measured by calculating sperm motility and sperm motility is governed by intracellular calcium (Ca²⁺) concentration. However, the intracellular calcium increase found in essential hypertension cases may decrease acrosome reaction and increase ROS production, and may trigger sperm cell apoptosis. Ground cherry (Physalis angulata L) is an herbal plant containing bioflavonoid as antioxidant which is crucial to defend against free radicals and prevent toxic effects.

Objective: This study aims to test the capacity of Physalis angulata L. extract, in preventing disruption of sperm motility in male Wistar strain rats model of hypertension through oxidative stress reduction and cytosolic calcium regulation.

Method: Experimental animal male white rat (Rattus novergicus) model of hypertension were intraperitoneally inducted with L-NAME. The animals were divided into 5 treatment groups and given Physalis angulata L. leaf water extract with various doses for 14 consecutive days. At the end of the study, animals were sacrificed, and testes were taken for measuring the MDA levels, intracellular calcium, and sperm motility.

Results: Physalis angulata L. leaf water extract is proven to prevent increasing number of testicular MDA level, prevent increasing number of sperm intracellular calcium, and prevent decreasing number of motile sperm in male white Wistar strain rat model of hypertension.

Conclusion: The results show that the Physalis angulata L. leaf water extract is proven to prevent the increase of MDA testis level and the increase of intracellular calcium testis amount, and prevent the number of motile sperm on male Wistar strain white mice model of hypertension.

Keywords: Physalis angulata L., malondialdehyde (MDA), Sperm Intracellular Calcium, motile sperm, Hypertension.

Introduction

Infertility is defined as a failure to pregnant after one year of attempting pregnancy by having regular sexual intercourse without contraception(1). Among men with an average age of 38 years, 44% has infertility due to hypertension that results in testicular organ damage, but the mechanism remains unclear. In hypertension, ROS increases. It is strongly suspected that oxidative stress due to hypertension plays an important role in infertility pathomechanism(2-5). At the cellular level, Reactive Oxygen Species (ROS) has a toxic effect that can damage sperm(6, 6).

The sperm quality can be measured by calculating sperm motility because it reflects the normal development and maturation of spermatozoa in epididymis. Sperm motility is governed by intracellular calcium (Ca\(^{2+}\)) concentrations\(^7\). In the homeostatic state, calcium (Ca\(^{2+}\)) is the second messenger that regulates cell function, including sperm cells \(^8\). However, an increase in intracellular calcium found in cases of essential hypertension may decrease acrosome reaction and increase ROS production, which in turn triggers apoptosis in sperm cells. Apoptosis induction can increase ROS production in intertesticular levels that reduces fertility in men \(^9\).

Ground cherry (\textit{Physalis angulata} L.) is an herbaceous plant containing saponins, flavonoids, and also polyphenols \(^10\). Bioflavonoids are antioxidants that play an important role as a scavenger of free radicals from a disease, aging, and toxic effects of a substance \(^4\). Previous studies have shown that \textit{Physalis angulata} L. has the ability to suppress lipid peroxidation evaluated by MDA level measurement \(^11\).

This study aims to test the capacity of \textit{Physalis angulata} L. extract in preventing disruption of sperm motility in male Wistar strain rats model of hypertension through oxidative stress reduction and cytosolic calcium regulation.

**Material and Method**

The capacity is measured through MDA testicular measurement, calculation of sperm intracellular calcium and sperm motility. This study Male used white wistar strain rats (\textit{Rattus novergicus}) aged 2-3 months, and 150-200 gram in weight as experimental animal. The experimental animals model of hypertension were inducted with L-NAME intraperitoneally with systolic blood pressure >120 mmHg. The simplicia ingredient used was \textit{Physalis angulata} L. leaf water extract obtained and identified from Materia Medika Medicinal Plant Body, Batu-Malang.

**Experimental Protocol:** In this study the rats were divided into 5 groups, i.e. negative control (1) given NS solution intraperitoneally without treatment, positive control group (2) hypertension without treatment, group 3 (3) hypertension + treatment dose of 250mg/kgBW, group 4 (4) hypertension + treatment dose of 500mg/kgBW, and group 5 (5) hypertension + treatment dose of 1000mg/kgBW. Induction of hypertension and administration of extract were given simultaneously for 14 consecutive days. Induction of hypertension was using L-NAME 40mg/kgBW intraperitoneally\(^4\).

**MDA Testis:** MDA level calculation is the measurement indicator of oxidative stress measured on mouse testicular organs. MDA tissue was measured using Thiobarbituric Acid test. The specimen tissues were weighed as much as 0.1 grams and then homogenized and added Trichloracetic Acid (TCA) 15\%, Thiobarbituric Acid 0.375\% and 0.25 mol/l HCL (in a comparison of 1: 1: 1)\(^12\). Then it was heated for 15 minutes on boiling water. After cooling, the precipitate in the tube was separated by centrifuging at 1000 rpm for 10 minutes. Then the supernatant absorbance was calculated using spectrophotometry at a wavelength of 532 nm \(^4\).

**Sperm Suspension:** Cauda epididymis was taken and inserted into a petri dish containing NaCl 0.9\% solution, chopped with a scalpel until the liquid was cloudy. The obtained spermatozoa suspension can be used for the analysis of the number of spermatozoa motility and Sperm Intracellular Calcium.

**Sperm Intracellular Calcium:** 10 μl sample of sperm suspension was added with 10 μl of Fluo-3 (Sigma-Aldrich) 40 μM, and then it was incubated for 30 min. Then 60 μl PBS (-) was added and centrifuged at 1500 rpm for 5 minutes, it was then observed under Olympus FV 1000 confocal microscope. The PBS (-) is without Ca and Mg content. PBS (-) composition consisted of NaH\(_2\)PO\(_4\) 18 g, NH\(_2\)PO\(_4\) 0.64 g, NaCl 4 g and then sterilized water was added until reaching 250 ml in volume.

**The Number of Motile Sperm:** The evaluation was done by observing spermatozoa in ten different fields of view with 400 x magnification light microscope. The spermatozoa would then be grouped into several categories according to WHO criteria of progressive mobility (A + B), non-progressive mobility (C), and immobile (D) \(^13\).

**Statistical Analysis:** One-Way ANOVA Test was used to see all treatment groups, and continued with Post hoc test. Pearson - Linear Regression correlation analysis was used to analyze the relationship of dose and motility. Meanwhile, Path Analysis was used to analyze the relationship between variables.
Results

MDA Testis: Notation differences in the histogram describe that there are significant differences based on Tukey test ($p < 0.05$; figure 1). The testicular MDA levels of the positive control were significantly higher compared to the negative control. The MDA testicular level at dose 1 was significantly lower compared to the positive control but not significant to the negative control.

Sperm Intracellular Calcium: The amount of intracellular calcium was calculated based on Fluo-3AM color intensity observed under a confocal microscope (figure 2). The amount of sperm intracellular calcium of positive control was significantly higher compared to that of the negative control. The amount of sperm intracellular calcium in all three doses was significantly lower compared to the positive control (figure 3).

The Number of Motile Sperm: The motile sperm number of positive control was significantly lower compared to the negative control (figure 4). The numbers of motile sperm in all 3 doses were significantly higher compared to the positive control but not significant to the negative control.

The Effect of MDA Testis and Sperm Intracellular Calcium on Sperm Motility: Based on the result of testicular MDA correlation, $r$ value = 0.789 with $p = 0.002$ was obtained which means that there is a very strong and significant correlation between the doses of ground cherry leaf water extract with testicular MDA levels. Based on path analysis, results were obtained as in Figure 5. The results of this study show that MDA testis and sperm intracellular calcium do not significantly influence the number of motile sperm.

Figure 1. Diagram of the Mean and Standard Deviation of Malonaldehyde (MDA) Testis Levels.

Figure 2. Results of sperm staining with fluo-3AM
Discussions

Testicular MDA levels were significantly higher in the positive control group compared to the negative controls. L-NAME-induced hypertension condition increases both vascular and systemic oxidative stress characterized by decreased antioxidant activity in the testes and increased lipid peroxidation due to decreased NO bioavailability (4).

The lowest testicular MDA content was found in the treatment group given Ground cherry leaf water extract of 250 mg/kgBW and was not significantly different from negative control. It shows that a dose of 250 mg/kgBW of Ground cherry leaf water extract can lower testicular MDA level to normal. This is caused by the antioxidant content of Ground cherry leaf water extract. Antioxidants are compounds that can delay, slow down, and prevent lipid oxidation processes. The inhibition mechanism of lipid peroxidation by Physalis angulata L. leaf water extract involves compounds that are capable of counteracting free radicals. One of the compounds that can inhibit lipid peroxidation to capture free radicals is polyphenol compounds, especially flavonoid compounds (14). Flavonoid ability as antioxidants is because flavonoids act as free radical scavengers. The presence of a 3', 4' (ortho-dihydroxy) hydroxyl group on flavonoid B ring, 2,3 conjugated double bond with 4-oxo group (1.4-pyrrole group) on C-flavonoid ring and
hydroxyl group (5-OH) on flavonoid ring A\(^{(14)}\). Several studies have concluded that bioflavonoids can prevent changes of tissue function by increasing NO level in the testicular tissue \(^{(4)}\). Thus, *Physalis angulata* L. leaf water extract can be used to prevent elevated testicular MDA level at doses of 250 mg/kgBW. Increased MDA level in the treatment groups can be assumed as an early marker of the pathogenesis of complications. This is consistent with research that conclude that MDA levels determine the pathogenesis of type 2 DM complications because increasing MDA illustrates antioxidant use to fight free radicals which leads to a decrease in total antioxidant status \(^{(15, 16)}\).

The results of this study revealed that the amount of sperm intracellular calcium was significantly higher in the positive control group compared to the negative control. This is due to a condition in hypertension from L-NAME induction, decreasing NO bioavailability and increasing ROS occur \(^{(4)}\). The decrease in Nitric oxide (NO) causes soluble guanil cyclase (sGC) not to be activated. As a result, the concentration of cyclic Guanin Monophosphate (cGMP) decreases and calcium increases. The decrease of cGMP gives an effect to inactivate the potassium channel so that the calcium canal is open due to increased voltage, so that there is an increase of Ca\(^{2+}\) entry to intracellular \(^{(17)}\).

In addition, the amount of intracellular calcium is also affected by ROS. ROS can induce increased cytosolic Ca\(^{2+}\) concentration through releasing from its storage and due to changes in clearance system. In oxidative stress state, there is an imbalance between calcium release and its storage. In mitochondrial dysfunction, there is an increase in Ca\(^{2+}\) uptake and Ca\(^{2+}\) release and in the endoplasmic reticulum Ca\(^{2+}\) uptake also increases. Therefore, an increase in intracellular Ca\(^{2+}\) happens \(^{(18, 19)}\).

In all three doses administered to the treatment groups, the amount of sperm intracellular calcium was significantly lower compared with the positive control group. The possible mechanism of antioxidant action of *Physalis angulata* L. leaf water extract was through releasing from mitochondrial and cytoplasm, and resulting in decreased number of sperm, activity, motility, and morphological changes \(^{(4)}\).

Excessive ROS in hypertension causes cell membrane damage because the cell membrane consists of fatty acids, which can be oxidized (lipid peroxide) and the cytoplasm has only small concentration of enzyme to neutralize ROS. Lipid peroxidation on the cell membrane cell causes cell membrane to lose its integrity and increase the permeability, so it inactivates cellular enzymes, DNA damage, and cell apoptosis, and resulting in decreased number of sperm, activity, motility, and morphological changes \(^{(4)}\).

However, data analysis on all three doses showed a significantly higher number of motile sperm compared to the positive control. This is because of the role of NO and antioxidants contained in *Physalis angulata* L. leaf water extract. Previous research show that *Physalis angulata* L. leaf can increase NO. NO affects increased sperm motility through dissolved gallyl cyclase (sGC) activation. Increased NO will be followed by increased cGMP cystesis \(^{(21)}\). In addition, NO can also increase motility through increased energy production in mitochondria \(^{(22)}\). Another mechanism that is assumed to be involved in increasing number of motile sperm...
is the activity of antioxidants. Reactive Oxygen Species (ROS) in the body is controlled by the body’s antioxidant system. So it is assumed that the antioxidant activity in *Physalis angulata* L. leaf water extract can decrease ROS as free radical, so the number of motile sperm increases. Thus it can be concluded that three given doses of *Physalis angulata* L. leaf water extract can increase the number of motile sperm.

This study shows that the levels of testicular MDA and sperm intracellular calcium can not be used as variables that directly or indirectly affect sperm motility. This is consistent with the other research showing that administration of *Physalis angulata* L. ethanol extract may have hypoglycemic effects without affecting sperm quality (23). Sperm motility can also be influenced by several factors, such as sperm flagellar length, intracellular pH, and intracellular calcium (24). Spermatogenesis abnormalities are influenced by endogenous and exogenous factors. Endogenous factors include hormone, psychology, and genetic. Exogenous factors can be chemical, drug, heavy metals, temperature, X-ray radiation, ultrasonic vibration, vitamin, nutrition, trauma, and inflammation. The effects of heavy metals such as lead also affect spermatogenesis process resulting in decreased sperm quality in terms of number, morphology, motility and abnormal forms of spermatozoa (25).

**Conclusions**

Administration of *Physalis angulata* L. leaf water extract dose of 250 mg/kgBW is proven to prevent increasing number of testicular MDA level and prevent increasing number of sperm intracellular calcium in male white Wistar strain rat model of hypertension. Administration of the three doses of *Physalis angulata* L leaf water extract is proven to prevent decreasing number of motile sperm in male white Wistar strain rat model of hypertension.

Abstract

Background: Infertility is a case assuming approximately 15 percent of couples in the world. At Italy, the evaluated percentage increases to 20 percent. There are many reasons for this case, among that a significant function appears to be manipulated by infections of the genital tract.

Aim of the Study: For assessments the influence of syphilis on the safety of infertile patients.

Materials and Method: All specimens of serum were initial evaluated utilizing a non–Treponema pallidum serologic (Ag) analysis to estimated for syphilis disease, & then a Treponema pallidum serologic (Ag) analysis was proceed to assert the positive specimen of syphilis recognized via the checking test.

Results: a total of 137 cases of infertile patients were collected (83 cases in male, 54 cases in female), from 83 cases of infertile male founded that 20 cases were suspected to T. pallidum infection while from 54 case of infertile female were founded that 15 cases were suspected to infection with Treponema pallidum bacteria. Also these results show that patients with continuous infertility have significant level of T. pallidum in females with age 41-50 years (54.55) while males with age 31-40 years (34.62) than the age suspected for T. pallidum is > or = 41 years.

Conclusions: A positive date of syphilis contagion may decrease the average of clinical gestation by sexual contact. Also, this decreasing in the average of clinical gestation needs a diversity of agents, including density of endometrial, grown oocytes number, the number of pollinated, splited oocytes under normal conditions, & the average of implantation.

Keywords: Infertility, T. pallidum, syphilis disease (STD), in vitro fertilization, rapid plasma regain, TPPA test.
initial & minor infertility respectively. Prevalence of a rising infertility is appeared in South Asia, and Africa\(^3\).

However, there are several agents that are responsible for weakness of sexual role of fertility in male & female. These agents involve disorders in hormone, condition of psychological. Every these agents can lead to weakness in the genital organs function, the reproductive cells production, quality of semen, transport cell of sperm to the oocyte, fruitfulness & stages of implantation in embryo\(^4,5\). However, syphilis can be defined as is a disease transmitted by sexual contact caused by bacterium \(T.\ pallidum\), & it's firstly prevalence through sexual contact, from blood or from mother to fetus \(^6\).

Also, infection of reproductive tract can cause approximately 8 percent & 35 percent of every situations of man infertility, respectively \(^7\). In female, it may result in obstruction of fallopian channel & inflammation of endometrium. Approximately 72.4 million people in the world have problems of infertility. Also, in vitro fertilization may be the end refuge for couples trying to control infertility \(^8\). On the other hand, if syphilis disease is left without treatment, the illness may continue for years & result in the incidence of severe complications, as well as granulomas, and paralysis \(^9\).

Also, Pregnant female which is infected with this disease may transport \(T.\ pallidum\) to the fetus, & this leads to reverse consequences of pregnancy, including stillbirth, fetus deaths \(^10\). On the other hand, testing of syphilis, connected with suitable and stimulate treatment of penicillin for infected patients, is proposed by the World Health Organization to stop syphilis transportation\(^11\).

### Materials and Method

**Selection of Patients:** Couples which flopped to conceive after minimum one year of sexual contact without contraception were deemed to be infertile. Infertility was caused by dysfunction of fallopian channel & factors related to man (a detection of asthenozoospermia depending on the World Health Organization laboratory manual for the investigation\(^12,13\).

Every patients afford new ET through the initial rotation & didn’t acquire any treatment for three months before in vitro fertilization. However, patients were precluded if they had ovary tumor, multiple cyst ovarian disorder, disease of thyroid gland, disease of adrenal gland, and diabetes.

Function of ovarian was investigated, and specimen of blood were collected on 2-4 days of menses to investigate the main FSH, LH, & levels of estrogen. Also, tests of sperm phenotype was managed\(^14\). Every participants received serological investigations in the laboratory (the rapid plasma regain \([RRR]\) and agglutination of \(T.\ pallidum\) particle tests \([TPPA]\) to test for the existence infection of syphilis before the treatment of in vitro fertilization.

**Test of syphilis:** All specimens of serum were initial evaluated utilizing a non-\(Treponema pallidum\) serologic (Ag) analysis to estimated for syphilis disease, & then a \(Treponema pallidum\) serologic (Ag) analysis was proceed to assert the positive specimen of syphilis recognized via the checking test\(^15,16,17\). For the rapid plasma regain test, cardiolipin is applied as an Ag to discover antibodies directed against cardiolipin in the patients serum\(^18\). Every specimens of serum for the rapid plasma regain test were gradually diluted (1:1-1:32) in natural saline solution for titer definition\(^19\). In the \(T.\ pallidum\) particle agglutination test, granules of gelatin sensitive to \(T.\ pallidum\) attach to antibodies against \(T.\ pallidum\) in the human serum. The collections of the rapid plasma regain & \(T.\ pallidum\) particle agglutination tests is commonly utilized to the identifying of syphilis through every stages of the illness with appropriate susceptibility & particularity\(^20\).

### Results

**Demographic features of the patient specimen:** SPSS (version 21) was utilized to analyze the current data. Important differences were acquired by utilizing the chi-squared test. Differences between variables were setting as significant in 5% (\(P \leq 0.05\)) & hardly Significant in 1% (\(P \leq 0.01\)).
Table (1): Explain infertile patient & related to the *T. pallidum* with male and female:

**A. Classification cases of infertile patients into male and female (Total=137 cases, 83 cases in male, 54 cases in female).**

| Age groups | No. of cases infertile patients | Male | | Male | Female | | Female | P value |
|------------|---------------------------------|------| | | | | | |
|            |                                 | M    | | | | | | |
|            |                                 | %    | | | | | | |
| 20-30yrs   | 66                              | 42   | | 24 | 36.36 | |       | 0.024* |
| 31-40yrs   | 45                              | 26   | | 19 | 42.22 | |       |       |
| 41-50yrs   | 26                              | 15   | | 11 | 42.31 | |       |       |

* = significant at P≤0.05, Chi-squared test, df=5, α=0.05

**B. Male infertile patients suspected to *T. pallidum* (Total=20 cases)**

| Age groups | No. of cases infertile Male | T. Pallidum + | | T. Pallidum - | P value |
|------------|-----------------------------|--------------| | | | |
|            |                             | M | | M | |
|            |                             | % | | % | | |
| 20-30yrs   | 42                          | 3 | | 39 | 7.14 | | 92.86 | <0.01** |
| 31-40yrs   | 26                          | 9 | | 17 | 34.62 | | 65.38 |       |
| 41-50yrs   | 15                          | 8 | | 7  | 53.33 | | 46.67 |       |
| Total      | 83                          | 20 | | | | | | |

** = significant at P≤0.05, Chi-squared test, df=5, α=0.01

**C. Female infertile patients suspected to *T. pallidum* (Total=15 cases).**

| Age groups | No. of cases infertile female | T. Pallidum + | | T. Pallidum - | P value |
|------------|-------------------------------|--------------| | | | |
|            |                              | F | | F | | | |
|            |                              | % | | % | | | |
| 20-30yrs   | 24                            | 2 | | 22 | 8.33 | | 91.67 | <0.01** |
| 31-40yrs   | 19                            | 7 | | 12 | 36.84 | | 63.16 |       |
| 41-50yrs   | 11                            | 6 | | 5  | 54.55 | | 45.45 |       |
| Total      | 54                            | 15 | | | | | | |

** = significant at P≤0.05, Chi-squared test, df=5, α=0.01

In the above table, a total of 137 cases of infertile patients were collected (83 cases in male, 54 cases in female), from 83 cases of infertile male founded that 20 cases were suspected to *T. pallidum* while from 54 case of infertile female were founded that 15 cases were suspected to infection with *Treponema pallidum* bacteria. Also these results show that patients with continuous infertility have significant level of *T. pallidum* in females with age 41-50 years (54.55) while males with age 31-40 years (34.62) than the age suspected for infection with *T. pallidum* is ≥ 41 years.

**Discussion**

This survey was directed to estimate the appearance of infections in couples with problems of fertility in Iraq. Urogenital tract inflammations are indirectly or directly a main reason of infertile patients in couples since they can damage the genital organ either in female & male, & because *T. pallidum* can perform to the motile sperm agglutination, a modifications in the morphological characteristics of the cell [21,22].

However, the patients plurality were negative & the percent of positive subject was elevated in male and female. Furthermore, in female there are a vast diversity of bacterial types responsible for the infections compare to man. Both these forms can be demonstrated regarding that female is more sensitive to infections of genitourinary tract because the urethra of female is wider and smaller compare to the urethra in the man &
because the vaginal region nearly the vaginal cavity is colonized with potential pathogen.

Also, infection with *T. pallidum*, the bacteria causing syphilis that is a general cause infertility in man[23]. Human immunodeficiency virus-seropositive female have been observed to be co-infected with the *T. pallidum*, and human papillomavirus[24].

However, there is a connection between sex steroids & danger factors of cardiovascular system, quality of semen, and levels of lipid[25]. Low-densitylipoprotein cholesterol and seminal plasma triglyceride may be useful biochemical signals for evaluating infertility in man[26].

A rising number of infertility in patients require aided genital technology treatments. Patients are exposed for viruses & bacteria, as well as HCV, cytomegalovirus, HIV, *T. pallidum*, and *Chlamydia trachomatis* before aided genital technology depending on the European community of person proliferation[27].

At least 90% of female is investigated for syphilis disease before birth & 90 percent of seropositive pregnant male acquire appropriate treatment[28].

Syphilis (as an sexual transmitted disease) may cause pelvic inflammation, that may lead to impairment of endometrium. Moreover, this deterioration produces renewal method, which may thicken the lining of endometrium & lead to functioning of abnormal endometrium & decreased receptivity of endometrium, producing infertility[29,30].

Every female must be investigated for *T. pallidum* through the initial investigation before birth & again in gestation but late[31].

In addition, cytokines and anti-cytokineantibody may influence the fertility of patients infected with syphilis toa particular extent. Also, ACAs are usually present in the patients serum & can suppress the segregation of Langhans layer into syntiotrophoblasts, therapy detrimental cultivated blastocysts which have clusters of an internal cells that forms fetus[32]. However, cytokines are carefully linked to all guise of the genital procedure & can be utilized to foretell the clinical consequence in vitro fertilization[33].

Conclusions
A positive date of syphilis contagion may decrease the average of clinical gestation by sexual contact. Also, this decreasing in the average of clinical gestation needs a diversity of agents, including density of endometrial, grown oocytes number, the number of pollinated, splited oocytes under normal conditions, & the average of implantation.

Abstract

The aims of this study to find the link between each of the parasites (E. histolytic and Giardiasis) infection and intestinal cancer. This study contain 4 groups: - Group (G1) People with cancer and diarrhea due to the parasite (42) Group (G2) People with cancer and diarrhea without parasites (8) Group (G3) People with diarrhea and parasites (24) and Group (G4) Control (30), blood samples were collected from patients suffering from diarrhea and parasite infection of both types, as well as cancer, Elisa kits were used in our study the proteins (mucin 2, TFF3, CALP) level were measure by using Elisa kit that provided from the China Origin Company Elabscience. The results of the current immunological study showed the level of serum (mucin 2, TFF3, CALP) among the study groups, where the levels of mucin 2 values were (14305.00), (10595.00), (13145.00) and (9350.00) in group (1), and group (2), group (3) and group (4) respectively, and the level of serum values (TFF3)(43.15),(11.90),(29.65) and (8.60) with the same sequence of groups above, and the level of serum values CALP(16320.00),(11220.00),(15275.00) and (8690.00) with the same sequence of groups above as well. The results of the statistical analysis showed that there is a significant difference between the study groups below the probability level (P<0.001). (mucin 2, TFF3, CALP) with both (carcinogenic parasite) and (parasitic infestation only) and (carcinogenic infection) with different high levels compared to other groups.

Our study was concluded there was relationship between E. histolytic and Giardia lamblia infection and intestinal cancer.

Keywords: Colorectal cancer, mucin 2, TFF3, CALP.

Introduction

Cancer is a group of diseases involving abnormal cell growth with the potential to invade or spread to other parts of the body(1). These contrast with benign tumors, which do not spread(2). Possible signs and symptoms include a lump, abnormal bleeding, prolonged cough, unexplained weight loss, and a change in bowel movements. While these symptoms may indicate cancer, they can also have other causes. Over 100 types of cancers affect humans(3). Intestinal parasites are one of the most serious health problems in developing countries, especially in tropical and subtropical regions(4). Parasites are a serious public health threat being living organisms that consume their food and other requirements from a host. Medicinal parasites are classified into three main groups: protozoa and helminthes (and some arthropods)⁵. This study aims to find out the link between each of the parasites (E. histolytic and Giardiasis) infection that causes diarrhea and cancer through some vital indicators that were taken in this study.

Materials and Method

Experimental design:

This study contain from 4 groups:

- Diarrhea Parasite and cancer group (G1).
- Diarrhea and cancer without parasites group (G2).
- Diarrhea and Parasite group (G3).
- Control group (G4).

Samples collection (Stool and Blood): Stool samples were collected from patients with diarrhea and parasite infections, as well as cancer. And blood
was collected from the same patients in addition to the control group.

**Immunological Examination:** Serum separation - Blood samples (EDTA-free) were left for 20 minutes at room temperature until the blood clotted, then the samples were centrifuged using a centrifuge at 3000 rpm for 10 minutes, separating the serum from other blood components using a pipette. Min and put into 10 mL tube. Then the tubes containing the serum were preserved at a degree of (-20 ° C) until immunological tests were performed on them. (A) Immunological detection of vital signs: The serum separated by this test is used to estimate the ratio of mucin proteins, trifoyl protein, and calprotectin, using a technique called Enzyme-linked immunoassay (ELISA) technology. immunology assay according to the manufacturer’s instructions (Elabscience).

Statistical analysis: - All results in this study were subjected to statistical analysis to find out the significant differences of the studied variables using the tests (kruskalwallis test) at a probability level ($p<0.001$).

**Kits:** Elisa kits in this study were obtained from the China Origin Company Elabscience.

**Results**

**Mucin (ng/ml):** The results of the study showed that the concentration of mucin 2, the serum levels were 14305.00 (3912.50), 10595.00 (387.50), 13145.00 (175.00) and 9350.00 (90.00) in group of cancer with parasite, cancer with no parasite group, diarrhea and parasite group and healthy control group, respectively. There was highly significant variation in mucin 2 level among study groups ($p<0.001$). The level was highest in group of cancer and parasite followed by diarrhea parasite group, then by cancer no parasite group and finally by healthy control group, table(1)(4) and figure(1). Thus both cancer and parasite infestation are associated with an increase in the serum level of mucin 2.

![Fig (1): Box plot shows the average level of mucin serum 2 in study totals.](image)

**Discussion**

The results of the study showed a significant increase in the concentration of TFF3 protein in the serum in patients with Parasites and cancer with diarrhea compared to the group of uninfected people and also a significant increase in the group of infected parasite. The reason for the increased concentration of TFF3 in the person with the parasite is its important role in protecting and repairing the mucous layer of the gastrointestinal tract and into cell migration, usually TFF3 increases when the gastrointestinal tract is damaged and in the case of cancer(7). The anomalous expression of trivoyl protein is associated with gastroenteritis and precancerous tumors(8). The results of the current study are consistent with what it did(9) where the concentration of TFF3 in serum for people with Giardia lamblia parasite increases and the reason is due to the important role of TFF3 in protecting the mucosa and also agrees with the study of(10).

The results of the current study showed a significant increase in the level of Mucinemymycin in the serum in patients with the parasite when compared with the healthy control group. Mucine is considered the type of MUC2 is the main mucous material secreted in the gut. The reason for the high level of mucin in patients with intestinal parasites is due to the important role that myosin plays in protecting the epithelial layer of the intestinal cavity and also works as a barrier to prevent penetration of germs and parasites into the intestinal wall when eating contaminated food and water Parasiteshosts the mucous layer of the intestine in which colonies are present (11) The presence of bacteria in the mucous layer of the intestine stimulates the immune response of the digestive system and enhances its health(12) when invading and colonizing the parasite of the mucous layer of the intestine It stimulates cystic cells in the intestinal cavity from mucus secretion and this reason leads to increased mucus secretion (13) as a fungal defensive state of the gastrointestinal surface layer of the intestine (14). The parasite has a virulence factor that, upon infection, can Stimulating excessive mucus secretion in the intestine and consequently the storage of myosin, which enables it to adhere to the outer mucous layer of the intestine · Myosin plays a protective role through the continuous regeneration of cystic cells and is excreted in the intestinal cavity and does an important job in capturing pathogenic and coexisting parasites and parasites, myosin eventually flows to remove these microorganisms during defection.(15) The current study is consistent with the study of(16) Also with the study of(17) that showed a high level of MUC2 expression after exposure to the parasite of Giardia lamblia also consistent with the study of(18) that showed a high level of myosin concentration in parasitic infections and agreed with(19) that confirm the high level of myosin in people People with the parasite Giardia lamblia, who adopted the reason for the increase to the pathological physiological response of the parasite Giardia, which develops disease and diarrhea and works to disrupt the mucous layer of the intestine and impede the absorption process.

The present study found an increase in the serum level of calcipectin in patients with the parasite compared with the control group. Also, there is a slight increase in the serum level of CALP in favor of the infected group compared with the group of infected. This increase may be due to differences in Statistics, sample size and working method can be an increase in the serum level of calcipectin due to intestinal parasites infection. Parasitic infections have a strong effect on the health of the digestive system, especially when the parasite is invasive like E. histolytica. This parasite invades the mucous membrane of the intestine and reaches To the epithelial layer which leads to the formation of calculus ulcers(20) upon parasitic infection, white blood cells multiply and calbrotectin is released,
which activates the action of neutrophils in the intestinal lining, as it participates in the binding and adhesion of white blood cells to the intestinal lining. The effect of infection with the parasite on the blood level in general, especially white blood cells, where the percentage of hemoglobin is low in a person. Injured patients, and this decrease in the percentage of hemoglobin in the blood can be explained by the persistent diarrhea that affects the necessary elements such as iron, copper, and zinc\(^{(21)}\). Fecal calprotectin (CF) is considered a vital indicator for the diagnosis of IBD but it is not accurate in the diagnosis, The calcipectin protein is profuse in the leukocytes of neutrophils as it is found in the epithelial cells of the intestine and in the monocytes and monocytes, and the level of calcipectin in the feces is proportional to the level of neutrophil in the gut\(^{(22)}\). Mucous membranes increase the liberation of calcipectin and can be found in serum and other body fluids as a clinical inflammatory indication\(^{(23)}\). It is due to an increase in white blood cells as an immune response against infection.

**Conclusion**

Our study was concluded there was relationship between \textit{E. histolytica} and \textit{Giardia lamblia} infection and colon rectal cancer.

Correlation of elevated serum value of mucin 2, TFF3 and CALP with carcinogenicity, parasite infection and co-infection (parasite with cancer) compared with other indicators.

Effect of Shift Report Training Program for Nurses on Quality of Reporting

Azza Galal Ahmed1, Mona Mostafa Shazly2, Rabab Mahmoud Hassan2

1Master student at faculty of nursing, Ain Shams University,
2Professor of Nursing Administration Faculty of Nursing, Ain Shams University

Abstract

Background: Shift report has crucial on achieving effective, safe, and high quality communication when the responsibility for the patient care is transferred from one nurse to another in suitable manner.

Aim of Study: The study aimed to develop quality of reporting among nurses after implementation of shift report training program.

Subjects and Method: The study was conducted at Shoubra General Hospital which affiliated ministry of health hospitals Total bed capacity is (200) bed. Two groups of subjects participated in the study, namely head nurses, staff nurses; 50 head nurses and their assistants in the designated setting, the only selection criterion for this group was working in the selected units during the time of the study; and 129 staff nurses out from 194 according this equation. Three data collection tools were used to carry out this study namely, knowledge questionnaire sheet, Observational check list, Audit sheet. The study involved assessment, planning, implementation, and evaluation phases at the end of training and three months follow-up.

Results: No one of the staff nurses in the study sample had satisfactory total knowledge scores at the pre-intervention phase and reach 100% at the post-intervention and follow up phases. No one of the head nurses in the study sample had satisfactory total performance scores at the pre-intervention phase and reach 100% at the post-intervention phase, while the follow-up phase showed some declines, down to 70% in total performance scores.

Conclusion and Recommendations: There was a statistically significant correlation between head nurses’ total knowledge, performance, and audit scores with p-value > 0.01, also, there was a statistically significant correlation between nurses’ total knowledge, performance, and audit scores with p-value > 0.01. The study recommends Periodic assessment of head nurses and their staff for reporting skills. Regular implementation of training programs regarding shift report.

Keywords: Shift report, Training program, Nurses, Quality of reporting.

Introduction

Nursing is an art and a science by which people are assisted in learning to care for themselves whenever possible and cared for by others when they are, unable to meet their own needs. Nurses coordinate care and apply their knowledge and skills to deliver care. Breakdown of communication between, nurses can interfere with the client’s treatment (Delaune and Ladner, 2016). Communication in nursing is at the heart of nursing and is essential in conveying caring and applying nursing skills and knowledge (Berman et al., 2015).

On a daily basis, in every “healthcare facility, the responsibility for the care of patients is transferred between care providers. This process occurs in active and interruptive environments that are typical of those in healthcare today. The communication of patient information to the next care provider can be known as “report,” “end-of-shift report,” “handoff,” or “handover.” This communicates the information necessary for
patient care to continue as planned; and for the purpose of this Project, the term “handover” will be used. Three primary things are transferred during every handover: information, authority and responsibility (Epstin, 2017).

Intradepartmental communication at the unit level among nurses and other health caregivers has been identified as a key factor in patient safety, particularly during an interaction called nurse to nurse handoff (Kentucky and Streeter, 2018). Intradepartmental communication with other members of the healthcare team affects patient safety and the work environment. Breakdown in communication is the more frequent cause of serious injuries in healthcare settings when patients move from one nursing unit to another; so accurate communication is essential to prevent errors (World Health Organization, 2007).

The ability of the team members to understand and communicate the information enables them to work together collaboratively and coordinate communication (Reader et al., 2015). Communication of information in healthcare is a vital component to provide safe patient care. Communication is necessary to report critical patient changes in a timely clear manner; such communication may be from nurse to physician, from nurse to patient, or from nurse to nurse as well as to other, members of the healthcare team (Harvey, 2017).

Reporting is the verbal communication of data regarding the client’s health status, needs, treatments, outcomes, and responses. When a report is given, it needs to summarize the current critical information? that facilitates clinical decision making and continuity of care. Recording and reporting are based on the nursing process, standards of care, and legal and ethical principles. The nursing process provides structures for an organized report, a challenge inherent in verbal communication. In order to do efficient verbal communication and well ‘organized report, the nurse must consider what needs to? be said, why it needs to be said, how to say it and what the expected’ outcomes are needed. Considering these aspects of; reporting before the communication happen will provide a concise, organized report (Daniels et al., 2015).

There are three patient-centered positive outcomes associated with nurse-to-nurse bedside’ shift report as patient empowerment, patient involvement and patient becoming an additional resource in diagnosis and treatment. Bedside shift reporting saves; time and allows the incoming nurse to ask questions. The nurses begin to know patients at the, beginning of the shift and doing assessments, so they can. carry out their clinical care tasks. This also gives them baseline, knowledge of the patients so they can monitor, changes or risks (Byers et al., 2019).

A bedside shift report reassures the’ patient that the nursing staff works as a team that everyone ‘ knows the plan of care. By working together, patients witness a safe, professional transfer of? responsibilities; patients can ask questions, allowing the nurse and- patient an opportunity to share information; and promotes involvement and improved satisfaction and patients’ empowerment (Anderson and Mangino, 2016). Bedside shift- report has been shown to empower nursing staff, improve patient involvement, and allow for a safe’ transition of care between providers. It establishes and promotes. trusting relationships between ‘patients and staff members, which serve as a foundation for teamwork (Bettyanne, 2015).

Continuing assessment of the patient’s needs and conditions requires accurate documentation. This documentation helps promote the -continuity of care given by nurses and- other healthcare providers. Because one nurse cannot provide twenty-four-hour coverage, significant information- must be passed on to others through reports, nursing processes- notes and care plans (Berman et al., 2016).

Power is necessary to be able to influence an individual or group. Nurses need power to be able to influence patients, physicians, and other healthcare- professionals, as well as each other. Powerless nurses are ineffective- nurses, and the consequences of nurses’ lack of power have only recently come to light. Powerless nurses are less satisfied with their jobs, and more susceptible to -burnout and depersonalization. Lack of nursing power may also contribute to poorer patient outcomes. Meanwhile, there are compelling reasons to promote power in nursing (Manjlovich, 2015).

Empowered employees provide exceptional service and experience this first-hand. Empowered employees have the power to make decisions without a supervisor. They are entitled to go off script, bend the rules, do what they see fit if they believe it is the right thing to do for the customer. More than any other kind of employee, the empowered employee is able to create a feeling of true customer service that ultimately yields much greater customer loyalty (Richard, 2015).
Most managers would agree that feedback is essential in order to keep employees on course and to help them reach their goals. However, giving employees feedback is difficult for many managers. Effective managerial feedback can be defined as verbal and nonverbal communication with employees regarding their performance, based on mutually agreed upon goals (Berman et al., 2016). Feedback is described as an integral ingredient in the communication process because it lets everyone in the interaction know that the message, has been received and also lets the sender know how those, who received it have interrupted it. Feedback is evident from both verbal and nonverbal responses equally and clarifies whether interpretation or understanding of the messages is mutual or shared (Timmins and McCabe, 2017).

Communication is the life blood of any organization and its main purpose is to affect change to influence, action. It is the chain of understanding that integrates the members of an organization from top to bottom, bottom to top, and side to side (Basaavanthappa, 2009). It is important, that all healthcare team members communicate with each other regarding assessment, intervention outcomes, and client status. Poor communication can lead to frustration of members of the healthcare team, and poor, documentation of complications or severity lead to significant lost revenue. Also, it has significant impact on quality, costs and revenue, and affects patients, safety (Salman, 2010). Accurate documentation is needed to protect patients from fragmented and possibly, dangerous care (Perry et al., 2016).

Significance of the study: Special emphasis on the hand-over procedures and nursing personnel must be acquainted with the different types of (intra-departmental reports with periodic training and re-training to refresh nursing personnel knowledge. Actually, the observation of handoff among staff nurses during change (of shifts in the study setting was inadequate and lead to lack of knowledge of (incoming nurse about all information related to the patient (Shazly, 2003). Therefore, the present study was conducted to improve the intradepartmental communication among nurses through providing evaluative feedback regarding their (performance of shift report and finding out its effects on nurses’ and patient’s empowerment.

Aim of the Study: The aim of this study is to develop quality of reporting among nurses after implementation of shift report training program.

Subjects and Method

Research Design: Quasi experimental research design was used in carrying out the current study.

Setting: This study was conducted at Shoubra General Hospital which affiliated ministry of health hospitals. Total bed capacity is (200) bed. It consists of the following units and departments; medical department, surgical department, neonatal intensive care unit, intensive care unit, cardiac care unit, burn department, emergency department, obstetric and gynecological department, hemodialysis unit, pediatric department, and ten outpatient clinics.

Subjects: The study subjects consisted of two groups of subjects participated in the study, namely head nurses, staff nurses. Head nurses group: It consisted of 50 head nurses and their assistants in the designated setting. The only selection criterion for this group was working in the selected units during the time of the study. Staff nurses group: It included 129 staff nurses out from 194 according this equation.

Data collection tools: Three data collection tools were used to carry out this study namely, knowledge questionnaire sheet, Observational check list, Audit sheet.

1. Knowledge questionnaire sheet: - (Appendix I)

It aimed to assess nurses knowledge regarding shift report. This tool will consist of two parts:

Part 1: It aimed to collecting data regarding characteristics of study subject as, age, gender, qualifications, years of experience as well as attendance of training course

Part 2: It developed by, (Shazly, 2003, Abd- Elal, 2014 and Atef, 2015) and will be modified by the researcher. It included (40 multiple choice questions), cover certain scopes as definition of shift had, importance and content of shift hand over.

Scoring System: Nurses response were scored (one) for the correct answer and (zero) for incorrect answer. Mean and standard deviation was calculated and then converted into percent score. The knowledge was considered satisfactory if percent score was 60% or more and unsatisfactory if less than 60%

2. An observational check list: (Appendix II): It aimed to assess nurses’ performance regarding shift
report. It developed by (Shazly, 2003, Abd-Elal 2014 and Atef, 2015). It covers three main domains namely; 1) pre report hand over preparation, 2) practice during the hand over procedure, and 3) hand over the department.

**Scoring System:** The observation scoring systems were “done” and “not done” which scored one and zero respectively. The scores of the items of each part were summed up and the total divided by the number of items, giving a mean score for the part. These scores were converted to percent score. Total score of nurses’ performance regarding shift report considered adequate if total percent score was 60% or more and inadequate if the total percent score was less than 60%.

3. **Audit Sheet:** This sheet was aimed to assess quality of report. It adopted from (Abed Elal 2014). It included the criteria for shift report (11 items) and the content of shift report (20 items).

**Scoring System:** Nurses’ response was; “present”, or “not present” and scored one and zero respectively. The scores of the items were summed up and the total divided by the number of items, giving a mean score. These scores were converted to percent score. Total score accepted if total percent score was 60% or more and not accepted if the total percent score was less than 60%.

**Tools validity and reliability:** Face and content validity of the tools was assessed by jury group consisted of five experts in nursing administration in faculty of nursing at, (Ain shams, Cairo university and shobra general hospital). Jury group members judge tools for comprehensiveness, accuracy and clarity in language. Based on their recommendations correction, addition and/or omission of some items were done. Study tools were tested for its internal consistency by Cronbach’s Alpha. It was 0.783 for knowledge questionnaire sheet and 0.815 for the observation checklist.

**Fieldwork:** Once official permissions were obtained, the fieldwork was started. The researcher met with the nursing director of the hospital to determine the suitable time to collect the data and confirm the days and times to implement the training program. The study was carried out through an assessment of nurses’ knowledge regarding shift report using a structured questionnaire sheet, nurses’ performance regarding shift report were assessed using the observation checklist. The questionnaire sheet took from 20:30 minutes to be completed while the observation checklist took from 30:45 minutes.

**Administrative Design:** An approval to conduct the study was obtained from the Faculty of Nursing at Ain-Shams University, and from Shoubra General Hospital which affiliated ministry of health hospitals.

**ethical Considerations:** Prior study conduction, ethical approval was obtained from the scientific research ethical committee of the faculty of nursing, Ain Shams University. The researcher met both medical and nursing directors of the hospital where the nurses worked to clarify the aim of the study and take their approval. The researcher also met the study subjects to explain the purpose of the study and to obtain their approval to participate. They were reassured about the anonymity and confidentiality of the collected data, which was used only for the purpose of scientific research. The subjects’ right to withdraw from the study at any time was assured.

**Statistical Analysis:** Data entry and statistical analysis were done using (SPSS) statistical software package. Quality control was at the stage of coding and data entry. Data were presented using descriptive statistics in the form of frequencies and percentage for qualitative variables; mean and standard deviation for quantitative variable. Qualitative categorical variables were compared Chi-square (X2) test; the hypothesis that the row and column variables are independent, without indicating strength or direction of the relationship, Analysis of variance (ANOVA) test. Statistical significance was considered at (P-value <0.05).

**Results**

Table 1 showed that, half of head nurses (50%) had from 30 to 40 years, majority of head nurses (90%) were females and three fifth of them (60%) were married, regarding half of them (50%) had bachelor of nursing science. Majority of the head nurses (80%) had 10 – 20 years of experience.

Table 2 shows that nearly half of staff nurses (48.8%) had more than 30 years, majority of staff nurses (85.3%) were females and nearly two thirds of them (64.3%) were married, nearly half of them (46.5%) had technical institute diploma. Nearly two thirds of the staff nurses (65.1%) had 5 – 10 years of experience.

Table 3 displays, highly statistically significant improvement in all mean scores as well as in total mean scores.
of head nurses’ shift report knowledge. There are highly significant changes between head nurses’ shift report knowledge in the pre and post and between pre and follow up knowledge with p-value <0.01.

Table 4 illustrates that, highly statistically significant improvement in all mean scores as well as in total mean of staff nurses’ knowledge. There are highly significant changes between staff nurses’ knowledge in the pre and post and between pre and follow up knowledge with p-value <0.01.

Table 5 states that highly statistically significant improvement in all mean scores as well as in total mean of head nurses’ performance. There are highly significant changes between head nurses’ performance in the pre and post and between pre and follow up performance with p-value <0.01.

Table 6 indicates that highly statistically significant improvement in all mean scores as well as in total mean of staff nurses’ performance. There are highly significant changes between staff nurses’ performance in the pre and post and between pre and follow up performance with p-value <0.01.

Table 7 demonstrates highly statistically significant improvement in all mean scores as well as in total mean of head nurses’ audit scores. There are highly significant changes between head nurses’ audit scores in the pre and post and between pre and follow up audit scores with p-value <0.01.

Table 8 shows that highly statistically significant improvement in all mean scores as well as in total mean of staff nurses’ audit scores. There are highly significant changes between staff nurses’ audit scores in the pre and post and between pre and follow up audit scores with p-value <0.01.

Table 9 shows that, there was a statistically significant correlation between nurses’ total knowledge, performance, and audit scores with p-value > 0.01.

### Discussion

Getting a good nursing report before starting shift is vitally important. It is not only important for the nurse but for the patient as well. Nursing report is given at the end of the nurses shift to another nurse that will be taking over care for that particular patient. Nurses’ shift reports are routine occurrences in healthcare organizations that are viewed as crucial for patient outcomes, patient safety and continuity of care. Nursing report is usually given in a location where other people cannot hear due to patient privacy (Inanloo, et al., 2017).

One of the major responsibilities of nursing profession is how to communicate, report, take report, and record information. Nursing report is the official exchange of information between nurses in written or oral form at the end of each shift. Besides recording the written report of nurses, oral report is a communication method which its purpose is to transfer essential and key information about patients’ medical care. As mentioned, one of the practical reports of nurses is work shift delivery report when the responsible nurse for caring the patient provides the other nurses with a summary of patient’s activities and condition at the time of leaving the unit to rest or deliver his or her shift (Ghosh, et al., 2018). So, the current study aimed to developing quality of reporting among nurses after implementation of shift report training program.

Regarding demographic characteristics of head nurses, the current study revealed that half of head nurses had from 30 to 40 years, majority of head nurses were females and three fifth of them were married, regarding half of them had bachelor of nursing science. Majority of the head nurses had 10 – 20 years of experience. Nearly three quarter of the head nurses attended training courses.

This result was in agreement with Mio, Fasan, & Costantini, (2020) who found that the majority of head nurses were female, and married. Also, this result was in congruence with Mardis, et al., (2016) who found that the majority of head nurses had bachelor of nursing science, and their year experience were from 10 to 20 years. Conversely, this result was in disagreement with Grimshaw, et al., (2020) who found that the majority of head nurses not attended training courses, and three quarter of them had technical institute of nursing.

Regarding demographic characteristics of nurses, the current study revealed that nearly half of nurses had
more than 30 years, majority of participants were females and nearly two thirds of them were married, nearly half of them had technical institute diploma. Nearly two thirds of the nurses had 5 – 10 years of experience. Also, two third of the nurses attended training courses.

This result was in agreement with Inanloo, Mohammadi, & Haghani, (2017) who found that the majority of nurses were female, and married. Conversely, this result was in disagreement with Ito, & Iijima, (2018), who found that the majority of nurses had bachelor of nursing science, and their experience year were from 3 to 5 years.

Regarding participants’ total knowledge throughout the intervention, the current study showed that no one of head nurses and nurses in the study sample had satisfactory total knowledge scores at the pre-intervention phase while all of them had satisfactory knowledge at the post-intervention. This result may be due to head nurses and staff nurses were very interested with training program that increased their knowledge.

This result was in congruence with Mitchell, et al., (2018) who found that the majority of nurses’ knowledge about communication skills improved at post intervention phase after implementation of the program. Also, this result was in agreement with La Torre, et al., (2019) who found that majority of nurses’ knowledge about shift report were generally low before the intervention, and improved after intervention.

Regarding participants’ total performance scores, the current study revealed that no one of the head nurses and nurses in the study sample had satisfactory total performance scores at the pre-intervention phase while all of them had adequate performance at the post-intervention phase. The follow-up phase showed some declines. This result may be due to staff nurses were compliance with training courses that improved their performance with shift report.

This result was in agreement with Biondi, Dumay, & Monciardini, (2020) who found that the no one of nurses had satisfactory performance during hand-over procedure before the intervention. Also, this result was in agreement with Buus, Hoeck, & Hamilton, (2017) who found that majority of nurses had satisfactory performance during hand-over procedure after the intervention.

Regarding participants’ total audit scores, the current study revealed that no one of the head nurses and nurses in the study sample had satisfactory total audit scores at the pre-intervention phase while all of them had satisfactory audit scores at the post-intervention phase, while the follow-up phase showed some declines.

This result was supported with Hajibabaee, et al., (2014) who found that the majority of nurses had unsatisfactory total audit scores at the pre-intervention phase. Also, this result was in agreement with Waage, et al., (2014) who found that the majority of nurses had satisfactory total audit scores at the post intervention phase.

Regarding correlation between head nurses’ total knowledge, performance, audit scores, the current study revealed that there was a statistically significant correlation between head nurses’ total knowledge, performance, and audit scores.

This result was supported with Prang, & Jelsness-Jørgensen,. (2014) who found that there was a statistically significant correlation between head nurses’ total knowledge, and audit scores. Also, this result was in congruence with Mardis, et al., (2016) who found that there was a statistically significant correlation between head nurses’ total knowledge, and performance.

Regarding correlation between staff nurses’ total knowledge, performance, audit scores, the current study revealed that there was a statistically significant correlation between nurses’ total knowledge, performance, and audit scores.

This result was in agreement with Inanloo, Mohammadi, & Haghani, (2017) who found that there was there was a statistically significant correlation between nurses’ total performance, and audit scores. Conversely, this result was in disagreement with Ito,, & Iijima, (2018) who found that there was no statistically significant correlation between nurses’ total knowledge, and audit scores.

Conclusion

The current study concluded that: Presence of improvement in nurses, knowledge and performance regarding shift hand over and quality of report after implementing the program.

Recommendation: In the light of results of this study, the following recommendations were suggested:
• Periodic evaluation of the nurses practice regarding shift report
• Conducting training program regarding shift report in different settings
• Provide continuous support to the nursing staff to enhance their writing skills.

Detection of Virulence Genes for the *Entamoeba Histolytic* Parasite in People with Colorectal Cancer

Ali Slwmee Serhan Al-halaly¹, Habeeb Waseel Kadhumand², Ahmed Sabah Ali³, Bashar Abd Alkadhim Najį⁴

¹Research, ²Assit. Prof., ³Research, ⁴Research,
University of Al-Qadisiyah/College of Science/Department of Biology, Iraq

Abstract

The aims of this study are to determine the virulence factors of parasitic infestation, especially of the *E. histolytic* parasite, for persons with cancer and parasites. This study contain 2 groups: Group (G1) People with cancer and diarrhea due to the parasite (50) and (G2) People with diarrhea and parasites (24). Stool samples were collected from both groups for the purpose of confirming the diagnosis of the microscopically diagnosed parasite, Molecular testing is used to confirm the diagnosis of the parasite first and then determine or diagnose its virulence factors, The result of the diagnosis of the parasite is (89.189%) in the study groups as a result of the PCR examination and the result of the diagnosis of the parasite’s virulence factor is 100.0%.

The study concluded that all parasitic infestations had virulence factors cysteine protease (CP).

Keywords: Virulence factor, *Entamoeba histolytica*, PCR, colorectal cancer.

Introduction

Parasites are among the serious health problems that threaten the public health of the human being due to their consumption of large quantities of the host’s food in addition to being a major cause of other health problems, the most important of which is diarrhea, which is a cause of death, especially in children under five years of age, as well as anemia, as hemoglobin levels may decrease, especially when Children infected with worms and other intestinal parasites. There are some other pathological effects caused by infection with intestinal parasites such as weight loss, loss of appetite, flatulence with pain, nausea, vomiting and fever, as well as causing unacceptable gaps that lead to Limiting or preventing absorption of proteins, carbohydrates and vitamins. The most common intestinal parasite is *E. histolytica*, which causes amebiasis, which causes about fifty million infections, with a mortality rate of more than 100,000 cases annually. Numerous studies indicate that infection with intestinal parasites, including the *E. histolytic* parasite, has a direct effect on the immune response, which prompts the recruitment of white blood cells from the bloodstream to the sites of infection, where the mucous layer of the intestine acts as a barrier to protect against infection with intestinal diseases, where the immunoglobulin IgA is the main component Which is stimulated by the mucous layer of the intestine against intestinal injury, as it works to prevent pathogens from attaching to and remove the mucous barrier. Also, having amebic dysentery causes a change in the protein (TFF3), which is a replacement protein secreted at the site of infection, which promotes reorganization. The cytoskeleton and prevents programmed cell death, and also there are many studies confirming an elevated level of mucin 2 in the serum of people with amebic dysentery, as well as other vital signs that the parasite plays an important role in changing it is the level of lipids, which increases the level of triglycerides. The *E. histolytic* destroying tissues and enabling the amoeba to survive and form colonies in the intestine, and among these factors is the production of the tissue-hemolytic amoeba, the cysteine protease (CP) has a role in analyzing the host cells. The cysteine stimulates the mucous layer of the colon to secrete mucus from the capsular cells, and the mucus is very attracted to the protein to bind to the Gal/lectin protein present on the surface of the TM, which in turn allows the parasite to form colonies in the intestine and works to inhibit the mucosal barrier.

Another virulence factor is the production of the protein Lectin Galactose N-acetyl-D-galactosamine,
which helps the parasite to attach to the mucous layer of the colon and form colonies. Formation of amebopores to kill host cells. The ability of the amoeba to produce a protein capable of forming holes in the lipid membranes of the lumen of the intestine. This protein is found in three types A, B, and C, all of which are present in the histolytic amoeba. This protein is composed of 77 amino acids that work to destroy and devour bacteria. According to the amoeba.

**Materials and Method**

**Experimental design:**

This study contains from 2 groups:

- Diarrhea and Parasite group (G1).
- Diarrhea Parasite and cancer group (G2).

**Samples collection (Stool):** Stool samples were collected from patients with diarrhea and parasite infections, as well as cancer.

**Molecular Examinations for the *E. histolytic* parasite and virulence factors:**

**Stool DNA extraction:** For parasite and virulence factor: DNA was extracted from human stool samples using the (Stool DNA extraction presto) kit provided by (Geneaid) Taiwan, according to the company’s instructions.

**DNA profile:** For parasite and virulence factor: The DNA extracted from stool samples was detected by using a Nano drop spectrophotometer, which is used to detect the concentration of DNA, by determining the concentration of the DNA (ng/µl DNA), it is detected.

**Diagnostic method using PCR examination:** This method included diagnosing the parasite with (PCR) as well as diagnosing the pathogen genes (PCR) for the diagnosed parasites. The PCR technique was performed by using the primers of 18SrRNA genes responsible for diagnosing (*E. histolytica*) parasite species from DNA extract by filtering (PCR) also from human stool samples according to the method. The PCR technique was performed using the primers of the virulence factor genes of *Entamoeba histolytica*, namely (*Entamoebahistolytica* cysteine protease (ECP) gene), which is responsible for diagnosing the virulence factor of the parasite.

**Gel electrophoresis (PCR) results of diagnosed parasites and their virulence factors:** Electrophoresis was performed using a 1.5% agarose gel to read the result of the polymerase chain reaction, PCR product analysis, according to the instructions of the manufacturer of the kit.

**Statistical Analysis:** All results in this study were subjected to statistical analysis to find out the significant differences of the studied variables using the tests (One way anova and Fischer exact test) at a probability level (p < 0.001) (Schiefer, 1980).

Kits: Provided by (Geneaid) Taiwan

**Results**

**The results of Molecular tests for the diagnosis of parasites:** The polymerase chain reaction (PCR) examination was used to identify the presence of the small ribosomal RNA gene associated with the parasites recorded in the current study and to show the results by gel electrolysis as in Figure (1-1), where Table (1-1) shows the number of patients. Those who suffer from infection with parasites were by (89.189%) in the study groups as a result of the PCR examination, where the PCR method was successful in identifying cases infected with parasites within the group of people with cancer and diarrhea with a rate of (84.0%). The results of the statistical analysis showed a significant difference below the level of probability \( P = (0.048) \).

to damage and destruction of blood-forming stem cells that the direct effect of radiation and chemotherapy leads the causes and cases of decreased immunity, as it stated rate of infection when immunity decreased, explaining patients histolytica and others are common in patients with the intestinal parasitic infections such as Entamoeba acquisition and parasitic infections and their consideration as a risk group for microbial drugs Chemical and radiological immunosuppression patients who are undergoing some treatments or who transplant organs and primary immunodeficiency especially colorectal cancer patients, as well as patients the high rate of parasitic infection in cancer patients, cases of parasite infestation, and the reason is due to PCR, has succeeded in identifying the vast majority of of optical microscopy and molecular diagnostics, the statistical analysis showed a significant difference under the probability level P = (0.048). The method of optical microscopy and molecular diagnostics, the PCR, has succeeded in identifying the vast majority of cases of parasite infestation, and the reason is due to the high rate of parasitic infection in cancer patients, especially colorectal cancer patients, as well as patients who transplant organs and primary immunodeficiency patients who are undergoing some treatments or drugs Chemical and radiological immunosuppression and their consideration as a risk group for microbial acquisition and parasitic infections. In short, most of the intestinal parasitic infections such as Entamoeba histolytica and others are common in patients with primary immunodeficiency and in the group of cancer patients.A study stipulated an increase in the rate of infection when immunity decreased, explaining the causes and cases of decreased immunity, as it stated that the direct effect of radiation and chemotherapy leads to damage and destruction of blood-forming stem cells and that many chemotherapy agents used in Treating malignant diseases damages lymphocytes and thus suppresses cellular immunity, and that chemotherapy and X-ray therapy by killing cancer cells as a treatment through programmed cell death is generally considered an immunosuppressive, as well as radiotherapy affects many immune mechanisms in body tissues as well as a decrease in immune interleukins As well as the effect of direct radiation on tumors by modifying the phenotype of cancer cells to make them more likely to kill T cells, and therefore these radiation-induced changes in the tumor immune microenvironment promote greater infiltration into T cells (immune cells) and thus damage these cells, as mentioned previously., and immunotherapy must be combined with surgical intervention and chemotherapy. Table 1-2 shows the molecular characterization of the cystine protease and E. histolytica using the PCR method, and all investigated and PCR diagnosed cases showed positive results. As all results of gel electrophoresis were positive.

The results of completely positive infection of the examined samples are due to the fact that all the diagnosed parasites contain the virulence factors (cystine protease), which is known as a protein that the E. histolytica secretes for the purpose of survival within the host due to the immune defense lines that the host members use to resist the parasite invasion This protein is naturally produced by parasites during their invasion of the host due to the host’s immunity and resistance to this invasion, as its presence indicates the presence of the parasite infection through the mechanisms that we will explain in detail below and in order for the protozoan parasites to cause an invasive intestinal infection, in order to lead to its pathogenicity and great mortality. The protective mucus layer must be disrupted by the secretion mechanism of the cysteine protein, as the cysteine proteins secreted from the amoeba parasite disrupt the protective mucous network of the gastrointestinal tract, thus overcoming the protective mucus barrier, as the mechanism of this protein breaks down the MUC2, which is the main structural component of the mucous chain Processes by targeting myosin and protein lysis, The main cleavage site degrades MUC2 polymers, thus inactivating the protective mucus gel. The ability of cysteine proteases to dissolve mucus gels can be seen by treating mucus from the MUC2-producing cell line with amoeba proteases, These results indicate a major role for cysteine proteases in overcoming the mucus protective barrier and the parasitic infection of
invasive amebiasis occurs, the use of a specific cleavage mechanism used by an intestinal pathogen to disrupt the polymeric nature of mucin gel (19). Intestinal pathogens must overcome a series of innate host defenses before contacting the intestinal epithelium. The first herpetic I encounter during an invasion is protection by the mucus barrier, mucus plays a protective role by being constantly renewed from epithelial cells and expelled in the intestine. The mucus traps both commensal and pathogenic microorganisms, and this mucus outflow ultimately removes these microorganisms during defecation, after successful colonization of the mucous layer. From the digestive system by parasites the mucus barrier must be overcome, The present study also agrees with the study of (20).

Conclusion
The current study concluded with determining the virulence factors of the amoeba histolytic parasite, as it was observed that all positive cases in the above parasite diagnosis contained a virulence factor and that all samples were positive for determining the virulence factor.

The partial examination was more accurate, sensitive and specific than the microscopic examination in diagnosing the above parasite

Role of Vitamin AD3E in Pregnancy Period and Calving of Dairy Cattle Strain Friesian

Fawzyea B. Toma¹, Kayfi J. Hassan², Muhamad J. Muhammad Salih³

¹Assist Lecture, ²Assist. Lecture, ³M.Sc., Veterinary Department, Shaqlawa Technical Institute, Erbil Polytechnic University, Iraq

Abstract

Utilization of vitamin AD3E during three periods of pregnancy for Friesian cows by injection and non-injection at the same periods was studied in different places in Shaqlawa technical institute farm and private local farms. (Vitamin and energy requirements are covered in their feed for all groups of treatments) Nine of female cows divided into three group’s three cows for each the control group (C) non-pregnancy and non-injection of vit AD3E, first group and the second group were pregnancies divided each of them in three treatments. The first group was non-injection but the second group was injection with vit.AD3E. Each of group first and second had three treatments treatment one (T1) first three months of pregnancy, treatment 2(T2) last three month of pregnancy and treatment three (T3) after two weeks of parturition. The results shows that was a significant increase (p≤0.01) and best value observed for [White blood cell(WBC)/×10⁹/L in G1T1(11.97), Red blood cell (RBC)/×10¹²/L in G1T3(19.90), Packed cell volume (PCV)/Fl in G2T3 (43.22), Hemoglobin (HB)/g/Dl in G1T1(77.33), Mean size cell volume RBC (MCV)/Fl in G2T3(55.96), and Mean corpuscular Hemoglobin(MCH)/pg in G1T3(16.93)]. Its concluded from this results that vitamin AD3E of a (It can be concluded from this study that vit. AD3E have useful impact on blood parameters during pregnancy and after parturition due their high demands to these vitamins)

Keywords: Vitamin AD3E, Friesian strain, pregnancy, calving and blood parameters.

Introduction

Composition of Vit AD3E, Contains per ml:
Vitamin A, retinol palmitate 80000 IU. Vitamin D3, holocalciferol 40000 IU. Vitamin E, α-tocopherol acetate 20 mg. Excipients ad1 ml. (Vitamin A is very important in the process of formation and conservation of epithelial tissues and mucous membranes functions, is essential for fertility and is fundamental for vision. Vitamin D3 controls and remedies calcium and phosphate metabolism in blood system and plays a critical role in absorption of calcium and phosphate from the digestion tracts. Particularly in young, growing animals, vitamin D3 is fundamental for the normal development of skeleton and teeth. Vitamin E is, as a fat-soluble intracellular antioxidant, involved in stabilising unsaturated fatty acids, thereby preventing toxic lipo-peroxides formation.)

Some vitamins have been recognized as having unique influence on immunity during vaccination, affecting both humoral and cell mediated response [⁸]. This immune- stimulatory effect reported is proven in vitamin A, E and D in livestock[⁹]. Several researched showed that vaccination efficacy can be more improved by supplementations especially vitamins which have effect on immune system such as vitamin A,E and D[⁷].

Some studies refer to that the deficiency in the vitamins & minerals may increase the incidence of retained fetal membrane (RFM) in dairy cows [³] [²]. (Injection of AD3E weekly during second stage of pregnancy before calving progressed the reproductive performance with normal placental expulsion, rapid uterine involution and increase the incidence of pregnancy protection).

Another study done by concluded that the supplementing per parturient lactating buffalo with protected fat and injecting vitamin AD3E mixture increase milk production efficiency throughout the final 100 days of lactation[⁶]. Fat soluble vitamins (A and E) are potently antioxidants. Ruminants cannot synthesize these vitamins in their body, therefore
supply these vitamins in feedstuff are very essential to cover physiological requirements and to preserve their high production performance) during the per-parturient period (transitional period) the concentrations of these vitamins reduce dramatically in the peripheral blood [5] and [12]. Thus, animals are venerable to different metabolic disorders, contagious diseases and a reduction in milk production and quality during this period [4]. The aim of the current study is to evaluate the effect of AD3E vitamins in blood parameters during different reproductive periods in dairy cattle.

**Materials and Method**

**Experimental Intervention:**

(The study was performed on local private farms and shaqlawa technical institute farms)

**Vitamin AD3E dosage:** In this study vitamin A 80,000 IU, vitamin D3 40,000 IU and vitamin E 20 mg .4 ml/50 kg per body weight were used as intramuscular injection weekly, the vitamin solution was preserved in slandered techniques.

**Animals groups under experiment:** The scheme and design of experiment was using nine dairy cattle were used in this study and divided in three groups, control group (C) non pregnancy, Group one (G1) Without injection Vit. AD3E and Group two (G2) With injection Vit.

(In this study, nine dairy cattle were used for the project and design of the experiment and were divided into three groups each one includes 3 animals, non-pregnancy as control group (C), first group (G1) without vit. AD3E injection and second group (G2) With vit. AD3E injection, each of G1 and G2 consists of three treatments covering various phases of pregnancy and postpartum, T1 (first three months of pregnancy), T2 (last three months of pregnancy), T3 (last two weeks of parturition) in three groups).

**Blood samples and tests:** At the end of the treatment period, blood samples were collected and send to the lab to make several tests, like hemoglobin concentration, PCV, ESR, RBCs and WBCs counting.

**Statistical Analysis:** (The complete random design of the experiment and two groups in each group contained three treatments for statistical design and data analysis)

Treatments were determined. Data in all experiments were subjected to ANOVA procedures appropriate for a completely randomized design and the significance of differences between the means estimated using Duncan test Duncan’s All statistical analyses were performed using the software SPSS 17.5 for Windows®[11].

**Results**

The present work was undertaken to evaluate the effect of different of Vitamin AD3E in different reproductive periods in dairy cattle, it was observed that the usage of the vitamin increased the concentration of hemoglobin, ESR, PCV, total RBCs counting, in group of after parturition and in lower rate in late pregnancy group. These findings agreed with Sarker et al[10], showing that the use of AD3E which significantly improves hemoglobin, PCV, ESR development in broilers)

**WBC:** From the table (1) the results of experiment shows that insignificant (P≥0.01) between T2, T3 in G1 but significant (P≤0.01) among all another treatments (G1 & G2).

(Among all other therapies, T1 G1 is considered important (G1 & G2) compared with control (T1, T3) and T2 G2 which was insignificant with T1, T3 in the same groups, but important with all G1 and control treatments).

**RBC:** (As the effect of Vit AD3E on the number of RBCs in two different groups depends on statistical analysis, the table shows that insignificant treatments in group 2 but significant with G1 were, on the one hand, insignificant in G1 C and T1, on the other hand, significant with each of T2 and T3 in the same group and, by looking at the accuracy of T2, T3 between them, are significant within G1 unite)

**PCV:** (Several references have published that the standard PCV range in milk cattle blood about 40-60 depends on several variables such as diet, estrous status, hormone irrigation, pregnancy, etc. Our findings show that the lowest PCV was in T2 G1 and the high value was clearly prominent in T3 G2)

**HG:** Normal average of HG is around 80-150 in blood of dairy cattle the (The normal HG average in milk cattle blood is around 80-150; the lower level of this average is in C of our treatment (80.53(g/dL)); however, the function of the level of nutritional composition of this treatment may be important among all treatments in both group 1 and 2, at the start of G2.)

#### MCV: MCV mean size cell volume RBC this harmonic with decrease of Vit B12 and related with low level of iron and peroxide while some diseases infection or low level of nutrition. (The usual MCV range is between (40-60fl/L) by international unit in G2 the number begins to increase as shown in T2,T3 in the same group and they are insignificant between them but significant with T1 in the same group and well level compared to measure arrangement level but at least better than G1, as shown in the table T3 significant with all G1 and G2 treatments while T2G1 insignificant with C, T1 in the same g)

#### MCH and MCHC: Table 1 showed that MCH in G1 was insignificantly consistent with C in T1 with the same outcomes or all treatment in G2. On C for MCH, we found a low percentage of iron in feed stuff for that cause, also insignificantly analyzed. But low than of normal percentage suppose be, at the last three month of pregnancy the cows need more of feed stuff to be keep balance for embryo so herdsman make more interesting and bring balance of feed stuff for that reason returned. According to the results showed in table (1) there is a slight elevation in WBCs counting in after parturition group while there was significant decrease in lymphocyte counting in after parturition group in comparison with other groups. Also there was a significant increase in monocyte counting in before pregnancy group and significant decrease in Neutrophil and in group after parturition on different blood parameters.

#### Discussion

**WBC:** For results in table 1 observed about WBC this can be attribute by the again in dairy cattle by effect of release estrogen hormone be incentive of LH, FSH and prolactin hormones to be sensitive of strange body so increase of WBC at first period of pregnancy after that build of corpse luteum the percentage of WBC come back, this case without injection of Vit AD3E but in G2 established of percentage just calcite differs but insignificant, this clearly shows of role Vit AD3E to arrangement of incentive hormones while ovulation, these result agree with[6].

**RBC:** For results showed on RBC in same table. It can be explain this phenomenon at the growth of embryo need more of hemoglobin and o2 for burn energy by increasing of growth hormone so increase of RBC while in opposite we noticed regaled of RBC in G2 but by investigated of the reasons we discovered the low level of nutrient in feedstuff which bring to G2 (after seeking on real with farmer) even it treat by injection of Vit AD3E. Because suppose must be increased we did not find another reason while this group in accept situation of health[10].

**PCV:** Results of range number PCV compared with range number of many studies can be says in our experiment this can be explain role of Vit AD3E to returned from uterus to normal situation after two week of parturition while in other side table shows significant for G1 especially in T2 as significant with other treatment
of all treatment in both groups 1 and 2, the T1,T2 G1 were insignificant even they in low level of range but not affected of decrease PCV but in last period of pregnancy was clear affected this can be attribute of growth embryo need a huge of RBC [3]. This state agree with results of [7] while they studies on effect of vitamin AD3E supplementation for hemorrhagic septicemia vaccine in laboratory mice. The animals were also different, but the percentage of PCV in the blood had the same effect. On the other hand, the role of VitAD3E injection in all G2 treatments was significantly increased.

HG: The level of HG decrease related with advance time of pregnancy more less than in G1 even all treatment in this group are insignificant just calculated simple differs, the same insignificant between T2, T3 G1. These results explained same reason and agree reached results of [11].

MCV: The results of MCV clearly shown role of Vit AD3E in G2 and low level of iron content in feedstuff of G1 these results agree with results of [6].

MCH and MCHC: (Analysis (MCH) or what is known as the pellet average of himocalobin (Mean Corpuscular Hemoglobin) is an analysis based on a blood test to assess the average amount of hemoglobin in a blood sample by averaging the mass of hemoglobin in the red blood cells separately, therefore, is an important measure of the iron content of the blood that is part of the blood that serves as president in oxygen carrying, as is this analysis, and that also gives red blood cells their color, and in the same way, this analysis is part of the CBC or full blood count analysis)

The results indicate a decrease in the levels of hemoglobin Central pellet under the normal range iron-rich feed stuff. But if the results indicate an increase in the levels of hemoglobin pellet average above normal (normal average in airy cattle 11.0-17.0pg) it may be due to the incidence of certain other types of anemia, which may also indicate the existence of problems in the thyroid gland, which is mainly engaged in work on the secretion of important of the various hormones and functions of the body organs. It involves an analysis of hemoglobin pellet Usually divided this type of analysis within the analysis of a complete blood count (CBC) along with white blood cells, red blood cells, red pellet size (MCV), hemoglobin concentration of particulate matter (MCHC), platelet size. The normal level of hemoglobin pellet average is between 26 and 33 pg, but if the level of more than 34, considered this too high, due usually to a large poverty in the blood due to a lack in levels of vitamin B12 or folic acid, which leads to disorder in the blood works on not produce enough red blood cells.

(But if the average level of hemoglobin pellets is less than 26, it is known to be very poor, owing to long-term blood loss, due to the incidence of poverty in microscopic blood, which means that small red blood cells are abnormally compared to other red blood cells, which means smaller quantities of hemoglobin. Thus, the attribute of loose hug of blood with parturition can be relied on or results with this specific scientific knowledge. Such findings agree with the outcomes of [8].

**Conclusion**

Role of vit AD3E in period of last three month of pregnancy will helpful for well growth embryo and for easy born calve further that increase of blood content especially WBC but in condition care of type nutrition.

**Recommendation:** On depended the results we recommend

1. At the last of 3 months pregnant must the raiser take more care of management, nutrition and by Follow program of veterinary vaccination.
2. It can be make more experiment on different type genetic of dairy cattle under on condition they have same period of pregnancy and prefer same age with same number of pregnancy.
3. Vit AD3E as a co-enzyme prefer to do may experiment with different level injection to find effected on blood parameter.

**Acknowledgments:** The team of this work presents the whole thanks after Lord God to Officinal of Shaqlawa technical institute and much thanks to Shaqlawa veterinary center office for their advice and help seeking for private local farm and provides all appropriate conditions for research.

Abstract

Excessive ethanol intakes have been reported to be linked to liver diseases such as hepatitis and cancer-related diseases of ethanol. Excessive ethanol can lead to the accumulation of reactive oxygen species (ROS) and to the depletion of glutathione (GSH) in the liver. Ethanol-induced oxidative stress substantially increases peroxidation of the lipid and decreases GSH levels in human hepatocyte and animal models. Ethanol contributes to sterol regulating element-binding protein activation (SREBP)-1 by regulating main genes such as Acetyl-CoA carboxylase (ACC) and Stearoyl-CoA desaturase 1 (SCD1) to facilitate lipid accumulation in the liver. The liquid fraction derived from wolfberry is lycium barbarum polysaccharide (LBP). In many animal disease models, it is an effective antioxidant and tissue protective agent. Researchers have shown hepato-protective functions in acute hepatic injury, NAFLDs, drugs-induced liver injury and hepatocellular carcinoma models. The protection effect of L. barbarum polysaccharides (LBP) in this study on ethanol-induced injury in human hepatocytes was explored. In addition, the influence of LBP on oxidative stress protein activity was examined.

Keywords: L. barbarum polysaccharides (LBP) - ethanol-induced injury - drugs-induced liver injury - reactive oxygen species (ROS).

Introduction

A spectrum of hepatic injuries, from steatosis to cirrhosis, is encompassed by alcoholic hepatic disease (ALD). Alcohol misuse continues to be a significant global health and social burden. Alcohol-related diseases account for 9.2 percent of all lifespan adjusted for disabilities in the developing world¹. Chronic alcohol intake contributes to steatosis in more than 90% of heavy drinkers².

Advanced hepatitis, fibrosis, and even hepatocellular carcinoma (HCC) may be advanced from prolonged alcoholic fatty liver intake. Whilst several key events have been identified during the development of ALD, the disease’s comprehensive pathological mechanisms and associations with other risk factors (for instance, age, obesity and smoking) are still not clear³. Increased inflammation of the liver and oxidative stress are thought to play crucial roles in the development of ALD among these defined mechanisms⁴,⁵.

From 2006–2010, excessive alcohol consumption caused about 88 000 deaths, shortening lives in the United States by 30 years⁶,⁷ While many new, target drugs are currently being tested, strict abstinence and nutritional support appear to be the best choice for alcohol diseases of the liver⁸.

Ethanol is first metabolized by alcohol dehydrogenase to acetaldehyde and cytochrome enzymes P450 in hepatocytes after consumption. Excessive acetaldehyde induces oxidative hepatic stress
which reduces β-oxidation and increases lipogenesis in fatty acids\(^9\).

Excessive ethanol intakes have been reported to be linked to liver diseases such as hepatitis and cancer-related diseases of ethanol\(^10\). Excessive ethanol can lead to the accumulation of reactive oxygen species (ROS) and to the depletion of glutathione (GSH) in the liver\(^11\). Ethanol-induced oxidative stress substantially increases peroxidation of the lipid and decreases GSH levels in human hepatocyte and animal models\(^12\)\(^\text{-}^13\).

Ethanol contributes to sterol regulating element-binding protein activation (SREBP)-1 by regulating main genes such as Acetyl-CoA carboxylase (ACC) and Stearyl-CoA desaturase 1 (SCD1) to facilitate lipid accumulation in the liver\(^14\).

It is widely agreed that women are affected by alcohol-mediated liver disease\(^15\). Whilst the underlying mechanism is not completely determined, clinical results clearly indicate an association of sex hormones with ALD\(^16\). Estrogen receptors (ERs), primarily expressed in the cells of Kupffe and in sinusoidal endothelial cells\(^17\) and have a very low expression level in hepatocytes\(^18\) are believed to mediate the production of pro-inflammatory cytokines and reactive oxygen species during hepatic ethanol metabolism\(^19\).

The evidence has shown the closely associated pathogenesis of alcoholic liver disease (ALDs) with ROS and malondialdehyde (MDA) as well as ethanol metabolism by-products and toxic metabolization. Because of their few side effects, herbal medicine was commonly applied in research into drug discoveries. Lycium Barbarum is part of a Solanaceae family plant and its fruits have been used in China for thousands of years as traditional medicine and edible food. L. barbarum fruit usage was first recorded about 2,300 years ago. L. barbarum fruits have a number of biological and pharmacological functions and they prevent and treat chronic conditions like diabetes, hyperlipidemia, hepatitis, the function of hypo-immunity, thrombosis and infertility among males\(^20\).

The treatment of ALDs includes free radical scavengers or antioxidants\(^21\). L. Barbarum is effective for the eyes, liver, and kidney as an anti-oxidative and nutritive agent. Polysaccharides have been isolated from fruits and tested in various models as the major component of antioxidant activity\(^22\). Extracts of L. barbarum, for instance, by the increased superoxide dismutase (SOD) activity is used to exert an anti-oxidative effect in brain and heart tissue of the mice\(^23\).

The liquid fraction derived from wolfberry is lycium barbarum polysaccharide (LBP). In many animal disease models\(^24\), it is an effective antioxidant and tissue protective agent. Researchers have shown hepatoprotective functions in acute hepatic injury\(^25\)\(^\text{-}^26\), NAFLDs\(^27\)\(^\text{-}^28\), drugs-induced liver injury\(^29\) and hepatocellular carcinoma models\(^30\).

This study aimed to explore the protection effect of L. barbarum polysaccharides (LBP) on ethanol-induced injury in human hepatocytes. In addition, the influence of LBP on oxidative stress protein activity was examined.

**Materials and Method**

**Material Preparation:** For 2 hours in a water bath at 60°C, LBP powder (100 g) was extracted with 1.000 ml water. The extracts have been purified and concentrated at a reduced pressure of 348 K to 200 ml in the revolving evaporator RE-52C. In addition to the concentrated extract, ethanol (75%) allowed for 4 hours, was filtered, concentrated and dried to obtain a polysaccharide extract. At −20°C, the dry extract was screened and placed in a refrigerator. In order to obtain sufficient concentrations, the extract was diluted with deionized water.

**Experimental Cell Culture and Treatment:** Human normal liver cell l-02 in humidified 5 percent CO2 atmosphere has been developed at 37°C in the medium of RPMI-1640 with an addition of 10 percent fetal serum bovine as well as 1 percent antibiotic penicillin and streptomycin. The cells (5 = 103 cells/well) have been seeded and grown overnight on the 96-well plate and treated at various LBP concentrations for 24 hours, followed by 5% ethanol (0, 12, 24, 48, 96, 192 μg/ml) treatment for another 4 hours. Or 5% ethanol treated for 4 hours and followed by a LBP treatment (0, 12, 24, 48, 96, 192 μg/ml) with different concentrations for an additional 24 hours.

The MTT assay assessed the cell viability. A 96-well plate has been used in cultivating and growing cells overnight (5 × 103 cells/well). 20 μl MTT (5 mg/ml) were applied to each well after LBP and ethanol were treated. The culture medium was extracted and formazan precipitate dissolved in 150 μl DMSO after incubation for a period of 4 hours at 37°C. A spectrophotometer (BioTek Instruments Inc., Winooski, VT, USA) was
used to test absorbance at 492 nm. Cell viability ratio was determined using the formula:

\[
\text{Cell viability ratio (\%)} = 1 - \left( \frac{\text{OD}_{\text{control}}}{\text{OD}_{\text{treated}}} \right) \times 100\%
\]

The cell apoptosis rate was analyzed by flow cytometry. L-02 was harvested and re-suspended at a density of \(5 \times 10^5\) cells/ml in PBS buffer. Cells were stained with FITC-Annexin V and propidium iodide (PI) and the findings were analyzed using an Amnis ISXmkII flow cytometer fitted with IDEAS v6.0 image analysis software according to manufacturer’s instructions. At least three times all the experiments have been replicated.

**ROS generation measurement in vitro**: In the complete growth medium L-02 cells (1.5\times10^5 cells/well) were seeded and grown overnight in 12-well plates. Cells were trypsinised and centrifuged at 1500 rpm at room temperature for 10 min following treatment with lbp and ethanol. Then removed the supernatant and re-suspend the cellular pellet in a full medium of 0.5 ml, then added 1 ml DCFH-DA at a final concentration of 10 \(\mu\text{mol/L}\), incubated in a water bath for 20 minutes at 37 °C, and mixed and inverted once every 3–5 min to permit the spectrum to fully contact the cells. Then, the cells were washed three times with serum-free medium, and laser confocal microscopy (Olympus, Japan) was used to observe for the fluorescent state of the cells, with a fluorescence spectrophotometer measuring the amount of the reactive oxygen species in the cells (Perkin Elmer, USA). Finally, the findings are shown in relation to control as the percentage of cells with a rise in ROS levels.

**Biochemical Assay**: The biochemical experiments were carried out in compliance with the instructions of the manufacturer using commercial detection kits.

**Total protein detection and automated capillary western blot**: Plated cells were treated with LBP, Silybin, and ethanol, in six-well plates and \(5 \times 10^6\) L-02 cells extracted and washed with PBS. Cytoplasmic proteins, nuclear proteins, and total proteins were collected from the cytoplasmic nuclear protein extraction kit and the RIPA cell lysate, respectively. The extracted protein has been tested with a BCA protein quantification kit for protein concentration and is ready for machine use.

**Ethical consideration**: Taking acceptance from ethical committee faculty of medicine, Assuit University in March 2019.

**Statistical Analysis**: The statistical software SPSS 21.0 was used for data analysis. In the case of variances not uniform, the ranking sum test was used for results analysis and data analysis results were mean±standard deviation. The Multi-group comparisons of the means were calculated in the analysis of a one-way variance analysis (ANOVA) test with post hoc comparisons. The \(\alpha\)-test level was statistically important when compared to the model group * \(p < .05\), * * \(p < .01\), * \(p < .05\), * * \(p < .01\) was statistically relevant compared with the control group.

**Results**

![Figure (2): Effect of ethanol on the viability of cells as well as ALT and AST content.](image_url)
Establishment of the liver cell model induced by alcohol: The final concentrations of L-02 cells were 2%, 3%, 4%, 5% and 6% (v/v) in the medium ethanol for 4 hours, and changes to the cell viability were studied. Figure 2(a) indicates the results. Their operation was significantly lower than normal control group (CON, p < 05) following treatment of ethanol cells at different concentrations during 4 hours. With increasing concentration of ethanol, cell viability steadily declined. The ethanol levels were set to 5% (v/v) for hepatocyte damage and to ensure an adequate numbers of cells for the subsequent step of the test. Their vitality was 60.7%±4.19%.

After ethanol injury to hepatic cells, the content of ALT and AST was detected in the supernatant. In comparison with the model group, the ALT and AST contents of cells in the group CON increased respectively by 128.27% and 254.45% (MOD, p < .01). The AST content in the model group was greater than the ALT content (p<01, Figure 2b). A model was successfully developed for ethanol-induced hepatocyte injury in vitro. Induced injury to the L-02 cells at 5 percent ethanol (v/v) for 4 hours.

(a) The effect on the viability of liver cells of various ethanol concentrations. In regular L-02, cell viability 2%, 3%, 4%, 5%, 6%; cell viability 2%, 4%, 5%, 6% in alcohol-intoxicated L-02, 5%, 6%. Cell viability in normal l-02

(b) The ethanol-induced hepatocyte injury ALT and AST content. Con: normal L-02 ALT and AST; MOD: Ethanol-induced L-02 ALT and AST content. *p < .05, **p < .01

LBP intervention concentration screening: Figure 3a demonstrates the effects on the viability of L-02 cells of different LBP concentrations. LBP interfered without proliferation or toxicity 24 hours with L-02 cells at concentrations of 12, 24, 48, 96, and 192 μg/ml. The LBP and L-02 cells were co-cultured at test concentration over 24 hours without the exception of LBP’s false-positive and false-negative effects on hepatocytes and had no effect on the hepatocytes. The concentration gradient could therefore be used to screen the intervention concentration.

Figure 3b, c show cell viability at different LBP concentrations in the 24-hour prevention group (24 hours after incubation and 4-hour ethanol injury) and 48-hour prevention group (48 hours after incubation and 4-hour ethanol injury) respectively. The protective effect of LBP was compared with a hepatic protective agent in the same test. The positive control was Silybin (SM) at 24 μg/ml. LBP has achieved its maximum capacity of 24 μg/mL on increasing cell viability. The disparity between model group is statistically significant (p<0.05) but is not statistically significant (78.34 %±3.31 %, p>0.05), as compared to models. When 24 μg/ml of LBP was added to cells for 24 hours, cell viability was up to 81.61 %±3.12 %.

Figure 3d demonstrates cell viability at variable concentrations of LBP in the 24-hour repair group (first with ethanol for 4 hours before LBP for 24 hours). Figure 3e shows cells in a 48-hour repair group with different concentrations of LBP (first ethanol for 4 hours and LBP for 48 hours).

Figure 3e indicates a higher cell viability at 24 μg/ml than at the other four stages. The viability of cells at 24 hour repaired was 87.51 percent±3.02 percent (p < 0.05), and the percentage was above that of SM group 83.89 %±3.69 % (p < 0.05). Cells in the LBP repair group were selected at 24 μg/ml and were better than the preventive model (p < -05, for the 24-hour treatment).

Figure (3): Cell viability effect of LBP.
(a) The effect on the viability of L-02 cells of various LBP concentrations.

(b-c) Effects of LBP prevention for viability of PA hepatocyte wound induced with alcohol at various concentrations for 24 hours (b) and 48 hours (c).

Figure (3): Cell viability effect of LBP. (d-e) LBP repair of alcoholic hepatocyte cell viability injured at different concentrations for 24 h (d) and 48 h (e).

Evaluation of the LBP Hepatic Function in Alcoholic Hepatocyte Injury Prevention and Repair:
Figure 4 shows the levels of ALT and AST to avoid and restore hepatocyte injury from alcohol with LBP. The ALT content in the LBP repair group was higher than in the CON Group (2.489±0.34 U/L) and lower than in the MOD. The ALT content in the LBP repair group is less than in the CON group. The differences in cells that were treated with alcohol were statistically significant (p < 0.05). These findings have shown that after ethanol injury, LBP repair decreased ALT and AST levels. The activity in the LBP prevention group was greater than in the control group, with the ALT (4.40±0.64 U/L) and AST (3.818 ± 0.54 U/L), and statistically relevant differences (p < .05). The prevention effect of LBP was stated by these findings. Following ethanol injury, LBP also decreased ALT and AST levels.

ALT content in normal L-02; LBP-Pre: LBP followed by ethanol followed by ethanol; Silybin-Pre: Silybin-Pre: LBP; LBP-Pre: Ethanol followed by ethanol; Silybin-Post: ethanol followed by silybin; LBP-Pre: ethanol followed by LBP: Con: ALT in normal L-02

Figure (4): ALT and AST LBP content in alcoholic hepatocyte injury prevention and repair
LBP effect in L-02 cells on ethanol-induced ROS:
The effect on ROS levels in ethanol-injured hepatocytes is shown in Figure 5. The impact of LBP action on the ROS levels in alcoholic hepatocytes has been identified qualitatively and quantitatively and oxidative stress in L-02 cells has already been observed. The control group had a large density, a transparent cytoplasm and the fluorescence intensity was weakest and the ROS was 147.83±10.55 the lowest. The cell density was considerably decreased, the nucleus condensed and after ethanol stimulation cell debris occurred. The intensity of the fluorescence within the cells increased dramatically and the amount of ROS rose by 2.99. The cell density increased and the intensity of fluorescence decreased following LBP interference. The rate of LBP repairs and prevention decreasing in comparison with the model group by 56.91% and 56.89% respectively (p < 0.1). LBP decreased the amount of ROS intracellularly, likely due to LBP ROS inhibition or clearance. The cell state of the fluorescence channel under the Laser Confoal Spiegel is observed in Figures A1, B1, C1, and D1. In non-fluorescent channel microscopes, cells are A2, B2, C2, and D2, respectively. The fluorescence spectrophotometer will detect A3, B3, C3, and D3 quantitatively.

Figure (5): LBP reaction to ROS levels in ethanol-injured hepatocytes. (a) Control group (b) model group (c) LBP prevention group (d) LBP group repair group.

The LBP effect in the L-02 cell liver-induced liver-injury anti-oxidation pathway of a nuclear factor (Nrf2)/heme-oxygenase-1 (HO-1):
Hepatocyte expression levels were observed in hepatocytes of Nrf2 expression levels, NRf2 expression levels, NQO1 extension, and GCLC proteins. The expression of Nrf2 and its HO-1, NQO1 and GCLC downstream proteins is shown as illustrated in Figure 6. The Nrf2 protein expression bands in cytosol and nucleus are shown in Figure 6a. The expression of Nrf2 in model group cytoplasm was substantially greater than in the nucleus, suggesting the nuclear expression of cytosolic Nrf2 for the internal cytosolic reference β-actin and the internal nuclear reference PCNA. The volume was minimal and the injury incurred by free radicals could not be resisted. Increased nuclear translocation of the NoRF2 cytoplasm in a varying degrees was demonstrated by the LBP prevention and repair groups.

The expression Nrf2 in the LBP repair group decreased by 30.44% (p<.01) in the quantitative expression histogram as shown in Nrf2 in Figure 7c, compared to models for the LBP prevention group, Nrf2 exposition also declined by 20.05 percent, compared to a rise of 153.04% (p<.01) of the LBP repair group. Thus the nuclear transport of the cytoplasm of NRF2 to the nucleus was encouraged by LBP. Nuclear Nrf2 was higher than the preventive group (p < 0.05) in the repair group. The results indicate that LBP is controlling the Nrf2 protein and that its repair effect could increase the promotion of Nrf2’s nuclear expression.

In this paper the alterations in the Nrf2 pathway’s downstream protein expression after LBP intervention were examined. Figure 6b will use the protein expression bands to qualitatively demonstrate that HO-1, NQO1 and GCLC are the weakest in the model group. Expression levels of these three proteins have increased to various degrees in the LBP repair and prevention groups. The expression levels of HO-1, NQO1, and GCLC in the LBP repair groups increased by 109.65%, 754.81% and 74.76% respectively in comparison with the model cells, as shown by the quantitative histogram in Fig. 6d. The LBP prevention group did not have an improvement in expression of HO-1, compared to NQO1 and GCLC, which respectively grew by 418.27% and 186.18%.
Discussion

The development of liver disease including alcoholic steatosis, alcoholic hepatitis, cirrhosis and hepatocellular cancer can be caused during long-term alcohol consumption. Ethanol flows into the liver and causes hepatic damage as a result of oxidative stress and hepatocytic lipid accumulation. Therefore, inhibiting oxidative stress and ethanol-induced lipid accumulation will stop and treat ALD.

Edible foods or medicinal herbs are generally compatible with natural antioxidants, and it is thus an important method for the prevention and treatment of ALD. In this study, a regulation of oxidative stress associated with the enzymes in L-02 cells elucidated its protective potential against ethanol-induced oxidative stress.

The cell culture medium in the preliminary experiments included a dose-dependent dose of ethanol at 2 percent – 6 percent (v/v) gradient concentration and four hours of co-incubation. The rate of survival was decreased to 40% following 5% of ethanol injury for 4 hours. However, the cell survival rate improved significantly when LBP was pre-treated for 24 hours, treated for 4 hours with ethanol, and pre-treated for 4 hours with LBP and then treated with LBP for 24 hours, which indicated a hepatitis protection effect of LBP. LBP ‘s maximum capacity was reached at 24 μg/ml in terms of rising cell viability. The cell viability increased
sharply at lower concentrations, steadily rising with the LBP concentration. It was believed. The levels ALT and AST are commonly tested as biochemical liver injury markers.

In this research, LBP reduced the ALT/AST of ethanol-treated cells significantly and demonstrated its anticipatory and repair effects on hepatotoxicity of ethanol. LBP decreased significantly the ALT and AST levels, generation of MDA and ethanol-induced intake of GSH, demonstrating that LBP had an effect on the liver injury caused by ethanol. This safety is likely due to the antioxidant properties of LBP, as evidenced by the slowdown in ethanol-induced L-02 cells for ROS and MDA production. SOD is the major enzymatic mechanism for protecting the body from oxygen-free radicals. If there is not enough SOD activity, antioxidant activity could not be exercised in due course, and radicals without oxygen assault the cells and cause cell harm. GSH-Px is a central enzyme that catalysis hyperoxide decomposition. The reduction reaction of GSH to hydrogen peroxide can be precisely catalyzed and cell membrane structure and functions are preserved. In this study, after 4 hours of ethanol treatment, the SOD activities and GSH – Px decreased significantly.

The SOD and GSH-Px behavior in each group increased after LBP intervention. There was a substantial difference between them and the injury group. Increased activities in SOD and GSH-Px suggested that LBP could increase the activity in cells of the active oxygen-scavenging enzyme, enhancing the body’s antioxidant protection mechanism. Instead of accumulating in cells, oxygen-free radicals could therefore be eliminated in time. The peroxidation of cell lipids causes damage to the cell. The decrease in lipid per-oxidants and the increase in cell antioxidant capabilities will decrease cells’ oxidative stress harm. By preserving the activity of antioxidants such as SOD and GSH-Px, LBP show their antioxidant activity and thus reduce the level of active oxygen. Thus, LBP protects liver cells by increasing antioxidant enzyme activity and by inhibiting hepatocyte apoptosis and decreases the incidence of alcohol hepatic harm.

The Early Apoptotic Hepatocyte Prevention and Repair Groups, induced with ethanol, increased in that experiment. LBP had protective and repair effects on the early apoptotic cells after the stimulating factors were removed, but the later apoptosis cells eventually died. The LBP repair group’s apoptotic rate was almost the same as that of the control group. The LBP’s reparative effect was stronger than the preventive impact on ethanol-induced liver injury cells, suggesting LBP has greater capacity to restore hepatocytes than to prevent harm. Therefore, in alcoholic liver disease, LBP has defensive capabilities. The findings of this research help therapeutic substance use potentially. However, further analysis is needed of the basic mechanism.

This study showed that LBP could reduce the production of O2 by increasing antioxidant enzymes after alcoholic hepatic cell injury, reducing other oxygen-free radical production of radicals-based radicals and improving the resistance to superoxide and free radicals. A large amount of oxygen-free radicals was reduced by the chain reaction which alleviated L-02 cell injuries and had a therapeutic effect.

**Conclusion**

Finally, our current research has shown clearly that LBP has a protective impact on liver cell injuries caused by ethanol. Cell apoptosis and oxidative stresses may be included in the potential process.

A Single-center, Single Blinded, Randomized Controlled Trial Protocol of Therapeutic Listening Programme Versus Traditional Music Therapy on Depression and Quality of Life in Institutionalized Adolescents

Gandhi Karunanithi Balaji1, Preethi John2, Gokulakannan Kandasamy3

1,2Chitkara School of health sciences, Chitkara University, Punjab, India,
3School of Health and Life Sciences, Teesside University, United Kingdom

Abstract

Introduction: Depression is a typical, constant, and debilitating issue occurring during adolescence and influencing near a fourth of all grown-ups. In adolescents, depression related with impaired social connections, lower educational accomplishment, poor scholarly execution, family and social brokenness, physical sick wellbeing and expanded danger of self-destruction. Music therapy intervention could essentially diminished symptoms of depression, increased cognitive functioning and improved quality of life

Objective: To determine the effects of therapeutic listening programme versus traditional music therapy on Depression and Quality of Life in Institutionalized Adolescents.

Method: A single-center, single blinded, two group pretest-posttest randomized controlled trial of 36 institutionalized adolescents with depression will be recruited through the simple random sampling. Recruited institutionalized adolescents will be randomized into one of the two groups namely, therapeutic listening programme group and traditional music therapy group through block randomization. Both the groups will receive their respective interventions for 30 minutes a day, 2 days a week for 8 weeks. Participants in dance group performed, 30 minutes of dance for 3 days/week for 6 weeks. The primary outcome measures will be Children’s Depression Inventory (CDI) and Youth Quality of Life Instrument – Short Form (YQOL-SF). Urine test and electroencephalogram (EEG) will be recorded in addition to CDI and YQOL-SF. All the outcome measures will be measured at baseline and 8 weeks post intervention.

Results: Normality of the collected data will be analyzed using Shapiro-Wilk test of normality. Descriptive statistics will be expressed in mean±Standard deviation/mean (95% confidence interval) with range and parametric tests/non-parametric tests, paired t-test/Wilcoxon signed rank test and independent t-test/Mann-Whitney U-test will be used for within and between group comparisons based on normality.

Conclusion: The study outlines the importance of therapeutic listening programme on institutionalized adolescents with depression. Successful completion of this RCT will create evidence on the best treatment options for institutionalized adolescents with depression.

Keywords: Adolescents; depression; music therapy; quality of life; therapeutic listening programme.

Introduction

More than 264 million of world population are suffering from depression. Injuries, and Risk Factors Study 2017 (GBD 2017 The worst consequences of depression is suicide which ranks second in leading cause of death among the age groups between 15 and 29
Depression is a typical, constant, and debilitating issue occurring during adolescence and influencing near a fourth of all grown-ups. Around 21–28% of youth encountering major depression by the age of 19 years.3 World Health Organization evaluates that depression is the third leading cause for worldwide illness, anticipated to be the second cause by 2020, and will be the first leading causes by 2030.4 Depression is related with numerous physical, passionate, mental, and social changes in youngsters. They experience intense emotions and may go through many stressful events in this period. These rapid changes in all aspects of their life affect their mental health and increase the risk of depression.

In adolescents, depression related with impaired social connections, lower educational accomplishment, poor scholarly execution, family and social brokenness, physical sick wellbeing and expanded danger of self-destruction.5 Depression is the significant reasons for morbidity among youths, frequently taking a constant, repetitive, and episodic course.4 Major Depression Episode are weigh or appetite changes, sleep difficulties (sleep deprivation or hypersomnia), exhaustion or loss of vitality, psychomotor agitation or impediment, reduced capacity to concentrate, sentiments of uselessness or guilt, and suicidal thoughts. Cognitive dysfunction, age, psychosis, joblessness, self-destruction thoughts are related with severity of depression.6 named main criteria. Although the secondary symptoms can be divided into somatic and non-somatic clusters, the DSM-5 identify depression in all or none fashion. In contrast, depression severity is a continuous variable. Therefore, it is commonly assessed with scales such as the Hamilton Depression Rating Scale (HAMD)

Bill Ahessy surveyed if investment in music therapy can decrease depressive symptoms and improve quality of life and cognitive functioning in older population. In the music therapy group, depressive symptoms were decreased by 54%, 57% improvement in Quality of life score and there was a critical increment in cognitive functioning. The investigation inferred that music therapy intervention essentially diminished symptoms of depression, increased cognitive functioning and improved quality of life.7

One such strategy, Therapeutic Listening® utilizes electronically modified music using high-quality headphones. Auditory input adds to arousal, self-guideline, and emotions.8,9 Therapeutic Listening created by Sheila Frick in 1990s for people with sensory processing difficulties.10 According to advanced brain technologies (ABT) therapeutic listening program (TLP) uses psycho-acoustically modified classical music listened through a set of sennhieser headphones focusing on certain recurrence extends that guarantee to affect functional capabilities.11 relating to 28 individual school-based programs, were identified through the Cochrane Library, PsyInfo and PubMed databases. A large proportion of the programs identified were based on cognitive behavioural therapy (CBT It was initially recommended that auditory intervention training (AIT) was gainful for youngsters with listening tuning and attentional troubles.

Therapeutic listening activates the vestibular-cochlear framework by means of the vestibular nuclei, and helps to strengthen muscles of middle ear and improving the capacity to tolerate sound. Modulated music exercises and retrain the tensor tympani and stapedius muscles to permit them to contract. The adjusted music is prepared utilizing low pass- high pass channel. In high pass channel, sounds over 1,000 Hz pass continuous while sounds underneath 1,000 Hz are quieted. Music triggers centers in the brainstem that are involved in basic sensorimotor modulation and integration where the sound is modulated and just the low and high sounds are sent up to the cortex. AIT animates reticular activating system, role in neuroplasticity, gets information from vestibular system and release neurotransmitters which aid in arousal, learning and emotion.10,12

Therapeutic listening programme (TLP) expands on altered music in recurrence zones. These frequencies zones affects the functional capabilities. Zone one lower-recurrence sounds (0–750 Hz) help with sensory integration which incorporates rhythm, coordination, balance, muscle tone, laterality and right/left discrimination, sense of direction and body awareness. Zone two spotlights on midrange recurrence sounds (750–4000 Hz) and connected to language and speech development. Abilities in this zone incorporate language, speech, focus, memory, attention and vocal control. Zone three connect to high-recurrence sounds (4000 Hz or more) intended to improve abilities, for example ideas, energy, spirituality, intuition and creativity.9,12–15

There is a dearth of evidence supporting the use of TLP in people having depression. Literature on therapeutic listening had been limited to children with sensory processing disorders.10,12,16,17 implementing.
The Listening Program(R Till date only conservative and traditional interventions along with music therapy are used to treat depression in adolescent. Hence, we aimed to explore the effect of therapeutic listening on severity of depression and quality of life in institutionalized adolescent. The objectives of our proposed study are to explore the effects of therapeutic listening over traditional music on severity of Depression and quality of life in institutionalized adolescents.

Materials and Method

**Ethical Statement:** The study protocol for the Single blinded Randomized Controlled Trial was approved by the institutional ethics committee and the study will be performed according to the principles laid by, declaration of Helsinki (Revised 2013), Council for International Organizations of Medical Sciences (CIOMS) guidelines, International ethical guidelines for health-related research involving humans (2016) and National guidelines for biomedical and health research involving human participants by Indian council of Medical Research (ICMR), 2017. The ethical guidelines that followed the national ethical guidelines for biomedical and health research involving human participants by Indian council of Medical Research (ICMR), 2017. Consent for participation in the study will be obtained from the participants and their parents/guardian prior to the start of the study.

**Recruitment:** Qualified therapist will screen the institutionalized individuals and recruit the study participants based on the inclusion and exclusion criteria displayed below as the selection criteria.

**Selection Criteria:**

**Inclusion Criteria:**

- Institutionalized Adolescent boys and Girls (age 12-18 years)
- Participants Assessed by Children depression Inventory (having average/lower, high average and elevated)

**Exclusion Criteria:**

- Presence of any other psychiatric disorder (Schizophrenia, Bipolar Disorder, Anxiety Disorder etc).
- Patients with Hearing impairment
- Patients with untreated active ear infection

After screening, the participants will be recruited thirty six samples by the simple random sampling method from NGO (Gur aasra, Mohali & Prabh Aasra, Kurali). After obtaining the consent, their demographics will be recorded.

**Randomization:** Total recruited sample size 36 will be randomly allocated by Block Randomization method by SNOSE (Sequentially numbered opaque sealed envelope) method by Principle investigator into one of the two groups, therapeutic listening programme group (TLPG) and traditional music therapy group (TMTG). The blocks will be in even numbers and the matrix will be $4 \times 9$ (36). There will be total 4 blocks and 9 rows. Then subjects will be allocated in the blocks by using random allocation sequence. Randomization will be done by $4 \times 9$ matrix design. There will be random blocks of 4, with each block randomizing 4 participants into TLPG and TMTG each with two participants. The participants will be allotted to group based on the generated randomized sequence. Once the block will be allotted next row block sequence will be opened for the recruitment. Thus equal number of participants will be assigned to both the group overtime. The outcome assessor will be blinded and hence, the randomized controlled trial will be single blinded.

**Study Intervention:** Intervention will be administered by an experienced physiotherapist who is certified and trained in therapeutic listening programme. Participants in the experimental group will receive therapeutic listening therapy for the duration of 30 min per session twice a day for 5 days a week for 8 weeks. Detailed week wise therapeutic listening protocol is listed below in Table 1. The sound to be used will be of rhythm and Rhyme, Peach Jamz, Nature Winds, Mozart for modulation and Strawberry Jamz, Vivaldi for modulation. Traditional music therapy group will receive traditional music therapy intervention using earphones with duration of 2 sessions of 30 minutes each per day, 5 days a week for 8 weeks. Intervention will be delivered in a quiet room using Headphones - High-quality Sennheiser headphones which has high resistance-impedance with a minimum of 150 ohms and 23,000 Hz frequency sensitivity. Therapist will be maintaining the treatment record of each participants. Post intervention evaluation of the outcomes will be measured by using Children’s Depression Inventory (CDI), Youth Quality of Life Instrument – Short Form (YQOL-SF), Urine test and EEG. If the participants develops unexpected seizures or syncope during the ongoing therapeutic listening, the study will be discontinued.

### Outcome Measures:

**Children’s Depression Inventory (CDI):** The Children’s Depression Inventory (CDI) was developed by Kovacs and Beck in 1977. From Beck’s Depression Inventory as a downward revision, CDI was developed originally. This is the commonly used depression measures to assess the severity of depression among the children between 7 and 17 years. CDI has 27 items and takes approximately 10 to 15 minutes to complete the test. CDI has acceptable reliability and validity with other psychometric properties.

**Youth Quality of Life Instrument–Short Form (YQOL-SF):** Youth Quality of Life Instrument – Short Form (YQOL-SF) derived from 41-item instrument through Rasch methodology. Youth Quality of life developed to measure the quality of life among youth aged 12 to 18 years. YQOL-SF has 16 items and four domains to measure, self, social relationships, environment, and general quality of life. Psychometric properties of YQOL-SF is acceptable to measure quality of life among the youth with and without chronic disease and disabilities.

**Other Outcome Measures:** Urine test will be performed to check the levels of Serotonin, cortisol, testosterone, estrogen and electroencephalogram (EEG) to measure the electrical activity of brain to music.

All the outcome measures will be measured at baseline and 8 weeks post intervention.

### Results and Discussion

Normality of the collected data will be analyzed using Shapiro-Wilk test as the sample size is less than 50. If the data follows normal distribution, then descriptive statistics will be expressed in mean±Standard deviation and parametric tests, paired t-test and independent t-test will be used for within and between group comparisons. On contrary, if the data does not follow normal distribution, then descriptive statistics will be expressed in mean (95% confidence interval) with range and non-parametric tests, Wilcoxon signed rank test and Mann-Whitney U-test will be used for within and between group comparisons. For all the statistical analysis, p<0.05 will be set as significant.

This will be the first RCT to be conducted to gain deeper understanding on the effect of therapeutic listening technique on depression and outlines the importance of therapeutic listening programme on institutionalized adolescents with depression. Successful completion of this RCT will create high level of evidence on the best treatment options for institutionalized adolescents with depression.

### Conclusion

The feasibility of implementing therapeutic listening programme will be tested by the end of this trial and therapeutic listening programme could be an adjunct tool along with exercises to decreases the depressive symptoms in adolescent.

Factors Affecting Adolescents in Determining the Ideal Number of Children

Alya Rohma Indrastuti¹, Lutfi Agus Salim²

¹Bachelor Student in Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia, ²Associate Professor in Department Biostatistics and Demography, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia

Abstract

The preference of ideal number of children among adolescents can predict future fertility rates and population growth. This study aims to analyze the determinants of preference of ideal number of children in adolescents aged 15-24 years in Indonesia. The method used in this study is descriptive with data analysis of IDHS 2017. The results show that the preference of ideal number of children among adolescents in Indonesia is 2.7 children. This figure increase from the average preference of ideal number of children in 2012 and is higher than the 2015 Total Fertility Rate, which is 2.28. Factors that influence the preference of ideal number of children among adolescents are the characteristics and socio-demographic background, exposure to media, and the discussion on adolescent reproductive health.

Keywords: Preference of ideal number of children, Adolescents, Determinants of preference of ideal number of children.

Introduction

The total population of Indonesia is 237.6 million (2010 Population Census). This count has increased to 255.18 million people based on the 2015 Inter-Census Population Survey. Central Bureau of Statistics projects that the total population in Indonesia will increase until 2025. Currently, Indonesia is ranked fourth in the country with the most total population in the world. First place is China with 1.4 billion total population of the 7.8 billion total population in the world. Based on the Indonesian Population Projection for 2015-2045, the growth rate is 1.04%. There are several components that affect population growth. These components include birth (fertility), death (mortality), and movement (migration). Total Fertility Rate (TFR) in 2020 is 2.1¹.

Data from the Central Bureau of Statistics in 2019 shows that the number of adolescents (18-24 years old) in Indonesia is 44,209.8 million². Adolescence is a period of transition from children to adults. One of the things that marked this transition was starting a new life by forming a family. Starting a family life, of course, must be carefully planned by the adolescents. This planning cannot be separated from the desire to have children, including the preference for the number of children. Preference is a form of expressing feelings of preferring something. Preference has in common with closed behavior. Skinner (1938) in Notoadmodjo (2010) states that closed behavior occurs when the response to a stimulus cannot be clearly observed by others. The responses that appear are only limited to attention, perceptions, feelings, and attitudes. Therefore, the preference for the number of children in adolescents can be interpreted as a form of expression for the number of children they want to have. The preference for the ideal number of children desired can be used to predict future fertility rates³.

National Population and Family Planning (NPFP) introduced the Family Development, Population and Family Planning (Bangga Kencana) Program at the end of 2019 as a change in the name of the Population, Family Planning and Family Development (KKBPK)

program. To realize that program, NPFP 2020-2024 Strategic Plan (Renstra) was used as a reference in program implementation. One of the strategic issues that must be considered in developing Renstra is the population structure. Indonesia has the opportunity to get a demographic bonus with the increasing proportion of the population of productive age in the demographic structure. This structure must be maximally utilized, one of which is by keeping the TFR at a certain level. Therefore, this study aims to analyze the determinants of preference for the number of children in adolescents aged 15-24 years with unmarried status in Indonesia.

**Method**

The research was used Indonesian Demographic and Health Survey (IDHS): Adolescent Reproductive Health in 2017. The research method used was descriptive. Data were collected by means of literature study and analyzed descriptively. The samples of this study were young men and women aged 15-24 with unmarried status in Indonesia. The number of samples was adjusted to the number of samples in the Adolescent Reproductive Health IDHS 2017, which was 22,583 people. As many as 12,612 boys and 9,971 girls.

**Result**

**Preference for Ideal Number of Children in Adolescents:** Based on data from the 2017 IDHS for Adolescent Reproductive Health, the average preference for the ideal number of children for both male and female adolescents in Indonesia is 2.7. This figure has increased from 2012. For male adolescents, the average preference for the ideal number of children has increased from 2.5 children to 2.7 children. Meanwhile, female adolescents increased from 2.3 to 2.7 children.

![Figure 1. Average Preference of Ideal Number of Children by Adolescent in 2012 and 2017](image)

**Characteristics and Social Demographic Background of Adolescents:** Based on data from the IDHS2017, the majority of adolescent respondents in Indonesia are 15-19 years old (64%). In addition, the majority of respondents were male adolescents (56%), the highest level of education was not graduating from high school (50%), and mostly on highest economic status (23%).

Average ideal number of children is 2.8 children. Adolescent aged 20-24 years have a higher preference when compared to adolescents aged 15-19 years. Based on the level of education, the highest average preference for ideal number of children is owned by adolescents with a tertiary education level and not completing elementary school, both for male and female adolescents. The highest average preference for ideal number of children based on economic status is owned by male adolescents with the lowest economic status. While the average preference for the ideal number of children in urban and rural adolescents was not found to be different, as many as 2.7 children.

Figure 2. Preference of Ideal Number of Children in Adolescents Based on Age and Sex

Figure 3. Preference for Ideal Number of Children in Adolescents Based on Education Level
Mass Media Exposure: The most dominant mass media for obtaining information on reproductive health is television. At least in the last week, as many as 77% of young women watched television, 12% listened to the radio, and 11% read printed newspapers or magazines. Meanwhile, 73.1% of male adolescents watch television, 11.4% listen to the radio, and 10.4% read print media. In addition, the majority of young men and women also used the internet to get information about reproductive health during the last 12 months prior to the survey.

Percentage of male and female adolescents exposed to the three mass media has decreased when compared to 2012 and 2007. Boys who access the three mass media have decreased from 14%, 9%, to 4%. Likewise, the percentage of young women decreased from 13%, 8%, to 4%.

Youth Discussion About Reproductive Health: Most of adolescent men and women in Indonesia discuss reproductive health with friends. Respectively, 51.1% of the total male respondents and 61.6% of female respondents discussed with friends. Adolescents also discuss reproductive health with teachers, mothers and fathers. For male adolescents, respectively 42%, 10.8%, and 8.3% of the total male adolescent respondents. Meanwhile, female adolescents were respectively 47.1%, 53% and 4.3% of the total female respondents.

Discussion

Preference for Ideal Number of Children in Adolescents: The average preference for the ideal number of children based on the IDHS 2017 data for Adolescent Reproductive Health is 2.7 children, which is higher than the average preference in 2012, the 2015 TFR, and the 2020 TFR projection can be used to predict future fertility rates. This is because the preference for the ideal number of children in adolescents can determine the number of children they have in life(4).

As with the definition of fertility according to demographics, fertility is more related to the number of children born alive. Fertility also influences the
population growth rate in a positive way. This means that the higher the fertility rate, the higher the population growth rate\(^{(5)}\). In addition, with controlled fertility rates, Indonesia can take full advantage of the demographic bonus.

Preference for the ideal number of children to have depends on how one views the value of children. In adolescence, of course, it is still quite strange about this. However, that does not mean that teenagers cannot plan what family life will be like, including the number of children they want to have in the future. These decisions and plans are of course inseparable from the influence of various factors such as characteristics, mass media exposure, and discussions on reproductive health.

**Characteristics and Social Demographic Background of Adolescents:** Both male and female adolescents aged 20-24 years have a desire for more children than adolescents aged 10-19 years. Preference for the number of children desired by young women and men in the future. A more mature age encourages adolescents to think further about what kind of family they want to form, including the ideal number of children they want to have\(^{(6)}\).

In addition, education is also a factor that influences a person in planning the number of children he wants. The results showed that adolescents with incomplete primary and secondary education had a higher average preference for ideal number of children compared to other levels of education. A person’s knowledge will increase along with the education taken. It also affects the mindset to be broader and more open. Teens with higher education are more likely to consider the number and limits of children they want to have. Even so, it does not rule out if adolescents with higher education want to have children in large numbers\(^{(7)}\).

Another factor that drives decisions in planning the number of children is economic. When viewed from an economic point of view, the number of children desired is closely related to the costs and benefits that are obtained from a child. Economic status and how a person perceives the value of children will influence the demand or desire for the number of children in the future. For some people or adolescents, children can be seen as workers. Children are considered as contributors to income for families with low economic levels so that the preference for the ideal number of children is higher compared to other economic statuses\(^{(8)}\).

There are differences in the value of children in underdeveloped communities (low economy) and advanced communities (high economy). Low economic society places more emphasis on the quantity or number of children they have. The number of children born can be a guarantee and bring many benefits to the family. One of them is increasing productivity and family income\(^{(9)}\). The presence of children is considered to be able to help the family economy when parents are not productive so that their needs can still be met. Whereas for high economic communities, children are invested in quality\(^{(10)}\). Children who are born tend to be few but their growth and development are optimized. Starting from fulfilling nutrition, education and health with the hope that children can compete in the labor market. In addition, children are the successors of the offspring who will then carry the good name of the family\(^{(11)}\).

Based on the research results, it can be seen that the preference for the ideal number of children in urban and rural adolescents was not found to be different. Adolescents in urban and rural areas, of course, have different behavior patterns. However, this does not mean that the preferences for having children in the future will be significantly different. The exposure of adolescents to mass media which provides information about certain reproductive health can explain this.

**Mass Media Exposure:** Understanding of reproductive health is influenced by several factors, one of which is access to information\(^{(12)}\). The majority of adolescents get information about reproductive health through television channels. The results also showed that most teenagers had used the internet to get information. One of the information obtained is about family planning. Getting information about family planning can certainly influence adolescents in making plans for family life in the future. This includes deciding the ideal number of children they want to have.

**Youth Discussion About Reproductive Health:** Children are a natural thing for discussion among married people. However, discussing reproductive health issues and the number of children they want is certainly a foreign topic among adolescents. Adolescent tend to think more about present than planning about family life. This makes Adolescent think that the ideal number of children can be decided after marriage\(^{(13)}\).

The idea that the number of children does not need to be eliminated now certainly indicates that
adolescents need to have further discussions about reproductive health. In the modern era, adolescents are more preoccupied with daily activities and activities related to academics or non-academics. The results showed that the majority of adolescents discussed reproductive health with friends. Listyaningsih and Sumini (2015) state that adolescent more discussion about introductions, friendships, and dating. Teens do not feel the need to discuss the problem of family size, including the number of children they will have\textsuperscript{(14)}. This becomes a challenge in itself considering the rampant phenomenon of promiscuity. It is feared that teenagers cannot plan their own lives.

The role of discussion on reproductive health is very important to guide adolescents into a planning generation. Families, especially fathers and mothers, have a big role to play in providing knowledge about reproductive health in adolescents. Even though as many as 53\% of young women discussed with their mothers about reproductive health, there was still a low number of discussions among boys. Likewise, the discussion rate for adolescents regarding reproductive health with fathers only reached 8.3\% for male adolescents and 4.3\% for female adolescents\textsuperscript{(15)}.

For some parents, information regarding the number of children is not appropriate for adolescents, especially those aged 15-19 years. This condition can encourage adolescents to discuss with peers who have almost the same understanding. The values that are absorbed by adolescents from their families and the environment can influence their preferences for the number of children they want. Adolescents tend to wish to have the same number of children as their current family condition.

Apart from families, schools, including teachers, also have an important role in discussions about reproductive health for adolescents. Information about the number of children, children’s grades, benefits and reasons for having children can be obtained at the secondary school level. Furthermore, this information can trigger teenagers to have further discussions with the people around them. Fertility preferences show adolescents with reproductive knowledge are more likely to choose the recommended number of children. Having discussions and interactions with parents, teachers and friends will increase adolescent knowledge and make adolescents trained to plan and make decisions regarding the ideal number of children they want to have\textsuperscript{(4)}.

### Conclusion

The preference for the ideal number of children among adolescents (15-24 years) based on the IDHS data for Adolescent Reproductive Health is 2.7 children. This figure is an increase from the preference for the ideal number of children in 2012 and is higher than the Total Fertility Rate (TFR) in 2015 of 2.28 children. This will affect the fertility rate and have an impact on increasing population growth rates and demographic bonuses if not controlled properly.

The factors that influence the preference for the ideal number of children among adolescents are the characteristics and socio-demographic background of adolescents including age, education and economy. Another factor is exposure to mass media and youth discussions about reproductive health.

Characterization of NPM1 and FLT3-ITD Mutations in Iraqi Patients with AML

Hussam R. Hamed¹, Rakad M. Kh AL-Jumaily², Areej E. Kadhom³

¹Scholar Researcher, ²Assistant Professor, Department of Biology, College of Science, University of Baghdad, Baghdad, Iraq, ³Scholar Researcher, Department of Laboratory, Baghdad Teaching Hospital, Medical City Center, Baghdad, Iraq

Abstract

Acute myeloid leukemia is a malignant disease results from mutation in a multipotent haemopoietic stem cell. The study aimed to investigate NPM1 and FLT3-ITD mutations in Iraqi patients with AML and correlate results with other clinical and laboratory findings. Fifty-eight AML patients, admitted to Baghdad Teaching Hospital from October 2019 till March 2020 in addition to 25 normal controls, were included in the study. A detailed history, laboratory investigations including FLT3-ITD and NPM1 mutations were collected from and analyzed. FLT3-ITD was detected in 17.24% of patients, NPM1 mutation in 10.34%. Most of the patients are presented with pallor. FLT3-ITD mutation had a higher blast cell count (74%) while NPM1 mutation had higher WBCs count.

Conclusion: AML is common in middle age group, patients with NPM1 mutation had significantly higher WBCs count while patients with FLT3-ITD mutation have higher blast percentage compared with non-mutated patients.

Keywords: AML, NPM1, FLT3.

Introduction

Acute myeloid leukemia (AML) is characterized by clonal explanation of differentiated myeloid precursors which results in bone marrow failure.¹ Fundamentally, the investigation of the genome profile in AML has Changed the approach of patients with AML. AML Patients are regularly tested for the existence of FMS-related tyrosine kinase 3 (FLT3) and Nucleophosmin 1 (NPM1) gene mutations.² NPM1 is a predominantly nucleolar of protein with important homeostasis and cell growth functions, including regulation of ribosome biogenesis and response of stress.³ Disruption of NPM1, either by chromosomal translocation or mutation, disturbs its normal function as a transporter protein leading to the notion that NPM1 mutation plays a role in early leukemogenesis as recorded in about 35 percent of AML cases.⁴

FLT3 encodes a tyrosine kinase receptor preferentially expressed in hematopoietic progenitor cells and mediates the differentiation and proliferation of stem cells.⁵ This receptor is activated by binding to its extracellular domain of the fms-related tyrosine kinase 3 ligand (FL), which induces the formation of homodimers in the plasma membrane and autophosphorylation.⁶ About 30 percent of all AML cases, (FLT3) gene mutations occur, with internal tandem duplication (ITD) being the mainly widespread form of FLT3 mutation which constitute about 25 percent from all cases of AML.⁷ FLT3-ITD has consistently been related to increased white blood cell levels, higher bone marrow (BM) cell counts, increased risk of relapse, and lower survival rates.⁸ These results indicate that the mutation of the FLT3-ITD gene plays an important role in the development of leukemia, rather than initiation.

The aim of this study is to investigate the characterization of NPM1 and FLT3-ITD mutations
in Iraqi patients with AML and correlate the presence of these mutations with other clinical features and laboratory findings.

**Material and method**

After the approval of the Ethical Committee at Faculty of Biology, University of Baghdad and taking informed consents from the patients, the current experimental work was carried out at the Laboratory Department, Hematology Center and the National Center of Educational Laboratories at Medical City Complex, over a period extending from October 2019 till March 2020. A total of 58 patients, admitted to Baghdad Teaching Hospital, Medical City Complex, recently diagnosed with AML on the basis of findings of blood smear, bone marrow (BM) examination and flow-cytometry immunophenotyping, were included in this study with an age ranged from 14 to 72 years in addition to another group of 25 apparently healthy individuals with an age ranging from 15 to 65, those subjects were not found to have medical issues with normal investigations, therefore were used as normal controls for comparison with AML patients. A detailed information including residence, occupation, family history, past medical history, previous exposure to radiation or chemicals, smoking history and clinical presentation were collected from all patients and controls. The LeukoStrat® FLT3 Mutation kit (Cat No./ID: 9-412-0091, Invivoscribe) and ipsogen NPM1 MutaScreen Kit (Cat No./ID: 677013, Qiagen) were used to detection of FLT3-ITD and NPM1 mutations according to manufacturer’s instructions. All Primers, materials and protocol were provided with the kits. Regarding molecular detection of FLT3-ITD and NPM1 mutations in brief; DNA was extracted using Qiagen extraction kit (Cat No./ID: 69504), FLT3-ITD mutation was detected by conventional PCR (AppliedBiosystems) with gel electrophoresis. NPM1 mutation was investigated by real time PCR (Rotor-gene Q). Hematological parameters were obtained by Nihon Khoden Celltac F Automatic CBC analyzer. Hematological parameters result that obtained were subjected to statistical analysis and p < 0.05 was considered significant.

**Results**

This study was conducted on 58 patients with AML and 25 healthy subjects all of them were selected randomly in relation to age and sex. the age of patient ranged from 14 -72 years, of median age of 30.5 years, and a mean of 42.9 years, 31 patients were male and 27 were female with a male to female ratio of 1: 14.1 While in control group the age ranged from (15 – 65 years, with a median of 26 years and a mean of 30.6 years,12 were males and 13 were female and as shown in figure (1) and table (1).

Statistical Analysis

Pearson’s $\chi^2 = 0.208$; D.F. = 3; p = 0.649 (NS)

NS: Not significant (p > 0.05).

FLT3-ITD mutation was detected in 10 out of 58 AML patients (17.24%) while NPM1 mutation was detected in 6 patients (10.34%) and as shown in table (2). FLT3-ITD mutation was detected in 7 (12.1%) females and in 3 (5.2%) males, on the other hand, NPM1 mutation was positive in 5 (8.6%) males and in 1 (1.7%) female as in table (2). The most common AML subtype according to FAB classification was AML-M5 which constitute about 18 (31.03%) of the patients followed by AML-M2 in 14 (24.13%), and as shown in table (2). Most of the patients are presented with pallor which was seen in 35 (60.34%) of them followed by fever in 22 (37.9%) and bleeding in 17 (29.31%) as shown in table (2).

Regarding the bone marrow blast cells percentage mean was 74±0.13 in patients with FLT3-ITD mutation, 66±0.10 in patients with NPM1 mutation and 62±0.22 in non-mutant patients as shown in figure (2). Regarding the relation of FLT3-ITD and NPM1 mutation to hematological parameter of the patients, the mean WBC count in NPM1 was (49.56±15.77×10^9/L) which was significantly higher than in patients without the mutation for NPM1 & FLT3-ITD (29.36±16.52×10^9/L) and as shown in figure (3).

**Discussion**

Acute myeloid leukemia is a heterogeneous disease results from mutation in a multipotent hematopoietic stem cell. It is a common malignant myeloid disorder in adults. A total 58 AML patients were enrolled in this study, the mean age was 42.9 years, comparable to Tawfiq et al with a mean age of 42 years. Male to female ratio was 1.14 : 1 which agrees with Figueroa et al and Dhahi et al who reported male to female ratio of 1:2: 1 for both, this slight male predominance could be due to being more exposed to environmental carcinogenic risks than females. FLT3-ITD mutation was detected in (17.24%) of our patients similar to Yusoff et al where (16.1%) of their patients had the mutation. Female have FLT3-ITD mutation more than male, in (12.1%) and (5.2%), respectively, comparable to Juliusson et al with detectable mutation in (29%) of female and (22%) of males. However, Chauhan et al disagree in reporting FLT3-ITD mutation in males more than females. NPM1 mutation was found in (10.34%) of the patients and this was not so far from Abdulateef et al who detected it in (18.86%) of the patients. NPM1 mutation was reported more in males in (16.1%) of them than in females (3.7%), this results are similar to Abdulateef et al with a detection in (28.1%) of males and (4.7%) of females. On the other hand, this differs from Dhahir and Dhahi who reported NPM1 mutation in (60%) of females more than seen in males (37.5%). The variation of results between studies may be due to possible differences in sample size as well as different method that have been used to evaluate these mutations. Regarding morphology, AML-M5 was the most common FAB subtype constitutes (31.03%) of the cases followed by AML-M2 (24.13%), parallel to Govedarovic and Marjanovic, 2011cƘ. On the other hand, this results are different from Khan, 2018 where AML-M2 was reported in (59%). However, study the subtype of AML is very important because it help to choose the best treatment and also affects a patient’s outlook. For instance, the acute promyelocytic leukemia (APL) subtype is often treated using drugs that are different from those used for other subtypes of AML. Pallor was the most common presentation followed by fever, equivalent to findings of Dhahi et al but different from Chauhan et al which hepatosplenomegaly was the common clinical feature followed by lymphadenopathy. This variation may be due to the different immunological and physiological status of individuals among different populations. Patients with FLT3-ITD mutation had significantly higher mean B.M. blast cell percentage of (74%) when compared with NPM1 mutation and AML without these mutations in (66%) and (62%), respectively. This close to Notopuro et al with blast cells of (79.5%). Patients with NPM1 mutation had significantly higher WBC count mean (49.56±15.77×10^9/L) as compared with AML without any mutation (29.36±16.52×10^9/L) similar to findings of Döhner et al and 22 but different from Abdulateef et al which reported that WBC count was non-significantly higher than in non-mutated group. Despite low mean of RBC count, hemoglobin levels and platelets count in AML patients, there were no significant difference among different groups, low levels of these parameters is a logical consequence with AML which is a cancer of the myeloid lineage of blood cells, characterized by the rapid growth of abnormal cells that impede normal blood cell production and this will cause anemia, pallor and bleeding tendency. Indeed, study the features of BM blasts may not only allow us to better know the biology circulation of bone marrow blasts, but may also help in better understanding and developing a new strategy of therapeutic. Also, many studies have shown that genotypic subgroup and WBC count without FLT3-ITD are independent predictors of effect.
the molecular markers including NPMc and FLT3-ITD on outcome of patients is still not clear18.

**Conclusion**

AML is common in middle age group with slight male predominance, AML-M5 was the most common FAB subtype, most of the patients presented with pallor, patients with NPM1 mutation had significantly higher WBC counts while patients with FLT3-ITD mutation have higher blast percentage comparable to other local and worldwide reports.

Assessment of Associated Factors and Complications for Women with Poly Cystic Ovarian Syndrome in Baghdad City

Alyaa Khazaal Neamah¹, Hala S. Abdulwahid², Hind Sadoon Lateef³

¹Assistant Teacher, ²M.Sc. Professor, ³PhD. Physician, Maternal and Neonate Nursing Department, College of Nursing/University of Baghdad, Iraq & Specialist Physician, Ministry of Health

Abstract

Objectives: To assess the associated factors and complication for women with poly cystic ovarian syndrome.

Methodology: A descriptive study conducted on purposive sample of (65) women whom attended Hospitals in Baghdad city suffering polycystic ovarian syndrome for the period of (20th October 2019 through 25th February 2020). Descriptive & Inferential statistical analyses were used to analyze the data.

Results: The highest percentages (50%) in age group were (19-22) years, primary schools graduates, housewife, from “urban area”, with irregular cycle. Take high grains, fat, sugar in their food And suffered from obesity, hirsutism, acne, amenorrhea, infertility among short term complication.

Conclusions: The study concluded that there is significant relationship between occupation, body mass index, food consumption, dietary habits, environmental factors, with short term complication of PCOS.

Recommendations: Need to developed training program to upgrade their knowledge and skills about healthy food and life style to reduction the complication of PCOS.

Keywords: Assessment, Associated Factors, Complication, Poly Cystic Ovarian Syndrome.

Introduction

The life style ways, environmental and genetics factors it could be the reasons to some of diseases, one of these diseases is polycystic ovary syndrome which affects about one in 15 women in the world(¹).

Polycystic ovary syndrome defines as hormonal and endocrine disorder affect women in their reproductive age which described in 1935 by Stein and Leventhal, as represents of an estimate of 10 small cysts of a diameter ranging between 2 and 9 mm develop on one or both ovaries and/or the ovarian volume in at least one ovary exceeds 10 mL(²).

These syndrome can diagnosed if two of three symptoms are found: (1) hyperandrogenism (detected by clinical and/or biochemical testing) in meaning hormonal disturbances of LH, Prolactin and testosterone levels (2) ovulation abnormalities, and/or (3) 12 or more cysts on one ovary and/or ovarian volume > 10 mL(³)(⁴).

Insulin resistance effect about (44-70%) of women with PCOS which consider the main causes of metabolic disturbance that lead to hyperinsulinemia, hyperglycemia, and increased oxidative all these factors contributes to occurrence the condition(⁵).

Many sign and symptom can appear in woman with pcos with leading to health complication, the most common abnormalities associated with PCOS include menstrual disorders (amenorrhea or oligomenorrhea), often leading to infertility (in 73–74% of the cases), abdominal obesity (30–70%) and type 2 diabetes (approximately 10%). Other frequent disorders include hirsutism (85–90%), arterial hypertension (approximately 20%)⁶.

The long complications like dyslipidaemia, cardiovascular disease, endometrial cancer occur when the ovarian syndrome leave untreated so we concern with this factors and complications in this study⁷.
**Methodology**

A descriptive study was applied to assess the associated factors and complication of poly cystic ovarian syndrome among purposive sample of (65) women aged between (19-34) years old attended the hospitals in Baghdad city. Data is collected through using the questionnaire format which consisted of three parts, including demographic, associated factors of PCOS, included reproductive characteristics, food consumption, environmental factors, and complications of PCOS included short and long term complication, the items of questionnaire are rated by (yes) scored as (2) and (no) scored as (1) expect food consumption is scored by (3) for always (2) for sometimes (1) for never. Data are collected through using the study instrument and the interview technique in purpose of data collection after agreement of woman which suffering from PCOS which implemented for the period of (20th October 2019 through 25th February 2020). The reliability and Content validity of the questionnaire are determined through a panel of (6) experts and the. Descriptive and inferential statistical analyses were used to analyze the data by using frequency (F), percentage (%), mean of score (MS), assessment (ASS), and Bivariate Pearson correlation, through SPSS program the statistical procedures tested at p ≤ 0.05.

P-value: Probability level, S: Significant, NS: Not significant

This table shows that most of studied variables had significance relationship with Short Term Complications of PCOS, and not significant with age, marital status, education, place of residence, consanguinity and family history.

Discussion

The study show that the most women are in the age group (19-22) year old, was married, primary school graduates, housewife, live in urban, suffered from obesity, and they relative in consanguinity. The age and education level considered important factors that effect the woman health and make her more susceptible to pcosthis finding is agreement with the study done in los Angeles the majority of the study sample was (18-30) years old with low education level another substantial factor leading to PCOS is the obesity, obesity or overweight infect 50% of women with PCOS in a study conducted in Italy.
Reproductive characteristic results (Table 1) illustrates that most of their menstrual age are (9-12) years old with irregular cycle, oligomenorrhea and severe dysmenorrhea, begin every (33 days and more), stayed (2-7) days, these characteristic of menstrual cycle put the women at risk for development PCOS this finding is constant with the study in Aristotle University of Thessalonik which found that patients with amenorrhea, oligomenorrhea and irregular menstrual cycles are more likely to progressive PCOS from woman with regular cycles (10).

Food consumption in table (2) reported that most food taken by women are: (grains, meats, fats, high sugar foods, milk, and diary food), these unhealthy food lead to obesity which is among the associated factors these result agreement with the study done in Shiraz, Iran that seems that PCOS has augmented in adolescent girls due to unhealthy food habits and obesity (11).

Environmental factors items in table (3) as: use of plastic-packaged food, disposable plastic cup for drinking and exposure to cooking oil fumes are most factors found in this study which contribution to ovulatory dysfunction that causes PCOS correspond with study done in china (12).

Short term complications of PCOS items in table (4) as: (obesity, hirsutism, acne, amenorrhea, infertility) which represents the most common complications that appear in affected women with PCOS which compose a great risk to their health unless treated, in the other study shows that the diagnosed of PCOS is depended on the presence of hyperandrogenism with lead to hirsutism, acne, oligo-anovulation resulted to amenorrhea, infertility, and Insulin resistance (IR), with increasing body mass index (13).

To define the relationship between studied variables and short term complications of PCOS the study used the Pearson correlation test (Table 5), which depicts that there is significant relationship between occupation, body mass index, food consumption, dietary habits, environmental factors, and short term complication of PCOS, while not significant in age, marital status, education, place of residence, consanguinity, family history with short term complication of PCOS, all these factors if not mange correctly will perform to the complication of PCOS, these result is similar to the study done in India that indicated to the main risk factors of complication of PCOS; (Hirsutism, acne, dysmenorrhea and oligomenorrhea) are Obesity, socioeconomic status, family history, insulin resistance (14).

This study shows there are no long term complication of PCO as: (dyslipidaemia, cardiovascular disease, endometrial cancer), and the reason for that is short time comes in collecting the sample, as is known, the complications for a specific disease needs a long period of time to appear, which indicated in a different study conducted in India indicates that women with PCOS are more likely to develop complications as: (obstetric, cardiovascular, metabolic and psychological) with the time (15).

Conclusions

The study concluded that there is significant relationship between occupation, body mass index, food consumption, dietary habits, environmental factors, with short term complication of PCOS.

Recommendations: The study recommended to developing study about management to women with PCOS, training program to upgrade their knowledge and skills about healthy food and life style to reduction the complication of PCOS and more study with long time to identify the long term complication of PCOS.

Ethical Clearance: Nil

Source of Funding: The source of funding is Self

Conflict of Interest: Is obtained from the Ministry of Health/Al-Russafa Health Directorate (Kamal Al-Samarraee Hospital and Elweya Maternity Teaching Hospital), and All women with PCOS participants in the research have been approved before the questionnaire is started.

Abstract

This study was intended to determine rubella virus seroprevalence in pregnant women. The samples included 240 women who attended during the duration from October 2018 to May 2020 Al-Batool Gynecology Hospital in Baqubah District. Women’s age ranged from 16-45 years; their age mean was 26.38 years. Data including age, number of previous abortions. Sera were collected from each woman, and the levels of rubella IgG and IgM were detected by use Electrochemiluminescence (ECLIA), enzyme-linked immunosorbent assay (ELISA) and On Site Rubella IgG/IgM Rapid (OnSite) tests. Also, RT-PCR test are used to detect rubella viral RNA. The results revealed that anti-rubella IgG antibodies for the 240 pregnant women were ranges from 84.58 % to 89.58 % depending on the method tested used. While the anti-rubella IgM antibodies for the 240 pregnant women were ranges from 5 % to 5.41 % depending on the method tested used. Only 8 from 240 specimens of pregnant women are rubella viral RNA positive with (3.33 %) percentage by RT-PCR test. In relation to the history of abortion, the seropositivity of rubella antibodies were (61.42 %) of pregnant women had history of abortion with significant relation P< 0.05, however the abortion frequency among Pregnant patients have the past of one or more abortions with the nonsignificant P>0.05 relation.

Keywords: Rubella, IgG, IgM, ELISA, Electrochemiluminescence.

Introduction

Rubella is caused by an RNA virus belonging to genus Rubivirus and family Matonaviridae (formerly belonged to Togaviridae)[1]. Most infections with rubella cause mild, self-limiting measles-like disease, the real danger occurs when the fetus is infected with the rubella virus[2]. Before 20 weeks of pregnancy, problems such as miscarriage or birth defects can occur if contaminated by childbearing women [3]. As the virus may attack any portion of the growing fetus, any organ may be damaged[4], this number of congenital malformations known as congenital rubella syndrome (CRS) may involve the brain, heart, hearing, and vision. [5]. Laboratory studies for CRS include immunoglobulin rubella M (IgM) in cord blood or baby serum, immunoglobulin G (IgG), and chain reaction polymerase (PCR). The infection of maternal rubella sometimes goes unnoticed, as there is always no rash [6]. Reliable laboratory confirmation of confirmed cases of rubella is a prerequisite to successful control of this disease's removal process [7]. This study was planned to analyze a sample of the awareness of pregnant Iraqi women about the risk of rubella during pregnancy; assessing their attention to pre-conception prevention and knowledge of their serological status, correlated with the miscarriage and rubella congenital syndrome, to verify the likelihood of achieving the elimination of rubella congenital syndrome. Therefore, the goal of that analysis was to determine seroprevalence of the rubella virus; precisely the seropositivity of rubella immunoglobulin G (IgG) and immunoglobulin M (IgM) rates, compared to three laboratory method for rubella IgG and IgM detection. Additionally, molecular viral infection detection through real-time polymerase chain reaction (RT-PCR). Also study the relationship between rubella infection in a sample of pregnant Iraqi women with and without prior history of abortion.

Materials and Method

The study consisted of 240 pregnant women who suffered from gestational disruption or had a history of previous abortions. The age of pregnant women varied between 16- 45, age mean of them was 26.38 years. A
consent form explaining the dimensions of the study was obtained from each woman either as a written form or an oral form. Data including age, number of previous abortions, via a straightforward interview. Samples from these persons were collected only if we had no records of serious or extreme diseases. Blood collection was done using disposable syringes and needles. Each individual had obtained 5 ml of venous blood in the appropriate vein. The blood collected was passed directly into sterile plain gel activator tube then allowed to stand at room temperature for 10 minutes to give the clot activator included in the tube time to react, And then centrifuged at room temperature to remove the serum at 5000 rpm for 10 minutes. The serum was dispensed through three closely packed, Sterile, and polished eppendorf tubes (-20 °C) screened for detection of IgM and IgG against Rubella in serum specimens by using three techniques: the enzyme-linked immunosorbent assay (ELISA) method, (Abnova kit, Spain), Rubella IgG/IgM Rapid on-site (OnSite) (Biotech, Germany) and Electrochemiluminescence (ECLIA) immunoassay method (using Rubella IgG, IgM Cobas Entegra 411 kit (Roche/Germany). Also RT-PCR test are used to molecular detect rubella viral RNA by use (RNA extraction kit and Real-time PCR search for qualitative identification of Infectious rubella, both were from Sacace, Italy).

Statistical Analysis: The machine helped in processing results. Statistical research the test was performed using SPSS (Statistical Social Science Package), version 20 of the program. Distribution of frequencies and percentage was done for the element you chose. The standalone t-test was used, and a significant amount of P-Value less than 0.05 was deemed.

The results in a table (1) showed that anti-rubella IgG complete seroprevalence in pregnant women that are obtained in the present study ranged from 84.58 % to 89.58 % depending on the method tested used. This result is almost similar to a previous study conducted in the target population, Diyala province, Iraq, has obtained higher rate (91%) of rubella IgG[8]. While the Synchronized study conducted in Zakho City,
Kurdistan Region, Iraq has obtained a slightly lower rate (83%)⁹, another study also Synchronized with this study conducted in Baghdad has obtained a higher rate (95%) for IgG and (9.8 %) percentage for IgM antibodies [10].

Studies in the other countries had reported variable results. The seropositivity rate of rubella virus in pregnant women of Turkey are recorded (86.5%), (0.5%) for IgG and IgM respectively[11]. In Sweden, rubella seropositivity had (89 %) of all female and (93.4%) of the male donors tested [12].

Seroprevalence studies offer information on the susceptibility to infection of certain populations, including women of childbearing age [12]. Nonetheless, all of these studies refer to the same message: that some women of childbearing age may be susceptible to rubella given that CRS is a serious concern for rubella infection during pregnancy, immunity to rubella is of particular importance in post-young women. Consequently, it advises (i) taking any opportunity to evaluate rubella immunity in women of childbearing age (e.g., consultation with preconceptions), (ii) all pregnant people must be tested for their rubella serostatus, and (iii) prone adults must be vaccinated either preconception or postpartum due to removal from the hospital [13].

In this study only 12 (5 %) of cases were positive for IgM antibodies, that’s as rubella IgM typically declines the next 2-3 months post-infection [14], this result proposes that women positive for IgM can have an active infection by the virus. The specimen’s women of IgM positive and IgG negative reflects the occurrence of the new seroconversion (a new infection with rubella virus) or reinfection [15]. While those who exhibited IgG positive sera with negative IgM reflects those immunized or previously infected persons, which instituted the majority of the studied populations.

These differences in results among laboratory techniques that are used in this study (ECLIA, ELISA, The rapid onsite diagnosis method can be attributed to many chief factors such as its variance in the gray zone, cutoff, and the antigens that using in Complete virus assays (or recombinant antigens). In Iraq, many test procedures are used to identify persons whether or not they are contaminated or immunized with the rubella virus. The rapid onsite diagnosis method is used in private laboratories on a large scale and the Electrochemiluminescence method is used in the laboratories of government health centers and the ELISA method is used on a smaller scale.

The development of rapid and perfect laboratory competencies for the identification of pathogens is essential in the application of effective prevention and control strategies against infectious diseases [16]. Although much progress has been made in diagnostic testing such as that for the care of individual patients or the quick detection of pathogens during disease outbreaks, several of these testing modalities need a skillful operation and complex equipment, which has restricted their use for onsite testing [17].

According to the statistics of the Iraqi Ministry of Planning, central statistical organization; the population of Iraq is approximately thirty-nine 39 million in 2019. And by performing a calculation, 48% of the Iraqi population is female, this means nearly 18.7 million women in the Iraqi population, and 49% of these women are of childbearing age, which approximately 9.16 million women at childbearing age [18]. According to our study, 12.5% of specimens were negative for rubella IgG antibodies, that is, approximately 1.145,000 of Iraqi women are of childbearing age and at risk of contracting rubella virus and developing CRS. Taking into consideration that Iraqi women who become 32 years old or older were not immunized against rubella, as MMR schedule was incorporated into the Iraq National Immunization Program in 1988.

The results in a table (2) showed that only 8 from 240 specimens of pregnant women are rubella viral RNA positive with (3.33 %) percentage, while 232 specimens of pregnant women are rubella viral RNA negative with (96.66 %) percentage. The results in the present study were also consistent with the results of another study, the result has been reported by [19] showed only 6 (10.5%) were positive for Rubella virus by use RT-PCR test from 46 (80.7%) are positive by ELISA test. This negative result is very low concerning the positive result when measuring the samples depending on the presence or absence of rubella IgG and IgM antibodies. Where from 12 or 13 positive IgM results, which represent an acute infection, only 8 of them appeared positive in a way of RT-PCR. This result can be explained on the basis that the positive result with the RT-PCR technique appears only when the RNA of the virus is present in the sample.

A conclusion in a table (3) indicates the association between anti-rubella antibodies and abortion and the number of abortions. The total rate of abortion was 61.42 %. The rate of abortion number was 32.85 %, 15.71 %, and 12.85 % for one, two, and three abortions.
or more respectively. Furthermore, pregnant women that had a history of abortion with significant relation P< 0.05, however, the abortion frequency were had no more deferent recorded among pregnant women with a history of one abortion or more with non-significant relation P>0.05. The current study showed a significant relationship between the history of miscarriage and the presence of rubella antibodies (as shown in Table 3), 61.58% from the total seropositive pregnant women had a history of abortion. The miscarriage may be due to the effect of rubella on systemic and local (placenta) immunological response. There was non-significant relation (P>0.05) between the presence of rubella antibodies and the number of abortions, this finding may reveal the ability of the rubella virus to cause miscarriage only one time. This finding is consistent with the findings of most other studies that found a history of miscarriage and is significantly associated with rubella seropositivity[20,21].

Conclusion

Most women are seropositivity of rubella IgG. Rubella virus is presented as an etiologic factor for spontaneous abortion in this area of Iraq; therefore routine screening rubella is needed for pregnant women. This study limitation, future study including children and adolescents of various ages would allow the knowledgeable susceptible women and determine the outcome of the pregnancy and hazardousness of CRS in our province. The differences in results among laboratory techniques that are used in this study (ECLIA, ELISA, The rapid onsite) diagnosis method can be attributed to many chief factors such as its variance in the gray zone, cutoff, and the recombinant antigens that using in complete virus assays.

Abstract

Aim: To investigate the effect of brochure concerning to early postpartum hemorrhage on enhancing nurses’ knowledge, practices and satisfaction.

Results: The result of the present study findings was highly significant improvement in total knowledge and total practical skills among the studied sample pre intervention compared to immediate and eight weeks post intervention. P= < 0.01 Additionally 83% among studied sample satisfied with the advanced knowledge included in the brochure.

Conclusion: The present study findings concluded that a significant improvement among studied sample’ knowledge and practices post intervention. Also the majority among the studied sample were satisfied the implemented brochure.

Recommendations: Nursing standards, protocols and guideline must be designed to enhance nurses’ knowledge, practices and satisfaction.

Keywords: Improving Nurses’ Practices, Early Postpartum Hemorrhage.

Introduction

A brochure is an informative paper document that can be folded into a template, pamphlet or leaflet. Brochures are promotional documents, primarily used to introduce services for decreasing maternal, fetal and neonatal morbidity and mortality from early Postpartum hemorrhage (PPH). Early postpartum hemorrhage is defined as blood loses over 500 ml or more from the genital tract within the first 24 hours post the vaginal birth of neonate. Incidence of early postpartum hemorrhage is accounting for a quarter of all maternal deaths. In total there are 14 million cases of hemorrhage occurred every year in association with pregnancy and childbirth. According to world health statistics 2015, every day, approximately 830 women died from preventable causes related to childbirth. Among 830 deaths occurs daily, 250 women are died due to early postpartum hemorrhage (PPH).(10) Causes of early postpartum hemorrhage can be explained by the 4T’s theory: Tone – Uterine a tony (70-90%), Retained tissue that was estimated for 6–10% of all cases, Trauma leading to 20% of all cases and coagulation defects that accounting for 1% of all early PPH mortality.(1) Furthermore, immediate complications of early postpartum hemorrhage are disseminated intravascular coagulation (DIC), Hypovolemic shock, severe anemia, clotting disorders, acute renal failure, sepsis, wound infection, pneumonia, venous thrombosis or embolism and acute lung injury, damage to the anterior pituitary gland may result in delay or failure of lactation as well as secondary infertility and
Less commonly myocardial ischemia\(^9\). Moreover, the successful management of early PPH must be focused on three components, medical therapy, Mechanical procedures and surgical therapy\(^4\). Nurses play a multidisciplinary role as a direct care provider, health educator and counselor, as a manager and as a researcher for patients with early postpartum hemorrhage.

**Significance of the Study:** In Egypt, especially in rural areas, postpartum hemorrhage (PPH) is still one of the main causes responsible for maternal morbidity and mortality. That’s it still needs a radical solution. Moreover, According to Damanhur teaching hospital statistics 2017, approximately, the incidence of early postpartum hemorrhage (PPH) was 12.5%. Furthermore, early postpartum hemorrhage (PPH) was the nursing concern because she plays a multidisciplinary role as a care giver for early detection, screening and referring patients with early postpartum hemorrhage to minimize maternal and fetal morbidity and mortality. No previous studies implemented brochure for early postpartum hemorrhage at Damanhur teaching hospital.

**Aim of the Study:** To investigate the effect of brochure concerning to early postpartum hemorrhage on enhancing nurses’ knowledge, practices and satisfaction.

**Research Hypothesis:** Nurses who received brochure about early postpartum hemorrhage has shown better knowledge, practices and satisfaction more than those who didn’t participated.

**Subject and Method**

**Setting:** The study was conducted at obstetric departments in Damanhur teaching hospital at Beheira Governorate.

**Study Design:** A Quasi-experimental (an intervention study) pre and post test

**Sampling:**

(a) **Size:** All nurses (44 nurses) who were working at obstetric departments and accepted to participate in study, at previously mentioned study setting.

(b) **Type:** purposive sample was included.

**Exclusion Criteria:**

1. Age less than 18 year and more than 40 years.
2. Working as an administrator nurse.
3. Education with Bachelor of Nursing.

**Tools of Data Collection:** Three tools were used by the researcher after reviewing the advanced related literature. All tools of data collection implemented pre intervention then immediate and eight weeks post intervention but satisfaction tool was implemented eight weeks post intervention only.

**First Tool:** Structured interviewing questionnaire schedule which included two parts: The first part: assessed nurse’s general characteristics (age, level of education, qualification, area of residence, years of experience and attendance of training programs).

The second part: assessed nurses’ knowledge regarding early postpartum hemorrhage. Which involved 14 multiple choice questions.

The knowledge scoring system was 2 score for correct answer and 1 score for incorrect answer. The total knowledge correct score was \((\geq 60\%)\) while, the total knowledge for the incorrect score was \((<60\%)\).

The second tool was an observational checklist: To assess nurse’s practices while providing patient’s care every 15 minute for the first four hrs with early postpartum hemorrhage. **Scoring system for an an observational checklist was evaluated as 2 score for correct practice and 1 score for incorrect practice.** The total correct practice was scored as \(\geq 60\%)\) while incorrect practice total scored as \(<60\%\).

The third tool was “Nurse Satisfaction tool” adopted from (Sayed, et al., 2015), and included two parts.

**First part:** Assessed nurses’ satisfaction regarding an instructional supportive guideline which involved eight statements. Upon which nurses respond as satisfied, dissatisfied and uncertainly satisfied.

**Second part:** Assessed barriers that prevent nurses to comply with implemented guideline while providing patient’s care which involved six statements. This was evaluated eight weeks post intervention.

**An instructional Supportive brochure** was designed by researcher according to nurses learning needs pre intervention based upon advanced related literature.

**Content validity and reliability:** All tools of data collections were developed and sent to three specialized university Prof. according to their comments, modification were considered.
Pilot Study: A pilot study was conducted for 10% from total number of sample to evaluate the simplicity and clarity of tools that was used in the study.

Field work or Operational design: The study was implemented through three phases included the preparatory, implemented and evaluation phase.

Phase one (preparatory Phase): The researcher was reviewed the current advanced national and international literature related to the study topic, then prepared tools for data collection and designed an instructional supportive brochure. Finally, pilot study was conducted.

Phase two (implementation phase): Firstly, the researcher was interviewed three nurses/day according to sequence of their attendance in hospital registration book and explain the aim of the study to obtain their oral consent. Interview was conducted in a separate place to maintain confidentiality of the study. (duration of each interview 20 min).

• Secondly, nurses' practices were assessed using an observational checklist, while they are providing patients care with early postpartum hemorrhage.

• Each day, two nurses’ practices were assessed from 9 Am to 9 pm.

• After the completion of assessment of nurses’ practices. An instructional supportive brochure was implemented through 10 sessions for each program for six months duration of each session was 20 minute, number of participant (6) nurse/each session. Three sessions for theoretical learning and seven sessions were implemented for practical training.

• Method of teaching were (group discussion, lectures, brain storming, demonstration and bed side teaching).

• Media were (lab-top computer, figures, flip chart as well as audiovisual aids (data show presentation) and role play.

Phase three (evaluation Phase): This phase was utilized to evaluate the effect of implemented brochure on enhancing nurses’ knowledge and practices among patients with early postpartum hemorrhage. All tools of data collection were used pre intervention then immediately and 8 weeks post intervention but the nurses’ satisfaction tool was used only eight weeks post intervention. Nurses’ practice was assessed on three patients three times then the mean was obtained for statistically analysis.

Discussion

The present study was aimed to investigate the effect of brochure concerning to early postpartum hemorrhage on enhancing nurses’ knowledge, practices and satisfaction. This aim was significantly approved within the framework of the present study’s research hypothesis which was nurses who received brochure about early postpartum hemorrhage has shown better knowledge, practice and satisfaction more than those who didn’t participated. Concerning nurses’ knowledge related to early postpartum hemorrhage. The present study research findings revealed that, there was a highly significant improvement of nurses’ knowledge post intervention compared to pre intervention. The present study findings was agreed with(6) who found that there was significantly improvement of nurses’ knowledge post intervention compared to pre intervention because he found that educational programs (both booklet and education) for the prevention and management of early PPH led to significant improvements in the knowledge of obstetric nurses.

Also, the present study was agreed with(2) who illustrated that there was a highly significant improvement among nurses regarding total knowledge score post intervention compared to pre intervention. Furthermore, a study was conducted by(3). Who pointed out that, there was highly statistically significant difference between pre and post intervention among nurses’ knowledge regarding early PPH. This similarity may be due to their sample was from Egyptian community and the same culture.

Concerning nurses’ practices, the present study findings had revealed that a significant improvement in nurses’ practices immediately and eight weeks post intervention. This result is in line with(4) who found that
nurses had incorrect practice at pre intervention phase and highly improved immediately and three months post intervention. Additionally, this result is in the same line with the present study (6) who reported that a significant improvement in nurses’ practices regarding early PPH after implementation of brochure.

These findings point out the successful effect of implementation of brochure to maternity nurses as method for continuous updating and improved their knowledge and skills to promote and improve their competences. Thus, there is a clear role in continuing professional development activities of nurses which have ultimate reflection on improving patient’s care outcome.

Finally, it was observed from present study findings that highly significant relations between nurses’ knowledge and their practices. This because nurses’ knowledge was considered the base for their practices. This result was supported by (5), who had found highly significant association between obstetric nurses’ knowledge and their practices. As well (7), who reported that positive statistically significant correlation between the studied subjects’ knowledge score and their practices.

The present study findings had pointed out our attention toward the importance of implemented brochure because it was illustrated from the present study findings that there was a highly retention of study sample knowledge and practices eight weeks post intervention. This is due to the effectiveness and practicability of the implemented brochure. The majority nurses among studied sample were satisfied with the implemented brochure the majority had reported that the brochure language was easily understood and the aim was matched with its content. Also, the place of implemented brochure was comfortable with good ventilation and lighting.

Additionally, the implemented brochure contributes to the development and updating with advanced knowledge regarding early PPH and enhance nurses’ practices. Moreover, the majority among studied sample was suggested to replicate the present study brochure to other nurses in another setting in the future to enhance nurses’ knowledge and practices and the majority among nurses was highly satisfied with implementation brochure.

**Conclusion**

It was observed in the present study findings a highly significant on enhancing nurse’s knowledge, practices and satisfaction post intervention compared to pre intervention. Additionally, the majority among the studied sample was highly satisfied with the application of nursing brochure.

**Recommendations:**

- Hospital administrator must direct their attention toward relieving nurses from administrative work and to devote their time for nurses’ activities only.
- Design and implement monitoring system to evaluate nurses’ practices at obstetric department continuously.
- Designing nursing standards, protocols and brochure for all nurses at obstetric department.
- The present study, implemented brochure was recommended to replicate at another setting and on larger sample.
- Periodically planned pre service, in-service and on job training programs related to early post-partum hemorrhage.
- Further study investigates health team immediate intervention related to early Postpartum Hemorrhage at obstetric department.

**Ethical Clearance:** Taken from the Scientific Research Committee at the Faculty of Nursing, Ain Shams University.

Abstract

This study was conducted in the hatchery belonging to Al-Anwar Poultry Company, by injecting the hatching eggs at the age of 17.5 days from the age of the embryos with nano Silver, after that, and raised hatching chicks from the injected eggs in the field of poultry belonging to the Department of Animal Production, College of Agriculture, University of Al-Qasim Green for the period from 6/8/2017 until 9/9/2017, and after that the laboratory work was done, as it used 168 broiler chickens and was reared in cages 1 x 1.5 m, the chicks were randomly divided into seven treatments, and each treatment had three replicates, including each replicate of 8 chicks. Nano-silver was used by injecting it into the eggs in concentrations (0, 4, 6, 8, 10, 12, 14 ppm) for treatments (T1, T2, T3, T4, T5, T6, T7) respectively. The chicks were raised in the field for a period of 35 days, and in this study we reached the following results, a significant excelled (P<0.01) of the T3 treatment in the length and width of the villi in the Jejunum and the excelled of the two treatments T3, T7 in the depth of crypts of Lieberkuhn, and in the ileum there was a significant excelled (P<0.01) for the treatment T2 in the villi length, while the treatment T7 excelled in the villi width and the treatment T5 and T6 treatment was excelled in the crypts depth

Keywords: Broiler Ross 308, Nano silver, Histological traits.

Introduction

The poultry industry has recently witnessed multiple technologies, including nanotechnology, which is the study of materials on the Nano scale, where the size of the particles ranges between (1-100) nanometers4,11, where nanomaterial’s are distinguished in that they take up a very small area but it has relatively large surface areas, and as a result, when massive materials are reduced to Nano, their surface becomes chemically more effect and the physical properties of the material change without changing their chemical properties4. The expansion of the ratio of the surface area to the volume allows the nanoparticles to be more diversified and hence more frequent, as nanomaterial’s can be used alone or carrying other materials for the purpose of connecting them inside the body or coated with other materials21, and the nanoparticles have been used as diagnostic and therapeutic agents in the medical field Human for some time, although its application in veterinary medicine and animal production is still relatively new. In recent times, the demands for the production of nanomaterial’s and their uses in the poultry industry have increased due to the fact that the use of antibiotics as a treatment for disease infections of birds has become ineffective due to the increase in cases of bacteria resistant to antibiotics16 and this determines the need to find suitable alternatives, as the nanoparticles As a good antimicrobial to improve the growth of birds9. The sources showed that the injection of Nano-silver increased the immunity of the incubated chicks17,10,13,14 indicated that the injection of hatching eggs with Nano-silver promoted the absorption of yolk fat in embryos and stimulated growth and embryonic development where the Nano-silver is silver Nano is an anti against a large number of germs.2 also indicated that the injection of hatching eggs with silver nanoparticles at concentrations (12, 14, 16, 18 ppm) increased the length and width of villi, therefore the present study aims to know the effect of injecting hatching eggs at the age of 17.5 days from the age of embryos at different levels of Nano-silver in some
hatching traits and in the histological traits of the chicks hatched and determining the best level of injection.

**Materials and Method**

Salt solution (NaCl) was used in the preparation of egg injection solutions. A Nano-silver material was obtained from the Nanosany Corporation company (20nm) and morphological (spherical). Use 168 broiler chickens and raised in cages 1x1.5m. The chicks were randomly divided into four treatments. Each treatment included three replicates, each replicate included 8 chicks. Nano-silver was used by injection into eggs at concentrations (0,4,6,8,10,12,14 ppm) for treatments (T1,T2,T3,T4,T5,T6,T7) respectively, where hatching eggs were injected at the age of 17.5 days From the age of the embryos and injected (0.25 ml/egg).

**Feed Treatment:** The chicks were fed on the starter diet from the age of one day until the third week of the bird’s life, after that they were replaced by the final diet (finisher) until the end of the fifth week. Feed and water were provided in a free manner (ad libitum) and the diet used is as shown in the table below.

*BROCON-5 SPECIAL W protein concentrate: Chinese origin, each kg contains: 40% crude protein, 3.5% fat, 1% fiber, 6% calcium, 3% phosphorous available, 3.25% lysine, 3.90% methionine + cysteine 2.2% sodium, 2100 kcal/kg energy represented, 20,000 IU vitamin A, 40,000 IU vitamin D3, 500 mg vitamin E, 30 mg vitamin K3, 15 mg vitamin B1+ B2, 150 mg B3, 20 mg B6, 300 B12 mg, 10 mg folic acid, 100 mcg biotin, 1 mg iron, 100 mg copper, 1.2 mg manganese, 800 mg zinc, 15 mg iodine, 2 mg selenium, 6 mg cobalt, 900 mg antioxidant (BHT).** According to the chemical analysis of the diet according to NRC (15).

**Preparing the histological sections:** The two birds were slaughtered from each replicate. The tissue samples were taken for the shortest possible time period to ensure that the bird’s body tissue is not damaged. A section (2 cm) in length was taken from the second part of the small intestine (jejunum). The contents of the intestine were removed, all the sections taken with tap water were washed and the processes of preparing the histological sections were performed, according to him (16).

**Examination of histological sections:** The histological sections were examined using a compound-type Olympus BH2 of Japanese origin. The histological sections were imaged by a digital camera attached to a Lenovo computer. The small intestine (jejunum) were examined using an accurate ocular micrometer of 100x magnification for the purpose of recording measurements of the small intestine (villi length, villi width and crypts depth) in microns 10-3 mm, and used the stage micrometer for the purpose of Calibration of the Eyepiece according to what he mentioned (6). The villi length was measured from the top of the villi until its association with the villi mysteries, while the crypt depth was defined as the depth or distance of immersion between adjacent villi (3,8). As for the villi width, it was measured according to what he mentioned (3). It was measured from the middle of the villi height or from the curvature of the villi that divides the villi while (5) the villi width was estimated from the base of the villi, so the villi width was measured (3) by taking the average for the two readings, knowing that all measurements were made for (10) readings for each measurement and taking average.

**Statistical Analysis:** The statistical program (18) was used in data analysis to study the effect of different factors on the studied traits according to a completely randomized design (CRD), and The significant
differences between the averages were compared to the Duncan (7) polynomial test

Mathematical Model:

\[ Y_{ij} = \mu + T_i + e_{ij} \]

Results and Discussion

The length and width of the villi and crypts depth in the Jejunum and Ileum: Table (3) shows the effect of injecting hatching eggs with Nano silver on the length and width of the villi and the crypts depth in the Jejunum at the age of 35 days from the age of birds. While T3 treatment was significantly excelled (P<0.01) on villi length traits on the rest of the treatments followed by treatments T7 and T4, respectively. While treatment T2 excelled on the treatments T1,T5, and T6, while treatment T6 excelled on treatments T1,T5,while the T5 excelled on control treatment T1.As for the villi width, the T3 treatment continued to excelled, as P<0.01) significantly excelled on the rest of the treatments, while the T2 treatment was excelled on the T1,T4,T5,T6,T7 treatments, while the T4, T5 treatments were excelled on the T1,T6,T7 treatments. The T7 and T6 treatments were excelled on the control treatment T1 and there was no significant difference between the treatments T4, T5 and T6, T7 treatments. At the Lieberkuhn crypts depth, the T3,T7 treatments were significantly excelled on the rest of the treatments while the T5, T4, T2 treatments were excelled to the T1 and T6 treatments, and no significant difference occurred between T2,T4,T5 treatments, while the T6 treatments was excelled on treatments T1. In the Ileum, Table (4) showed a significantly excelled (P<0.01) in the villi length traits for the T2 treatment on the rest of the treatments and the T6, T7 treatments were excelled on the T1, T3, T4, T5 treatments and the T3 treatment was excelled on the T1, T4, T5 treatments, While treatments T5 was excelled on treatments T1 and T4,The T4 treatment was excelled on the T1 treatment. In the villi width,P7 treatment was significantly excelled on the T7 treatment, and the T2,T3 treatments were excelled on the T1,T4,T5 and T6 treatments, and the T4 and T6 treatment excelled on the T1 and T5 treatments. While the T5 treatment was excelled on the T1 treatment and in the crypts depth, the T5,T6 treatments were significantly excelled on the rest of the treatments, and the T3,T7 treatments were excelled on the T1,T2,T4 treatments, and the T2,T4 treatments on the T1 treatment (18) mentioned that nano-silver could affect the outer layer of the intestinal wall and consequently a change in the length and width of villi and depth of crypts also found (12) that feeding on nano-silver at a concentration of 5 mg/kg feed resulted in an increase of 11% in the average length And the width of villi and 7% in the depth of crypts and the reason may be due to the fact that nano-silver improved the intestinal environment and thus led to an increase in the length and width of villi and depth of crypts, This study agrees with(2), which found that the injection of hatching eggs with nanosilver at concentrations (12,14,16,18 ppm) improved the intestinal environment because it is a bacterial antagonist, it increases the length and width of villi and depth of crypts. The histological sections of the Jejunum region of the small intestine of different nano-silver injection treatments were studies, The results showed a significant increase in the length and width of villi and regularity of their forms, as well as an increase in crypts depth for injection treatments at the age of 35 days compared to the positive and negative control treatments (images 1-7), Also, the cellular activity in the intestine sections showed an increase through the multiplication of intestinal cells in the crypts region, as well as in the surface of villi, especially in injections with nano-silver at a concentration of (4 ppm), as another section appears in the Jejunum region to treat the injection with a concentration (6 ppm), which shows an increase in the width and regularity of villi, In the Ileum, we note the treatment of injections with a concentration of (8 ppm). The regularity of the villi forms appeared with the increase of their lengths and the appearance of cell propagation in the crypts of Lieberkuhn. As for the injections with a concentration of (10,12,14 ppm). The prolongation of the villi appears with its regularity and an increase in cellular activity in the crypts region. As for the control treatment, it is found that the length and width of the villi are varied and their forms are irregular. And the reason for the excelled of the nano-silver injection treatments to the control treatment may be that the nano-silver injection into the Amniotic fluid of the embryo is swallowed orally by the fetus in the last third of the incubation (19 days), which causes the activity of the gastrointestinal tract in general and the gut region and in the Jejunum, in particular, This led to an increase in the length and width of villi and an increase in crypts depth(1).
Table 2: The effect of injecting hatching eggs with nanosilver on the length and width of villi and crypts depth in the Jejunum for broilers.

Level of significance

** **

The averages that have different letters within one column differ significantly among themselves at the level of **(P<0.01). The T7,T6,T5,T4,T3,T2,T1 treatments are a control treatment without injection and injection, at concentrations of 14,12,10,8,6,4 of the silver nano solution, respectively.

A: The control treatment T1, Irregular length and width of villi are observed in Jejunum (hematoxylin and eosin tincture) 200x
B: treatment T2, regular length and width of villi are observed in Jejunum and the activity of the crypts region (hematoxylin and eosin tincture) 200x.
C: treatment T3, and an increase in cellular activity is observed in the crypts region in the Jejunum (hematoxylin and eosin tincture) 200x.
D: T4 treatment. It is noted that the length and width of the villi are regular and the cellular activity increases in the crypts region in the ileum (hematoxylin and eosin tincture) 200x.

Abstract

Current research emphasizes the contribution of gut microbiome to numerous health conditions including cancer and skeletomuscular disorders. Cachexia is a debilitating condition of progressive loss of body tissues. It occurs in up to 80% of patients with tumors, and it impairs their functioning and quality of life and increases morbidity and premature death. Several randomized trials indicate that interventions, which target gut microbiome can correct and revert tissue loss in aged people. However, less is known about the effect of such strategies in cachectic muscle loss. This report briefly sheds the light on the role of gut-muscle axis in cachexia and demonstrates few examples on interventions addressing gut microbiome and their effect on cachectic muscle. It also speculates the literature for the skeletal muscle-promoting activity of bee products, particularly bee honey and propolis (which are quite handy), within the context of cachexia. Implications for future studies are discussed.

Keywords: Bee honey, cachexia, cancer, gut microbiome/microbiota, gut-muscle axis, probiotics, propolis, skeletal muscle loss.

Introduction

Overview of Cachexia: Excessive unintentional weight loss is a common feature of neoplastic disorders. Cachexia is a syndrome characterized by progressive weight loss due to tissue loss that involves fat and non-fat components of the body. It occurs in 50–80% of cancer patients.1-3 Cachexia increases sense of fatigue, alters patients’ functioning, decreases mobility, threatens their wellbeing and quality of life, and heightens morbidity. Cachexia is a direct cause of mortality in 20% of cancer patients while cachectic patients with neoplasms exhibit a one-year mortality rate of 80%.2

There is less agreement on the definition of cachexia, and several models have been proposed (Table 1). The common feature among all the available classifications is unintentional weight loss.4,6 According to a proposal set by the SCRINIO Working Group, unintentional loss of 10% or more of body weight is sufficient to diagnose cachexia in cancer patients.5 Fearon and others defined
cachexia as either weight loss >5% within the last 6 months, weight loss >2% along with a body mass index < 20 kg/m², or fat free mass index < 14.6 and 11.4 kg/m² for men and women, respectively. According to Evans and colleagues cachexia diagnosis is based on weight loss and low body mass index, in addition to the presence of 3 of 5 criteria: fatigue, anorexia, muscle wasting, muscle weakness, and abnormal biochemistry including high levels of inflammatory markers e.g., c-reactive protein or anemia indicated by low hemoglobin level.

The mechanism of cachexia: The dynamic of cachexia is multifaceted. The immune system of individuals with neoplasms is continuously activated, which is associated with high production of pro-inflammatory cytokines and free radicals. Tumors also induce major alterations in the cellular antioxidant system in host tissues. Disturbed redox and high levels of cytokines accelerate the activity of molecules involved in proteolysis and lipolysis. In fact, cumulative evidence attributes the progressive nature of muscle loss occurring in cachexia to excessive accumulation of factors that negatively regulate protein turnover in skeletal muscle. Common molecules that derive muscle atrophy in cachectic muscle include atrogin-1, ubiquitin-proteasome system, muscle ring finger-1, myostatin, etc.

Anorexia and decreased food intake experienced by most cancer patients is a major contributor to cachexia. On one hand, low food intake decreases body supply with nutrients necessary for cellular function, which promotes break down of proteins and lipids in major stores in the body (e.g., skeletal muscle) as an alternative source of energy. Thus, inadequate protein intake promotes muscle wasting. Therefore, cachexia is associated the development of malnutrition and other wasting disorders e.g., sarcopenia and frailty. On the other hand, improper dietary supply evokes major alterations in the structure of the resident intestinal flora.

A wealth of studies reports a strong causal relation between gut microbiome and pathologies contributing to many serious disorders such as cancer, obesity, insulin resistance, depression, major neurodegenerative disorders such as Alzheimer’s disease and Parkinson’s disease and even the current coronavirus disease 2019. What is common between all these conditions is that ingestion of pathogenes, toxins, and unhealthy food such as food high in fat and low in fiber promote the growth of toxic intestinal microbes and limit the growth of beneficial bacteria. Metabolites of toxic bacteria cause local insults to the gut (permeability or dysbiosis) and pass to the systemic circulation where they reach many organs and trigger gene mutations that support pathogenesis. Recent studies confirm the presence of a strong association between gut microflora and skeletal muscle wasting, which is mediated by numerous physiological alterations that promote muscle protein degradation such as insulin resistance as well as increased production of free radicals and inflammatory mediators in skeletal muscle (Figure 1). These studies strongly suggest the presence of a gut-muscle axis.

Generalized wasting and muscle weakness associated with cachexia lead to serious functional decline, general weakness, exhaustion, and promote inactivity. Limited physical activity promotes extra muscle loss via multiple mechanisms involving gut microbiome alteration, oxidative stress, and metabolic...
dysfunction. In addition, refeeding attempts through the use of amino acids fail to counteract anabolic resistance (i.e., increase protein synthesis) under conditions of low physical activity.

**Targeting cachexia through gut promoting interventions:** The literature shows that dietary proteins and amino acids promote muscle protein synthesis during early stages of muscle atrophy, which is associated with preservation of body tissues. However, cachectic individuals respond poorly to refeeding. In other words, cachectic muscle mass does not increase with increasing dietary intake of proteins. In the meantime, treatment options for people with cancer-induced cachexia are quite limited, and treatment effects are rather discouraging, which entails poor quality of life in this group of patients.

Gut bacteria represent a major factor in anabolic resistance since pathogenic ones degrade amino acids and impede the delivery of amino acids to skeletal muscle in order to trigger muscle protein synthesis. Experimental evidence shows that the development of cancer alters the composition of microbiome of the gut by promoting flagellated pathogens, which boost the production of inflammatory cytokines and reactive oxygen species resulting in cachexia. The classical phenotype of cachexia associated with tumors involves reduced levels of *Lactobacillales* and propagation of *Enterobacteriaceae* and *Parabacteroides*. Experimentally, blocking activin receptors, which regulate the continuously occurring turnover of the epithelial membrane of the gut, could not correct cancer-induced alterations in gut microbiota. However, cumulative knowledge denotes that manipulation of the gut microbiota through fecal microbiota transplant as well as prebiotics and probiotics may treat cachexia in laboratory animals.

**Figure 1.** Schematic illustration of the contribution of gut alterations to muscle loss along with the protective role of interventions that target microbial community in the gut.

Probiotics have been increasingly used in the last few decades as a treatment approach that involves implanting live microorganisms in specific doses e.g., *Lactobacilli* and *Bifidobacteria*. “Prebiotics” is a closely related approach, which involves nutritional modifications that nurture beneficial gut microflora. Health-promoting species of gut microbiome contribute to health of the host by activating xenobiotic metabolism system, stimulating mucosal immunity (secretory IgA), inhibiting the growth of endotoxic bacteria, enhancing the expression of mucin, which promotes stability of the mucosal barrier, and synthesizing beneficial substances e.g., short-chain fatty acids, amino acids, antioxidants, and vitamin K.
Evolving knowledge denotes effectiveness of probiotics in the treatment of muscle wasting in cachectic animal models. Oral consumption of probiotics containing *lactobacillus* (*L.*) *reuteri*, *L. gasseri*, and *L. plantarum* by cachectic mice was associated with restoration of the normal structure and balance of bacterial phyla in the gut as well as with less intestinal permeability. Accordingly, circulating levels of toxic bacterial metabolites dropped resulting in significant reduction in the production of inflammatory mediators and negative regulators of muscle protein turnover such as Atrogin-1, MuRF1, LC3, Cathepsin L, and negative regulators of muscle protein turnover such as Atrogin-1, MuRF1, LC3, Cathepsin L in the gastrocnemius and tibialis muscles. It is noteworthy that not all lactobacillus species can affect microbiota of the gut in a fashion that allows suppression of the activity of molecules involved in muscle atrophy. For instance, treating cachectic rats with *L. acidophilus* could not inhibit inflammatory responses in skeletal muscle or prevent muscle atrophy. In addition, successful administration of probiotics is rather challenging since secretions of the upper gastrointestinal tract e.g., gastric and pancreatic secretions contribute to the damage of a considerable portion of externally administered probiotic bacteria, especially when administered in a free form.

Research reports limited diversity of gut microbiome in people with musculoskeletal dysfunction such as frailty and cachexia. People with altered gut-microbiome profile express nutritional deficiencies and higher production of inflammatory markers. Healthy foods represent a major source of amino acids and prebiotic dietary elements, which can modify the structure of gut microbiome and promote its diversity. Evidence denotes that around 35% of lactic acid bacteria in fresh fruits and vegetables can successfully survive gastric conditions and reach the intestine.

Bee honey contains a variety of health-promoting lactic acid bacteria e.g., *Bifidobacterium*, *Fructobacillus*, and *Lactobacillaceae*. These bacterial species demonstrate strong antimicrobial activity even against the most antibiotic-resistant pathogens. Moreover, honey’s high contents of phenolic acids and internal hydrogen peroxide inhibit the growth of endotoxic bacteria in the gut. In fact, honey is considered a full food, which is consumed by bee workers during winter where foraging decreases or stops. It is rich in carbohydrates, proteins, amino acids, vitamins, flavonoids, and oligosaccharides. The latter function as prebiotics, which promote the growth of healthy intestinal microflora such as *Bifidobacterium*.

Propolis is a multifunctional bee product that bee workers produce by mixing their saliva and bee pollen with plant exudates they collect from various plants. Propolis is rich in more than 400 bioactive compounds, including phenols, flavonoids, amino acids, vitamins, and trace elements. It expresses several pharmacological activities such as being an antioxidant, anti-inflammatory, anti-aging, anti-microbial, anti-cancer, anti-lipidemic, immunomodulatory, etc. Owing to its countless bioactivities, propolis is widely used as a dietary supplement to promote health and well-being.

Bee products such as honey were reported to hinder skeletal muscle wasting and promote weight gain, body fat, and nitrogen contents in cachectic rodents with Walker 256 carcinoma, which mimics the human neoplastic syndrome. These effects were achieved via a multidimensional mechanism that involves attenuation of chronic inflammation, oxidative damage, and catabolism. A mixture of honey and *Aloe vera* (*L.*) *Burman* modulated the antioxidant system in rats injected with tumors. Antioxidant enzymes such as super oxide dismutase (SOD) and catalase represent the first defense against oxidative stress where SOD catalyzes the dismutation of the superoxide anion (*O*₂) into oxygen and hydrogen peroxide (*H*₂*O*₂) while catalase subsequently converts them into water and oxygen. Honey also downregulated calcium-dependent protein degradation pathway, a key contributor to cell death in cachectic muscle, by modulating the activity of its upstream effector, cysteine protease calpain. It also decreased the chymotrypsin-like activity in the gastrocnemius muscle. The chymotrypsin-like activity corresponds to the catalytic core of the 20S subunit of the ubiquitin–proteasome pathway, which is considered the most important pathway for intracellular protein degradation under catabolic conditions. Likewise, a combination of grape seed polyphenols and propolis, also known as bee glue, attenuated the production of proinflammatory cytokines and corrected muscle wasting in cachectic rats with chronic adjuvant-induced arthritis. Positive effects occurred in animals on continuous low doses compared with animals receiving five different high doses—signifying that correction of cachexia requires chronic treatment. Although the effect of honey and propolis on gut microbiota was not examined in these studies, the contribution of these bee products to the resident microflora could not be excluded. This is because honey and propolis were orally consumed,
and there’s a probability that they expressed their strong antimicrobial activity in the gut, at least in part, leading to gut healing and repair.

Honey is reported to modify gut microbiome in constipated mice, mice with ulcerative colitis, and human intestinal microbe culture. Experimental evidence shows that honey promotes the growth of health promoting species such as indigenous Bifidobacterium in cultures from human colon while co-administration of bee honey with probiotic Bifidobacterium prevents the destruction of these bacteria by gastric secretions allowing a large number of cells to reach the intestine to produce their health-inducing activity. In the same way, propolis, which expresses bioactivities similar to those of honey, can positively alter the structure of gut microbiome. For instance, diabetic rats receiving propolis extracts exhibited increased growth of beneficial bacterial species in the gut. This effect was associated with increased production of health-promoting bacterial metabolites (e.g., short chain fatty acids) and levels of tight junction proteins in the ileum denoting correction of gut dysbiosis. Accordingly, levels of fasting blood glucose and glycosylated hemoglobin significantly dropped while glucose tolerance and insulin sensitivity index remarkably increased. It is well-known that glucose-metabolism dysregulation is a key contributor to skeletal muscle loss in diabetes. The mechanism involved entails impairment of protein anabolism in muscle fibers and alteration of the structure of blood vessels resulting in less blood supply to skeletal muscle. Moreover, propolis is reported to correct gut microbiome in rodents on high-fat-diet (HFD). HFD creates pathogenic patterns of gut microbiome involving colonization of bacteria that promote intestinal aberration and promote inflammation and multiple dysfunctions in various remote organs including skeletal muscle, a condition known as sarcopenic obesity—muscle loss along with high fat mass. Interestingly, modifications in gut microbiome induced by propolis were associated increased muscle mass in treated animals.

Bee products, although distinct in their composition and pharmacological activities, share some of their composition and bioactivities. The effect of bee products on gut microbiome has been examined in many studies including cancer samples. In this regard, trans-10-hydroxy-2-decenonic acid (10-HDA, also known as queen bee acid or royal jelly acid) expressed strong antimicrobial activity against numerous pathogenic bacterial species in human cancer colon cells. In addition, 10-HDA is considered a strong anti-inflammatory and anti-oxidant agent, which demonstrates protective effects against skeletal muscle wasting by modulating muscle metabolic functioning and glucose uptake.

To our knowledge, natural honey and propolis are the only bee products known to restore cachectic muscle. In the light of the presented literature, the current article sets a number of questions that worth investigation in future studies: do honey/propolis improve muscle loss in cachexia through modulation of gut microbiome? If so, what is the exact nature of change e.g., in terms of microbial phyla affected, change in bacterial metabolites, repair of gut dysbiosis, and signaling cascades involved in oxidative and inflammatory reactions both locally in the gut and in skeletal muscle? What constituents of honey/propolis are likely to therapeutically affect gut microbiome? Are other bee products (e.g., bee venom, bee pollen, royal jelly, and their key constituents) capable of improving metabolic gut microbiome composition and correcting metabolic and inflammatory dysregulations in cachexia? If so, what are the most muscle promoting agents among all bee products? Accordingly, further investigations of the role of such natural products in cachectic models would promote the development of successful randomized trials in the future.

**Conclusion**

Use of probiotics and multifunctional foods such as bee honey/propolis is likely to decrease muscle atrophy in cachectic models. Probiotics improve muscle condition by altering gut microbiome structure. Although honey/propolis decreased systemic inflammation and improved skeletal muscle mass in cachectic rodents, their effects on the composition and functionality of gut microbiome were not examined yet, which worth investigation in future studies. Evaluation of the effect of other bee compounds (e.g., bee venom, royal jelly, and bee pollen) on cachectic muscle is also necessary for identification of the most effective substances.

Optically Sensing for Thyroid Profile Hormones in Blood

Rawia Shatti¹, Layla M.H. Al-ameri²

¹Scholar Researcher, ²Lecturer, Institute of Laser for Postgraduate Studies, University of Baghdad, Iraq

Abstract

Optical biosensors present great characteristics compared to traditional analytical techniques because they allow direct, realistic, and label-free detection of many biological and chemical materials. Thyroid hormones are created by the thyroid gland, which is found in the abdomen of the thyroid cartilage. Thyroid hormone governs metabolic processes necessary for normal outgrowth and evolution in addition to regulating metabolism in adults. It is established that the condition of the thyroid hormone is related to body weight and energy disbursement. This work using a single-mode tapered fiber biosensor to detect changes in the level of thyroid hormone by measurement of the intensity changing with the concentration of hormone by using a diode laser (450 nm) wavelength as an optical source, the single-mode tapered fiber as the sensor connected with ocean (HR 2000) spectrum analyzer by an adapter and finally connected to the pc to show the result. The lowest intensity of transmitted light recorded with a higher concentration of the hormone because of the high matching and specific selection of laser wavelength with the structure of the thyroid hormone in which give the specific amount of the hormone present in the sample. Thyroid hormone can be detected by using a laser biosensor. The higher concentration of thyroid hormone referred to the lowest intensity of light.

Keywords: Optically sensing, thyroid profile, hormones.

Introduction

Thyroid hormone governs metabolic processes necessary for normal outgrowth and evolution in addition to regulating metabolism in adults. It is established that the condition of the thyroid hormone is related to body weight and energy disbursement. Hyperthyroidism, promotes excessive metabolic status characterized by increased energy consumption during rest, weight loss, low cholesterol levels, increased fat decomposition, and glucose formation. On the contrary, hypothyroidism, low levels of thyroid hormone, is associated with a lack of metabolism which is characterized by low resting energy consumption, weight gain, increased cholesterol levels, low-fat degradation, and reduced sugar development. TH catalyzes both lip formation and fat decomposition, although TH levels are high, the net effect is fat lack [¹].

The core volume of single-mode fiber is little. The size of the core (diameter) is usually about 8 to 10 micrometers (µm). The core of fiber of that volume is allowed only to place the platform or minimum to spread around the wavelength of 1300 nm (nm). Single-mode fibers are spread in only one mode because the base size approaches the operational wavelength (λ). This is accomplished using lasers as a source of light [²]. The primary refraction coefficient can be referred to as n, which is larger than the n cladding refraction coefficient. The little diameter of the nucleus lets the transfer of one position of the light. No dispersion, no degeneration of the signal transmitted through the fiber, low attenuation due to the number of waves spreading along with the core of the fiber giving the signal ability to spread over long distances and faster. As shown in figure (1)

![Figure (1): Schematic_configuration of (single mode–multimode single mode fiber) structure](image)
Optical biosensors present great characteristics compared to traditional analytical techniques because they allow direct, realistic, and label-free detection of many biological and chemical materials. Its features include high privacy, sensitivity, little size, and cost-effectiveness [5]. Biochemical processes play a very important role in medicine, biology, and biotechnology. However, it is very rough to convert biological data directly into an electrical signal, biosensors can transform these signals and biological sensors to this difficulty. In recent years, thanks to improved technologies and devices, the use of these products has increased [6].

While sensors have himself group of components: light sources and optical fiber to direct light between them and the optical detectors. So Understanding the principle of the action of different fiber optic sensors, it is important to find out the optical components used [7]. The study aimed to assess of the level of concentrations of thyroid hormones (Thyroid-stimulating (TSH) and thyroxin (T4) & Triiodothyronine (T3)) by using a single-mode optical sensor (SMF) as a new method.

**Material and Method**

**Sample Collection:** Ten ml was taken from the blood sample of each patient, each sample then centrifuged to get serum and this serum is divided into two parts, each part is five ml, the first part is used for manually detection of (T3 and T4 and TSH) by using Vida’s device, the other part (5 ml) is used for detection the three hormone (T3, T4, and TSH) by using a single-mode optical sensor (SMF).

**Biological Measurement:** The levels of serum thyroid hormone (T3, T4, TSH) were measured by Vida’s device is an automated quantitative test for use on Vida’s family instruments for the quantitative measurement of total thyroid hormone (T3, T4, TSH) in human serum (lithium heparin) using the ELFA technique (Enzyme-Linked Fluorescent Assay).

**Fabrication of SMF:** A (30 cm) long fiber sensor is considered a traditional optical fiber cut a length of about (2 cm) in the middle of the fibers using a cut Make grooves on each side. The buffer was removed byways of dipping the pieces in 40% acetone concentration for (30 minutes). Washed with distilled water. to get rid of impurities and clean it well. A part of the fiber is immersed in pure hydrofluoric acid (HF) 40 %. to remove the cladding of the fiber, in a (10-minutes) setup and then washed with distilled water. The full fibers (30 cm), was put in the aplastic device using an adhesive silicone. The ends of the fibers are connected to a transformer device. The terminal tools are connected to optical fibers by optical fiber connectors. Splicing has been used to Join two organized fibers to form an unending optical waveguide. The first end is connected to a laser exporter (blue diode laser) and power supply. Diode laser, (450) nm wavelength, and an output power<50,000 MW was used. The Laser wavelength matches the absorption peaks of the three thyroid hormones (T3, T4and TSH). So it connected to a stable power supply. This laser was selected depending on the absorption spectra of the hormones which were measured by using a spectrophotometer. Another part is connected it is a spectrum analyzer (ocean HR2000) to get an intensity signal.

Optical Spectrum Analyzer (Ambient Optics HR2000) with accuracy (0.035 nm) of high wavelength and works at a wavelength of (200-1100 nm), and connects the spectrometer Via a USB port or serial port to a laptop or desktop computer.

Assess variation in thyroid hormone level by using a single-mode fiber optical biosensor. As shown in figures (2,3,4)

![Figure (2) T3 specimen and stander Intensity peak in SMF](image-url)
Figure (3) T4 specimen and stander Intensity peak in SMF

Figure (4) TSH specimen and stander Intensity peak in SMF
Results and Discussion

Tables 1 and 2 show the concentration of the standard hormone which obtained from the ELFA kit and the concentration of the hormone after using the ELFA technique (Enzyme-Linked Fluorescent Assay). Method and the intensity of each concentration obtained from the optical biosensor. From the result inverse relationship between the concentration and the absorbance intensity, the highest the intensity was in the lowest concentration and that indicates the low amount of thyroid hormone present in the serum and because of the specific absorbance and high matching in the 450 nm wavelength for thyroid hormone we could know the specific amount of the hormone in the sample by using the Single-Mode Fiber sensor and this agrees with the manufactured one sensor using type of fiber (SMF) for detection some on types of female hormones (LH) by using a diode laser (blue) at a wavelength (450um) as a source of light. This agrees with where she manufactured one sensor using Mach-Zehnder interferometer (MZI) for detection of the hemoglobin concentration in human blood was designed by Green laser with a wavelength of 532 nm and input power of 12.2 nw has been used as a source of light.

Conflict of Interest: None

Funding: Self

Ethical Clearance: Not required

Conclusion

Use a single-mode optical fiber sensor with a laser source (450 nm) to detect the thyroid hormone level. From the result of the study, we found that the maximum laser intensity indicates the lowest concentration of the hormones. A sensor is most accurate, with a rapid diagnosis, less costly method than the method.

Association between Nitric Oxide (Sputum Induction and Asthma Control Level on Asthma Outpatients

Andi Yanti1, Muhammad Aminuddin2

1Students of Department of Pulmonology and Respiratory, Faculty of Medicine, Universitas Airlangga, Jalan Mayjen. Prof Dr. Soetomo 47 Surabaya 60131, Indonesia, 2Lecture of Department of Pulmonology and Respiratory, Faculty of Medicine, Dr. Soetomo Teaching Hospital, Universitas Airlangga

Abstract

Background: Asthma is a heterogeneous disease with chronic inflammatory characteristics of the respiratory tract. (Nitric Oxide) (NO) levels increased significantly in patients with inflammation such as asthma in this study. Nitric Oxide (NO) levels in normal people and asthma patients are different, but no sputum of Nitric Oxide (NO) levels are associated with asthma control levels.

Method: Thirty-patients consecutive sampling was conducted at asthma unit Dr. Soetomo Teaching Hospital Surabaya. The subjects were met the inclusion and exclusion criteria that assessed their asthma control with asthma control test (ACT) then measured by NO levels.

Results: In this study, the subjects were divided into asthma control level; full-controlled was 4 subjects (13,3%), partially-controlled was 8 subjects (26,7%), and uncontrolled was 18 subjects (60,0%). The mean asthma control level was 18.3±4.2 with the lowest Asthma control test (ACT) score was 8 and the highest ACT score was 25. The mean NO sputum induction level was 92.043±29.040 μM, with the lowest NO was 14.566 μM and the highest NO was 138.350 μM. The result of the statistical test showed a negative correlation significantly between NO-induced sputum level and asthma control level (p <0,05).

Conclusion: The examination of NO sputum level could be used as an indicator in determining the level of asthma control.

Keywords: Asthma, nitric oxide, induced sputum levels, asthma control level, asthma control test score.

Introduction

Asthma is a heterogeneous disease with chronic inflammatory characteristics of the respiratory tract. This diagnosis is based on a history of respiratory symptoms such as wheezing, shortness of breath, heavy chest, and cough with long and intense time, along with the limitation of expiratory airflow.(1) An estimated 300 million people worldwide are suffering from asthma.

The rates of global prevalence of asthma was 1% to 18% over various countries(1), it mentioned that asthma prevalence was 4%(2) (Basic Health Research data In Indonesia 2007). Although asthma was not the main cause of death the impact of illness on asthma causes work productivity to decrease due to absent from work or school. Mortality rates in asthma increase steadily over the time(3). The 1986 Household Health Survey (QRT) showed that asthma ranked fifth out of ten causes of morbidity along with chronic bronchitis and emphysema(4).

Diagnosis and monitoring of asthma are performed based on clinical symptoms, the degree of respiratory tract obstruction and bronchial hyperactivity. The clinical symptoms reported by the patient depending on the patient’s perception and subjective, also the degree of respiratory tract obstruction that detected

DOI Number: 10.37506/mlu.v21i2.2669
by the measurement of the expiratory peak (APE) or the first forced velocity (VEP1). Whereas, bronchial hyperactivity could be detected by stimulation (bronchial challenge test) such as histamine or methacholine and measure the function of the lung phase thereafter. International Guidelines recommend assessment of APE series or spirometry to establish the diagnosis of asthma.\(^{(3),(4),(5),(6)}\)

Nitric oxide (NO) plays an important role in the physiological function of the and as an indicator of respiratory tract inflammation. NO could be detected in the animal expiratory air. Some studies advocate NO assessment of expiratory air which is a non-invasive inflammatory marker in asthma. Mild asthma patients often provide normal values in VEP1, thus NO expiratory and sputum airborne measurements are proposed as noninvasive testing to assess respiratory tract inflammation in asthma. Bronchial challenge test for methacholine or histamine is a measure of bronchial hyperactivity, but it is difficult to assess the degree of inflammation.\(^{(6),(7),(8),(9),(10)}\)

Research on the measurement of nitric oxide (NO) levels began to grow wider and NO levels increased significantly in patients with inflammation such as asthma.\(^{(8),(9)}\) Administration of corticosteroids lowering the NO levels in asthmatics and in air expiration that showed the correlation of the degree of respiratory tract hyperelastic and the number of eosinophils sputum. Thus, it could be used as a marker of respiratory tract inflammation and plays an important role in diagnosing asthma.\(^{(7)}\) 15 people with asthma and 10 normal people get NO sputum rate of asthma patients was higher than control (p <0.01).\(^{(11)}\) In another study from 23 samples studied, higher NO sputum levels were found in asthma compared to control (p <0.01).\(^{(12)}\) The Normal NO value of sputum is set 502 μmol/L with a standard deviation of 41413. The half-life of NO in the tissue is very short (about 1-5 seconds), the direct NO test is not easy to do so the examination is performed indirectly using Griess reaction.\(^{(13)}\)

Further research suggests that Nitric oxide (NO) levels of expiratory or sputum air could be used as a tool to monitor respiratory tract inflammation and assess whether asthma is controlled or no\(^{(7),(8),(9)}\). Although it is known that NO levels of normal people and asthma patients are different, NO sputum levels are associated with asthma control levels, especially in Dr. Soetomo Teaching Hospital, Surabaya Indonesia. Based on this background, then through this research, it will be examined about the correlation between induced sputum NO and asthma control level in asthma patients.

**Method**

This type of research was observational analytical cross-sectional. Research samples that met the inclusion criteria were; Patients who had diagnose bronchial asthma and control routinely in Asthma Unit/chronic obstructive pulmonary disease (COPD) Dr. Soetomo Teaching Hospital, Surabaya Indonesia (Age >15 y/o), do not consume food and drink containing nitrate 1 hour before nitric oxide (NO) test, Inhaled steroid users, Willing to participated the research also sign informed consent.

Materials needed consisting of sputum induction were 3% NaCl, 0.1% DTT (dithiothreitol), phosphate-buffered saline solution, Eppendorf tube, sputum pot, and filter paper. Data analysis using SPSS 17.0 statistic program with significance level p <0.05. Analysis of the association between NO sputum induction of bronchial asthma with ACT score was used Pearson correlation test while, comparative analysis of NO-induced sputum content with each group was used student T-test or ANOVA test.

**Results**

**Normality Test:** The result of the normality test of the research data variable was using the kolmogorov smirnov test. Table 1 explains that the kolmogorov smirnov test on the data of the research variables yielded a p>0.05. These results conclude that the study variable data were normally distributed.

**Table 1. Normality Test**

BMI: Body Mass Index, FEV: First Forced Velocity, ACT: Asthma control test, NO: Nitric oxide

On the other hand, figure 4 describes the education of 30 research subjects, there were 11 people with high school education (36.7%), 6 were undergraduate (20.0%), 5 of were an elementary school and junior high
school (16.7%), and 1 person educated were D3, D4 and S2, respectively (3.3%). Figure 5 shows the body mass index BMI mean was 24.59, with the lowest was 16.23 and the highest was 36.44, it was known that 2 subjects (6.7%) were underweight, 14 subjects were normal weight, 11 subjects (36.7%) were overweight, and 3 people (10.0%) were obese. The first forced velocity FEV1/Pred average was 91.1%, with the lowest FEV1/Pred 42% and the highest FEV1/Pred 160%.

**Asthma Control Test (ACT) Score Correlation with NO Sputum Induction Level:** Pearson correlation was used to find out whether there was a relationship between ACT scores with induced sputum NO levels. The result of pearson correlation between ACT score and NO-induced sputum level was in Table 5.

<table>
<thead>
<tr>

ACT: Asthma control test, NO: Nitric oxide

From Table 3 we can make a comparison graph of induced sputum NO content based on ACT score category as follows. While in Figure 7 shows the average of the lowest control induced NO-induced sputum rate and the highest uncontrolled induced NO sputum content level. One way ANOVA NO-induced sputum content based on ACT score category yielded p-value <0.05, meaning that there was a significant difference in induced sputum NO content based on ACT score category. This result reinforces that the higher the ACT score the lower the NO-induced sputum level.

**Correlation of First Forced Velocity (FEV1)/Pred, Age, and IMT with ACT Score**: The following will present the results of pearson correlation between first forced velocity FEV1/Pred, age, and body mass index (BMI) with ACT scores of study subjects in Table 7 that known pearson correlation between FEV1/Pred, age, and BMI with ACT scores was p>0.05. These concluded that there was no significant correlation between FEV1/Pred, age, and BMI with ACT score.

ACT: Asthma control test

This result concludes that there was no significant relationship between sex, job, and education with the ACT score category of research subjects.

Discussion

The statistical test of the correlation between induced sputum induction and ACT score was using one way ANOVA, which showed the lowest controlled NO sputum rate, and the highest uncontrolled NO sputum level was p <0.05. This means that there were significant differences in induced sputum NO content based on ACT score category. These results support that the higher ACT scores the lower NO sputum level. In some studies, NO levels increased in severe asthma and uncontrolled asthma. The result of the study using NO expiratory air level correlated with ACT score showed median NO in uncontrolled asthma was 40 ppb and controlled asthma 27 ppb also there was a statistically significant difference (p <0.002). The ACT ratio to NO expiratory air level, the median value of NO in full
controlled asthma was 19 ppb, in partially controlled asthma was 20 ppb, and in uncontrolled asthma was 43 ppb with statistical test result showed that overall there were significant difference(20).

The results according to the body mass index(BMI) distribution showed the mean was 24.59, with the lowest was 16.23 and the highest was 36.44. There were 2 (6.7%) subjects classified as underweight, 14 subjects as normal weight, 11 (36.7%) subjects as overweight, and 3 (10.0%) subjects as obese. The result of the statistical test with pearson correlation between BMI and ACT score was p>0.05. These results concluded that there was no significant association between BMI with ACT score. This was inconsistent with research that stated there was a significant relationship between ACT and BMI (p = 0.03) and asthma severity (p = 0.003).(14).

This study showed the mean of first forced velocity(FEV1)/Pred was 91.1%, with the lowest was 42% and the highest was 160%. Statistical test with pearson correlation states there was no correlation between FEV1/Pred value with asthma control test (ACT) score. The validated ACT was a questionnaire that performed briefly, simply, easily on its own, available, and shows continuous accuracy. In this study, the level of asthma control measured by ACT score was 18 (60.0%) as uncontrolled, 8 (26.7%) partially controlled, and 4 (13.3%) as fully controlled. The mean ACT score of bronchial asthma subjects was 18.3±4.2, with the lowest was 8 and the highest was 25. The prevalence of uncontrolled asthma was greater compared to a controlled (75.7 and 24.3%)(14). This was also consistent with research in Persahabatan Hospital consisting of uncontrolled asthma was 47(49%) higher than 41(42.7%) partially controlled asthma and 8 (8.3%) fully controlled asthma(17). Similarly, the results of a study consisting of uncontrolled asthma was 12 (40%), partially controlled was 8 (26.7%), and fully controlled was 10 (33.3%) (18). In this study low population with full controlled asthma might cause by various factors, such as low adherence to therapy or possible resistance to treatment.

This study measured nitric oxide(NO) sputum level using the Griess method. Sputum NO concentration could be used as an inflammatory process in the respiratory tract as in asthma. Several factors might affect NO levels such as NO measurement techniques, smoking habits, genetics, infections, anti-inflammatory drugs, and nitrate-containing diets. To avoid bias, this study has been included in the criteria of inclusion and exclusion of research. All of the study subjects included in the study, asthma patients in the non-exacerbated condition and no other accompanying infections such as acute respiratory infections. The result of measurement was the average of NO concentration was 92.043±29.040 μM, with the lowest was 14.566 μM and the highest was 138.350 μM.

The result of the variable normality test with kolmogorov smirnov was p>0.05. This concludes that the research variable data were normally distributed, so to investigate whether there was a correlation between asthma control test (ACT) score with nitric oxide(NO) sputum content of induction was used pearson correlation. Pearson correlation coefficient is the negative value equal to -0.562 with p <0.05. This result concludes that there was a significant negative correlation between ACT score with NO-induced sputum, the higher the ACT score the lower the NO sputum content of induction of the research subjects

**Conclusion**

The results showed that subjects with fully controlled asthma control were 4 (13.3%) subjects, partially controlled was 8 (26.7%) subjects, uncontrolled was 18 (60.0%) subjects. The mean asthma control level was 18.3±4.2, with the lowest asthma control test (ACT) score was 8 and the highest was 25. The result of induced sputum nitric oxide (NO) level with the mean sputum measurement was 92.043±29.040 μM, with the lowest was 14,566 μM and the highest was 138.350 μM. In this study, there was a significant negative correlation between ACT score with NO-induced sputum NO and asthma control (p <0.05).

Knowledge Among Women at Reproductive Age About Intrauterine Device in Baquba City

Sahar Qasim Saee1, Shahab Ahmed Shakir1, Raakad Kamel Saadi1

1Scholar Researchers, College of Medicine, Diyala University, Iraq

Abstract

Background: The intrauterine device (IUD) is the most popular form of reversible long-acting contraception in the world which is inserted into a woman’s uterus to prevent pregnancy.

Objectives: To study knowledge among women at reproductive age about intrauterine device in baquba city. Subjects and Method: a cross-sectional study was conducting among women at reproductive age who attended outpatient clinics of Al-Batool Teaching Hospital in Baquba City from the period of the 1st of January to the 30th of June 2020.

Results: Among 900 women who included in this study, with mean age about 32.2±8 years old, about 77.1% of women respondents had poor knowledge about this method of birth control. The knowledge score was affected significantly by level of education, age, residency, occupation, years of marriage, number of parity as well as the use of IUD. The main source of information is friends and relatives who represent about 93.3% and a limited role of health care providers. This may cause negative beliefs as well as many myths and rumors about IUD. Conclusion: in this study women were unaware about the basic knowledge of IUDs.

Keywords: Knowledge, women, contraception, IUD.

Introduction

There are various and significant current health issues around the world, but enhancing the quality of maternal health is a significant matter for researchers globally. Family planning in definition is the use of method and practices that allow couples and individuals to anticipate and attain their desired number of children and make the proper spacing and timing of their births. It is obtained through use of contraceptive method and the treatment of involuntary infertility. The ability of a woman to space and limit her pregnancies has a direct impact on her health and well-being as well as on the outcome of each pregnancy.[1]

The intrauterine device is the most widely used reversible method of contraception in the world which is reported by the world Health Organization that about 160 million women use IUCDs globally today.[2]

It is a method surrounded by misconceptions among women, especially about IUD awareness. In this way, many assume that cancer or infertility may be induced, which is not suggested for young or nulliparous women either, and some show considerable concern or fear regarding the procedure of insertion[3,4]. In Iraq, among women who are already using IUDs the fears and misbeliefs about IUD contributed to discontinuation of use in almost half of the women requesting IUD removal[5].

Such perceptions and fears are common; however, research addressing such problems shows that if health providers have accurate and sufficient knowledge about the method, trust in the IUCD may be strengthened, thus increasing the incentive to utilize it[6].

The IUCDs are very safe, effective, and convenient for postpartum, post-abortion, non-pregnant, and breastfeeding mothers. While it is not protective against Human Immunodeficiency Virus (HIV) transmission, it is safe in HIV infected women. It is equally effective and safe for use in the young and/or nulliparous, older women, and women unable to use hormonal method for preventing pregnancy[7,8].

Intrauterine device users are among the most satisfied women who use contraceptive procedures.
Contraception satisfaction is correlated with high rates of continuity of use\textsuperscript{[9,10]}.

**Subject and Method**

A cross-sectional study including 900 women at reproductive age who attended Al-Batool Teaching Hospital in Baquba City, was conducted between the 1\textsuperscript{st} of January to 30\textsuperscript{th} of June 2020. A structured questionnaire was used by the researcher to interview the participants. The first part of the questionnaire included information about socio-demographic characteristics of women: age, residency, level of education, marital age and parity. The second part of the questionnaire contained questions related to women knowledge about IUD and included nine questions. The questions were in the form of (YES, NO and Don’t know) questions, where 1 score was put for right answer and 0 score for wrong answer and don’t know answer. And the total scores were categorized as: > 50% (0-4 knowledge score) was poor score, 50-75% (5-7 knowledge score) was fair and those with more than 75% (8-9 knowledge score) was very good score.

**Statistical Analysis:** data was analyzed using statistical package for the social sciences (SPSS version 23) computer software program. Descriptive statistics were presented as frequency tables, variables were expressed as mean ± standard deviation and categorical variables as numbers and percentages.

**Results**

A total of (900) women were enrolled in this study, the mean ±SD of women was 32.2±8 years. The knowledge score about IUD for the studied women has shown that 77.1\% (694) of women had poor knowledge about IUD with mean score 2.63, fair score was found in 21.8\% (196) of women with mean score 5.75 and only 1.1\% (10) of women had very good knowledge, table 1.

The poor knowledge score in women with more than five years of marriage was lower than poor knowledge score in women with less than 5 years of marriage. Also, the poor knowledge score in women who had never used IUD (84.9%) was higher than women who currently used IUD(61.6%) or past used IUD(75.6%), Table 4.

The sources of information about IUD were health care provider in 15.8%(143), friends represent 93.3%(840) of sources, mass media represented 15%(135) of sources and other sources which was self-experiment and readings represent 11.6%(105), figure 1.
Discussion

The majority of women had inaccurate knowledge about the IUD, for example, 10.8% of women know about two types of IUD (the majority know about copper IUD and had no knowledge of LNG-IUS) (table 2). This can be attributed to the fact that copper IUD is available free of charge in public sector family planning clinics, while the levonorgestrel-IUS is not available to women accessing these services. This finding agrees with a study done in USA in which nearly all sexually active women know about Cu-IUD and 20% of them know the levonorgestrel-IUS [11]. Also 89.3% of women announced that IUD causes infection (table 2), while infection associated with IUD, only would occur in the first 20 days of insertion and it is due to cervical infection which is not diagnosed during the IUD placement. The World Health Organization found that the risk of development of pelvic inflammatory disease (PID) in women with IUD is the same as or less than the risk of PID in women without IUDs [12]. In Iran, a study 50.8% of the participants had wrong knowledge about IUD in increasing the risk of infection [13]. A high percentage of women believed that IUD causes cancer, infertility and heavy bleeding (table 2). This agrees with a study done in USA in 2011 in which the common misperceptions about intrauterine contraception included concerns that intrauterine contraception increases the risk of an ectopic pregnancy, infertility, cancer, or a sexually transmitted infection [14], along with a study in Uganda (2016) where over 40% of the participants had incorrect information about the IUD in relation to breastfeeding, return to fertility, and protection against STIs. Participants also believed incorrectly that IUDs causes cancer and damages the womb [15].

In addition, women couldn’t recognize the appropriate candidate for IUD use (table 2). Where half of women believed that after caesarian section are good candidates for IUD use and the majority believed that nulliparous women are not candidates for IUD use. This can be attributed to the inadequate clients counseling about the IUD, and while this method would be suitable for many women, they avoid using it because they think it is not a good contraceptive option.

However, the general knowledge regarding intrauterine contraceptive devices was limited (table 3), even among IUD users and the existence of myths and rumors about IUD was obvious among the study sample. This may result in discontinuing their IUD use as well as propagate false beliefs amongst their peer groups. This agree with another Iraqi study in Baghdad which is entitled “influence of IUD perceptions on method discontinuation” showed that almost half of the women asked to take the IUD out; fears and false beliefs were the cause of IUD discontinuation [5]. Therefore, by training and consulting the clients about possible side effects and how to confront them would remove their concerns.

Interestingly, differences in knowledge about IUD emerged between age groups, duration of
A possible explanation for that may be due to the idea that most women with increasing age, duration of marriage and parity, had completed their families and they feel that they need more spacing for preserving their health, so they began to seek advice about the safest ways of contraception. This findings is agree with USA study[^14] which reported that current age of the mother, years of marriage and parity were significant predictors for knowledge about intrauterine contraception. Residency also reflected differences in knowledge about IUD, suggesting that there are differences in levels of awareness based on women’s life state. Also, educational level and occupation showed differences in knowledge about IUD. This agree with Indian study that found a strong association between education & working status of participants to their awareness about IUD[^16].

The major source of information about IUD were friends and relatives in 93.3% of the women with secondary minimal role of health care providers & mass media (figure 1). This is agree with Indian study in 2015[^16] which has shown that 90% of information about IUD were from friends, and also agree with a study done in Saudi Arabia 2010 in which the main source of women’s knowledge was the family members, media came next. Health workers were reported by small proportion of the participants[^17]. This highlights the failure of mass media in creating awareness about IUDs and the failure of health care providers in providing contraception knowledge where it should be prioritized as it is a two way communication process and will provide correct and complete information as compared to friends or mass media.

**Conclusions**

**It is concluded that:**

1. Women in this study were unaware of the basic knowledge regarding IUD.
2. Age of women, residency, educational level, occupation, duration of marriage, parity, history of use of IUDs significantly affect the knowledge scores of the participants regarding IUD.
3. The main persons affecting the decision regarding IUD use were the relatives and friends of respondents.

Abstract

The prevalence of overnutrition among primary school aged children, which ranges from the risk of obesity globally including Indonesia, is currently increasing. This study aimed to assess the difference in behavior change in physical activity and habit of soft drinks consumptions before and after the intervention with the dissemination method of resources and information. The research was conducted at primary schools in Makassar City. This research used a Quasy Experiment approach with a pretest and post-test examination through control group design. The study was conducted for 3 months by providing health information related to overnutrition and obesity while monthly visit or monitoring of children was carried out using a 24 hour food recall. The sampling technique was carried out by means of proportional random sampling. Data were analyzed by univariate, bivariate, and multivariate analysis. The results showed that there was an effect of dissemination of resources and information on physical activity (p = 0.000) and soft drink consumption habits (p = 0.000) before and after the intervention. The conclusion is that the application of the method of dissemination of resources and information is effective in changing the behavior of preventing overnutrition in primary school children. It is expected that efforts in schools such as the method of dissemination of resources and information with peer education will become a reference in efforts to prevent more nutrition in improving students’ healthy eating patterns through dissemination of resources and information.

Keywords: Physical Activity; Soft Drink Consumption; Overnutrition.

Introduction

The prevalence of overnutrition among primary school aged children in the world has increased over the last few decades due to changes in shifting eating habits such as soft drinks consumption and low physical activity with the following risks(1). Globally, the prevalence of overweight and obesity in children of 5-17-old years is 10%(2). Based on Riskesdas (2018), it shows that the prevalence of overweight in South Sulawesi province is 13.6% obese and 21.8% obese. Meanwhile, in Makassar City children are 13.9% overweight and 16.5% obese(3). School age children who are overweight and obese are included in the vulnerable group(4).

The consequences of obesity for schoolaged children will have an impact on social stigma. They are being bullied by their playmates, have experienced discrimination, and appear to have low self-esteem. Preventing overnutrition is prioritized in primary
prevention efforts, namely promotion efforts, which means it is started from the school and home environment. Preventive action is the best and safest way for school aged children who are still in their infancy. The basic principle of preventing over nutrition in primary school children is to increase physical activity, increase movement and limit the consumption of foods that contain calories\(^{(5)}\). The nutrition education method used in primary school children can involve students so that students feel responsible for determining the healthy behavior they should do and are given nutritional information. In addition, many studies that analyze the factors affecting that cause obesity and determine obesity prevention method in primary school age children have not been widely carried out recently. This is the gap research and can be done by the method of dissemination of resources and information. This method is carried out in the form of providing nutritional information\(^{(6)}\). Therefore, there is still a need for a method of obesity prevention based on peer nutrition education in an effort to reduce the prevalence of obesity and improve children’s health status by means of dissemination of resources and information. This study aimed to assess the differences in changes in physical activity and consumption habits before and after the intervention using the dissemination of resources and information method. Further study on the factors affecting is needed to conduct so that we can prevent the cases of obesity and overweight primary school aged children.

### Method

This research uses a “Quasy Experiment” design, namely pretest and post-test with a control group design. The research was conducted at primary schools in Makassar City. The research intervention was conducted with three months period by providing dissemination of resources and information related to obesity and overnutrition cases in children. Monthly student visit or monitoring was conducted regularly. The research instrument were a form of recall food, digital scales, and microtise, determining the student BMI using the WHO Anthroplus software. The sampling technique was carried out by means of Sample Size Determination in Health Studies and proportional random sampling\(^{(7)}\). Data were analyzed using the chi-square test, Independent T-Test, Mann Whitney, Wilcoxon test, and hotelling test. The results then reflected to the case of obesity in primary school aged children.

### Results

The distribution of student characteristics can be seen in Table 1, which shows the largest proportion of the age group before the intervention, namely 9 years of age in the intervention group (52.5%), the majority of whom were female (52.5%), and were in class IV (70.0%). While in the control group, the oldest children was aged 9 years (45%), the majority were male (60.0%), and were in class IV and V (50% and 50% respectively from both classes). The results showed that there was no difference in the proportion of age, sex, and class before the intervention ($p>0.05$). Based on the average BMI/age before the intervention, the highest in the intervention group was 20.60 ± 2.21, while there was a difference in the average before nutrition education was given in the treatment group and the control group ($p<0.05$).

Δ1 = Difference of Pre–Post 1; Δ2 = Difference of Pre–Post 2; *Wilcoxon Test; **Mann Whitney Test

The highest average score of physical activity in Table 2 in the pre group is in the intervention group, which is 22.93. Likewise at post-test 1, the highest average value was found in the intervention group, which is 34.05. Based on the Wilcoxon test results, it showed that both the intervention and control groups had a significant difference between pretest and post-test 1 (p <0.05) of the physical activity scores. In addition, there was an increase in physical activity scores from pretest to post-test 1 for each group, where the highest increase was in the intervention group, which is 10.13. Based on the Mann Whitney test, there was a significant difference (p <0.05) from the difference in score improvement for the two groups. Meanwhile, the average score of physical activity at post-test 2 was the highest in the intervention group, namely 43.78. Based on the Mann Whitney test, there was a significant difference (p <0.05) from the difference in score improvement for the two groups.

Figure 1. Changes in Students’ Physical Activities

It can be seen that the average score of high students’ physical activity in the intervention group compared to the control group from baseline has increased, from the beginning of the experiment, the progress happened in post-test 1, and the progress happened in post-test 2.

</table>

Δ1 = Difference of Pre–Post 1; Δ2 = Difference of Pre–Post 2; *Wilcoxon Test; **Mann Whitney Test
Table 3 shows the highest average score of soft drink consumption habits in the pretest is in the control group, which is 71.78. While at post-test 1, the lowest average value was in the intervention group, which is 58.75. Based on the Wilcoxon test results, it showed that both the intervention and control groups had a significant difference between the scores for the habit of soft drink consumption at pretest and post-test 1 (p <0.05). In addition, there was a decrease in the score of soft drink consumption habits from pretest to post-test 1 for each group (intervention and control group), where the highest decrease was in the intervention group, which is 12.20. Based on the Mann Whitney test, there was a significant difference (p <0.05) from the difference in score reduction for the two groups. While the average score for the habit of soft drink consumption at post-test 2 was the lowest in the intervention group, which is 45.83. Based on the results of the Wilcoxon test, there was a significant difference between the scores for the habit of soft drink consumption at pretest and post-test 2 (p <0.05).

Figure 2 shows that the average score of students’ soft drink consumption habits was higher in the control group than the average score of students’ soft drink consumption habits at the intervention group at the beginning of the measurement. Between post-test 1 and post-test 2, the average score of students’ soft drink consumption habits was lower in the intervention group than in the control group. Multivariate analysis was used to simultaneously assess both groups before and after intervention/treatment applied to the intervention group.

Table 4 shows that the results of statistical tests with Hotelling’s T test obtained the value of F = 3716.72 and p = 0.000 (p <0.05). This means that there are differences in the students’ physical activities who did not receive the treatment of dissemination of resources and information with students’ physical activities who did not receive the treatment of dissemination of resources and information. Based on the results of the analysis, it was found that the students’ physical activity variable was the most influential among the other variables due to
the reinforcing factor of the treatment of dissemination of resources and information so that there was an increase in understanding of students’ physical activity after the intervention and greatly influenced the formation of preventive behavior patterns for students resulting in changes in decreasing the incidence of overnutrition cases in primary school aged children.

Discussion

Health and Nutrition Education through Dissemination of Resources and Information Method on Students’ Physical Activities: Physical activity is one of over nutrition prevention forms. Physical activity can burn calories in students while the use of technology can positively prevent obesity. If we combine both ways to prevent obesity in children, the case of diseases caused by obesity will decrease. Children physical activity is needed in the form of running, playing basketball, playing soccer, and playing futsal. Beside decreasing obesity cases, physical activities can improve daily childrens’ health. Therefore, the role of teachers, health workers, and parents of students is very important to provide information related to the importance of moving and doing physical activity, can prevent overweight in students, and can monitor students’ physical activity continuously by applying the rules of a healthy lifestyle in the environment, at school, and at home. Based on the Wilcoxon test, the p value was obtained <0.05, which means that there was a difference in physical activity between the treatment group and the control group at post 1 and post 2. Based on the results of the analysis there were differences in the physical activity of students after the treatment in the intervention and control groups, changes in physical activity indicated that there was increase to 100% in the third month while the physical activity of the control group students decreased. This proves that there is an effect of the dissemination of resources and information method intervention on students’ physical activities.

The physical activity of obese children increases and can reduce and reduce the consumption of food and drinks that have an impact on weight loss. Strenuous physical activity and more sweating is very effective in losing more weight than by adjusting only a diet. Therefore, doing physical activity can maintain human body functions to be more optimal, so that it can reduce the risk of obesity. Proper and optimum metabolism can help enhancing good body shape. The high student consumption of calorie intake that exceeds the need has a negative impact on increasing body weight over normal body weight. It is influenced by increased family income and the ease of buying food and drinks so that more nutritional sufferers increase and become a risk factor for obesity. The incidence of overweight in primary school students in Makassar City tends to be light activities compared to heavy student activities. This is in line with Erni Yeti (2018) research showing that fat intake is higher in students with less activity levels so that students who are less active in movement have the opportunity to experience more nutrition or fat. In this study, activities that are usually carried out in the home environment are cycling and playing football, while at home children sometimes play video games, computers, and watch television. In physical activity, it can be seen that there is a decrease in physical activity in the third month of the intervention due to the influence of the rainy season, so that children’s activities are being at home by playing video games or watching television which can also affect changes in students’ body mass index. It can lead to fluctuated body mass index in students and students’ health.

Health and Nutrition Education through Dissemination of Resources and Information Method on Students’ Soft Drink Consumption Habits: Soft drinks are carbonated drinks added with flavorings and sweeteners such as additive ingredients and sugar. Soft drink consumption habits put a negative impact on health to both short term and long-term period. Unfortunately, students tend to consume these kinds of drink. The results showed that all students owned soft drinks consumption habits obtained from the post-test 1 and post-test 2 which decreased when the scores were compared to the pretest. It shows that there are differences in the soft drink consumption habits between the pretest and post-test 1 and post-test 2 in both the intervention and control groups. This is influenced by the method of dissemination of resources and information. The decline in soft drink consumption habits was higher in the intervention group than in the control group. The results of the Wilcoxon test obtained that a p value <0.05, which means that there is a difference in soft drink consumption habits between the intervention group and the control group at post-test 1 and post-test 2. One of several factors cause an increase in the prevalence of overnutrition globally in students is soft drink consumption habits. This finding was obtained because the students’ soft drink consumption habits were influenced by the factor of knowledge, where the
knowledge of lack of nutrition was caused by rarely getting information or nutrition counseling related to the adverse effects of consuming soft drinks. In addition, consuming soft drinks can increase body weight so that students can become overweight if they have consumed soft drinks continuously. The high glucose content can lead to overnutrition and more importantly can lead to obesity cases among children. A study by Collins et al. (2015) concluded that students who have a hereditary history of obesity have the opportunity to be overweight due to the habit of consumption high-sugar fast food. The increased risk of overnutrition can be prevented and limited by consuming low sugar levels of foods and drinks. It can also be maintained by actively engaged in regular physical activities such as running, cycling, and playing basketball. Students also need to get used to consuming fruits and vegetables (13). Prevention of overnutrition at school and family environment can be done by implementing a healthy diet according to a balanced menu, monitoring children’s foods and drinks, limiting pocket money, scheduling reports on children’s foods and drinks consumed for one day, and measuring the children’s weight regularly to map the difference between before and after the measurement at least once a week. Children’s physical activities can also be increased actively.

Conclusions

The conclusion of this study is that there is an effect of the method of dissemination of resources and information before and after the intervention on students’ physical activity and students’ soft drink consumption habits which have an impact on increasing student overnutrition prevention behavior and reducing the prevalence of overweight cases.

Funding Sources: The funding sources in this study were established from personal funds during the research conducted and analysis of factors affecting in students’ overnutrition cases. This research was supported by the Directorate of Research and Community Service, the Directorate General of Research and Development Strengthening.

Acknowledgments: The authors wish to thank all the Public Health students who helped in the collection of the data during the research of children overnutrition cases. We also acknowledge the Makassar City Government, the Health Office, and the Head of the Community Health Center in Makassar which had given the research permission. We also like to thank all of respondent who have been willing to give their consents and time during the interview process.

Internal Conflict: The author(s) declare that they have no conflict of interest during the research conducted and analysis of factors affecting in students’ overnutrition cases in Makassar City.

Ethical Clearance: Ethical approval of this study has been obtained from Ethical Commission of Health Research, Faculty of Public Health, with the protocol number of UH910183005.

Abstract

Plastic waste has become one of the most serious threats to the marine environment. Among the plastic waste of special concern is microplastic because of its small size. This study aimed to analyze the level of risk of microplastic exposure through fish consumption in communities in the coastal area of Tamasaju Village, North Galesong District, Takalar Regency. Microplastic abundance found as many as 18 particles, microplastic types found are the shape of a line or fiber with different color and size variations. Blue fiber dominates at 77.77%. The average microplastic concentration (C) in fish is 0.2 mg/kg. The respondents interviewed were 30 people and mostly fishermen. Average intake rate (R) ± 155 grams/day, Average frequency of exposure (FE) of fish consumption ± 190 days/year, Average duration of exposure (Dt) of fish consumption ± 39 years and. Average respondent’s weight (Wb) ± 58 kg. The average Non-Carcinogenic Intake Rate in fish consumption is 0.004754 mg/kg/day and the average Carcinogenic Intake Rate in fish consumption is 0.009328 mg/kg/day. The results of calculations with one-way ANOVA obtained P-Value = 0.009867 <value α = 0.05, then there is a strong relationship with microplastic concentration, intake rate, frequency of exposure, and duration of exposure to Intake Rate or Risk (RQ).

Keywords: Risk Analysis, Microplastic, Coastal Areas, Fish.

Introduction

Plastic has become a part of everyday life, from clothing to coatings and vehicles to cleaning products. So that the losses caused by the abundance of plastic waste are very visible in the environment. A particular concern among plastic waste is microplastics due to their small size[1,2]. Microplastics are defined as small pieces of plastic smaller than five millimeters in size [3–5]

Globally, the discharge of primary microplastics into the sea is estimated at 1.5 million/year[3]. Most of the microplastics come from a land that enters the marine environment, including those flowing through rivers[6,7]. Microplastics have been found in drinking water, bottled water ranges from 0 to more than 104 particles/ltr with an average value of 103 particles/ltr[8].

The consumption of microplastics by fish is closely related to plastic pollution in the marine environment[2,9,10]. Microplastics digested by fish are dominated by microplastics that are < 1 mm in size, film-like shaped, and transparent in color[11,12]. Also, microplastic particles are found in sediments and filter-feeding animals [13].

In Indonesia, plastic waste pollution has reached serious limits, according to Jambeck et al. (2015) Indonesia occupied 2nd rank as a country that produces vast plastic waste[14]. Indonesia contributes 0.48 - 1.29 million metric tons of plastic waste to the sea every year.
Thus, in Indonesia, total plastic waste is predicted to reach 9.52 million tonnes in 2019 [15]. The identification of microplastics in the Makassar region has not found any alarming cases, including their effects on humans [16–19]. However, research, as conducted by Rochman (2015) at TPI Paotere Makassar, showed quite high results, namely the number of particles in each fish ranged from 0 – 21 particles/individual [20].

One of the famous auction place of fish in Makassar is Beba North Galesong in Takalar district. Various types of seafood are traded at this auction [21,22], even visitors or buyers who come can directly enjoy the catch of fishermen which are provided in food stalls along the entrance to Beba auction place of fish, Tamasaju village, including a village that is very close to Beba auction place of fish. In this village, people have the main profession as fishermen, and most of the people here use seafood as their daily side dish.

The presence of microplastics in marine species that are often consumed by the people raises concerns about the level of risk of microplastics to human health. Therefore, in this study, we will examine the evidence of seafood contamination (fishes) by microplastics, and the level of risk from the presence of microplastics in the marine environment to human health.

**Methodology**

**Type of Research:** The type of research is descriptive analysis with the Environmental Health Risk Analysis approach, by using questionnaires, interviews, laboratory examinations, and calculations using its formula. This research will be conducted in May-June 2020. Fish samples were taken for 1 day at 06.00 - 07.00 a.m. on June 25, 2020, at the Beba auction place of fish. Fish samples were taken by random sampling, namely as many as 20 fish, 10 each of red kurisi, and 10 mackerel. Furthermore, fish samples are stored in a coolbox and taken to the laboratory for analysis.

**Laboratory analysis:** Microplastic analysis consists of several stages [20]. These stages are sample preparation, dissolve organic matter with KOH% solution, microplastic observation with a microscope, microplastic measurement using ImageJ software. The fish sample is dissected and separated from the intestine. The fish intestines are broken and then placed into the sample to extract plastic debris from the fish intestines. Each sample pot containing 10 grams of fish intestine was filled with 20% (20-50 ml) KOH (Potassium Hydroxide) solution up to 3 times the volume of tissue in ultrapure water and incubated for 7 days at room temperature to digest organic matter. For each sample, the digested material was carefully sorted and examined under the euromax nexus zoom trinocular microscope.

**Statistical Analysis** The statistical analysis method used in this research is a descriptive statistical test and one-way ANOVA.

**Results Dan Discussion**

**Microplastic Identification in Fish:** The fish found based on the respondent’s consumption map were red kurisi fish (Nemiptus japonicus) and mackerel fish (rastrelliger sp.). Red kurisifish is demersal fish most often consumed by almost all coastal fishing families in Tamasaju village. Meanwhile, mackerel fish is pelagic fish which is also the favorite fish of the coastal residents of Tamasaju village, besides the price is very cheap it is also because the texture of this fish meat is very tasty after being processed.

Microplastic content was only found in samples D1, D2, D6, D9, and D10 as shown in Table 2. Total microplastics found in red kurisi fish were 11 particles. Generally, the types of microplastics found are line-shaped microplastics, consisting of blue, mix, purple, and green colors[24]. The largest microplastic size of 2.168 mm is found in sample D9 in the form of blue lines, and the smallest microplastic size of 0.68 mm is found in sample D10 in the form of a blue line. The largest abundance of microplastics was found in sample D6, namely 4 microplastics/individual, and the smallest abundance of microplastics was found in samples D1 and D10, namely 1 microplastic/individual. While, samples D3, D4, D5, D7, D8 were not found to contain microplastics.

The identification result of microplastic in mackerel fish is shown in the table below.

Microplastic content was only found in samples P1, P2, P3, and P6 as shown in Table 3. The total microplastics found in mackerel fish were 7 particles. Generally, the types of microplastics found are line-shape microplastics, which consist of blue and mix colors. The largest microplastic size of 3.854 mm was found in the P3 sample in the form of a blue line, and the smallest microplastic size of 0.713 mm was found in the P2 sample in the form of a blue line. The abundance of microplastics in samples P2, P3, and P6 is 2 microplastics/individual and the abundance of microplastics is 1 microplastic/individual in sample P1. Meanwhile, samples of P4, P5, P7, P8, P9, and P10 were not found to contain microplastic.

**Microplastic Abundance of Fishes:** Generally, the type of microplastic found was line-shaped microplastic, consist of blue, mix, purple, and green colors.

Table 4 shows the shape of microplastic found in the fish’s body is generally line and fiber-shaped. Meanwhile, the most dominant of amount color is blue as many 77.77%.

**Risk Analysis of MPs Exposure to Human:** The step of EHRA is a risk characteristic that conducted to determine the risk or one other hand to determine whether the risk agentsat a certain concentration of EHRA by the Directorate General of PP and PL, the Ministry of Health[25] and relevant study about health risk assessment [26] were analyzed for risky EHRA arise health disturbance by the communities or not. Risk analysis of microplastic exposure for humans refers to the guideline book.

The Calculation of Ingestion Path Intake Rate

The following is the calculation result of Intake rate through ingestion exposure (digested):
Table 5 shows that the mean body weight of respondents is ± 58 kg, with the lowest body weight in the BC2 sample, namely 38 kg, and the highest body weight in the SA6 sample, namely 85 kg. The average intake rate is ± 155 grams/day of processed dry weight, where the minimum intake rate value is 40 grams/day in the BC2 sample and the maximum intake rate value is 320 grams/day in the BB5 and the CA8 samples. Generally, fish consumption by respondents is 1-2 fish/day and 6 fish/week. The average frequency of exposure to fish consumption is ± 190 days/year with a minimum frequency of exposure of 104 days/year is found in the BC4 and the BC5 samples and the maximum value of frequency of exposure 260 days/year are found in BB3, CA1, CA2, CA5, and CA6 samples. The average duration of exposure to fish consumption was ± 39 years with a minimum exposure duration value of 10 years in BC 1 and BC 7 samples, and the maximum duration of exposure was 60 years in SA1 and BB7 samples.

Based on the above tables is obtained the calculation result of the intake rate for respondents both carcinogenic and non-carcinogenic. If the intake rate <RfD (Reference Dose) then it is safe, otherwise if the intake rate >RfD (Reference Dose) then it is not safe. Meanwhile, RfD of microplastic is not yet determined by EPA, then the first RfD microplastic must be found by using the derivation of NOEL’s formula.

</tbody>
</table>

The table above shows that deviation standard I-non carcinogenic = 0.002549 < mean = 0.004754. The minimum value of Intake Rate Non Carcinogenic = 0.00095 found in BC7 sample, and the maximum value of Intake Rate Carsinogenic = 0.009328 found in CA6 sample. Meanwhile, deviation standard I-Carsinogenic = 0.001092592 < mean = 0.002037599. The minimum value of Intake Rate Carsinogenic = 0.000407045 found in BC7 sample, and the maximum value of Intake Rate Carsinogenic = 0.003997763 found in CA6 sample.

Based on the calculation by using ANOVA is obtained p-value = 0.009867 < α = 0.05, then there is a relationship with microplastic concentration, intake rate, exposure frequency, and exposure duration on Intake Rate or magnitude of risk (RQ).

**Conclusion**

Microplastic as found in red kurisi fish *(Nemiptus japonicas)* is 11 particles, and mackerel fish *(rastrelliger sp.)* is 7 particles. Microplastic is found in the line or fiber-shaped only. Blueline dominates other colors is 77.77%. These lines or fiber-shaped microplastic is predicted comes from the degradation of fishnets, cover tarpaulin of fisherman boat, and seat layer along the edge of the coastal of Beba, Tamasaju village.

The calculation result of Intake Rate, both non-carcinogenic and carcinogenic showed a strong relationship with the concentration (C) of microplastics in fish, intake rate (R), frequency of exposure (FE), duration of exposure, and body weight (Wb) of respondents.

Physiological and Molecular Study of Iraqi Women with Polycystic Ovary Syndrome

Zainab Khidhair Hussain
Lecturer, Department of Biology, College of Science, University of Baghdad, Baghdad, Iraq

Abstract
Polycystic ovary syndrome is define as illness in women that a reproductive age because common endocrinopathy and lead to reproductive dysfunction also infertility. PCOS is usually alignment with insulin resistance and metabolic syndrome, it is think that PCOS is the outcome of genetic effect addition to ecological factor. In this study (100) samples which divided into 40 samples of heath women and 60 samples of women with PCOS. It diagnosed by ovarian morphology on ultrasound also test the fasting blood sugar, insulin, insulin resistance and testosterone hormone by biochemical method also used molecular method to detect the genotype of TCF4 gene (rs290487) by RFLP-PCR technique. The results revealed that the frequency of allele T was recorded a highly significance (P<0.01) in patients (0.81%) while in control (0.89%), the frequency of allele C allele significant (P<0.01) in patients (0.19%) while in control (0.11%). We can be concluded from this study that the genetic variation in Iraqi women of gene (TCF4) was linked with PCOS while contrary in control (healthy women).

Keywords: Ovary, Testosterone, gene, polycystic, polymorphism, Insulin resistance.

Introduction
Polycystic ovary syndrome (PCOS) is a symptom because endocrinopathy or elevated androgens (male hormones) in females at reproductive age, with a incidence of upper 10% of women [1]. PCOS is produce to a mixture of genetic and environmental factors [2]. Rate of alterations among people may reveal that the effect of factors on the phenotype such environmental features, ethnic origin and race [3]. Many factors such as increased adiposity, mainly visceral adiposity lead to waist circumference (waist-to-hip) ratio elevation, may be related with hyperandrogenemia, glucose intolerance, dyslipidemia, and insulin resistance [4]. In actuality, about fifty percent of women with PCOS women have obesity or overweight [5]. Overweight in women suffer from PCOS align endocrine syndromes than in women with non over weight [6]. One of the most complaints in women with PCOS is an ovulatory (infertility), also have risk factor as cardiovascular analogous to metabolic syndrome [7]. Stein and Leventhal who first explained PCOS since 1935 after they introduced and published it about seven women has amenorrhea, enlarged ovaries showed with polycystic shape, hirsutism, also obesity[8]. Actuality, PCOS known since 1844 via [9]. PCOS, also describe via ultrasonography (the occurrence of cyst about (2-8) mm in width or diameter, the number of it 10 or extra cysts, placed either peripherally position in core of stroma or scattered in it lead to stroma and ovarian volume increasing), this very most important diagnostic way for PCOS[10,11], the aim of study was to estimate some physiological and molecular parameters of Iraqi women with polycystic ovary syndrome

Material and Method
Experimental design: The study was directed afterward gaining ethical approval from Scientific Research Committee University of Baghdad/College of science/Department of biology, fulfillment this work in laboratories in Department of biology/College of science. The samples of study included (100) Iraqi women with PCOS the age of women about 18-45 years old, all of it diagnosed by morphology on ultrasound added to the biochemical method. They were divided into two main groups: the first group included 40 healthy women and the second included 60 women with PCOS.

Collection of Blood Sample: Blood was collected after more than 12 hours fasting by syringes from vein. Venous blood was transported into tube covering with
EDTA for extraction of DNA and other amount of blood used to measurement some physiological parameters.

**Biochemical Tests:** Serum was separated after clot for 15-25 minutes at room temperature by centrifugation at (3500 rpm 15 min) to measurement biochemical tests. The fasting blood glucose test determined by (biosystem kit, Spain). Serum concentrations of insulin and testosterone were assessed using an ELISA kit (DRG Instruments Mbh, Germany).

**Statistical Analysis:** The program is system SAS 2012 was used to compare between difference of means such as Least significant difference test (ANOVA).

**Results and Discussion**

The study revealed that the differences in values of biochemical parameters as fasting blood level also hormones like insulin and testosterone, also level of insulin resistance when compare this result between women with PCOS and normal cases. The study showed high significant increasing (P≤0.01) (23.401) in weight of patients (92.20 ± 9.66) if compare with control (56.80 ± 3.10). At the same time, high significant increasing (P≤0.01) (35.333) of fasting blood level (177.20 ± 14.23) while in healthy women (92.78 ± 5.67). The differences high significant increasing (P≤0.01) (7.929) in insulin hormone concentration in serum in patient’s women with PCOS (42.10 ± 1.98) while in control group (24.06 ± 2.81), insulin resistance showed high significant (P≤0.01) (4.549) in patients with PCOS (15.61 ± 1.61) that differ from healthy women (7.23 ± 1.13). Also the same result, high significant (P≤0.01) (127.91) of testosterone hormone concentration in women with PCOS (228.88 ± 98.24) while in healthy women (49.40 ± 10.78) Table 3.

The differences of genotype and allele frequency in patients with PCOS and control showed in (Figure-1). It was performed by RFLP- PCR, restriction enzyme BstUI digested products of PCR and were separated on agarose gel. Red stain was used of bands to stain in the gel.

** (P≤0.01).
In this study we depended on biochemical tests and ultrasonic method to determine any changes may be PCOS in women\(^{12}\), the results in we study showed that increasing significantly in weight of women with PCOS versus normal women, our result agree align Dunaif et.al. result, who revealed that most of patients women with PCOS have obese contrary to normal \(^{13}\). Our results showed increasing significantly in level of blood glucose, insulin concentration and insulin resistance, Furthermore, \(\beta\)-cell dysfunction is one of metabolic abnormalities linked with PCOS and diabetes T2, may heritable factor of families. There are close linked both PCOS and obesity, because similar genes may causes fatness in affected patients with PCOS \(^{14}\). Also the insulin resistance addition to diabetes T2 is a common result of women with PCOS in state without obesity and insulin resistance with obese PCOS\(^{15}\). As many as the insulin resistance about 70% in women with PCOS but it nearly 10% in women with DM \(^{16,17}\), the study revealed that increasing in level of testosterone with elevated of glucose levels, insulin, and insulin resistance which may lack the sensitivity to expect risk of PCOS in women. Our study similar with this study which the women patients with PCOS suffer from hyper-insulinemia also have increasing in testosterone level, the testosterone level may greater than the normal value and middle raised level \(^{18}\), but very high level of testosterone concentration is not usually in PCOS because a virility tumor \(^{19,20}\). The recent study showed that correlation between high testosterone concentration with obesity, exacting with fat in abdominal distribution\(^{21}\), also insulin resistance with a elevated of glucose level rate\(^{22}\). In addition to, hyperandrogenism guide to PCOS as well as ovulatory dysfunction in vivo and vitro\(^{23,24}\). Level of insulin might increase peripheral steroidogenesis, whereas lead to destruction activity of CYP17 \(^{25}\) inducing generally to testosterone overload without androstenedione and DHEAS excess therefore, hyperinsulinemia and insulin resistance raise production of ovarian testosterone in women with PCOS without effect on secretion of androstenedione\(^{26}\). In fact that, no association between adrenal androgen secretion and insulin resistance in PCOS or eumenorrhoic patients \(^{27}\).

Our results revealed that the genotype and allele frequency of TCF4 (rs 290487) gene, allele T was recorded a highly significance (P<0.01) in patients (0.81%) while in control (0.89%), the frequency of allele C allele significant (P<0.01) in patients (0.19%) while in control (0.11%), while this study revealed that there is no contribution of TCF4 gene variation of Tunisian women with PCOS \(^{28}\). The confirmation of relationship with (2) independent loci of TCF4 in a PCOS first1: relationship between insulin level and the diabetes type 2 locus; and second 2: connection through reproductive PCOS phenotype. The study recommends that polymorphism in altered loci of a vulnerability gene donate to divergent phenotypes, also showed no proof for relationship among the rs7903146/rs12255372 polymorphism and PCOS. Though, there are observing first round proof for relationship with PCOS on a loci about (100 kb) downstream in the Caucasian type 2 diabetes locus\(^{29}\). Other findings recorded that relationship among the proinsulin:insulin ratio and glucose tolerance in patients with PCOS and the TCF4 Caucasian type 2 diabetes locus that confirmation for other studies which reveal in variation of TCF4 gene with defects in insulin secretion \(^{30}\), possibly by changing alteration of proinsulin to insulin in pancreatic beta-cells \(^{31}\). Lyssenko et al. recorded that the type 2 diabetes related genotype of rs7903146 besides rs12255372 gene are linked with deficiency in arginine-stimulated insulin production in patients with irregular glucose level but not healthy\(^{32}\).

**Conclusion**

The genetic variation of gene TCF4 was linked with PCOS while contrary in control (healthy women). The genotype and allele frequency of TCF4 (rs 290487) gene, allele T was recorded a highly significance in patients when compare with control. The frequency of allele C allele lower significant in patients than in control. There are relationship between the allele frequency of TCF4 (rs 290487) gene and genetic variation with PCOS.

Abstract

Background: A sequential descriptive analysis of the government events related to 85% PW implementation and ENDS ban is lacking. There is also a dearth of public interest analysis in such policy making.

Objectives: To descriptively analyse the sequence of government events in both the policies and evaluate the public interest analysing trends from the respective events.

Method: Government events in India on 85% PWs were collected from media articles ranging from October 2014 to April 2016 while on ENDS ban, the information was obtained from Ministry of Health & Family Welfare, Government of India from August 2018 to December 2019. We compared Google Trends relative search volume data for ‘smoking causes cancer’, ‘smoking danger’, ‘pictorial’, ‘ITC limited’ as keywords for Pictorial Health Warnings from April 2014 to April 2016 (Policy A) while keywords such as ‘electronic cigarettes’, ‘Vape’, ‘Juul’ were used as surrogate for ENDS ban from October 2017 to October 2019 (Policy B).

Results: According to the Google trends analysis, ‘pictorial’ was searched significantly more in Policy A time period (4298 vs 2599) while ‘Vape’ had distinctly more searches in Policy B time period (6136 vs 1042). However, the volume of difference between the two policies time period was significantly higher for Vape (5094 vs 1699).

Conclusion: Strategy and experiences from delayed implementation of pictorial health warnings has laid down the path for faster enactment of future anti-tobacco policies.

Keywords: Pictorial Warnings, Electronic Nicotine Delivery Systems (ENDS), Government Actions, Tobacco products.

Introduction

Approximately 1 billion people living on this planet consume tobacco in some form (smoking/smokeless). It is estimated that half a billion human beings would prematurely die due its usage unless they quit1 2. There are various ways in which anti-tobacco health workers have been working hard against mighty tobacco industry...
to save such lives. One of the ways being the Pictorial Warnings showing ill-effects of tobacco on the packaging itself. However, there has been strong resistance from tobacco industry against such mechanism to reduce the usage of tobacco all over the world. India’s long journey of pictorial health warnings (PW) implementation from 40% to 85% on tobacco products was no different than in other countries. The Government of India notified the 85% PWs on October 15, 2014 for the implementation on April 1, 2015 but these were implemented after a delay of over 12 months on April 1, 2016. There was much learning from the implementation of pictorial health warnings for future policies such as recent ban on Electronic Nicotine Delivery Systems (ENDS) in India on 18th September 2019.

Apart from the Government’s will, success of the implementation of any government policy largely depends on the existing public interest. Google is one of the most popular search engines in the world. Google trends give real-time data thus has proven to be a potential tool to gauge public interest. Such data of public interest between the two events can give us potential reason for the difference in the success. This research paper analyses Government actions and public interest on PW and ENDS policies in their respective time periods.

**Method and Material**

We examined the government events on 85% pictorial health warnings and ENDS ban in India, comparing two time periods by means of actions taken by the government in both the policies. Time period for Policy A events was from October 2014 to April 2016 and for Policy B from August 2018 to December 2019. The information on government events on 85% PWs were collected from the media reports provided by a PR agency ‘Comma Communications Management’, which tracked news everyday related to tobacco. For ENDS ban Government events were taken from Ministry of Health & Family Welfare, Government of India. The data was collected for further analysis into an excel sheet. Events were defined as those which were related to policy announced by the Government on (i) Pictorial health warnings, such as notification, delay in implementation of 85% PWs, contempt by Rajasthan High Court, Committee on Subordinate Legislation formed to assess PWs, etc. (ii) In case of ENDS Ban announcements made by the Government such as Advisory issued by the MoHFW, the White Paper by Indian Council of Media Research, the Ordinance, etc. The collected Government events were then manually classified as pro and anti, based on the following criteria: (1) Pro actions included statements in favour of both the policies (2) Negative government events included statements against both the policies. The classifications of the government events were cross-checked by a second researcher to remove any bias or error. We collected the events of both the policies i.e., PWs & ENDS Ban. Events of both policies were then compared in order to observe for government actions. In order to gauge the public interest on both the policies, we compared the Google Trends relative search volume data for terms ‘smoking causes cancer’, ‘smoking danger’, ‘pictorial’, ‘ITC limited’ as keywords for Pictorial health warnings policy from April 2014 to April 2016 (Policy A) while keywords ‘electronic cigarettes’, ‘Vape’, ‘Juul’, ‘ENDS’ were used as surrogate for ENDS ban from October 2017 to October 2019 (Policy B). India was selected as the geography for all the searches on Google Trends.

**Statistical Analysis:** Normal distribution of the scores was tested using the Kolmogorov–Smirnov test and homogeneity of variance was tested using Levene’s test. Categorical data was represented in Frequency form and continuous data was presented as the Mean ± SD or median (IQR). The Spearman correlation coefficient was used to measure the associations, descriptive analysis was performed to identify distribution of variables included in the study. Mann Whitney test was used to compute difference between the two groups. All analysis was tested with two-sided hypothesis testing and significance was considered at a p-value less than 0.05. Statistical analyses were performed using SPSS (Statistical Package for Social Sciences) IBM Corp. Released 2017. IBM SPSS Statistics for Windows, Version 25.0. Armonk, NY: IBM Corp.

**Results**

A total of 19 Government events occurred on Pictorial health warnings from October 2014 to April 2016. Of these 10 (52.63%) were pro policy events and 9 (47.36%) were anti policy events. On ENDS, a total of 6 Government events took place. Of these 100% were pro policy events (Table-1).

In the present study, it was observed that, while the media was reporting real time, each and every move of the Government, all stakeholders as media, lawyers, public health activists, tobacco industry, were also...
playing their roles. It is evident from the table above that even though the Government was in favour of the 85% PWs, there was huge pressure from the tobacco industry, Committee on Subordinate Legislation (CoSL) and public health activists. After many interferences and reports from the CoSL, Public Notice was finally issued. This was taken as affirmation by the public health activists who were monitoring this issue closely. On 16th March 2016, the Ministry issued a statement that there will be no course of change in warnings and it will stick to 85% implementation from April 1, 2016 (Table-1).

The Government was alert in policy on ENDS ban. The MoHFW took proactive actions right from the beginning immediately after there were studies from western world on the multitude of harms of electronic cigarettes. Table 2 represents how the Indian Government then took faster actions for ban on ENDS. An Advisory issued by the MoHFW to all states of India followed by the White Paper on ENDS in India on the World No Tobacco Day 2019 was evidence that the Government was all set to ban ENDS in India and indeed, within three months of this white paper, ENDS was banned in India through an Ordinance. During this time, various stakeholders including public health activists, media, lawyers got involved quickly. Soon after the Ordinance, the Lok Sabha & Rajya Sabha supported the Bill on ENDS and without any anti actions, the ENDS ban came into force on December 5, 2019.

Table 2 shows the intensity of pro actions that took place in the preceding 7-8 months to the Ordinance, despite of attempts by the anti-forces to derail the process (Table-2).

Relative Google search volumes for Policy A, included ‘smoking causes cancer’, ‘smoking danger’, ‘pictorial’, ‘ITC limited’ representing 85% PWs policy. Total volume search for keyword search of ‘smoking causes cancer’ was 873 (0-21 per week), ‘smoking danger’ was 443 (0-15 per week), ‘pictorial’ was 6491 (37-100 per week), ‘ITC limited’ was 3584 (13-58 per week) when searched together (Figure-1). While relative Google search volumes for Policy B, included electronic cigarettes was 1373 (7-100 per week), ‘Vape’ was 807 (5-12 per week), ‘Juul’ was 140 (1-4 per week) for the time period from October 2017 to October 2019 when searched together (Figure-2).

Total volume of searches between the two policies could not be compared as they were from different time periods. Thus, from the above results ‘Pictorial’ and ‘Vape’ were compared for both the time periods Policy A (2014-2016) and Policy B (2017-2019) as these search words were most comparable (Figure-3 and 4). Total volume search for ‘Pictorial’ and ‘Vape’ was 4298 (25-67 per week) and 2599 (4-100 per week) respectively for Policy A time period (Figure 3) while total search volume for ‘Pictorial’ and ‘Vape’ was 1042 (6-18 per week) and 6136 (6-100) respectively for Policy B time period (Figure-4). Thus, in Policy A time period Pictorial was searched significantly higher than Vape while in Policy B time period Vape was searched more than pictorial.

However, Figure-5 represents that volume of difference between the time periods (5094 vs 1699) for Vape was significantly higher than pictorial (p<0.001) (Figure -5).

Fig. 1: Pictorial Warnings Timeline and Google keyword searches
Fig. 2: ENDS Ban Timeline and Google keyword searches

Fig. 3: Pictorial Warnings timeline and average Google search
Tobacco is a product, if consumed as it is, kills half of its users. As per the World Health Organization, it kills 8 million people every year, globally. Tobacco-related deaths and disease burden are maximum from the low-and middle-income countries. In India, there are 1.3 million deaths every year due to tobacco use. India has a very effective tobacco control policy which focuses on reduction of prevalence. Large Pictorial Health Warnings policy is an important deterrent for smoking initiation amongst non-smokers. It also promotes smoking cessation behaviour in the current smokers. Previously, pictorial health warnings in India covered 40% of the front panel of packets of the tobacco products. Tobacco industry interference was profoundly seen against the implementation of 85% pictorial health warnings in India due its proven efficacy for tobacco control. Similarly, few years later, there was a perceived threat of logarithmic spread of Electronic cigarettes.
amongst the youth demographic of India. The United States had already seen its growing influence on its future generation with its prevalence being as high as 37.7% in their high school students. As a result, there were 2,601 lung injuries requiring hospital admission and 59 deaths in the USA. Thus, Electronic Nicotine Delivery Systems (ENDS) ban in India came right on time. India is a developing country and implementation of policies remains a big challenge. Even so, the Government took immediate actions in the direction of banning ENDS, before it could spread its roots in the country. Western world companies had already planned to set up industries in India and were promoting these as less harmful and an alternative to quit smoking. There was no research on the statements made by the ENDS manufacturing industry and the medical fraternity unanimously stood against it in India. In fact, in one of the instances more than 1000 medical doctors wrote to the Prime Minister to ban ENDS immediately as it contained unregulated levels of nicotine with the potential to cause neural damage. This paper analysed the resistance faced by the government and other tobacco control stakeholders in enlarging the pictorial health warnings from 40% to 85% even after its notification in October 2014. In implementation of 85% pictorial health warnings, India witnessed a delay of 12 months from the scheduled to actual implementation whereas policy on ENDS ban moved much faster right from advisory by the Ministry to research to Ordinance to passing of Bill in the Parliament of India. This study, therefore, shows in conclusion that there was significant uncertainty about policy implementation of 85% PW until it was finally implemented on April 1, 2016 whereas in ENDS the Government events were all in favour of the policy. This study also deduces that there was contrasting difference in the fall of events in making of two policies. On the one hand, there were intense false propaganda by tobacco industry which delayed the process the implementation of the Policy A by more than 12 months while on other hand, the government, and many other jurisdictions, civil society, medical fraternity were equipped enough due to earlier hardships faced during policy A implementation leading to expedite release of the White paper against ENDS. Unlike during policy A, anti-tobacco warriors had local study, i.e., the White Paper as an evidence available against ENDS.

Government does take into account the public opinion, which in turn shapes policies. The Google searches clearly depict the public interest on both the issues in India. Public interest was present for all the keywords representing pictorial health warnings like “smoking causes cancer”, “smoking danger”, “pictorial”, “TC limited”. Similarly, people searched for words related to electronic cigarettes like “Vape”, “Juul”, “e-cig”. As described before, there was a lot of communication from October 2014 to April 2016 till the eventual implementation of enhanced pictorial health warnings. This is truly represented by the google search volumes in those time periods appreciated in the Figure 2. Similarly, there was surge in public interest for policy B events during the month of September (month in which the ordinance was passed). Thus, our results validated our keywords search representing public interest in those periods. We tried to compare the public interest between two policies and found that pictorial was searched more during the policy A time period and Vape was searched more in Policy B time period. However, when the difference of volume of searched keywords was compared, vape representing ENDS was found to be significantly higher. Thus, our google trends analysis suggested that the issue of ENDS was more popular than pictorial health warnings and that the obstacles faced by the Government during the implementation of PWs provided them with much needed insight about the adoption and enforcement of stricter time lines for banning ENDS.

**Limitations:** Though keywords rightly depicted the peak of the events in our study representing public interest but whether the interest was for or against is unknown. In the PWs policy implementation, there were hearings in the Rajasthan High Court but only those involving the MoHFW announcements are considered.

**Novelty of the Study:** This is the first study in the literature to sequentially describe detailed pro and anti-events which led to the delay of the implementation of pictorial health warnings.

This is also the first study to compare the levels of public interest between two health policies in India.

**Implications:** Descriptive analysis of events between two policies with differing results would better equip tobacco control organisations for future policy implementation.

Google trends analysis can be a quick, cost-effective adjunctive tool to assess the public interest thus redefining expensive traditional method.
Conclusion

Intense tobacco control efforts during pictorial health warnings implementation led down a pathway for future policy implementation including ENDS ban. Public interest may also play a pivotal role in hastening policy enactment process as depicted in ENDS ban.

Study the Possible Levels of Inflammatory Marker TNF-α and Microalbuminuria in Type 2 Diabetic Nephropathy Patients of Babylon Province/Iraq

Asma’a H. Mohamed¹, Haider K. Zaidan², Ali H. Al-Saadi³

¹Lectural PhD. Department of Radiology Techniques-Al-Mustaqbal University College, ²Prof. Dr. Department of Scholarships and Cultural Relations, Ministry of Higher Education and Scientific Research, Baghdad-Iraq, ³Prof. Dr. Department of Biology-College of Science-University of Babylon.

Abstract

Background: Diabetic nephropathy is referred to as the kidney damage that occurs in people with diabetes developing it over many years characterized by gradually increasing urinary albumin excretion (>300µg/mg) from microalbuminuria to proteinuria, blood pressure, and declining in glomerular filtration rate (GFR) (thickening in glomerulus) which represents the late event.

Aim: Study the relationship between the levels of urinary TNF-α and the progression of diabetic nephropathy in type 2 diabetic patients.

Objective: Fasting blood and urine samples were collected from seventy type 2 diabetic patients with enrollment the age, duration, blood pressure, and Body Mass Index (BMI) of each patient. The levels of urine TNF-α were established by ELISA.

Results: Forty patients have normal albuminuria (Albumin/Creatinine Ratio <30 µg/mg) and only thirty patients have microalbuminuria (Albumin/Creatinine Ratio>300 µg/mg) with increased urinary TNF-α levels.

Conclusions: A significant positive relationship between urinary TNF-α and severe microalbuminuria.

Keywords: Diabetic nephropathy, Microalbuminuria, TNF-α, Hypertension.

Introduction

Diabetic nephropathy is the chronic kidney disease (CKD) that occurs as a result of diabetes characterized by increased urinary albumin excretion (albuminuria) and decreased glomerular filtration rate (GFR)⁴. Microalbuminuria >300mg/24 hour associated with hypertension is the first marker of this disease occurring in 20-40% of patients with diabetes leading to end stage renal disease (ESRD) or renal failure with glomerular filtration rate GFR<10mg/mintypically in patients with type 2 diabetes after a diabetes duration of about 10 years, with some risk factors like genetic factors, blood pressure, dyslipidemia, metabolic syndrome, inflammation, growth factors, smoking, and others diabetes complications, the presence of these risk factors lead to dramatically increase of cardiovascular disease and eventually progresses of renal failure⁵. Microalbuminuria is considered to be as a marker of both kidney disease and endothelial dysfunction (decreased glomerular filtration) because of diabetes or hypertension or both, is strongly associated with an increased risk for cardiovascular events⁶, increasing microalbuminuria in urine led to the formation of proteinuria which increase overtime to macroalbuminuria (300>µg/mg) are linked with kidney disease and increased risk for progression to end stage renal disease. Impaired glycemic control is related with increasing in urinary microalbumin levels very low levels or absence of microalbuminuria is associated with low CVD, which also increases markedly with increasing albumin amount in urine⁷.

Tumor Necrosis Factor Alfa (TNF-α) is synthesized and produced by stimulated kidney cells
and especially by glomerular, tubular, and active monocytes, causing the elevation of the levels of other inflammatory factors such as cytokines, chemokines, growth factors, and acute phase protein\(^6\). TNF-\(\alpha\) plays an important role in the development of diabetic nephropathy by decreasing glomerular blood flow and a consequence reducing filtration rate, vasoconstriction, and damage of the glomerular filtration barrier leading to macroalbuminuria, in addition the elevated TNF-\(\alpha\) levels leads to the elevation of free radicals increasing the apoptosis of glomerular cells\(^7\). In general, hypertension present in type2 diabetic patients before the development of kidney disease because of the risk factors such as glucose intolerance and obesity. Hypertension causes the progression of kidney disease and contributes to the increased cardiovascular disease in diabetic nephropathy patients because of the destruction of renal function. The distribution of hypertension in diabetic nephropathy were elevated at each step of chronic kidney disease, reaching to about 90% for end stage renal disease patients\(^8\,9\).

**Subjects and Method**

Seventy patients with type2 diabetes The study was conducted between March 2019-June 2019 in Marjan teaching hospital in AL-Hilla City/Babylon province-Iraq. Samples under study were divided according to the duration of disease and age, this study design focus on study some physiological and biochemical parameters.

Blood and urine samples were collected from type2 diabetic patients in the morning between 08:00 and 10:00 O’clock to minimize the effect of diurnal variation\(^10\), after a period of fasting 8-10 hours by vein puncture using 5 ml disposable syringes and it was divided into two parts: one part about 2 ml was put in EDTA containing tube; the blood was mixed gently for 3 minutes and then used for hematological tests and especially for HbA1c assay. The second part included 3 ml of blood was put in the centrifuge tube (glass tube) and allowed to clot for 15 min then it was centrifuged for serum separation at approximately 3000 rpm for 15 minutes\(^11\), the separated sera were used for biochemical tests such as determination of fasting blood glucose.

First emorningurinel samples were collected under sterile conditionse, 10 ml of urine were ecentrifuged at 1500 rpm for 10’ minute’ and the supernatant was stored at -80ºC until’ TNF-\(\alpha\) determination by ELISA assay. This samples also used for measurement of Albumin/Creatinine Ratio ACR (\(\mu g/mg\)), were ACR <30 \(\mu g/mg\) were known as normal albuminurin, 30-300 \(\mu g/mg\) as microalbuminuria, and > 300 \(\mu g/mg\) as proteinuria. Body mass index (BMI) were calculated by dividing the weight in kilograms (kg) by the square of the height (m\(^2\)). Blood pressure were determined by using mercury manometer, the blood pressure with systolic blood pressure SBP ≥ 140 mmHg and diastolic blood pressure DBP ≥ 90 mmHg were referred to as hypertension.

**Statistical Analysis:** The statistical analysis was performed by using the statistical package for social sciences (SPSS version 23.0) and found all of arithmetic mean and standard deviation (M ± S.D.) by using the T-test to know the signification between normal albumin and microalbumin groups at p value (p<0.05). Brivaraite correlations were performed by using the Pearson correlation coefficient at p value (p<0.05) considered to be statistically significant.

**Results**

The results of this study showed that the mean age and duration were 48.70 and 11.20 years, respectively. While, the mean of BMI was 27.70 kg/m\(^2\), with 133.90 and 81.53 mmHg for systolic and diastolic blood pressure. Laboratory results of Fasting blood glucose, HbA\(_1c\), ACR, and urinary TNF-\(\alpha\) were shown in table (1).

On the other hand, the correlation study showed significant positive correlation between ACR and urinary TNF-α with (r= 0.48, P= 0.006), as shown in figure (1).
Discussion

Diabetic nephropathy is a chronic disease in which the renal structure and function probably distorted, many pathways that causes the pathological alterations in the kidney of diabetic patients have been suggested and are effectively being inspected. Where, it has been found that hyperglycemia generally lead to elevation the levels of oxidative stress and the stimulation a lot of inflammatory and apoptotic mechanisms in the renal, resulting in abnormal renal cells with excessive predisposition of extracellular matrix in the glomerulus’ and tubulointerstitium(7,8). Also it has been determined that high’ glomerular’ blood’ flow is probably to result in glomerular capillary ‘distention, additionally dysfunction of glomerular and mesangial cell. Moreover, it has been indicated that the loss of regulation of signaling’ pathways comprising a number of inflammatory cytokines and growth factors, like protein kinase C (PKC) and transforming growth factor-β (TGF-β), is also destructive for glomerular hyperperfusion and hyperfiltration(12).

Glomerular injury is represents the early sign of diabetic nephropathy and microalbuminuria, which seem to be a strong predictor of renal damage progression. However, it has been proposed that the increased number of patients with normal albuminuria are probably to promote diabetic nephropathy, whereas not all patients with macroalbuminuria are perhaps to have advanced renal damage(13). This refers that multiple pathways may participate in the pathogenesis of this disorder. Many of structural and pathological changes’ may appear at the same time and proceed at different rates in the diabetic nephropathy causing high heterogeneity’ of the disease. So that, biomarkers with elevated specificity to different abnormalities are needed to determine the onset and progression of nephropathy in different groups of diabetic patients. Lately, a number of possible biomarkers have been reported, comprising markers of glomerular ‘injury, ‘tubular injury, oxidative stress and inflammation(14).

The results of this showed that there were a significant differences between microalbuminuria (nephropathy) and normal albuminuria (without nephropathy) groups in relation to age, duration of diabetes, FBG, ACR, urinary TNF-α, systolic and diastolic blood pressure were showed significant elevation in microalbuminuria than normal albuminuria, this study was in agreement with the study of(15). TNF-α of human is a protein composed of 157 amino acid and is differ from mouse TNF-α in that it is not glycosylated and act through two types of receptors TNF-R1 and TNF-R2, TNF-α mainly produced by inflammatory cells such as activated monocytes and by specific renal cells(16). TNF-α play an important role in nephropathy pathogenesis and progression which stimulate the expression of adhesion molecules on the leukocytes and endothelial cells, increase the production of endothelin-1 leading to narrowing of blood vessels and reduction of blood flow and consequence decreasing glomerular filtration rate (GFR), TNF-α has an ability to stimulate glomerular cell apoptosis by damaging junctions between cells and increasing permeability resulting casing high levels of macroalbuminurea, urinary› TNF-α function as a biomarker of kidney inflammation(17,18).

In this study, urinary TNF-α levels were significantly correlated with microalbuminuria where both levels higher in microalbuminuria than normal albuminuria group making urinary TNF-α as an independent indicator for the degree of microalbuminuria, some studies were showed that TNF-R2 inflammatory pathway is already participated in the progression of macroalbuminurea through the onset of diabetic nephropathy(19,20).

Abstract

Objective: To assess maternal serum amyloid A (SAA) levels among women with primary unexplained recurrent missed miscarriages.

Patients and Method: A prospective study (case control study) in Al-Zahraa Maternity Hospital, Najaf, Iraq, from first of January to the first of December of 2019 the study was conducted among 91 who were divided into two groups:

1. Group 1: Patient with miscarriage in the early trimester with at least two consecutive primary unexplained REPLs and no previous live births were enrolled.

2. Group 2: A control group was formed of women with miscarriage no history of REPL who had at least one previous uneventful pregnancy with no adverse outcomes.

Serum samples were collected to measure SAA levels. The main outcome was the association between SAA and primary unexplained REPL. A total number of 91 participants. Mean SAA level increased in women with early missed abortion than those women in the control group (p<0.001). The level of SAA was dependent indicator of primary unexplained REPL, (p<0.001). found that serum amyloid A level in women with missed miscarriages represent as biomarker of this complication of pregnancy.

Conclusions: Serum amyloid A theoretically a promising marker that prompts further study for primary unexplained missed miscarriage. in the Studies may be performed, for example, measurement of SAA level in women with history of early recurrent missed abortion during pregnancy and before and also compare SAA levels in women with non-pregnant state Such studies may direct the timing for initiating new therapies the future.

Keywords: Serum amyloid A, maternal, Recurrent early pregnancy loss.

Introduction

Recurrent early pregnancy loss (RPL) is the incidence of minimally two failed-pregnancies before ten week-gestation (confirmed by ultrasound or histological examination). Recurrent early pregnancy loss (REPL) affects 1-2% of all pregnant women¹. Two or more clinical pregnancies documented by ultrasound or confirmed by histopathology end pregnancy loss² in approximately 15% of all known clinical cases while
three or more losses affect almost 1-2%, and two or more losses affect 5% of all clinical cases this indicates that most RPLs are not occur by chance and therefore, require a clinical investigations and assessment. There are many risk factors could contribute to pregnancy loss such as advancing maternal age, paternal age over 40 years, frequent previous miscarriages. RPL could be primary when women experienced RPL without giving any live birth, secondary RPL when woman experienced RPL.

Serum amyloid A (SAA) is an immunoregulation protein involved in the acute phase response. It is known that amyloid is arise from a variety of proteins. SAA has a modulating effect on the immune system, and effect on migration, invasion and differentiation of trophoblasts.

At low concentrations, SAA regulates trophoblastic attack and mineral protease activity in the placental microenvironment, which is important for placental homeostasis. However, it is clear that this chain of events is hampered by the high level of the SAA. Some researchers have found that SAA reduces the secretion of hCG. This indicates a possible impairment of SAA-induced synthesis, which in the trophoblast is stimulated by another inflammatory mediator, TNF-α. The role of SAA may be related to the placenta, regulating the primary trophoblastic attack in early pregnancy and maintaining the balance between pro-inflammatory and anti-inflammatory cytokines. Therefore, the current study tried to investigate the hypothesis that unexplained early RPL may be related to maternal higher levels of serum SAA.

**Patients and Method**

A future study (case control) was Continued at Al-Zahraa teaching Hospital, Najaf, Iraq, from first of January to the first of December of 2019.

A total number of 91 [30 patients (RPL) and 61 controls] were enrolled in the study.

Women were involved missed after diagnosis women have two or more successive unspoken key (MM) and they didn’t have a prior birth.

**Inclusion criteria included:** In the first trimester of current pregnancy (6-12 weeks), patients with miscarriage had at least 2 or more consecutive repeated pregnancy losses and maternal age ranged from (19-35) years.

The control group includes a patient have no history of (MM) and Only one prior non-adverse pregnancy with no side effect in the study.

**Exclusion criteria:** women were excluded if they had one or more of the following: acute or chronic inflammatory condition, poly cysticovariansyndrome, smoking, multiple gestation, diabietic mellitus, hypertension, irregular hysteroscopy, irregular HSG, history of pre-, eclampsia and/or, thyroid disorder or abnormal karyotype.

The protocol was approved and research was carried out at AL-ZAHRAA Maternity Hospital, Najaf, Iraq. The goals and method were clarified to qualified patients, and all participants subsequently received written informed consent in aseptic conditions a participant was given a 5-mL sample of venous blood and used for the Amyloid A serum assay.

The sample size was analyzed by using of SPSS version 24.0 and MedCalc version 12.5 the data was analyzed. for the normal distribution using the Shapiro–Wilk test and kolmogorov-smirnov test. Mean and standard deviation was used for the distributional data. Student t test had been using for comparing between two groups.

Qualitative information was presented as number (percentage); Pearson’s R. compare between two groups, as appropriate... Analysis of the recipient. Service characteristic Curve executed to analyze the serum amyloid A degree needed to differentiate among two groups.

The region under this curve was calculated and serum amyloid A ‘s Optimum value for the cut off was defined according to the highest Youden index (J)... Logistic multi-variable regression (OR and CI 95%) was used to evaluate SSA dependent indicators of recurrent missed abortion All P values were double queued with a value deemed statistically important by less than 0.05.

**Results**

No statistically relevant variations between groups differences regarding the age, duration of miscarriage (days) and gestational age (weeks) table (1) while there was significant difference regarding BMI.

**Discussion**

Early recurrent pregnancy loss is a challenging and frustrating condition for both patient and clinicians, so that its prediction and prevention and adequate management is significantly reduce the complications or unnecessary intervention. There are a lot of studies concluded that infection and inflammations whether in the gestational tissue or elsewhere in the body, are an important cause of early recurrent miscarriage. We study the serum amyloid A as biochemical predictor of subclinical infection as several studies conclude that SAA is a significant acute phase reactant and an important inflammatory marker.

The decidual cells and synsiotrophoplast cells and extra villous cytotrophoblasts released amyloid A serum amyloid a have important role in placentation when present at low concentrations of amyloid A. In our study, the difference was significantly high in serum amyloid A level between studied group (p<0.001), it was higher in women with missed miscarriage with REPL followed by group of missed miscarriage with no history of any miscarriage previously. The mean serum amyloid A 72.800mg/L, 32.918mg/L respectively. Moustafa I, Ibrahim et al., (2017), mentioned that Patient with recurrent missed abortion demonstrated SAA significantly higher than in women in control group after adjustment with maternal age and gestational age as an in-dependency predictor of this pregnancy complication. This analysis agrees with our outcome.

Sandri S et al., (2015), serum amyloid A facilitate Invasión trofoblástico into the decidua (a critical phase during the early stages of pregnancy) through receptors modulator activation. In comparison, SAA level are increase this is associated with disturbed trophoblastic tolerance this agree with our result.

Knebel FH, Ruano R, et al., (2014), High levels of SAA observed in the potential represent an inverted physiological role for this protein in early recurrent missed abortion, leading to disturbed invasion trophoblast and syncytialisation. SAA levels were measured in early pregnancy (6–10 weeks), indicating a significant early fetal development role.

Sharma S, et al., (2010), Such SAA-induced syncytialization impairment could be facilitated by another mediator and tumor necrosis factor. These results may support this study by association of high SAA levels with the incidence of consecutive miscarriage in women with recurrent early missed abortion through impairing syncytialization.

Engin-Ustun et al., (2007), recorded that increase in SAAN patient with pre eclampsia leading to recurrent early missed miscarriages agree with our research.

Leisser C et al., (2006), SAA stimulated trophoblastic invasion and effect on both metalloprotease gene and enzymatic activity therefore, SAA had no affect trophoblast syncytialisation and decreased human chorionic gonadotropin β isoform secretion. The researchers have find the biochemical syncytialisation signal (β-HCG) in a concentration-dependent manner, this is disagree with our result.

Urieli-Shoval et al., (2000), Trophoblast invasion is impairment when level of SAA IS HIGH, suggesting
a ADVERSE effect of THAT protein that may be activated during an acute-inflammatory response where serum SAA level can rise over 1000 times. 16

Trophoblastic invasion failure can also occur through rise levels of inflammatory mediators like TNF, this leads to early pregnancy loss. In equilibrium development of PROINFLAMMATORY mediator and failure of trophoblastic invasion show in preeclampsia and restriction of intra uterine growth 17,18. The stressful condition that associated with these disorders courses release of SAA. 19 this study agrees with our findings.

Conclusions

Serum amyloid A theoretically a promising marker that prompts further study for primary unexplained missed miscarriage. in the Studies may be performed, for example, measurement of SAA level in women with history of early recurrent missed abortion during pregnancy and before and also compare SAA levels in women with non-pregnant state Such studies may direct the timing for initiating new therapies the future.

Factors Related to Stunted in East Java Province in 2019: An Ecological Analysis

Azizah Andzar Ridwanah¹, Hario Megatsari², Agung Dwi Laksono³, Mursyidul Ibad⁴

¹Officer, Health Office of East Java Province, Surabaya, Indonesia, ²Lecturer, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia, ³Researcher, National Institute of Health Research and Development the Indonesia Ministry of Health, Jakarta, Indonesia, ⁴Lecturer, Faculty of Health, Nadlatul Ulama University, Surabaya, Indonesia

Abstract

East Java Province has a high prevalence of stunted. The study aimed to analyze the factors associated with stunted in East Java Province. The study was conducted using secondary data sourced from the 2019 East Java Province Health Profile report. The study was designed with an ecological analysis approach. All 38 regencies/cities in East Java Province were analyzed. Apart from the prevalence of stunted toddlers as the dependent variable, 4 other variables were analyzed as independent variables, namely the coverage of toddler health services, Universal Child Immunization (UCI) village coverage, coverage of families accessing healthy latrines, and percentage of samples of drinking water facilities that meet the requirements. The results showed that the trend of regencies/cities with low coverage of toddler health services has a high prevalence of stunted toddlers. There was a tendency for regencies/cities that have a higher level of immunization coverage which tends to have a lower percentage of stunted toddlers. Meanwhile, the trend of regencies/cities that have better coverage of families accessing healthy latrines has a lower prevalence of stunted toddlers. Finally, regencies/cities with a high percentage of babies receiving exclusive breastfeeding have the lowest prevalence of babies receiving exclusive breastfeeding. It could be concluded that there is a tendency for a negative relationship between the independent variables analyzed and the prevalence of stunted toddlers. The higher the coverage on the independent variable, the lower the tendency for the coverage percentage to be stunted in East Java Province.

Keywords: Ecological analysis, secondary data, stunted, community nutrition.

Introduction

Stunted in toddlers is a nutritional problem that is a world issue, including in Indonesia. Stunted is a condition in which toddlers have less length or height compared to age. This condition is measured by a length or height that is more than minus two standard deviations from the WHO median growth standard for children¹.

Based on the 2019 Health Profile of East Java Province report, East Java Province still has a fairly high prevalence of stunted. In 2016 the prevalence of stunted was 26.10%, while in 2017 it increased to 26.70%, and in 2018 it decreased to 22%². Meanwhile, based on the 2018 Basic Health Survey, the record of the prevalence of stuntedness in East Java Province is even higher, higher than the national average. The prevalence of stunted toddler in East Java Province is 19.9%, while the national one is 19.3%. The prevalence of severely stunted in East Java Province is 12.9%, while the national one is 11.5%³.

Stunted is known to be one of the main causes of morbidity in children under five years of age⁴,⁵. Children who are stunted can have a higher risk for chronic diseases such as obesity and hypertension⁶. The final impact, stunted can reduce the quality of human resources which can result in decreased welfare of

society. Stunted can lead to long-term effects including cognitive impairment and physical development, lower performance, lower per capita income, increased risk of poverty, increased risk of pregnancy disorders and asphyxia during childbirth, as well as increased risk of degenerative diseases such as obesity, diabetes mellitus, heart disease, stroke, hypertension, and cancer.\(^7,8\)

HL Blum stated that the factors that affect health are divided into four elements, including environment, heredity, lifestyle, and health services\(^5\). Stunted as one of the national health problems that are now a concern requires an in-depth analysis of the causative factors in prevention and overcoming efforts. When viewed using the Blum theory, several variables that can be analyzed include the coverage of under-five health services and the Universal Child Immunization (UCI) village coverage which is one of the elements of activity of the determinants of health services. Besides, there is a variable percentage of babies who are exclusively breastfed as one of the variables of parenting/behavior that can be analyzed. The coverage of households that have access to healthy latrines is the chosen variable to analyze environmental factors against stunted. Based on the background description, this study aims to analyze the factors related to stunted in East Java Province in 2019.

### Materials and Method

The study was designed using an ecological analysis approach. Ecological studies focus on comparisons between groups, not individuals. The data analyzed is aggregate data at a certain group or level, which in this study is the regency/city level. The variables in an ecological analysis can be aggregate measurements, environmental measurements, or global measurements\(^9,10\).

The study was conducted using secondary data from the 2019 East Java Provincial Health Profile report. A total of 38 regencies/cities in East Java were involved in this analysis. The dependent variable in this study was the prevalence of stunted toddlers. There are 4 independent variables analyzed, namely the coverage of under-five health services, the coverage of UCI villages, the coverage of households that access healthy latrines, the percentage of infants receiving exclusive breastfeeding. All variables are categorized into 3 parts of the same size. Data were analyzed by univariate and bivariate. Bivariate analysis was performed using cross-tabulations. The entire analysis process utilizes SPSS 21 software.

### Results and Discussion

Table 1 shows the descriptive statistics of the variables in the ecological analysis of stunted toddlers in East Java. Table 1 shows the distribution of stunted as the dependent variable with positive values in the low category and negative in the high category. In general, the target of stunted performance is to reduce its prevalence in the community. The 5 independent variables include the percentage of infants receiving exclusive breastfeeding, the coverage of under-five health services, UCI village coverage, the percentage of families accessing healthy latrines. The sample was 38 regencies/cities in East Java Province. Based on the table, it is found that the figure is more than 100% due to regencies/cities reporting coverage that exceeds the target set at the beginning of the evaluation year. The lowest prevalence of stunted toddler was in Tulungagung Regency at 5.3% and the highest was in Batu City at 25.4%. The average prevalence of stunted toddlers from 38 regencies/cities was 13.72%.

Table 2 shows the cross-tabulation between the prevalence of stunted toddlers and the coverage of toddler health services. The analysis showed that the trend of regencies/cities with a high prevalence of stunted toddler had low coverage of health services for children under five. The trend shows that the coverage of toddler health services contributes to reducing the percentage of stunted toddlers. Information in Table 2 shows that regencies/cities with low coverage of health services for children under five tend to have higher rates of stuntedness. This is in line with previous research which states that there is a relationship between the higher the quality of health services the better impact on child growth and stunted\textsuperscript{11}. The inability of families to reach health services due to lack of knowledge, financial capacity, or other causes can affect the nutritional status of children. Health services for children can be associated with changes in nutritional status that lead to stunted\textsuperscript{1,6}.

Table 3 is the result of cross-tabulation between stunted toddler prevalence and UCI village coverage in East Java Province. Table 3 shows the tendency for regencies/cities with the highest percentage of stunted toddlers to regencies/cities with high UCI Village coverage, namely 53.8%. It can be seen that there is a
tendency that regencies/cities that have higher levels of immunization coverage tend to have a lower percentage of stunted. Previous studies reported that cases of stunted toddler and wasting were found to be more in children with incomplete immunization status\textsuperscript{12,13} i.e., BCG; measles; polio 3; and Diphtheria, Tetanus toxoids, and Pertussis, i.e., DTP3. Apart from having an impact on the nutritional status of children under five, immunization is needed because it is an effort to reduce child morbidity and mortality\textsuperscript{14}.

Source: The 2019 Health Profile of East Java Province

Table 4 shows the cross-tabulation between stunted toddler prevalence and coverage of households accessing healthy latrines in East Java Province. The apparent trend is that regencies/cities with a low percentage of stunted toddlers are found in regencies/cities with high coverage of households accessing healthy latrines. The information presented in Table 4 shows the trend of regencies/cities with better coverage of families accessing healthy latrines having a lower percentage of stunted. This shows that access to sanitation has an impact on the percentage of stunted in the community. This tendency is in line with the results of previous studies which state that there is a relationship between latrine use and being stunted in children\textsuperscript{7}. In previous studies, hygiene and sanitation have been shown to have a linear relationship with growth in children\textsuperscript{15}. Poor sanitation increases the risk of infectious diseases and impaired absorption of nutrients. Research states that health problems due to poor sanitation are associated with growth problems that can result in stuntedness\textsuperscript{16,17}. Broader efforts are needed that reach beyond the nutrition sector to tackle the underlying determinants of undernutrition. There is growing interest in how water, sanitation and hygiene (WASH).

Source: The 2019 Health Profile of East Java Province
Table 5 is a cross-tabulation between stunted toddler prevalence and coverage of babies receiving exclusive breastfeeding in East Java Province. The cross-tabulation results show that the prevalence of high-category stunted toddlers is most dominant in city districts that have coverage of middle-category ASI, while regencies/cities with a high percentage of babies receiving exclusive breastfeeding have the lowest stunted toddler prevalence. In line with this trend, several previous studies have also informed that one of the factors that influence the incidence of stunted is exclusive breastfeeding. Stunted toddlers are more common in babies who are not exclusively breastfed. Thus, exclusive breastfeeding is highly recommended.

This research, which was conducted using the ecological analysis approach, has limitations in its use as a policy basis because the data used is aggregate data at the provincial level. Further study is needed at the individual level to obtain more accurate information in choosing intervention policy.

Conclusions

Based on the results of the study, it could be concluded that the coverage of toddler health services, UCI village coverage, coverage of households accessing healthy latrines, and coverage of infants receiving exclusive breastfeeding were factors related to the prevalence of stunted toddlers in East Java Province in 2019.

Acknowledgments: The author would like to thank the East Java Provincial Health Office for providing the report which was the source of the data in this study.

Abstract

Background: Insulin-sensitizer treatment with metformin is widely used in polycystic ovary syndrome (PCOS). However, the treatment effectiveness shows individual differences in PCOS patients. Organic cation transporter (OCT1) have been reported to mediate metformin transport in the liver. Polymorphisms of OCT1 genes may affect the activity of metformin transport and further influence the treatment response of metformin in PCOS patients.

Materials and Method: In this study, we investigated the association between the polymorphism of OCT1 and the treatment effectiveness of metformin in PCOS patients. The single nucleotide polymorphism (SNPs) of OCT1 – R61C analyzed in 222 PCOS and 106 control women. Fasting serum glucose (FSG), fasting serum insulin and HbA1c which represented metformin treatment response, were conducted at the start of treatment and after three-month treatment.

Results: The results demonstrated that the polymorphisms of OCT1 was associated with the variability of metformin response, most patients with reference allele (wild type) and heterozygous alleles of OCT1 (R61C) showed statistically significant metabolic response to metformin, while patients with mutant alleles showed less or statistically not significant response.

Conclusion: Genetic polymorphisms of OCT1 contributed to different metformin treatment responses, and further study is needed to establish personalized treatment programs using a pharmacogenomic algorithm approach in PCOS patients.

Keywords: Polymorphisms, Polycystic Ovary Syndrome, Metformin, Organic cation transporter.

Introduction

Polycystic ovary syndrome (PCOS) is one of the most common endocrine disorders in women of reproductive age. The main features include menstrual irregularity, oligoanovulation, infertility, as well as hirsutism, acne and polycystic ovarian morphology on ultrasonographic imaging. The aetiogical causation behind PCOS is yet to be precisely defined, but it is evident that familiar genetic predisposing factors interact with environmental stimuli both in utero and in pre-pubertal life.

Metformin is an off-label medication used in PCOS patients as an insulin sensitizer. Metformin can not only lower elevated parameters such as insulin, androgens, and circulating free T levels, but can also...
increase levels of sex hormone-binding globulin (SHBG) and insulin-like growth factor-binding protein (IGFBP) (4). The well-known action of metformin is to suppress the production of hepatic glucose. Moreover, metformin has been demonstrated to increase the synthesis of SHBG and to improve menstrual frequency, ovulation, conception, and live birth rates (5,6).

Organic cation transporter (OCT) proteins mediate the transport of organic cations across the cell membrane. Metformin has been demonstrated to be a substrate of liver-specific OCT1 and kidney-abundant OCT2 (7,8). Recent studies indicated that the pharmacokinetic and pharmacodynamics profiles of metformin are mediated by the activity of OCT1 and OCT2 (9,10). In Oct1-deficient mice, the hepatic metformin concentration in the liver was found to be significantly lower than that in control mice, and the glucose-lowering effects of metformin were completely abolished (11). This indicates that OCT1 expression and activity is essential for the hepatic uptake of metformin (12-15). However, the polymorphisms of OCT1 gene may affect the activity of metformin transport and further influence the treatment response of metformin in individuals. Therefore, in this study, we investigated the association between the polymorphisms of OCT1 and the treatment effectiveness of metformin in patients with PCOS.

### Materials and Method

**Subjects and Study Design:** In this prospective study, 222 PCOS Iraqi female patients and 106 healthy control participants were included. All patients diagnosed by consultant gynecologist according to Rotterdam criteria and treated according to practice guidelines. This study was conducted at Kerbala Teaching Hospital, Iraq, from June 2019 until April 2020 and the study protocol approved by the committee of local ethics in the college of pharmacy, University of Kerbala, Iraq with written informed consent signed by all patients. A blood sample was collected from each overnight fasted subject in day two of the menstrual cycle and any day in case of amenorrhea in some patients for genetic, and biochemical tests fasting serum glucose, fasting serum insulin and HbA1c before the study for all participants and after three months of treatment with metformin 500 mg twice daily for patients.

**Polymerase Chain Reaction:** Genomic DNA was isolated from EDTA whole-blood tubes with a G-DEX Ib DNA Blood Kit (Intron, Korea). Polymorphism of R61C was genotyped using Allele Specific-PCR method and specific primers were designed through Primer-BLAST, (Table 1). Optimization of PCR was recorded, (Table 2). The PCR product was run and sized by electrophoresis in the 1.5% concentration of agarose gel at 70 V for 60 min and visualized under Ultraviolet transmillator, the gel was photographed using a digital camera.

Data Analysis: Statistical analysis were used by software SPSS program version 20, P–value less than 0.05 was considered a statistically significant in all groups, Continuous and Discrete variables were presented using number and percentages. Chi-square test used for comparisons of discrete variables between each study group. To compare the studied parameters within PCOS group, before and after treatment, Wilcoxon Signed Ranks Test was applied.

Results and Discussion

Metformin was the first insulin-sensitizing drug to be used in PCOS to investigate the role of insulin resistance in the pathogenesis of the syndrome. Velazquez and colleagues reported a significant improvement in menstrual regularity and reduction in circulating androgen levels in PCOS patients treated with metformin(15). Considerable inter-individual variability exists in response to metformin, up to one-third of patients do not respond adequately, both non-genetic and genetic factors are determinants of the metformin effect.(16) The majority of pharmacogenetic studies performed with metformin have been focusing on the identification of gene variants related to metformin pharmacokinetics. Organic cation transporter (OCT) proteins mediate the transport of organic cations across the cell membrane. Metformin has been demonstrated to be a substrate of liver-specific OCT1, several studies indicate that the pharmacokinetic and pharmacodynamics profiles of metformin are mediated by the activity of OCT1 (17).

Table 3 demonstrates that 222 PCOS patients and 106 healthy control enrolled in this study were at the reproductive age. Both groups in this study were overweight, BMI for PCOS patients was 31.4 ±4.9 and for healthy control 27.8 ±4.7. Barber et al. confirmed that weight gain and obesity occur in approximately (76%) of women with PCOS(18). Alopecia and hirsutism were (92%) and (83%) in PCOS patients, PCOS can cause both alopecia and hirsutism as one of the most reliable results of hyperandrogenism associated with this syndrome(19).

Genetic Analysis: Analyses were conducted to assess the association between the OCT1 polymorphism R61C (rs12208357) [CC (Reference allele), CT (heterozygous type), and TT (mutant type)] and metabolic response of metformin.

Fasting serum glucose, insulin level, HbA1C, and HOMA-IR were significantly reduced in patients with reference alleles and heterozygous alleles but they did not in mutated alleles for R61C. Metformin exerts pleiotropic actions in several tissues, primarily the liver, where it inhibits hepatic gluconeogenesis and glycogenolysis, through which the drug contributes to improving insulin sensitivity. The potential mechanisms for inhibiting the hepatic gluconeogenesis including direct inhibition of gluconeogenic enzymes (e.g. phosphoenolpyruvate carboxykinase, fructose-1,6-bisphosphatase, and glucose-6-phosphatase), reduced hepatic uptake of substrates for gluconeogenesis, and increased phosphorylation of insulin receptor and insulin receptor substrates (IRS)-1 and -2 (20,21). Other investigators have also demonstrated the inhibition of mitochondrial respiration by metformin, may reduce the energy supply required for gluconeogenesis.

Patients with mutated alleles didn’t have a significant response and this may be due to reduce or loss of OCT1 function and diminished hepatic uptake of metformin due to gene polymorphisms. Our study was compatible with Yan Shu et al. who showed that the effects of metformin on glucose tolerance tests were significantly lower in individuals carrying reduced function polymorphisms of OCT1(22). Sundelin et al in their study showed that hepatic distribution of metformin was significantly reduced after oral intake in carriers of 420del and R61C variants in OCT1 (23).

**Conclusion**

OCT1 polymorphism can be considered as one of the genetic factors responsible for heterogeneity in the metabolic response to metformin in Iraqi female suffering from PCOS. For future studies we recommend further OCT1 SNPs can be studied in order to determine the effect of multiple SNPs on response to metformin. Studying polymorphisms of genes encoding other metformin transporters such as OCT2 and OCT3. All that can lead to prescribe the right medication in precise dose for accurate duration and minimize the chance of side effects to reach the goal of therapy for polycystic ovary syndrome.

**Ethical Clearance:** Informed consent was obtained from all participants. Data were collected in accordance with declaration of Helsinki of the World Medical Association, 2013, all other ethical issues were approved by the authors from the University of Kerbala

Evaluation of Aflatoxin B1 and Patulin in Blood of Iraqi Renal Failure patients

Basaad Abdzaid AL-Fatlawi

*Department of Biology, Faculty of Science, University of Kufa, Najaf, Iraq*

**Abstract**

**Objectives:** The current study aimed to investigate and evaluate Aflatoxin B1 and Patulin in blood samples of patients with Renal Failure.

**Method:** Hundred fifty blood samples collected from patients with Renal Failure were included in this study. The age range of patients was 1-61 years. Toxin extraction from the samples was done by Thin Layer Chromatography technique (TLC).

**Results:** There were 100 from 150 samples of blood contained Aflatoxin B1 and Patulin. The highest percentage blood samples contamination with Aflatoxin B1 was (18.181 %) at age group (11-30) years and Patulin was (20 %) that collected from persons at age group (11-20) years, the percentage of blood samples that contamination with Aflatoxin B1 and Patulin that collected from the female was (52.727 % and 53.33%).

**Conclusion:** Persons in Najaf province high exposure to mycotoxins from foods (apples, pear and peach) that present in local markets, that are contaminated with mycotoxins. This suggests that these mycotoxins may be a risk factor of renal failure.

**Keyword:** Mycotoxin, Aflatoxin, Patulin, Thin Layer Chromatography.

**Introduction**

In human and animals, Mycotoxins are secondary metabolites of moulds. The toxic effect of mycotoxins in human is called mycotoxicosis. Mycotoxicosis severity depends on the toxicity of mycotoxin, the duration of exposure, the characteristic feature of individual. In general, the mycotoxins are organic molecules with low molecular weight\(^1\). *Aspergillus* molds produce mycotoxin known as Aflatoxin. It is predominant mycotoxin in addition to trichothecene, due to their highly toxicity and their carcinogenic effects\(^2\). In high humidity and temperature conditions, Aflatoxins present predominantly in rice, nuts, and cereals. Both of A. flavus, and A. parasiticus, are the *Aspergillus* species producing B and G aflatoxins\(^3\). In the southern USA, in 1952, because of the consumption of mouldy corn by swine caused an outbreak of ‘moldy corn toxicosis. Also, in Turkey in 1960 there was another outbreak, Turkey ‘X’ disease. Actually, Aflatoxins are powerful hepatocarcinogens produced by A. nomius, *Aspergillus* flavus, and A. parasiticus. Anorexia, lethargy, muscle weakness, liver haemorrhages and necrosis, engorged kidneys and liver cancer are their symptoms\(^4\).

During the 1940, Patulin was first isolated via antimicrobial active principle from *Penicillium patulum* later called *P. urticae*, now *P. griseofulvum*\(^5\). In previous studies, the blue mold *P. expansum*, that causes softrot of fruits, was recognized as one of the most common offenders in patulin contamination. It is commonly present in unfermented fruit juice, although it does not survive the fermentation into cider products. Remarkably, Patulin is toxic at high concentration\(^6\). Chemically, Patulin is a polyketide lactone. Fungal species of *Penicillium*, *Aspergillus* and *Byssochlamys* growing on fruit and vegetables, cereal grains and silage produce Patulin\(^7\). Throughout the world, Chronic Kidney Disease is the third most common disease\(^8\). It is affecting ten percent of the world’s population; it is related with poor quality of life\(^9\). Prevention and determination the risk factor of renal Failure become the major goal for many studies\(^10\). Therefore, the aim of this study was to evaluate the Aflatoxin B1 and Patulin Iraqi renal Failure patients.
Materials and Method

The study protocol was approved by University of Kufa, College of Science. One hundred fifty blood samples collected from Iraqi renal failure patients visited Dialysis unit at Al-Sadder Medical City, in Iraq. The entire participant or their parents approved performing the study. The range of age of the patients was 1-61 years. Blood samples were collected in gel tube and transported to laboratory.

Extraction of Aflatoxin B1 and Patulin were carried by placing the tubes containing the blood into the centrifuge 6000 RPM to spread the serum. Sera were separated. To each sample one drop of proteinase K (BioBasic, Canada) were added. After the addition of the enzyme, the tubes were placed in water bath 35°C for 10 min. The mixture was the exposed to centrifugation in 8000 RPM for 3 mints, the supernatant were taken and the deposit were leaved. The filter double volume from chloroform and well mixed as it formed two layers. Were used to extract Aflatoxin B1 and Patulin, chloroform layer and serum layer then The chloroform layer was withdraw and Put in a small, clean and sterile tube.

Detection of Aflatoxin B1 and Patulin; Thin Layer Chromatography (TLC) technique were used in detection of patulin serum. Thin Layer Chromatography plates were putted in oven at 120°C for one hour to activate it. Straight line was made on TLC plate in distance of about 1.5 cm from the base plate. Patulin stander (15 µl) was putted as spot on TLC plate by capillary tube and putted 15µl on plate from each extracted samples with a distance 2 cm between sample and another then let the spots to dry in laboratory condition. Separation tank was used that containing 100ml from mixture chloroform: acetone in a ratio 8:2. The plate exited from the tank and leaved it to dry under the laboratory condition. Then plate examined under UV light (360 nm) and compared the color and RF (Relative Flow) of extracted samples with the standard toxin.

Qualitative investigation of Aflatoxin B1 and patulin in blood UV visible spectrophotometer were depended it to qualitative investigation of Aflatoxin B1 and patulin. A standard curve was drawn to absorption for different concentrations of standard Aflatoxin and patulin, the standard concentrations were 1, 2, 3, 4, 5, 6, 7, and 8µg/L. The unknown concentrations of toxin in the blood were determined from the standard curve11.

Result

The result showed 66.666% of renal failure patients infected (36.666% Aflatoxin, and 30% patulin toxin), also, 33.333% not contaminated with Aflatoxin and patulin as in Table 1.

Also this study clarified that highest percentage of patients with Aflatoxin at age 11-30 years, While, 18.181% of patients with Aflatoxin at age 41-50% years. As shown in Table 2.

The result in Table 3 high light the fact that the infected female patients percent were (52.727%, 53.333%), while the infected male patients percent were (47.272%, 46.666%) infected with Aflatoxin and patulin respectively.

**Discussion**

Worldwide, chronic consumption foods contaminated with aflatoxin is the major problem for human and animals, especially in developing countries\(^{12}\).

Previous studies reported that Aflatoxins disturb numerous body organs, such as heart, skeletal muscles, endocrine organs, lung, brain, liver and kidneys. Because more than 20% of blood in circulation reaching to the kidneys they are susceptible to high concentration of toxic agent in the blood\(^{13-15}\).

Also, the kidneys require high nutrients and oxygen, since their load of work\(^{16}\). Various segments of nephrons are attached by aflatoxins in addition to its metabolites. The possible reason, the aflatoxin prompts protein reduction so increases the kidney cells necrosis\(^{17}\). Previous studies reported that exposor to aflatoxins induced kidney syndromes\(^{18}\), deteriorating variations in renal tubular cells in addition to unusual change of glomerular epithelial cells\(^{19}\). Other studies, on animals predicted that there was decreasing in the GFR, reabsorption of glucose and organic anions in animal’s exposer to the aflatoxins\(^{20}\).

Numerous hostile health special effects causing from exposure to patulin have been labelled previously. Actually, patulin is stated to be very cytotoxic, genotoxic, neurotoxic, and immunosuppressive. Because, Patulin has a high affinity for sulphydryl groups in the proteins\(^{21}\). The major Kidneys function are maintain of total body salt, acid base balance and blood volume regulation, in addition to excretion metabolic waste products\(^{19}\). Accordingly, the levels of the toxic substance in the lumen and surrounding renal cells are fairly high making it a possible target for patulin induced toxicity\(^{22}\).

The data of the present study indicate that there are high percent of patient with renal failure contaminated with aflatoxin and Patulin in Iraq. This suggests that these mycotoxins may be a risk factor of renal failure.

**Conclusion**

Persons in Najaf province high exposure to mycotoxins from foods (apples, pear and peach) that present in the local markets, that are contaminated with mycotoxins. This suggests that these mycotoxins may be a risk factor of renal failure.

The Effect of Radiotherapy and Chemotherapy on Some Kidney and Liver Functions in Colorectal Cancer Patients

Bashar Abd Alkadhim Naji1, Ahmed Sabah Aliand1, Ali Slwmee Serhan Al-halaly1

1Research, University of Al-Qadisiyah/College of Science/Department of Biology, Iraq

Abstract

The current study was conducted in Al-Diwania Teaching Hospital/Oncology Division and Middle Furat Center for Cancerous Tumors in Al-Najaf, Babil Health Department/Marjan Hospital, Babil Health Department/Imam Al-Sadiq Hospital and Medical City Department/Al-Amal Hospital for the treatment of tumors and continued for the period from 2/10/2019 to 6/5/2020. 60 samples were taken from patients diagnosed with colorectal cancer and 30 samples from non-infected people as a control group, with ages ranging from 33 years to 80 years for both groups. The results showed an increase in the level of Creatinine in the patient group compared to the control group and it was the highest in the radiotherapy group, followed by the chemotherapy group and then the control group. The results showed high significant differences between the three groups (p <0.001), and there were significant differences between the radiotherapy group and the chemotherapy group. Through the results, it was found that the average level of Creatinine increased in the radiotherapy and chemotherapy groups compared to the control group. The results showed that the mean of AST was highest in the radiotherapy group, followed by the chemotherapy group and then the control group. The results showed high significant differences between the three groups (p <0.001). Through the results, it was found that there were no significant differences between the radiotherapy group and the chemotherapy group in the average level of the AST enzyme. It was also found that the average level of AST enzyme was higher for the radiotherapy and chemotherapy groups compared to the control group. The results of the current study showed the highest mean ALT enzyme in the radiotherapy group, followed by the chemotherapy group compared to the control group. The results showed high significant differences between the three groups (p<0.001) and significant differences between the radiotherapy group and the chemotherapy group. ALT for the radiotherapy and chemotherapy groups compared to the control group.

Keywords: Colorectal cancer, ALT, AST, chemotherapy, radiotherapy.

Introduction

The kidneys are important vital organs and have many functions, including the production of erythropoietin to stimulate the production of red blood cells, filter metabolites and electrolytes from the blood, and adjust blood pressure through fluid balance. Studies have shown the negative effect of chemotherapy agents and their role in the emergence of nephrotoxicity (Nephrotoxicity) and the damage is determined clinically through changes in the rate of glomerular filtration, creatinine clearance, urea nitrogen in the blood and urine excretion, as well as the negative effects of chemotherapy agents that can be radiographed, such as change Cystic, interstitial nephritis, urethral changes, and colitis, etc. Also, radiation therapy causes total body irradiation (TBI) to injure the kidneys with some damage, the most important of which is radiation nephropathy (RN). The incidence of clinical RN increases with the use of TBI and nephropathy usually develops very slowly over several years as proteinuria, hypertension, and impaired urine concentration. Studies have indicated that a dose within the range of 5 to 10 Gy, doses less than 5 Gy will not effectively affect the kidneys, while doses in excess of 10 Gy may cause rapid gastrointestinal death. However, given the threshold dose, adequate ionizing radiation affects most or all of the kidney components. The injury to the glomerulus is first with the development of glomerular scars due to thrombotic angiopathy. Chemotherapy is one of the main treatments used in treating cancer. Systemic cancer treatment has evolved from traditional toxic
agents to newer classes of partially targeted therapy. Although these treatments aim to prevent the growth of cancerous tissues, they have harmful effects on normal tissues where many negative effects of chemotherapy can be detected on various organs, including the liver.\(^7\) Among the most important of these effects is the fatty leaching of the liver tissue and the accumulation of fat cells in the liver cells, which is known as hepatic steatosis or what is known as hepatic steatosis, and steatohepatitis, which is a more severe form of fatty liver disease and is often asymptomatic and can be detected by elevated ALT and AST.\(^8\) These changes have been linked to chemotherapy agents, Methotrexate 5-fu, Irinotecan, Oxaliplatin\(^9\) as the steatohepatitis (steatohepatitis) associated with chemotherapy can be diffuse or focal and can be seen with an ultrasound scan (US).\(^10\) Hepatic steatosis can also be visualized through computed tomography (CT)\(^11\), as well as magnetic resonance imaging (MR)\(^12\). The detection of lipid changes in a chemotherapy patient is useful because it may prompt changes in treatment, especially in patients with metastatic colorectal cancer, as steatosis may increase the risk of postoperative complications.\(^13\)

Several studies have revealed the relationship between acute hepatitis and several chemotherapy treatments.\(^14\) Acute hepatitis ranges from asymptomatic inflammation to highly symptomatic inflammation such as nausea, vomiting, poor appetite and jaundice, with an increase in AST and ALT in the majority of patients. Hepatitis improves upon temporary discontinuation of cancer treatment.\(^15\) As for the effect of radiation therapy, the liver is exposed indirectly during radiotherapy (RT) to tumors located in the upper abdomen, lower lung, esophagus, entire abdomen or the entire body.\(^16\) Despite exposure to a limited area during radiotherapy, normal tissues in that area can receive a high dose of radiation and thus the liver can withstand severe damage such as fibrosis.\(^17\) The radiation effects resulting from radiation treatments for cancer patients depend on age and gender.\(^18\) It has been observed that radiation damage in cells is like breaking the double strand of DNA and this is at the molecular level and this damage leads to many biochemical reactions, which It subsequently leads to various pathologies such as cirrhosis as a form of acute radiological damage after exposure to high-dose radiation.\(^19\) Clinical symptoms known as «classic» radiation induced liver disease (RILD) usually occur. These symptoms occur within four months after exposure to radiation of the liver as the patient suffers from fatigue, weight gain, enlarged liver, and high alkaline phosphatase. Which is not compatible with other liver enzymes.\(^20\) In contrast to this «classic» RILD, a cancer patient may present with underlying chronic liver disease such as cirrhosis and viral hepatitis with liver function abnormalities such as jaundice within three months of completion of radiotherapy.\(^21\)

**Materials and Method**

**Collecting and testing blood serum:** Samples were collected from Al-Diwaniyah Teaching Hospital/Oncology Department and the Central Euphrates Center for Cancerous Tumors in Najaf, Babil Health Department/Morgan Hospital, Babil Health Department/Imam Al-Sadiq Hospital and Medical City Department/Al-Amal Hospital. For the treatment of tumors after the approval of the above-mentioned hospital departments and after taking the verbal consent of the patients and healthy people who were included in the study after clarifying the idea of the research and its purpose, and their data should be used only for the purposes of research and to maintain privacy. 2 ml of the patient’s blood was withdrawn and it was placed in a centrifuge at 3000 rpm for ten minutes, then the separated serum was taken and transferred to the Eppendorf tube. These samples were kept in continuous freezing temperature (-20 °C). As for the control samples, 30 samples were taken from healthy people in the same way as patient samples for the purpose of examining some liver and kidney functions.

**Examination of Biochemical parameters**

i. **Determination of serum creatine levels:** Serum creatinine levels were measured using a spinreact Kit.

ii. **Determination of serum ALT and AST activity (U/L):** I used a ready-made test kit, a kit manufactured by the Chinese company CUSABIO, using the color method used by Reitman & Frankel.\(^22\)

The results showed an increase in the level of Creatinine in the patient group compared to the control group and it was highest in the radiotherapy group (1.56 ± 0.08), followed by the chemotherapy group (1.28 ± 0.06) and then the control group (0.60 ± 0.05). The results showed high significant differences between groups. The three were (p <0.001). There were also significant differences between the radiotherapy group and the chemotherapy group. Through the results, it was found that the average level of Creatinine increased in the radiotherapy and chemotherapy groups compared to the control group.

The results showed that the mean of the highest AST was in the radiotherapy group (43.75 ± 0.63), followed by the chemotherapy group (41.14 ± 1.09) and then the control group (26.04 ± 0.50). The results showed high significant differences between the three groups (p <0.001). Through the results, it was found that there were no significant differences between the radiotherapy group and the chemotherapy group in the average level of the AST enzyme. It was also found that the average level of the AST enzyme was higher for the radiotherapy and chemotherapy groups compared to the control group.

The results of the current study showed the mean of the higher ALT enzyme in the radiotherapy group (56.11 ± 0.54), followed by the chemotherapy group (51.78 ± 0.32) compared to the control group (31.46 ± 0.29). The results showed high significant differences between the three groups (p <0.001). Significant levels were found between the radiotherapy group and the chemotherapy group. The mean level of ALT was found to be higher in the radiotherapy and chemotherapy groups compared to the control group.

Discussion

The percentage of creatinine is high in the serum of cancer patients, and the reason for this increase may be due to kidney injury, as there is a reciprocal relationship between cancer and the kidneys, as chronic kidney disease can increase the risk of cancer, and cancer patients often suffer from renal impairment resulting from associated factors. With disease or toxicity of the treatments used by cancer patients, the effect of radiation therapy is more concentrated on cells, being specific to the organ affected by the carcinoid tumor. Therefore, cell lysis in radiotherapy is stronger and faster than chemotherapy (23). Doses of less than 18 Gy of the whole kidney appear to rarely cause severe or long-term renal injury while doses of more than 20 Gy of disease lead to significant nephropathy (24).

(25) found a mean reduction of 8% in glomerular filtration rate (GFR) for each 100 mg/m2 dose received from cisplatin treatment. In serum or urine and cisplatin infusion rates. Decreases in glomerular filtration rate and hypomagnesaemia are rare after carboplatin use. Ironically, it is possible that the risk of renal insufficiency and tubopathy is higher with carboplatin/ifosfamide compared to the cisplatin/ifosfamide combination therapy (26). Radiation nephritis or radiation nephropathy develops after a latent period of 3 to 12 months and is manifested in varying degrees of hypertension, renal insufficiency and anemia (27). An elevated liver enzyme level is frequently present in cancer patients but is mostly due to the fact that chemotherapy and radiotherapy damage liver cells (28).

The administration of chemotherapy presents a challenge to the strict regulation and balance of these processes since most drugs tend to be lipophilic, so
the liver takes them easily. Under the influence of chemotherapy, about 85% of patients develop liver steatosis and steatohepatitis is the most serious event, especially if it is associated with an increase in bilirubin levels(29). Radiation therapy affects the liver and has negative effects. Treatments cause cirrhosis and venous obstructive liver disease, a feature of patients with radiation-induced liver disease (RILD). Radiation therapy also causes oxidative stress and the production of reactive oxygen species, which lead to the apoptosis of liver cells and acute inflammatory responses and increases the susceptibility of central hepatocytes («centrilobular» hepatocytes «HCs») to the apoptosis of the treatment and ultimately leads to the death and degeneration of hepatocytes. Chemotherapy also causes various tissue changes to the liver, including this fatty degeneration, and steatohepatitis associated with chemotherapy and sinus obstructive syndrome for sinus infection, as well as the treatment regimens and the quality of chemotherapy have a direct and important effect on the severity of the liver injury and this is in accordance with studies (30).

Abstract

\textit{Salmonella typhimurium} is a Gram-negative zoonotic bacterium which causes a wide range of illnesses to both humans and animals. The aim of this research is to study the pathogenicity of \textit{S. typhimurium} in vivo. A total of 40 adult white BALB/c mice were divided into 5 groups (8 animals each). Four groups were orally dosed by viable \textit{S. typhimurium} (1 X 10\textsuperscript{9} cfu/ml) suspended in phosphate buffer saline (PBS) by a stomach tube, while the fifth group was given PBS orally only (control group). Four mice were killed at 7, 12, 24, 48 hours after giving the infective dose plus one mouse from the control group. In addition, sera were collected after 2 weeks from animals of each group to detect the titer of antibodies. The viability of \textit{S. typhimurium} was checked by culturing on SS agar after mice death. Slides were prepared for histopathological examination (to assess the lesions) and immuno-histochemistry (to detect cytotoxic T cells in the affected organs). The results included bacterial isolation from duodenum, jejunum, ileum and liver which were positive from the infected groups. Histopathological examination showed hepatic granulomatous lesions with severe infiltration of mononuclear cells (MNCs) in the liver parenchyma and within small intestine. Finally, to detect cytotoxic T cells in the slides, immunohistochemistry showed presence of CD8 T cells in the hepatic cells. Titers of antibodies were measured by ELISA where IgG antibodies were detected. The conclusion of this study could be summarized by addressing the severity of infection after 12 hours of oral dosing in the stomach while severe lesions were seen in the liver after 48 hours of oral administration.

Keywords: Pathology; Immunohistochemistry, Pathogenicity; \textit{S. typhimurium}, IgG, CD-8 T cells.

Introduction

\textit{Salmonella enterica} serovar \textit{Typhimurium} (hereafter \textit{S. typhimurium}) is a Gram negative motile non spore forming encapsulated bacteria belongs to Enterobacteriaceae family that could cause a long list of infections (mainly diarrhea due to enteritis) to both humans and animals as a zoonotic virulent foodborne pathogen\textsuperscript{1,2,3}. Therefore, \textit{S. typhimurium} is responsible for being a major threat pathogen to public health globally as well as it causes huge economic losses in the field of veterinary medicine worldwide because of the biological damage to the intestine of infected animals which leads to poor absorption of digested food and weight loss\textsuperscript{4,5}. Recent publications referred to the capability of \textit{S. typhimurium} to develop a multidrug resistance to many antibiotics which worsen much more the economic losses in animals due to the added value of the cost of treatment\textsuperscript{6,7,8,9}.

In mice, \textit{S. typhimurium} is responsible for bacterial diarrhea and considered as an animal model for human
Infection of mice with *S. typhimurium* is mainly initiated due to oral-fecal route of transmission. After ingestion of *S. typhimurium* with the contaminated food, the bacteria survive and colonize in the small intestine. Settling of bacteria in the small intestine leads to expansion in numbers through multiplication of these bacteria. The clinical symptoms mainly characterized by anorexia, loss of appetite, and the most important clinical symptom is diarrhea (ranged from mild to bloody depending on the virulence of the *S. typhimurium* strain).

After propagation of *S. typhimurium* in the intestine and establishing clear clinical symptoms, it is essential to interfere this microbial attack by giving antibiotics. However, *S. typhimurium* is sensitive to most antibiotics except a few emerged strains which gained resistance properties against antibiotics.

The immune response against *S. typhimurium* differs according to the level of virulence of the strain. Innate immunity against *S. typhimurium* represents by phagocytic activity of neutrophils and macrophages in the early stages of infection which almost always not biologically effective, thus adaptive immunity is required. Adaptive immunity against *S. typhimurium* could be considered as the key role in the clearance of this bacterium through establishing production of more specific CD4+ and CD8+ T cells.

The pathogenicity of *S. typhimurium* in mice was studied before more than 2 decades, but this study did not focus on the liver as an important organ involved in *S. typhimurium* infection. Therefore, and due to lack of studies in Iraq, this study is designated to spot the light on infection which is evaluated by bacterial spread in intestine and liver through investigation of experimental studies.

**Materials and Method**

A total of 40 adult white BALB/c mice were divided into 5 groups (8 animals each). Four groups were given an oral dose of viable *S. typhimurium* (1 X 10⁹ cfu/ml) suspended in phosphate buffer saline (PBS) by a stomach tube, while the fifth group was given PBS orally only (control group). The bacteria were isolated from local Iraqi lambs. Four mice were killed at 7, 12, 24 and 48 hours after giving the infective dose plus one mouse from the control group. The viability of *S. typhimurium* was checked by culturing on SS agar after mice death. Slides were prepared for histopathological examination (to assess the lesions) and immunohistochemistry (to mainly detect cytotoxic T cells in the affected organs). Three mice were chosen from both infected and control groups and subjected to Widal test which was used to determine the presence of O and H antigens of *S. typhimurium* and the positive samples of Widal were further subjected to ELISA to confirm measuring the titer of the IgG antibodies in the serum against protein and LPS antigen of *S. typhimurium*.

**Histopathological examination:** The tissue specimens collected from liver, duodenum, jejunum and ileum were fixed in 10% formalin for 72 hour and processed for slide preparation and staining with Hematoxylin and Eosin (H and E) stain was done according to. Histopathological changes were observed under light microscope.

**Immunohistochemistry:** The kit used for this technique was purchased from “US Biological, USA” and the procedure was done according to. The stain used in this technique was 3, 3’ Diaminobenzidin (DAB) stain which is a stable liquid substrate. DAB is the most common reagent employed for the immunohistochemical detection of horse radish peroxidase (HRP) probes. In the presence of HRP and hydrogen peroxide, DAB is oxidized to a brown polymer easily recognized by light microscope.

**Preparation of protein and lipopolysaccharide (LPS) antigens:** *S. typhimurium* isolated from infected mice (biochemically and serologically proven by), were grown overnight on Trypticase soy agar (TSA) (Difco, USA) at 37°C. After that, the bacteria were harvested in normal saline solution and mixed with three volumes of acetone for inactivation. Inactivated bacteria were centrifuged, and the pellet further washed from acetone. The LPS antigen of *S. typhimurium* was extracted from acetone-dried cells by the following hot phenol-water method. The resultant protein antigen was obtained from the acetone dried cells by Veronal buffer extraction and purified by repeated precipitation with trichloroacetic acid. The carbohydrate and protein content of the prepared mixture was determined by Lowry and Anthrone method.

**Preparation of O and H antigens for Widal test:**

**Preparation of O-antigen:** Bacteria were grown on TSA agar at 37°C overnight, then harvested by adding...
normal saline solution to each petri dish. Bacterial cells were brushed off from the agar surface by cotton swab. The bacterial suspension was centrifuged at 6000 rpm for 30 minutes and the supernatant was discarded. The bacterial cell pellet was washed three times and resuspended in normal saline. Bacterial cells were killed by heating at 100°C for 30 minutes, diluted with normal saline at appropriate dilution and kept at 4°C until later use.

**Preparation of H antigen:** Trypticase Soya (TS) broth (Difco, USA) was heavily inoculated with *S. typhimurium* and incubated at 37°C overnight. Bacterial cells were killed with formalin at a final concentration of 0.5% and harvested by centrifugation at 6000 rpm for 30 minutes. The bacterial cell pellet was washed three times before being resuspended in PBS. It was kept at 4°C until later use. Optimal concentrations was determined in carbonate-bicarbonate buffer (pH = 9.6).

**Enzyme-linked immunosorbent assay (ELISA):** the kit (Biosource, USA) was purchased to measure IgG in the serum. Sandwich ELISA method was applied according to manufacturer instructions. Protein and LPS antigens were added into u-shape microtiter plates, then incubated at 37°C for 3 hours. After that, plates were washed three times by PBS containing (0.05% Tween20). Then a biotinylated detection antibody specific for IgG was loaded into the plates and Avidin-Horseradish Peroxidase (HRP) as a conjugate is added to each microplate well and incubated for 1 hour at 37°C. A blue color was developed as a result of positive IgG titer. The colorimetric reaction was stopped by adding enzyme-substrate (sulphuric acid solution) and the color turned into yellow. The optical density (OD) was measured by ELISA reader (Varioskan™ LUX multimode microplate reader, ThermoFisher Scientific, USA) machine (spectrophotometer) at a wavelength of 450 nm.

The samples used for ELISA were incubated for one hour with optimal dilutions of serum samples (1:40) for protein antigen, and (1:20) for LPS antigen.

**Statistical Method:** T test was used to compare statistically between the titer of antibodies in infected and controls at a level of significance (P<0.05).

**Results**

The histopathological data obtained in this research showed hepatic granulomatous lesions scattered through its parenchyma consist of central foci of necrosis, associated with severe infiltration of mononuclear cells (MNCs), mainly macrophages and lymphocytes (Figure 1). In addition, sections illustrated dilated congested central veins and sinusoids, also inflammatory cells particularly neutrophils and macrophages were seen in lumen with large areas of necrotized hepatocytes replaced by RBCs (Figure 2). The results of immunohistochemical examination manifested by deposited brownish color in the intracellular area of hepatocytes within the cytoplasm of infected cell when stained by (3,3’-Diaminobenzidine) which were recognized in the liver tissues (Figure 3).

The histopathological lesion in the intestine of mice after orally administered by (0.2 ml containing 1 X 10^7 cfu/ml of *S. typhimurium*), showed severe necrosis associated with massive infiltration of inflammatory cells particularly MNCs in the lamina propria and in mucosal glands, as well as severe congested blood vessels and edematous spaces appeared in the serosa layer of infected organ.

**Figure 1:** Histopathological section in liver of infected mouse after orally administered via (0.2 ml contain 1x10^7cfu/ml of *S. typhimurium*), shows granulomatous lesions characterized by, central of necrosis (yellow arrows) with severe infiltration MNCs mainly macrophages and lymphocyte in the liver parenchyma (green arrow) (H & E stain, 40X).
Figure 2: Histopathological section in liver of infected mouse after orally administered via (0.2 ml contain 1x10^7 cfu/ml of *S. typhimurium*), shows dilation of sinusoids (yellow arrow), neutrophils and macrophages infiltration (turquoise arrow) necrotic hepatocytes that replaced by RBCs (green arrow) (H & E stain, 40X).

Figure 3: Immunohistochemistry section in liver of infected mouse after orally administered via (0.2 ml contain 1x10^7 cfu/ml of *S. typhimurium*), show infiltration of immunohistochemical staining positive cells of CD8, that appear as deposited brownish color in the intracellular within cytoplasm of infected cell (Diaminobenzidine staining, 40X).
Figure 4: Histopathological section in intestine of infected mouse after orally administered via (0.2 ml contain 1x10⁷ cfu/ml of *S. typhimurium*), shows severe infiltration of inflammatory cells within and between the mucosa intestinal gland (green arrow) as well as severe congestion that appear in the serosa layer (yellow arrow)(H & E stain, 40X).

Figure 5: Immunohistochemistry section in intestine of infected mouse after orally administered via (0.2 ml contain 1x10⁷ cfu/ml of *S. typhimurium*), shows infiltration of immunohistochemical staining positive cells of CD8, that appear as deposited brownish intracellular color within and between the mucosa gland and intestinal villi (Diaminobenzidine staining, 40X).
Mean quantities of CD8+ T lymphocytes marked (table 1) with specific antibody by immunohistochemistry in tissue section of the Liver and Intestine (duodenum, jejunum, and ileum) of infected mice after orally administered via (0.2 ml contain 1x10^7 cfu/ml of S. typhimurium).

The serological results revealed detection of fair levels of antibodies against oral dosing of pathogenic S. typhimurium measured by Widal test after 2 weeks post infection (table 3). The antibody titer was 71.11 pg/ml against S. typhimurium O-antigen whereas, it was 94.22 pg/ml against S. typhimurium H-antigen. The antibody titers measured by Widal test were re-tested by ELISA and they were 150.83 pg/ml and 95.44 pg/ml for S. typhimurium protein and LPS antigens respectively (table 4).

**Discussion**

The genus Salmonella in general was extensively studied in Iraq in both animals and humans 28, 29, 30, 31, 32. However, there was no research done with regards to immunopathological studies on S. typhimurium in Iraq. There was one study in Iraq33 who isolated this bacterium from chicken meet.

The histopathological lesions caused by oral dosing of S. typhimurium in mice in this study revealed massive destruction to the epithelium of intestine accompanied by mononuclear cells (MNCs) infiltration as well as invasion of these bacteria into liver which caused inflammatory reactions represented by infiltration of MNCs into the hepatic tissue which developed into a hepatic necrosis to wide areas of liver in addition to scattered hemorrhages in the hepatic tissue. These findings are in line with previous studies 34, 35, 36 who reported microbial invasion and colonization of S. typhimurium to the enteric canal (GIT) of mice causing diarrhea (ranged from mild to severe bloody type). However, further research similar to we have found with regards to spreading of S. typhimurium into hepatic tissue was investigated by 37, 38 who described the penetrative ability of S. typhimurium to infect liver.
The immune response against *S. typhimurium* was measured in this study by three methods (Immunohistochemistry “IHC”, Widal test and ELISA). The cellular immune response was determined by IHC method to search for cytotoxic T cells (CD8+ T cells) in the liver which were prevalent in the slide sections. This finding is in line with previous studies who demonstrated that CD8+ T cells (T cytotoxic cells) are the predominant cell type in the immune response to *S. typhimurium* and explained how these lymphocytes killed the bacterium through production of bactericidal cytokines such as interferon gamma (IFN-γ) and interleukins (IL-17 and IL-23).

Humoral immune response was also assayed to measure the levels of antibodies in the sera against *S. typhimurium*. Initial attempts were made to measure the titer of antibodies through Widal test and then confirmed by ELISA (more specific and sensitive). IgG titers were relatively low in this study against *S. typhimurium* which was (150.83 pg/ml) against protein antigen and (95.44 pg/ml) against LPS. The titers of IgG were much higher in a study who measured IgG in the blood of mice orally dosed with bovine lactoferrin and infected (challenged by) pathogenic *S. typhimurium*. The titer of IgG measured by ELISA ranged from about 300 to 3400 pg/ml measured at multiple time points (7 days, 14 days and 21 days) post challenge.

Another study in Iran was performed to study the effect of alum as an adjuvant while vaccination against endotoxin-removed lysates of *S. typhimurium* in mice. They used ELISA to measure the titer of IgG which was significantly higher in the vaccinated groups by comparison with controls (given PBS only) at a level (P<0.05) plus a significant increase in the leucocytes count (mainly T helper 1 cells) compared with controls which is approximately in line to what we found.

Further research done by was applied to study antibodies’ titers (IgA, IgM and IgG) against African O antigen of *S. typhimurium* and found that IgG was increased 4 logs in the vaccinated mice by comparison with controls after two weeks of immunization. This finding is much higher than our results.

A contemporary study to found that *Rag1−/−* mice has the ability to eliminate *S. typhimurium* from the gut through the antibacterial activity of IgG in the mucus of GIT that immobilize bacteria which explains the beneficial role of humoral immunity against this bacteria and this is in agreement to the findings of our study.

Further serological research to compare between pIlgR knockout mice and wildtype mice was done to detect both IgA and IgG in the sera samples and stool specimens in response to oral dosing and intravenous injection of pathogenic *S. typhimurium*. The concentration of IgA and IgG measured by ELISA demonstrated significant increase of IgA and IgG (P<0.05) in the sera of pIgR knockout mice by comparison with the wildtype mice which resulted in elevation of survival rates in these mice against *S. typhimurium* infection with which we agree.

Finally, a recent study to discovered an essential role of core fucosylation in the immunological mechanism of Fut8+/+ and Fut8−/− mice against *S. typhimurium* infection. They demonstrated significant lower concentrations of IgA and IgG (P<0.05) in Fut8−/− mice plus remarkable fall (P<0.05) in lymphocytes count (both B and T cells) which is in contrast to what we found.

In conclusion, pathogenesis of oral dosing with *S. typhimurium* was studied in mice which spread into intestine and liver within 48 hours and this was examined by bacterial isolation from the infected organs and histopathological pictures. IgG antibodies against *S. typhimurium* were also detected.

Abstract

The purpose of this study is to establish reliability of estimating stature from the foot dimensions in South Indian population. Volunteers aged above 18 years were recruited for the study and measured using standard measuring using standardized measuring equipment. Anthropometric measurements taken include stature, foot length, foot breadth, navicular height and malleolar heights. Correlations, regression formula and linear regression equations derived for both male and female showed positive correlation coefficient between stature and foot dimensions. To conclude foot dimensions were correlated with stature and can be a better predictor of stature.

Keywords: Stature estimation, foot length, foot breadth, navicular height, malleolar height.

Introduction

Identification of an individual is the mainstay in forensic investigations. This becomes more essential when dismembered body parts are found. Forensic examinations to identify individuals depend on aspects that solely define them such as fingerprints. One of such investigations is stature estimation. Stature is the height of the person in erect posture and this can determine the physical identity of a person. It has a significant aspect in establishing identity of an unknown[1]. Stature of an individual belonging to a given combination of age, race, and sex have measurements of different body parts that are proportionate to it[2]. Measurements of long bones are usually used to estimate stature[3]. Different parts of the body can also be used for estimation[4][5].

As foot dimensions enable determine stature, they also determine age and sex of an individual[6]. This forensic assessment of stature helps identify individuals, thereby helping medico-legal and forensic investigations.

Materials and Method

It is a cross-sectional study consisting of South Indian population. Residents of Chennai irrespective of sex with age above 18 years and those who had given their informed consent were measured for stature, foot length (the maximum distance between the most posteriorly projecting point of the heel (pteron) to the most anteriorly projecting point (acropodion) of the first or second toe, whichever is bigger when the foot is fully stretched), foot breadth (the distance between the lateral and the medial sides at the metatarsal region or at the heel region, whichever is the broadest), navicular height (the distance between the prominent part on the medial side of dorsal foot (navicular bone being situated on the medial side) to the base of foot on the plantar aspect) and malleolar heights (the most superficial prominent point on the malleolus to the base of foot at the heel) using vernier calipers and measuring tape to the nearest centimeter. Since stature is variable among population and sex, regression formulas have been derived for the population and the data will be tabulated, analyzed and subjected to statistical calculations using SPSS software.

Regression equation:

Discussion

In forensic investigations difficulties are being experienced in identification of bodies dismembered in mass destruction. So as to minimize these difficulties many methods are developed and are being developed. One such investigation is stature estimation which helps in identifying individuals. Stature estimation can be done with different parts of the body. This assessment is of great importance in medico-legal and forensic examinations. The present study is to estimate stature from foot measurements and to analyze the relationship between foot dimensions and stature.

It is a cross-sectional study in South Indian population. Residents of Chennai irrespective of sex with age above 18 years and informed consent given are measured for stature, foot length, foot breadth, navicular height and malleolar heights. Those with deformities and below 18 years of age were excluded from the study.

Table 1 shows the mean and standard deviation of various measurements of both right and left feet in males and females, along with height. In the present study 62.30% are of females and 37.70% are males. The mean height of males is 167.0261 and females is 155.9184.

The mean height is more in males than females though female to male ratio is low. The mean of other foot dimensions also show more for males than females.

Table 2 shows correlation of stature with foot dimensions of both right and left. Also shows correlation of various parameters in males and females.

Almost all correlation coefficients show positive values indicating a relation between various parameters and stature. Foot breadth in females and malleolar height in males show negative correlation indicates less relation between stature and these two parameters.

Correlation coefficient of foot length in females is 0.649 and males is 0.188 says that foot length is more correlated to stature in females than males.

Correlation coefficient foot breadth in males is 0.502 and -0.046 in females indicates that foot breadth is more correlated to stature in males than females. Foot breadth in females have negative correlation with stature.

Correlation coefficient of navicular height in males is 0.840 and 0.680 in females says that navicular height is more correlated to stature in males than females.

Correlation coefficient lateral malleolar height in females is 0.675 in females and 0.038 in males indicates that lateral malleolar height is more correlated to stature in females than males.

Correlation coefficient of medial malleolar height in females is 0.507 and -0.061 in males says medial malleolar height is more correlated to stature in females than males.
Foot breath in females and medial malleolar height in males are negatively correlated to stature that is increase in one variable is associated with a decrease in the other variable.

Correlation of the parameters with stature show positive values in total indicating a relation between stature and foot dimensions.

Table 3 shows linear regression equations for males and females.

The SEE help predict the deviation of estimated stature from the actual stature. A low value indicates a greater reliability in the estimated stature.

The SEE ranges from 1.65959 to 3.05547 in males. Navicular height exhibits a lower value and gives better reliability in prediction of stature.

The SEE ranges from 4.11560 to 5.61211 in females. Navicular height exhibits a lower value and gives better reliability in prediction of stature.

In this study navicular height in both males and females presented a strong relationship with stature and more reliable in estimation of stature.

The results of the present study show that dimensions of foot show statistically significant positive correlation with stature of an individual. In this study males showed higher mean values in all the parameters studied than among females with statistically significant difference. Sexual dimorphism was noted for the foot dimensions recorded. The foot dimensions are relatively smaller in females than males. No significant difference was found in either right or left side measurements.

**Conclusion**

The present study established a definite relationship between stature and foot dimensions. The above findings suggest that foot dimensions can be predictors of stature. However, the results of this study is different from the studies previously conducted. Thus cannot be used to make any firm conclusions. It is important to note that results differ with races and geographical distribution.

Derivation of Regression Equation for Estimation of Height from the Length of Clavicles

Bipinchandra A. Khade¹, Dr. Vaibhav P. Anjankar², A.S. Mangalgiri³, Anil J. Anjankar⁴, Vilas K. Chimurkar⁵

¹Associate Professor of Anatomy, Chirayu Medical College and Hospital, Bhopal, ²Associate Professor of Anatomy, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Sawangi (Meghe), Wardha, ³Professor of Anatomy, Chirayu Medical College and Hospital, Bhopal, ⁴Professor and Head, Department of Forensic medicine and Toxicology, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Sawangi (Meghe), Wardha, ⁵Professor and Head, Department of Anatomy, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences, Sawangi (Meghe), Wardha

Abstract

Background: The various features of clavicle help to decide the gender and height of the individual. Stature is an important biological parameter in medico-legal forensic examination. The length of clavicle is considered as an important anthropological parameter. The present study was undertaken with the aim of deriving of regression equation for estimation of height from the lengths of clavicle.

Methodology: This cross sectional, observational study was conducted from October 2019 to February 2020 after getting approval from IEC. 489 healthy subjects (290 males and 199 females) were included in the study after getting the informed consent. Length of clavicle and height of individual were measured and mean was calculated. Regression equations were derived after statistical analysis.

Results: The values obtained by statistical analysis were found statistically significant. Equation were derived for estimation of height from right and left clavicles in males as well as females. The mean lengths of right sided clavicles are more than that of left sided clavicles in both the genders.

Discussion: Stature estimation is key parameter in the identification process of unknown individuals in which human remains are found in mutilated form or as skeletal remains. In the present study, we attempted to correlate the lengths of clavicle with stature of individual. The present study also proved that lengths of clavicles are more in males than in females which can be attributed to heavy built in males.

Keywords: Stature; correlation; mutilated; anthropological; decomposing.

Introduction

The clavicle is a modified long bone. It is the only long bone that lies horizontally, and shows variations in its morphometry. The locomotor behavior of superior extremity relies mostly on clavicle morphometry. The various features of clavicle help to decide the gender and height of the individual.

The length of clavicle is considered as an important anthropological parameter which is described as the distance between the lateral-most point of the clavicle in the acromio-clavicular joint and the medial-most point of the clavicle in the sterno-clavicular joint¹. Black S and Scheuer L¹ have mentioned that most of the adult morphological features of clavicle in humans are developed very early in fetal life well before birth³. Clavicle attains 80% of its total length by 12 years in males and 9 years in females⁴.
Stature is an important biological parameter in medico-legal forensic examination. The linear measurement of individual body parts plays a very important role in the field of forensic, anatomical and anthropological sciences. Out of various criteria for personal identification, stature carries the significant value. Anthropological database can be prepared from four basic parameters- age, race, stature and gender.

Establishment of an identity is very much important in both civil and criminal cases. Sometimes mutilated or decomposed bodies or the fragmentary remains of skeleton are brought for medico-legal examination. This is common in Indian setup where victims are attacked by wild animals in forests. This leads to difficulty in identification of the deceased. Literature shows many studies on stature estimation from percutaneous body measurements. But stature estimation from clavicle length is very rarely done especially in central India region. So, we have attempted to estimate the stature of individual from the clavicle length.

**Material and Method**

The present cross sectional, observational study was conducted in the department of Anatomy from October 2019 to February 2020 over a period of five months. The protocol was approved by the Institutional Ethics Committee. All the participants were informed about the procedure of the study and informed consent was taken before taking the measurements.

Total of 489 apparently healthy subjects of both the sexes were involved in the study. The age group of the participants was 18 to 30 years. Lower age limit of 18 years was considered because stature at this age is considered as adult height and multiplication factor remains mostly constant. Apparently healthy subjects without any noticeable deformities (congenital or acquired) of the spine or upper extremities were included in the study.

The length of clavicle was measured with the vernier caliper using palpable landmarks- most medial most point of the clavicle on the sterno-clavicular joint and the lateral most point of the clavicle on the acromio-clavicular joint.

Height of the individual was measured using stadiometer in standing position where he/she was asked to stand barefoot.

All the measurements were taken thrice and mean of it was used for documentation.

Statistical Analysis: All the values were analyzed statistically using SPSS software Version 22. Mean and standard deviations were calculated for both genders. Linear regression and correlation coefficients were calculated separately for males and females. Equations were derived in both genders individually for right and left sided clavicles.

Equation for height and right clavicle in females (FRTC): Height = 4.456 x FRTC + 98.178

Equation for height and left clavicle in females (FLTC): Height = 4.549 x FLTC + 97.445

Discussion

Stature estimation is key parameter in the identification process of unknown individuals in which human remains are found in mutilated form or as skeletal remains. Stature calculation from decomposing and incomplete skeletal remains is gold standard in establishing the identity of individual in anthropological studies and forensic examinations. Literature shows various studies undertaken on the stature determination from dry clavicle bones but very few studies are available where height is determined from the clavicle when the soft tissues are intact around it. It is easier to measure the length of dry clavicle as compared when it’s covered with soft tissues i.e. percutaneous measurements. In the present study, we attempted to correlate the lengths of clavicle with stature of individual.

The major conclusion in the present study is that the mean lengths of right sided clavicles are more than that of left sided clavicles in both the genders. Sehrawat JS and Pathak RK (2016) also observed bilateral asymmetry in all parameters like length, weight, mid-clavicular circumference etc. They further advocated that right clavicle is more robust due to its greater sagittal diameter and higher development of most of the ligaments and muscles than the left clavicles. Another differentiating factor might be physical activity pattern of right and side. King PR et al (2014) found longer left clavicle than the right clavicle in 65% male (4.55 mm) and 67% female (3.14 mm) cases. Cunningham et al (2013), found 28% clavicles were length-wise asymmetric (with up to 5 mm side differences). The different effects of genetic changes, mechanical loadings
and the muscular attachments might be responsible for such asymmetries of the clavicle. The various factors that may affect the lengths of clavicles are genetic, nutrition, geographical location, physical activity, and different races. The study carried out by Yashoda et al. (2011) in New Delhi population postulated that mean length of the left clavicle was higher than the mean length of the right clavicle for both sexes. Similar results were observed by Ukoha UU et al. (2019) in North Eastern Nigerian population.

The present study also proved that lengths of clavicles are more in males than in females which can be attributed to heavy built in males. Other possible factors might be higher skeletal size and body mass. The study conducted by Pande V et al. (2020) for correlation between stature and length of clavicle in female population in central India concluded with positive correlation and the linear relationship between the living stature and length of clavicle of either side. But the sample size was just 50.

**Conclusion**

We derived regression equations for height calculation from length of right and left clavicles in both males and females. These regression equations will be very helpful for calculating height of an individual from the length of clavicle.

Assessment of Diabetes Health Promotion Behaviors for Clients with Type 2 Diabetes Mellitus at Diabetic Center in Al-Diwaniya City

Haider Fahim Shafeea¹, Arkan Bahlol Naji²

¹MScN(c), Research Scholar, University of Baghdad, College of Nursing,
²Professor (PhD), University of Baghdad, College of Nursing, Community Health Nursing Department

Abstract

Background: Diabetes mellitus (DM) is a significant worldwide medical issue that causes high human, social, and financial expenses on nations at all pay levels. The constant hyperglycemia of diabetes is related to long-term damage, brokenness, and disappointment of different organs, particularly of the eyes, kidneys, nerves, heart, and blood vessels.

Method: A descriptive correlational design is used in this study which aims to measure health-related experiences and lifestyle behaviors for clients with type 2 diabetes for the period from (1st October 2019 to 27th August 2020). The study included a convenience sample of 358 clients with type 2 diabetes mellitus who were recruited from Al-Diwaniya Teaching Hospital at Diabetes and Endocrine Center.

Data were collected using a self-report study instrument that includes the socio-demographic sheet, the health profile, and the Type 2 Diabetes and Health Promotion Scale. The data were analyzed using Statistical Package for Social Sciences (SPSS) version 26 using the frequency, percent, arithmetic mean, standard deviation, Pearson correlation, Independent-sample t-test, and one-way analysis of variance (ANOVA).

The study results displayed that most of participants reported poor Physical Activity level (n = 266; 74.3%), more than two-fifth reported good Risk Reduction level (n = 148; 41.3%), less than two-fifth reported good Stress Management level (n = 134; 37.4%), less than two-fifth reported fair Healthy Diet level (n = 135; 37.7%), more than two-fifth reported good overall behavior (n = 193; 53.9%). Furthermore, there are statistically significant inverse correlations between participants’ age and their Physical Activity, Risk Reduction, Stress Management, Enjoying Life, and overall behavior.

Conclusion: The researcher concluded that the younger the clients, the poorer the Physical Activity, Risk Reduction, Stress Management, Enjoying Life, and overall behavior; the older the client, the better the Health Responsibility; the better socioeconomic status, the better the Physical Activity, Risk Reduction, Stress Management, Enjoying Life, and overall behavior.

Keywords: Diabetes, Health Promotion Behaviors, Clients, Type 2 Diabetes Mellitus, Diabetic Center.

Introduction

Diabetes mellitus (DM) is a significant worldwide medical issue that causes high human, social, and financial expenses on nations at all pay levels. The constant hyperglycemia of diabetes is related to long-term damage, brokenness, and disappointment of different organs, particularly of the eyes, kidneys, nerves, heart, and blood vessels(1).

Type 2 diabetes mellitus (T2DM) is an interminable illness which frequently creates for quite a long time with no clinical indications. It is the most widely recognized sort of diabetes around the world, the other two regular sorts being type 1 diabetes and gestational diabetes. T2DM represents 85%–95% of analyzed cases. Diabetes just as different ailments of abundance which incorporate heftiness and cardiovascular ailments are a significant wellbeing worry in the 21st century(2).
Health promotion behavior is the art and study of helping individuals find the cooperative energies between their core interests and ideal wellbeing, improving their inspiration to make progress toward ideal wellbeing, and supporting them in changing their way of life to push toward a condition of ideal wellbeing. Ideal wellbeing is a unique parity of physical, passionate, social, spiritual, and scholarly wellbeing\(^3\). Additionally, health promotion is more relevant today than ever in addressing general health problems. The health situation is situated at unique crossroads as the world is confronting a ‘triple weight of maladies’ established by the incomplete plan of transferable illnesses, recently rising and reappearing ailments just as the phenomenal ascent of non-communicable diseases (NCDs)\(^4\). Behaviors applicable to diabetes include self-checking of blood glucose levels, eating healthily, regular physical activity, taking medications as ordered, and the utilize of healthcare services, such as healthcare professional visits, and eye and foot assessments\(^5\).

**Method**

A descriptive correlational design is used in this study which aims to measure health-related experiences and lifestyle behaviors for clients with type 2 diabetes for the period from (1\(^{st}\) October 2019 to 27\(^{th}\) August 2020). The study included a convenience sample of 358 clients with type 2 diabetes mellitus who were recruited from Al-Diwaniya Teaching Hospital at Diabetes and Endocrine Center. Data were collected using a self-report study instrument that includes the socio-demographic sheet, the health profile, and the Type 2 Diabetes and Health Promotion Scale. The data were analyzed using Statistical Package for Social Sciences (SPSS) version 26 using the frequency, percent, arithmetic mean, standard deviation, Pearson correlation, Independent-sample t-test, and one-way analysis of variance (ANOVA).

**Results**

Figure 1. Participants’ distribution according to their BMI
Less than a half are overweight (n = 176; 49.2%), followed by those who are within normal BMI (n = 138; 38.5%), those who have class I obesity (n = 39; 10.9%), and those who have class II obesity (n = 5; 1.4%).

*Correlation is significant at the 0.05 level (2-tailed)., **Correlation is significant at the 0.01 level (2-tailed).

There are statistically significant inverse correlations between participants’ age and their Physical Activity, Risk Reduction, Stress Management, Enjoying Life, and overall behavior ($r = -.429$, at $p < 0.01$; $r = -.321$, at $p < 0.01$; $r = -.262$, at $p < 0.01$; $r = -.269$, at $p < 0.01$; $r = -.310$, at $p < 0.01$) respectively. On the other hand, there is a statistically significant positive correlation between participants’ age and their Health Responsibility ($r = .255$, at $p < 0.01$).
There are statistically significant positive correlations between participants’ socioeconomic status and their Physical Activity, Risk Reduction, Stress Management, Enjoying Life, and overall behavior ($r = -.461$, at $p < 0.01$; $r = -.579$, at $p < 0.01$; $r = -.499$, at $p < 0.01$; $r = -.451$, at $p < 0.01$; $r = -.482$, at $p < 0.01$; $r = -.750$, at $p < 0.01$) respectively. There is statistically significant inverse correlation between participants’ BMI and their Physical Activity ($r = -.199$, at $p < 0.01$). On the other hand, there are statistically significant positive correlations between participants’ BMI and their Health Responsibility and Healthy Diet ($r=.371$, at $p<0.01$; $r=.126$, at $p<0.05$) respectively.

There are statistically significant differences in Physical Activity, Risk Reduction, Stress Management, Enjoying Life, Healthy Diet, and overall behavior among the socioeconomic class groups (P-value = .000, .000, .000, .000, .000, .000) respectively.

**Discussion**

Physical activity is one of the most important modifiable determinants of disease. The study findings that most of participants reported poor Physical Activity level, followed by those who reported fair level, and those who reported good level. This finding is consistent with(6) who concluded that most of study participants have low level of physical activity. More than two-fifth reported good Risk Reduction level (n = 148; 41.3%), followed by those who reported fair level (n = 137; 38.3%), and those who reported poor level (n = 73; 20.4%). This finding could be explained as that clients may sensitizes the seriousness of DM. This finding is consistent with(7) who stated that the scores of Risk Reduction for more than a half of the study participants were high. Less than two-fifth reported good Stress Management level, followed by those who reported fair level, and those who reported poor level. This finding is lower than that reported by(8) who reported that most of study participants have good response to stress management. Less than two-fifth reported fair Healthy Diet level (n = 135; 37.7%), followed by those who reported poor level (n = 134; 37.4%), and those who reported good level (n = 89; 24.9%). This finding reflects participants’ poor health literacy; particularly about the healthy diet and its vital role in management of DM. This finding is lower than that reported by(7) who reported that most of the study displayed good commitment to healthy diet. Ultimately, more than two-fifth reported good overall behaviour, followed by those who reported poor level, and those who reported fair level. This finding goes in line with(7) who reported that more than a half of the study participants have good response to the domains of Physical Activity, Risk Reduction, Healthy Diet, and Stress Management. There were statistically significant inverse correlations between participants’ age and their Physical Activity, Risk Reduction, Stress Management, Enjoying Life, and overall behavior. On the other hand, there is a statistically significant positive correlation between participants’ age and their Health...
Responsibility. This finding could be explained as that the younger the client, the more the physical activity level they enjoy which enable them to adopt healthier health-promoting behaviors. Further cross-tabulation demonstrates that younger clients have higher educational levels. As such, clients who have higher educational levels could have better health awareness which provoke them to adopt health promotive behaviors. This finding is congruent with\(^9\),\(^10\) who concluded that there was a statistically significant correlation between participants’ age and the Physical Activity, Risk Reduction, Stress Management, Enjoying Life, and their overall behavior. There were statistically significant positive correlations between participants’ socioeconomic status and their Physical Activity, Risk Reduction, Stress Management, Enjoying Life, and overall behavior. This finding could be explained as that the better the socioeconomic status the family has, the greater the opportunity to engage in physically active lifestyle, healthier diet, and seeking mental health counseling. This finding is consistent with\(^11\),\(^12\) who stated that there was a significant effect of socioeconomic status and each of Physical Activity, Risk Reduction, Stress Management, Enjoying Life, and overall behavior. There was a statistically significant inverse correlation between participants’ BMI and their Physical Activity. This finding could be explained as that the higher the body mass index, the poorer the ability of the individual to practice physical activity. On the other hand, there were statistically significant positive correlations between participants’ BMI and their Health Responsibility and Healthy Diet. This finding be explained as that as the individuals has high BMI, they may sensitise a greater health threat which render them be more responsible in terms of their health and try to adopt a healthy diet. There were statistically significant differences in Physical Activity Health Responsibility among the BMI groups. Further post hoc analysis demonstrates that clients whose BMI is within normal have better Physical Activity levels. This finding could be explained as that the physical movement for individuals whose BMI is within normal would be easier than those whose BMI is higher. There was statistically significant difference in Physical Activity, and overall behavior among the socioeconomic class groups. Further post hoc analysis displays that the better the socioeconomic class, the better the Physical Activity level. This finding could be explained as that individuals with better socioeconomic status have better capabilities to have physical activity devices and/or seeking sport clubs or gyms than those with poorer socioeconomic status. There was statistically significant difference in Risk Reduction among the socioeconomic class groups. Further post hoc analysis displays that the better the socioeconomic class, the better the Risk Reduction abilities. This finding could be explained as that individuals with better socioeconomic status have higher educational levels which in turn enable them to have better capabilities of Risk Reduction. There was statistically significant difference in Stress Management among the socioeconomic class groups. Further post hoc analysis exhibits that the better the socioeconomic class, the better the Stress Management abilities. This finding could be explained as that individuals with better socioeconomic status could not be occupied with earn living. In other words, poor socioeconomic status could occupy individuals with earn living and hinder them from seeking mental health counseling. There was statistically significant difference in Enjoying Life among the socioeconomic class groups. Further post hoc analysis exhibits that the Enjoying Life scores were higher among individuals with better socioeconomic class. This finding could be explained as that individuals with better socioeconomic status could have better opportunities for recreation and leisure than those with poorer socioeconomic status. There was statistically significant difference in Health Diet among the socioeconomic class groups. Further post hoc analysis displays that the better the socioeconomic class, the better the Health Responsibility abilities. There was statistically significant difference in Healthy Diet among the socioeconomic class groups. Further post hoc analysis displays that the better the socioeconomic class, the better the Healthy Diet level. This finding could be explained as that individuals with better socioeconomic status have better capabilities to buy healthy foods than those with poorer socioeconomic status. There was statistically significant difference in overall Health Promotion Behaviors among the socioeconomic class groups. Further post hoc analysis displays that the better the socioeconomic class, the better the Health Promotion Behaviors. This finding could be explained as that individuals with better socioeconomic status have better Physical Activity, Risk Reduction, Stress Management, Enjoying Life than those with poorer socioeconomic status.

**Conclusions**

1. Most of study subjects are physically inactive and have poor stress management abilities.
2. Most of study subjects have been used to unhealthy diet.
3. The younger the clients, the poorer the Physical Activity, Risk Reduction, Stress Management, Enjoying Life, and overall behavior.

**Recommendations:**
1. There is a need to establish health education activities that aim to improve the physical activity level for individuals with DM type 2.
2. There is a need to establish health education activities to younger clients with DM type 2 that serve to raise their health awareness about the Health Responsibility.
3. There is a need to initiate health promotion activities that target older clients with DM type 2 that seek to improve their Physical Activity, Risk Reduction, Stress Management, and Enjoying Life.

**Conflict of Interest:** The researchers confirm that there is no any conflict of interest.

**Source of Funding:** This study is self-funded.

**Ethical Clearance:** The researchers obtained the ethical approval from the University of Baghdad, College of Nursing.

S (ORL-HNS), MD-CABS (ORL-HNS), at Al-Sadr Medical City in Najaf, 4M.B.Ch. B, Resident Doctor at Al-Sadr Medical City in Najaf

Abstract

Background: The use of Endoscope is increasing for otologic surgery because it is providing anew perspective on the intricate anatomy of the middle ear.

Study Design: Cross sectional study.

Objective Evaluation of outcomes of endoscopic aided transcanal underlay tragal cartilage Myringoplasty.

Patients and Method: This were a prospective clinical study included Fifteen patients who were operated on for chronic otitis media (COM) and their data and findings. All operations and surgical procedures were performed only with the use of a tragal cartilage graft, lining, and total transcanal endoscopic access. We assessed the postoperative graft up-taking rate and assessed hearing at 6-8 weeks.

Results and Discussion: Out of the 15 patients (9 female and 6 male) the graft take rate was 86% and the comparison of pre and postoperative mean AB gap revealed that the mean AB gap was 31 dB preoperatively while it changed (improved) to 16 dB at 6 to 8 weeks postoperatively, with a statistically significant difference (P<0.05).

Conclusions: Endoscopic Myringoplasty is minimally invasive, effective and safe procedure with good success rate and short duration.

Keywords: Endoscope, cartilage, Myringoplasty.

Introductions

Myringoplasty: Myringoplasty can be described as the surgical repair of tympanic membrane.1(1) Ear surgeries have traditionally been performed using a surgical microscope. Endoscopes have improved the field of otorhinolaryngology. Nowadays, various surgical procedures are easily performed using endoscopes, which reduces the morbidity of cases. Endoscopes are rapidly substitute the microscopic procedures in the otology practice, as first choice for assisting various operations.2(2)

Indication of Myringoplasty:

1. Infection, the presence of a perforation exposes the middle ear to the risk of recurrent infection from external sources.
2. Hearing loss, the repeated insult of infections is not only unpleasant for the patient but can affect hearing through both the presence of mucopus and the potential destruction of the ossicular chain.
3. Social to enable swimming without the need to protect the ear from water, particularly in children, is a relative indication for myringoplasty.

**Contra Indication:**

1. Cholesteatoma
2. Contralateral hearing
3. Bilateral perforation
4. Eustachian tube dysfunction

**Approaches and Incisions:**

1. The transcanal method is generally used for minor posterior perforations or can be used to doperforations in medium sized, when the anatomy of the ear canal is adequate and when complete perforation and the anterior edge of the tympanic membrane are visible.
2. Endaural access can be used for any perforation. A self-retaining retractor can be used with this approach.
3. Postauricular approaches. These can be applied in all sizes of and can provides the best viewing angle for anterior TM even without canaloplasty.\(^{(3)}\)

**Techniques:**

**Lateral graft technique (overlay):** In tympanoplasty using the lateral technique, also known as the overlay procedure (technique) in which the graft is laterally rested to the fibrous layer of the TM ruminants but medially to the malleus handle. Such procedures need to completely remove the squamous epithelium from the TM remnant lateral surface to prohibit the iatrogenic cholesteatomas. Bone canaloplasty is also required for preview and correct placement of the graft.\(^{(3)}\)

**Medial graft technique (underlay):** medial to the entire tympanic membrane, with an elevation of the skin flap of the auditory canal, together with the tympanic membrane, the most used for access, stabilization of the graft below the fibrous annulus.\(^{(1)}\)

**Graft Selection:**

1. Cartilage Myringoplasty
   
   **Indications**
   
   High risk perforation includes-1
   
   **Surgical Revisions**

   **Anteriorly to malleus**
   
   **Perforation Drainage during surgery**
   
   **Perforation exceeding 50%**

   When traditional techniques used in bilateral perforations they are usually associated with higher failure rate

2. Atelectatic ear: one of the most important indications for cartilage tissue tympanoplasty

3. Cholesteatoma: use of the surrounding cartilage in this operation, the shield and the posterior half of the tympanic membrane (cholesteatoma) were aimed at reducing the frequency of recurrent atrophy, as well as retracting the sac in these problem cases.

4. Pediatric Patients: A universal method for reconstruction of a ruptured TM should be avoided in pediatric patients in years of predisposition to otitis media (<3 years). It’s boring if the opposite ear is normal Tympanoplasty is performed on a child under 4 years old. Abnormal contralateral ear measurements are currently being performed, and adenoidectomy and tympanoplasty are usually delayed up to 7 years. If at this stage the disease is still contralateral, the ear can be considered at high risk of failure.\(^{(4)}\)

   The main advantages of cartilage are its stiffness and extremely low metabolic requirements, making it particularly suitable for adverse conditions such as partial perforations, adhesive otitis media, and reoperations.\(^{(5)}\)

   Cartilage may be harvested with its attached perichondrium from the tragus or the concha. Tragal cartilage is thicker and flatter than conchal cartilage, and it may be more suitable for larger perforations.\(^{(6)}\)

**II. Temporals fascia graft:** The anterior or posterior sectors perforations were restricted to one sector with normal tubaric function tests, with or without retractions of the pars tensa.\(^{(5)}\)

**III. Other grafting materials have also been used, including loose areolar tissue, vein, and fat. Perichondrium is frequently used in tympanoplasty.**

**Complication:**

1. Retraction of the drumhead following grafting can occur in up to 10%, with some suggesting the use of cartilage to try to prevent this.
2. Elevation of the anteroinferior aspect of the tympanic membrane runs the risk of anterior blunting, a risk with both overlay and underlay techniques.

3. The incidence of iatrogenic cholesteatoma, particularly with the overlay technique which runs a higher risk of leaving some squamous epithelium medial to the graft, can be as high as 4.4%.

4. Myringitis can occur, influenced by the presence of infection or choice of material, though most cases resolve within 3 months with short-term topical medication and observation. 

Endoscopic Middle EAR Surgery (historical view): The endoscopy of the middle ear firstly presented in 1967 by Mer. Et al. for diagnosis and for surgical procedures (El-Guindy, 1992). Finally, surgery has traditionally been performed on the middle ear. Under the microscope, this is now gradually achieved endoscopically.

Many producers of rigid Hopkins rod lens endoscopes with different diameters, but those for endoscopic ear surgery were come with diameters (2.7, 3 and 4 mm). larger size endoscopy was giving more better picture scope and quality, accordingly the best one to use in this operation is the largest one which can fit into canal of the ear.

Advantage of ENDOSCOIC EAR Surgery:

1. Ability to see outside the axis of large surgical instruments. When using a microscope, the field of view is most affected by the use of instruments and possibly the hands of the surgeon. In endoscopic surgery, the surgeon has a panoramic view of the area outside the stem of the instrument.

2. When using a microscope, it is important to position the structure almost at right angles to the axis of the microscope so that the endoscope can see structures in the same plane as the endoscope. Consequently, structures such as the ear canal, facial recoil and tegmen are much better visualized with an endoscope.

3. Operative time is shorter.

Disadvantage of Endoscopic Ear Surgery: Endoscopic surgery also has disadvantages. One-handed surgery is possible with the endoscopic technique, but restricting one-handed access can be an obstacle in certain situations, such as severe bleeding, where endoscopic vision may be blocked by blood and the operation is difficult. In addition, the autoendoscope itself can cause injury, including thermal injury, due to the light emitted from the endoscope tip. Mist can often accumulate over the endoscope.

Unfavorable anatomy of the ear canal or anterior perforation creates technically complex microscopic transcanal procedures and ultimately results in a high failure rate.

The endoscope offers a wide and comprehensive transcanal view of all elements of this procedure: the ear canal, tympanic membrane and eardrum, without the need to constantly move the microscope, even with an anterior ridge.

Objectives: To clinically assess the postoperative outcomes of endoscopic assisted Trans canal underlay tragal cartilage myringoplasty.

Patients and Method:

Study Design: This was prospective single group clinical trial been conducted at Al-Sadr medical city in Najaf province, Iraq in the department of otolaryngology-Head and Neck surgery during the period from (January 2019 to march 2020).

All participants were informed about the study: We have analyzed (15) patients (10 female and 5 male) their age ranged between 18 to 35 years. All of them complained of chronic suppurative otitis media of mucosal type and decrease hearing.

Hearing assessment done one week before the operation by PTA.

The surgeries were done entirely under total endoscopic transcanal method by means of tragal cartilage as an implant, motivated method.

We have assessed the postoperative implant uptake and done a hearing assessment post operatively after 6-8 weeks.

Inclusion Criteria: Patients with inactive mucosal CSOM with conductive hearing loss.

Statistical Analysis: Data of all patients were checked for any errors or inconsistency and then analyzed using the statistical package for social sciences (SPSS) version 24). Appropriate statistical tests and procedures were applied according the type of variables and requested outcome. Level of significance set at 0.05.
Results

Fifteen patients who met the inclusion criteria, fit for operation and consented to participate were selected and recruited in the study; their average age was 25.1±5.4 years. Additionally, 60% of the patients aged 18-25 years. Females were dominant gender, represented 66.7% of the studied group and the remaining 5 patients were males. Subtotal perforation of tympanic membrane was the more frequent type of perforation, contributed for 46.7%, followed by anterior perforation (40%) and the least frequent type was posterior perforation, (Table 1).

The success was considered when there is a good graft uptake, while those who failed and those with small residual perforation considered as unsuccessful, therefore, 13 out of the 15 patients had successful endoscopic myringoplasty giving a success rate of 86.7%, (Figure 1).

According to the air bone gap (AB gap) values at 6-8 weeks postoperatively, 5 patients reached an ABG of 10 dB, 6 patients with 15 dB, 2 patients with 20 dB, one patient with 25 dB and one patient with 35 dB ABG. Moreover, at 6-8 weeks postoperatively, the mean ABG reduced from 31.0 ± 3.4 at preoperative to reach 16.0 ± 6.8 dB with high-significant difference, (P. value<0.001), as shown in (Fig. 2).
Further analysis was performed to assess the relationship between success rate and other variables including age, sex, site of perforation and time of surgery, none of these variables showed a significant effect on or correlation with the outcome of endoscopic myringoplasty, in all comparisons, P. value non-significant > 0.05, (Tables 3 and 4).

Discussion

Endoscopes have been used for middle ear inspection for decades. However, recent improvement of camera and optical technologies have yielded endoscopes that provide extremely high-definition video with a wide-angle field of view, surgeons are increasingly using endoscopes not only for visual inspection, but also for dissection. The increased resolution and field of view of current endoscopes have provided surgeons with a fresh look at middle ear anatomy. (13)

In the present study we assessed the surgical outcomes in addition to the feasibility of procedures in 15 patients who were operated on with Endoscopic-Transcanal-Myringoplasty with the use of tragus-cartilage. In our study, the graft take rate was 86.7% (13 out of 15), and the other 13.3% (2 out of 15) with subtotal perforation, one failed due to infection and the other one residual small perforation present that healed by cauterization after 3 months of surgery. Comparable to Amit Saini et al study of 42 patients (19 were male and 23 female) in 2018 was 90.9 % is consistent with our study. (8)

In Muaaz Tarabichi study in 2010 the closure of perforation was evident in 59 ears, a success rate of 92%. (14) Gokgoz MC et al study at 2018 the take rate was 94% of fifty patient and 6 months postop. (15) Another study conducted by Leandro De Borborema Garcia et al, study in 2015, included 22 patients found that after 3 months of surgery, closure of TM perforation reported in 86.4% of cases. (16) Raj et al at 2001 found graft take rate 90% this result is consistent with our study. (17) A significant improvement in the hearing outcome was reported where the average ABG was 31 dB preoperatively and it changed (improved) to 16 dB at 6 to 8 weeks postoperatively, with significant difference (P<0.05).

ABG improved to 11.91+-8.41 db in Dipesh Shakya et al study comparable to our study. (17) The mean ABG was 22.40 db and improved to 9.1 db by Amit Saini et al study. (8) In the study of Dawood MR, in 2017 of 26 cases of successful myringoplasty, the mean ABG reduction was 20.73 db (18), and this is consistent with our study. Average air bone gap closure achieved was 10.1 db the study of 30 patient by Munish Kambatattishekharappa et al (19), this result compatible with our study. Mokbel et al at 2015 reported improved hearing outcome in patients undergoing myringoplasty and is consistent with present study. (20)

In present study, the operative time ranges between 50-90 min, with the mean of 67 min and this is consistent with Ghaffar et al 2006 they reported that the mean operative time 62-85 min (21) Huang et al (2016) reported the mean operative time 80.4 in patient underwent endoscopic myringoplasty. (22), the present study better than this study. In the study of Patel et al 2015 mean time was found to be 75 min and this is comparable to our study. (23) Furthermore, Raj et al. evaluated the value of rigid-endoscope in management of of dry central perforation of TM, their findings when compare endoscopic Myringoplasty versus conventional microscope indicated 90% uptake rate in endoscopic versus 85% in the microscopic, these findings supported ours. (17)

Guer RS et al. in their research showed that changes in the external auditory canal, such as stenosis, tortuosity and protrusions of bones, interfere with the view of TM under a microscope. Therefore, it is necessary to manipulate the patient’s head or microscope several times to see all parts of the TM. Sometimes, despite manipulation, TM cannot be fully visualized; hence canaloplasty must be performed. This can increase up the operation time. Conversely, endoscope brings the eyes of surgeons close to the scope end. The wide zero degree viewing angle allows visualization of the entire TM. Saves surgery time without the need to regularly adjust the patient’s head or doing a canaloplasty. (24)

Sekaattin Gulsen and others stated that transcanal endoscopic tympanoplasty is reliable alternate to Microscopy tympanoplastyin management of COM, with comparable success rate of graft uptake and outcomes of hearing (25) Similarly, Amit et al. in their study concluded that even novices and junior surgeons can used this procedures as it is safe reliable and with good outcomes, hence surgeons, can apply endoscopic procedure in this way without fear of serious complication or adverse outcomes. (17)

Conclusion

Endoscopic myringoplasty is minimally invasive, effective and safe procedure with good success rate and short duration.

Abstract

Background: Cervical cancer is the second leading cause of cancer deaths in low and middle-income countries. The International Agency for Research on Cancer (IARC) gauges that the frequency of cervical disease will increment by 75% worldwide by 2030.

Method: This descriptive correlational study was carried out to examine women’s readiness to perform Pap smear test. to (1) assess women’s readiness to perform Pap Smear test, (2) identify the association between woman’s age, family’s socioeconomic status, gravidity, parity, abortion, and their Stages of Change for conducting Pap Smear test, the Perceived Susceptibility to contract cervical cancer, the Perceived Seriousness of cervical cancer, the Perceived Barriers to conduct Pap Smear test, the Perceived Benefits of conducting Pap Smear Test, and the Health Motivation to conducting Pap Smear Test, and (3) investigate the differences in the Perceived Susceptibility to contract cervical cancer, the Perceived Seriousness of cervical cancer, the Perceived Barriers to conduct Pap Smear test, the Perceived Benefits of conducting Pap Smear Test, and the Health Motivation to conducting Pap Smear Test between the groups of the Stages of Change for conducting Pap Smear test woman’s level of education, family’s socioeconomic class, and family type.

Results: The target population of this study was selected from adult, married women on social media. The SR used a self-reported online survey for data collection. The SR prepared the online survey and published its link on the social media pages and groups, where the study objectives were demonstrated to study subjects

Conclusion: Most of the women are precontemplators. The older the age, the greater the Susceptibility to contracting cervical cancer and the better the family’s socioeconomic status, the greater the greater Susceptibility to contracting cervical cancer.

Keywords: Theoretical Framework, Health Belief Model, Women’s Readiness, Pap Smear.

Introduction

Cervical cancer is the second leading cause of cancer deaths in low and middle-income countries(¹). In Iraq, cervical disease is the twelfth malignant growth among ladies and the tenth among ladies somewhere in the range of 15 and 44 years old. The annual incidence is 1.2 per 100,000 and mortality rate of cervical cancer is estimated at 1.4 per 100,000 and there is rising threat to 0.3% for women in all her life. In Asia, the region which Iraq belongs, about 2.5% of female in the country are exposure to cervical HPV-16/18 infections during aperiod of time and 72% of invasive cervical cancers are documented to HPVs 16 or 18. Nononcogenic subtypes of HPV, e.g., 6 and 11, lead to low-grade cervical lesions and genital warts(²). These lesions if left long period without treatment, patients contact to high risk to HPV, so these cases must follow up and testing for HPV DNA, colposcopic evaluation and biopsy which preventcervical disease. gauges demonstrate that consistently 311 ladies are determined to have cervical malignancy and 212 pass on from the sickness (USAID, 2013). In view of the public program, Pap smear is offered to all ladies after marriage in medical services places gratis. This was accomplished for three back to back years, and if three ordinary Pap smear tests were gotten, after that this test ought to be rehashed like clockwork(⁴).
Fitting that programming may expect organizers to consider different models or speculations when they create projects and intercessions to help way of life conduct changes. A blend of approaches assists with offering the best help and direction to people, gatherings and networks as they work to create sound way of life practices(5).

Method

The study design for this study is descriptive predictive design. The descriptive design can be used to predict the value of one variable based on the values obtained for another variable or variables. Prediction is one approach for examining causal relationships between variables. The study was conducted at across Iraq by an online survey. The study included a non-probability, convenience sample of adult women. The SR prepared the online survey and published its link on the social media pages and groups, where the study objectives were demonstrated to study subjects. The target population of this study was selected from adult, married women on social media. The SR used a self-reported online survey for data collection. Data were collected for the period from February 20th, 2020 to March 31st, 2020.

Data were collected through a self-report instrument that includes First part: The study instrument includes the socio-demographic sheet, the body mass index (BMI), and Second part: the Mental Health Belief Model AssessmentThe Perceived Susceptibility Scale, The Perceived Benefits Scale, Self-Efficacy Scale, Health Motivation, The Perceived Severity Scale, and The Perceived Barriers Scale. Participants indicate how much they agree or disagree with each statement on a scale of 1 to 5 (1 = strongly disagree, 2 = Disagree, 3 = neutral, 4 = agree, 5 = strongly agree). Higher scores indicate stronger feelings regarding that construct. This scale originally demonstrated fair to very good internal consistency reliability. The Health Belief Model Scale for Cervical Cancer and the Pap Smear also demonstrated excellent discriminant validity(6). Data were analyzed using the Statistical Package for the Social Sciences (SPSS) for Windows, version 26, Chicago, IL. The statistical measures of frequency, percent, mean, standard deviation were used. The inferential statistical measures of Chi-square, and one-way analysis of variance (ANOVA) were used.

There is no statistically significant difference in the Health Belief Model constructs among readiness to Pap smear test groups.

**Discussion**

Most are in the Precontemplation Stage of Change (n = 263; 67.8%), followed by those who are in the Contemplation Stage of Change (n = 78; 20.1%), those who are in the Termination Stage of Change (n = 14; 3.6%), those who are in the Action Stage of Change (n = 13; 3.4%), those who are in the Preparation Stage of Change (n = 12; 3.1%), and those who are in the Maintenance Stage of Change (n = 8; 2.1%). These findings reflect that study subjects do not realize how severe the cervical cancer is and how important performing the Pap smear is in detecting the potential cervical cancer in early time. These findings are consistent with that obtained by Krok(7) who stated that women (84.4%) at Visit 1 were categorized in the Contemplation or Preparation Stages of Change, and (15.6%) women were in the Precontemplation Stage of Change and Kwak, (8) who concluded that 15.5% of women were in the Precontemplation SOC, 21.3% in the Contemplation, 31.3% in the Action, 15.4% in Maintenance, 10.4% in the Relapse risk, and 6.1% in the Relapse SOC; Abdullah and Su (2013) who concluded that more than two-fifth were in the Contemplation Stage of Change (43.8%), followed by those who were in the Precontemplation Stage of Change (35.8%), and those who were in the Preparation Stage of Change (20.4%).

On the other hand, these findings are incongruent with; Tung(9), who concluded that more than a half of the subjects were classified into the Maintenance Stage of Change (55.9%), followed by those who were in the
Contemplation Stage (17.6%), Relapse Stage of Change (14.7%), Precontemplation Stage of Change (9.8%), or Action Stage of Change (2%); Tung\(^{(10)}\) who concluded that more than a half of subjects were in the Maintenance SOC, followed by those who are in Precontemplation SOC (17%), those who are in the Relapse SOC, those who were in the Contemplation SOC (10%), the Action SOC (3%). None of subjects were in the Preparation and Relapse risk SOC; Tung\(^{(11)}\) who concluded that most of the participants were in the maintenance stage (60.3%) and in the Contemplation Stage of Change (25.6%), with smaller portions in the Action Stage of Change (1.7%), the Preparation Stage (5.8%), the Precontemplation Stage (4.1%), or the Relapse Stage (2.5%). None of the participants were classified in the relapse risk stage\(^{(12)}\) who concluded less than a half (46.3%) of the subjects were in the Maintenance Stage, followed by those who were in the Precontemplation Stage (18.8%), those who were in in the Relapse Stage of Change (16.3%), those who were in the Contemplation Stage of Change (10%), and Action Stage of Change (8.8%); Tung\(^{(11)}\) who concluded that most of subjects were in Maintenance Stage of Change (60%), followed by those who were in the Contemplation Stage of Change (26%), Preparation (6%), Precontemplation (4%), Relapse (2%), and Action Stage of Change (2%); Tung\(^{(12)}\) who concluded that less than a half (46.3%) of the subjects were in the Maintenance Stage, followed by those who were in the Precontemplation Stage (18.8%), those who were in in the Relapse Stage of Change (16.3%), those who were in the Contemplation Stage of Change (10%), and Action Stage of Change (8.8%); Tung\(^{(10)}\) who concluded that less than a half (46.3%) of the subjects were in the Maintenance Stage, followed by those who were in the Precontemplation Stage (18.8%), those who were in in the Relapse Stage of Change (16.3%), those who were in the Contemplation Stage of Change (10%), and Action Stage of Change (8.8%).

There was a statistically significant positive correlation between women’s age and their Susceptibility to contracting cervical cancer. This finding could be explained as that the better the socioeconomic status the family is, the greater the opportunity to use to unhealthy life style including physical inactivity and unhealthy diet which increase the chance of developing different types of cancer including cervical cancer. There was no statistically significant difference in the Health Belief Model constructs among readiness to Pap smear test groups. This finding reflects that study subjects lack health awareness that can motivate them to adopt health preventive behaviors including Pap smear testing. There was no statistically significant difference in the Health Belief Model constructs among SE status groups. This finding indicates that women; irrespective of their family’s socioeconomic status, have invariant, unsound health beliefs which do not motivate them or hinder them from adopting health preventive behaviors. There was no statistically significant difference in the Health Belief Model constructs between access to healthcare services groups. This finding reflects people’s dissatisfaction with the quality of healthcare delivery system in Iraq. That is, whether the access to healthcare services was easy or difficult, this doesn’t matter for women in terms of seeking the required healthcare services including Pap smear testing. There was a statistically significant difference in women’s Perceived Seriousness of cervical cancer among self-rated health status groups. The post hoc analysis using Scheffe test demonstrates that the Perceived Seriousness of cervical cancer scores were higher among women who described their general health as poor.

**Conclusion**

1. Most of the women are precontemplators.
2. The older the age, the greater the Susceptibility to contracting cervical cancer.
3. The better the family’s socioeconomic status, the greater the greater Susceptibility to contracting cervical cancer.
4. Women’s health beliefs do not predict their readiness to Pap smear test.
5. The Perceived Seriousness of cervical cancer scores were higher among women who self-rated health status as poor and vice versa.
Recommendations:

1. Education activities to raise awareness need to have cervical screening early.

2. It needs educational activities to increase women’s awareness of the risks of cervical cancer.

3. Health education needs to follow a healthy diet and know its impact on cervical cancer, from fitness and a healthy diet.

4. Improving the quality of health care services and facilitating access to them.

Conflict of Interest: The researchers confirm that there is no any conflict of interest.

Source of Funding: This study is self-funded.

Ethical Clearance: The researchers obtained the ethical approval from the University of Baghdad, College of Nursing.

Abstract

Background/Objectives: The purpose of this study is to evaluate the prevalence and related risk factors of problem drinking in the Korean elderly population.

Method/Statistical Analysis: Participants (n=817) aged 65 years or older were selected from the Korea National Health and Nutrition Examination Survey [KNHANES] of 2018. Sociodemographic characteristics and AUDIT-C score were obtained from the KNHANES dataset. AUDIT-C scores were categorized into two groups, including low risk, high-risk alcohol drinking according to WHO guidelines. Data analysis was performed using SPSS WIN 25.0 program.

Findings: In this study, the prevalence of high-risk alcohol drinking was 31.9%, respectively. Adjusted mean AUDIT score was higher in men, younger elderly individuals, as well as those with lower education levels and those that smoked. Results revealed that demographic variables, including sex, age, education level, and smoking, were important factors affected high-risk drinking. In particular, since family number and smoking were the most significant risk factor, the odds ratio for high-risk drinking among participants that smoked was 2.49 [(95% confidence interval (CI)=1.31-4.71)].

Improvements/Applications: This study suggests that men, younger age, low educational level, and smoking are the risk factors for a high-risk alcohol drinking

Keywords: Elderly, AUDIT score, Demographic factor, High risk alcohol drinking, Problem drinking.

Introduction

Problem drinking in Korea has become a serious social issue. Reportedly, 158 of 2,657 elderly men and 48 of 2,080 elderly women in Korea have demonstrated problem drinking in a study¹. Considering that the elderly do not live with their children or engage in social activities after retirement, the reported number might be lower than the actual number. Furthermore, as they show a characteristic tendency to lie about their drinking because of the negative stigma attached to this problem²³, the actual magnitude of problem drinking among the elderly could be more serious than what studies have indicated. In fact, a study examining 5,102 Korean adults showed that the percentage of the elderly diagnosed with alcoholism was lower than that of young or middle-aged adults with problem drinking⁴. Moreover, the pattern of drinking among the elderly was such that while the overall drinking quantity was low, the frequency was high as they favored aperitifs or relied on alcohol as a sleep aid. They also habitually drank stashed alcohol, a fact often neglected as a problem by the elderly and family members, which poses a challenge in improving the condition³⁵⁶.

As drinking leads to serious social consequences, there is an urgent need to develop response measures against it. Drinking causes physical⁷ and psychological⁸ problems, and may lead to impulsive crime or accidents⁹. The problems related to drinking often cause a tremendous social loss. The blood alcohol concentration of the elderly rises more rapidly than in young individuals because of reduced metabolic functions and body fluids. In addition, if they have a chronic disease,
the interaction between the currently administered drug and even a small quantity of alcohol may change the drug efficacy or induce side effects \[^{10,11}\].

Therefore, a social need to find solutions to problem drinking among the elderly has been highlighted. Thus far, many studies have investigated diverse factors related to problem drinking among the elderly. Problem drinking is associated with biological factors such as age and gender \[^{12}\], psychological problems such as stress and depression \[^{4}\], and family type such as living with a family member or not \[^{13}\]. Previous studies in Korea and overseas have described the relationship between problem drinking and various factors; however, identifying the correlation between problem drinking and socio-demographic and health-related factors has remained a challenge based on the latest dataset.

Thus, this study set out to determine the factors related to problem drinking among the Korean elderly to provide basic data for advancing practical measures to improve health among the elderly. To this end, the status of problem drinking in the Korean elderly population is analyzed, and related factors are identified based on socio-demographic and health-related data. Specifically, this study set out to:

- Examine the differences between low-risk and high-risk groups regarding problem drinking according to the socio-demographic and health-related characteristics of the Korean elderly population, and
- Analyze the factors related to high-risk problem drinking among the elderly in Korea.

**Method**

1. **Research Method:** This is a secondary data analysis study that identifies factors related to High-Risk Drinking in Korean Elderly by employing the 7th Korea National Health and Nutrition Examination Survey (KNHAES) conducted nationwide in 2018.

2. **Data Collection:** The KNHAES was conducted under approval by the Institutional Review Board (IRB) of KCDC (No. 2018-01-03-P-A). On April 5, 2020, the present study’s researcher received approval for data use and downloaded them via the link on the KCDC’s website (https://knhanes.cdc.go.kr), which releases and provides the KNHAES’s raw data. In addition, this study underwent a review for an examination exemption (IRB No. SMU-EX-2020-02-001) at the IRB of the organization to which the research belongs. The 2018 KNHAES involved 7,992 respondents in total. In the present study, 817 individuals without missing values were selected as final subjects from elderly people aged 65 or above.

**Research Tools:**

**Sociodemographic Characteristics:** As the subjects’ general characteristics, gender, age, areas of residence, education levels, marital status, income levels, and occupations were used. Of these variables, areas of residence were divided into “urban” and “rural”. The current marital status was reclassified into “having a spouse” and “living together”, and occupations were also reclassified into “having” and “not having.”

**Health Behavior:** Health behaviors include smoking, drinking, engaging in exercise or not, subjective health conditions, suicidal thoughts, and perceived stress. The number of comorbidities means the number of diseases from which one suffers after doctors’ confirmation. For smoking, those who had smoked at least five packs in their lifetime and were currently smoking were classified as answering “yes”. For drinking, those who had drunk at least one glass of alcohol over the past one year were classified as answering “yes.” In addition, those who performed at least one of 1) strenuous physical activities that cause severe shortness of breath, 2) moderate physical activities that cause moderate shortness of breath, and 3) walking were classified as engaging in regular exercise. Subjective health conditions were reclassified into “good”, “average”, and “poor.” For suicidal thoughts, the original survey’s answers were used without change. In addition, perceived stress was reclassified into “high” and “low.”

**Problem Drinking:** For problem drinking, the AUDIT-C (Alcohol Use Disorders Identification Test-Consumption) score of three questions on drinking frequency, typical drinking quantity, and binge drinking frequency was used. Each question was categorized as follows: (i) Drinking frequency: None, less than once a month, two to four times a month, two to three times a week, four times a week or more; (ii) Typical drinking quantity per week: ≤ 1–2 glasses, 3–4 glasses, 5–6 glasses, 7–9 glasses, ≥ 10 glasses; and (iii) Binge drinking frequency: None, less than once a month, once a month, once a week, almost every day. The total score for AUDIT-C is 12, and items are scored on a 4-point Likert scale. In addition, in this research, the criteria for problem drinking were based on the control point...
reported in a study examining Korean adults regarding the trimmed mean of the assessment tool on high-risk drinking. Thus, an AUDIT-C score of ≥ 6 for men and ≥ 5 for women was considered to indicate problem drinking.

**Data Analysis:** The study’s data were analyzed using SPSS 25.0, and differences in general characteristics and health related characteristics between low risk alcohol drinking and high risk alcohol drinking were identified using descriptive statistics and \( \chi^2 \)-test. To identify the factors that influence high risk alcohol drinking, a logistic regression analysis was conducted using a concurrent input method by applying the significant variables resulting from an univariable analysis as independent variables.

**Result**

**Differences in problem drinking according to socio-demographic and health-related characteristics in the Korean elderly population:** The differences in problem drinking according to socio-demographic and health-related characteristics were analyzed after subjects were categorized into the low-risk (n=556) and high-risk (n=261) problem drinking groups based on their AUDIT-C score [Table 1]. The high-risk group comprised a higher percentage of men \( (\chi^2=147.295, \ p<.001) \), higher number of elderly aged 65–70 years than those aged > 70 years \( (\chi^2=32.67, \ p=.017) \), more subjects with a low level of education \( (\chi^2=4.684, \ p=.030) \), more subjects with ≤ elementary school graduation than those with ≥ high school or college/university graduation \( (\chi^2=29.32, \ p<.001) \), more people living in urban rather than rural areas, more married individuals \( (\chi^2=16.882, \ p<.001) \), more unemployed individuals, and a higher number of individuals living with two family members \( (\chi^2=5.931, \ p=.029) \). For health-related characteristics, statistically significant differences between the low-risk and high-risk groups were found for subjective health status \( (\chi^2=18.379, \ p<.001) \), smoking status \( (\chi^2=119.272, \ p<.001) \), physical discomfort for ≥ two weeks \( (\chi^2=10.242, \ p<.001) \), rheumatoid arthritis \( (\chi^2=28.735, \ p<.001) \), osteoporosis \( (\chi^2=49.958, \ p<.001) \), cataracts \( (\chi^2=10.518, \ p<.001) \), limited activity \( (\chi^2=5.090, \ p=.024) \), exercise ability \( (\chi^2=12.584, \ p<.001) \), self-discipline \( (\chi^2=1.309, \ p=.253) \), daily activity \( (\chi^2=6.559, \ p=.010) \), pain \( (\chi^2=15.651, \ p<.001) \), anxiety/depression \( (\chi^2=4.001, \ p<.001) \), and fatigue \( (\chi^2=10.766, \ p<.001) \).

**Factors related to problem drinking in the Korean elderly population examined in this study:**

To determine the influence of socio-demographic and health-related characteristics on the high-risk problem drinking group, a logistic regression analysis was performed. Table 2 presents the results. For socio-demographic characteristics, a significant influence was found for gender, age, income level, residential area, education level, marital status, occupation, and number of family members. For health-related characteristics, subjective health status, smoking status, rheumatoid arthritis, osteoporosis, cataracts, exercise ability, daily activity, pain/discomfort, fatigue, and anxiety/depression were found to significantly influence the high-risk group. Among the socio-demographic factors, the odds ratio of high-risk problem drinking was 0.144 times lower for women (95% CI: 0.07–0.27) than men; 0.639 times lower for subjects aged 70–75 years (95% CI: 0.40–1.00) than those aged 65–70 years, and 0.499 times lower for subjects aged 75–80 years (95% CI: 0.30–0.81); 0.968 times lower for subjects with a middle-low income level (95% CI: 0.60–1.56) than those with a low level, 0.769 times lower for subjects with a middle-high level (95% CI: 0.44–1.34), and 1.586 times lower for those with a
high level of income (95% CI: 0.84–3.00); 0.78 times lower for subjects living in a rural area (95% CI: 0.49–1.24) than those living in an urban area; and 0.650 times lower for subjects who graduated from middle school (95% CI: 0.38–1.09) than those who graduated with ≤ elementary school, and 0.831 times lower for subjects who graduated with ≥ high school or from college/university (95% CI: 0.46–1.49). In addition, the odds ratio of high-risk problem drinking was 1.037 times higher for employed individuals (95% CI: 0.71–1.51) than for unemployed individuals and 2.542 times higher for individuals living with two family members than those living alone (95% CI: 1.24–5.21).

Of the health-related factors, the odds ratio of high-risk problem drinking was 1.438 times higher for subjects with poor subjective health status (95% CI: 0.79–2.61) than for those with good subjective health status, and 1.325 times higher for ex-smokers (95% CI: 0.79–2.22) than non-smokers and 2.492 times higher for current-smokers (95% CI: 1.31–4.71). In addition, the odds ratio of high-risk problem drinking was 1.306 times higher for subjects with rheumatoid arthritis (95% CI: 0.35–4.75), 1.114 times higher for subjects with cataracts (95% CI: 0.76–1.62), 1.688 times higher for subjects experiencing pain or discomfort (95% CI: 0.35–4.75), 1.267 times higher for subjects with anxiety or depression (95% CI: 0.63–2.56), and 1.783 times higher for subjects with fatigue (95% CI: 0.50–1.22).

Discussion

This study examined the elderly aged ≥ 65 years to determine the influence of socio-demographic and health-related factors on problem drinking. The following discussion is based on the results of the study.

First, among the socio-demographic characteristics that influence problem drinking, the risk of problem drinking was higher for men than women. This gender difference is consistent with the results of a previous study on problem drinking in Korea [1]. In addition, an overseas study has also found a higher level of problem drinking among men than women in terms of both drinking quantity and frequency [14]. This implies that problem drinking is more serious among the male elderly in Korea and overseas. The finding may be attributed to the traditional gender norms that seem to favor drinking among men [15]. Regarding age, the risk of problem drinking increased as age decreased. This supports previous studies reporting a decrease in the drinking quantity and number of drinkers due to the early death of individuals who had been drinking excessively since their youth or middle-aged adulthood, or decreased alcohol consumption caused by aging-related physical disability or reduced metabolic ability [16,17]. For income, the highest risk of problem drinking was evident for individuals with the lowest income level. In addition, individuals living with two family members showed a higher risk of problem drinking than other cases. These findings imply the need to consider the quality or satisfaction of family relationships as an influencing factor. The results support those of previous studies reporting a high risk of problem drinking among the elderly with a low-income level who have unsatisfactory family relationships [12].

Second, among the health-related characteristics that influence problem drinking, the risk was high for individuals diagnosed with rheumatoid arthritis or cataracts, and for those experiencing pain/discomfort, anxiety/depression, or fatigue. These results contrast those of a previous study reporting that a physical or psychological condition had no influence on problem drinking, thus indicating a need for replication studies. In addition, the risk was high for individuals with poor subjective health status, contradicting a previous study that found a higher subjective health status among individuals with problem drinking as they viewed themselves as healthy and thus drank more [21]. Therefore, replication studies are needed. The risk of problem drinking was also higher for employed individuals, contradicting a previous study conducted in Korea reporting a higher risk for unemployed individuals [16].

The risk of problem drinking was higher for individuals living in urban areas than those in rural areas. Noteworthy is that a previous study found that problem drinking deteriorated the quality of life of the elderly regardless of residential area [18]. This means that future research should focus on problem drinking among the elderly in both urban and rural areas. Regarding education level, a high risk of problem drinking was found for those who graduated ≤ elementary school, which supports the results of a previous study that showed the influence of education level on problem drinking among the elderly [19]. However, this result contrasts that of a previous study that showed the influence of education level on problem drinking among young and middle-aged adults, but not among the elderly [20], thus indicating a need for replication studies. The risk of problem drinking was also higher for ex- or current-smokers than for non-smokers, and smoking was the most influential factor related to drinking. This is aligned with a previous study on Korean adults that identified smoking as the most significant risk factor as it increased the risk of problem drinking 4.78 times [22].

Conclusion

This study is significant as it analyzed data collected through a nationwide survey to determine the general
factors related to problem drinking among the entire Korean elderly population. The research was conducted at a time when relevant studies are lacking despite the growing social concerns regarding problem drinking among the elderly and the increase in the elderly population. For the interpretation and application of the findings of this study, which re-analyzed the KNHANES dataset, the limitations and recommendations are presented as follows.

First, this study used a previously collected dataset; thus, potential errors in the process of subject interviews and data collection could not be identified. Second, the data used in this study was secondary data, which led to the limited use of the completed survey questionnaires. Furthermore, the variables used in evaluating the factors that influence problem drinking among the elderly could not be diversified. Third, this study found no significant correlations with problem drinking among the elderly for the variables reported in previous studies. This is likely because of the limitation of using secondary data, as mentioned, which prevented evaluating relevant variables such as the family function, social support, satisfaction with family relationships, and friendship. Further studies should use a larger set of samples that contain more diverse variables for reinvestigation. Finally, note that as a cross-sectional study, only the correlations among relevant variables were analyzed in this research, while cause-effect relationships could not be described. In future, a longitudinal study should analyze cause-effect relationships among the factors related to problem drinking among the Korean elderly in a more systematic way.

Ethical Clearance: For ethical consideration of the study subjects, data was collected after approval through the deliberation(IRB No. SMU-EX-2020-02-001) of Institutional Review Board (IRB) of S university. The informed consent was obtained from the subjects before data collection. Confidentiality of data collected was ensured.

Patent Granting on Marine DNA Discovery

Khoa Tran

II Year Student B.A. Legal Studies, University Abu Dhabi, Saadiyat Marina District, Abu Dhabi
United Arab Emirates

Abstract

In recent years, the world has experienced various medical treatments originates from the ocean, such as cytarabine, vidarabine, and ziconotide. Marine represents a great source of species with potential medical treatments due to these species’ unique properties; however, the research and discovery of this industry demand high financial resources and time management. Hence, the international government has employed intellectual property rights and patent granting as a mechanism to promote innovative research. This paper explores the benefits and disadvantages of patent granting on marine DNA discovery and application.

Keywords: Biomimicry, DNA, Intellectual Property Rights, Marine, Medicine.

Introduction

Nature is a complex but miracle system with various shapes, functions, and structures that are highly applicable in our modern lives and far more sustainable and efficient than human most cutting-edge technology. Therefore, over the last ten years, biomimicry has become a trend of bio-engineering and innovation across disciplines, ranging from robotic to business management. Many real-world applications are already available for human usages, such as the bullet train in Japan, superhydrophobic raincoat, temperature regulating systems in the commercial building, and lean business strategies. Applying biomimicry in innovation is highly recommended for a sustainable world, but it also comes with a legal question: can a company patent and own a product or a discovery from nature? To create a comprehensive picture of this legal issue, firstly, the essay will introduce the context of Marine pharmacology and the impacts of marine discovery on medical research. Moreover, it is essential to understand the nature of intellectual property rights and patent rights. Finally, this essay will explore the benefits and drawbacks of granting patent rights for a person, business, or research entities within the context of sea life.

Marine Research and Contribution to Medical and Pharmaceutical Studies: Marine represents a great source of species with potential medical solutions due to these species’ unique properties. For example, according to research from Arizona State University, the Whale can defy cancer due to their excellent genes. If the researchers can decode the Whale’s gene and manufacturing drugs based on the Whale’s gene properties, a human would find a cure to combat the cancer problems. The application of marine research in pharmacies can be categorized into three sections:

1. Genetically engineered marine organisms
2. Manufacture of pharmaceuticals and nutraceuticals of marine origin
3. Chemicals produced by or found in marine organisms shown to have a wide variety of applications as pharmaceuticals

Currently, there are many drugs application with the marine origin, such as

1. Cytarabine (Cytosar-UW, DepocytW) to treat leukemia,
2. Vidarabine (Vira-AW) to combat against herpes viruses, rhabdoviruses, hepadnaviruses, and RNA tumor viruses,
3. Ziconotide (PrialtW) as a pain reliever.

As marine research has provided breakthrough research on medical and pharmaceutical studies, the international government must develop a mechanism that promotes such research globally. One solution is granting patent and intellectual property rights.
Intellectual Property and Patent Granting:

According to the World Intellectual Property Organization (WIPO), “intellectual property (IP) refers to creations of the mind, such as inventions; literary and artistic works; designs; and symbols, names, and images used in commerce.” A patent is “an exclusive right granted for an invention, which is a product or a process that provides, in general, a new way of doing something, or offers a new technical solution to a problem.” The IP rights and patent specifically aim to balance the inventors’ interests and public interests; thus, they nourish the fair-use, innovative environment, and credit creativity. When an inventor patents an invention, he must share the technical information with the public, and he will get back the rights to prevent others from using his invention without permission. Based on WIPO’s definition, one can only fill a patent for “a new way of doing something” or “a new technical solution to a problem”; hence, one cannot patent a discovery of nature, such as the genetics of sea life creatures.

Intellectual Property in Biomimicry Research from Sea Life Creatures: Patent granting in biomimicry research from sea life creatures is the importance of its motivation and compensation for the research team’s time, expertise, and financial contribution. Creating a novel solution from a natural discovery is a challenging and lengthy process. A case of the underwater forest is a practical example. The sea creates, and the forest ecosystem guides innovation across disciplines, such as medical treatment, climate solution, and industrial food production. However, “a single specimen can generate dozens of strains of bacteria. Screenings are difficult and take months. If a compound passes all the tests, presuming funding continues, they might reach the clinic in 15 to 20 years.” In short, available research on sea creatures’ DNA only involves 13000 of the DNA of sea life from the American Association for the Advancement of Science, the problem is also at the inequality allocation of technology between the developed and developing countries. Although there is no direct causal relation between intellectual property rights and global inequality, patents’ unequal distribution would create an imbalance between multinational and local companies. Because the patent holders have exclusive rights on their invention for commercial, research, and non-commercial activities, companies from the highly developed nations can exclude other developing nations to access the ocean’s economic benefits. These technological and commercial exclusives would not benefit the global society and the sustainable usage of international water. Experts believe that the ocean is beyond any country’s
jurisdiction and the United Nations Convention on the Law of the Sea (UNCLOS) commits to inclusive and transferable marine technology. As countries share the ocean, a patent without commercial binding could benefit the global society and uphold the international marine treaty.

**Discussion on Patent Granting for Marine Discovery and Application on a Legal Perspective:**

However, having the majority share of global patents on sea creatures is not equivalent to owning the sea. From a legal perspective, the ocean is a library filled with books and knowledge rather than land for occupation. The act of one filling a new patent learned from the library’s books does not prevent other people from accessing the library. The United States granted patents for the first person who identified the new gene sequences and entitled him exclusive rights on commercial, clinical, and non-commercial uses for 20 years. However, this rule was over-rulled in the United States in 2013. It created a precedent for many other nations. Today for most countries, one cannot patent discovery from nature or the product of nature. In the context of genetics, Mr. Blasiak from Stockholm Resilience Center mentions one can only patent “synthesis organism; a little bit of DNA from a lot of different things.” The process of creating a synthesis organism is genuinely an innovative idea, equivalent to building a new car model from various raw materials from nature. A researcher can patent the collective synthesis organism, but he has no exclusive rights to each little bit of DNA from a natural sea creature. For example, genetic sequences from a purple sea urchin have been used by three companies across Germany, the United States, and Japan without any litigation occurring. This is the evidence for the inclusive usage of global sea creatures and other related discoveries about them.

Before the birth of IP rights and patents, companies usually keep their technical research as a trade secret, limiting the knowledge sharing between people to people. The patent also encourages knowledge sharing between business and academics. Technical information disclosure is a mandatory part of patenting an invention. This information will be presented at the marine genetic resources (MGR) for global researchers to learn. In the sea creature context, this can be researched from “species associated with deep-sea hydrothermal vent systems,” underwater microbes,....., which might not be accessible without advanced technology, technical experts, and extensive research time the individual researcher. The technical disclosure also prevents duplication of research effort and encourages building on existing solutions. Hence, the cumulative nature of science would benefit from this treatment.

Moreover, the majority of patents only last for 20 years. After this period, it is free and accessible for the majority of citizens. If there is a technical monopoly, it is just a temporal situation. In the long run, the patents of corporations will become a shared resource for all. Therefore, entities, such as BASF, “could play a very important and valuable role in supporting efforts to ensure that areas beyond national jurisdiction can be accessed by all and benefit all.” After analyzing the arguments above, it is more reasonable to grant companies patent rights for their innovative usage and new bio-synthesis inspired by nature. The suggested problems of patent rights could be solved with other solutions rather than eliminating the patent granting system. Firstly, to promote the inclusive usage of international water and its biodiversity, developed countries should support developing countries with cutting-edge facilities to research sea creatures. The support should encompass human capital, financial support, technological transfer, and machinery. With this collaboration, developed countries would also benefit from the unique natural system in developing countries and local expertise. Moreover, if there is sufficient evidence proving that BASF hinders innovation from other marine researchers, UNCLOS and WIPO could reduce the patent periods or redefine the scope of patent owners’ exclusive rights. These policies would ensure that patent owners’ creativity, works, and commercial rights are respected without compromising future research on sea creatures and biomimicry.

**Conclusion**

In conclusion, life underwater is an essential source of future technology and knowledge, such as medical treatment, pain reliever, and many drug inventions. Hence, governments should optimize the legal environment for promoting innovation in this industry. A single company should be allowed to patent an invention related to sea life because the benefits of patent granting overshadow the drawbacks in promoting innovation and research on sea life. To combat the domination of patent-holding, such as in the BASF case, the international government could modify the current patent laws to best fit society’s needs.

Risk of Violence among Nurses in Emergency Departments at Baghdad City Hospitals: The Mediating Role of the Work Environment

Mohammed Mahmood Hussein¹, Raad Kareem Faraj²

¹MScN(c), Research Scholar, University of Baghdad, College of Nursing, ²Assistant Professor (A PhD), University of Baghdad, College of Nursing, Community Health Nursing Department

Abstract

Background: Workplace violence is a problem of international healthcare among the workers in all departments of the healthcare systems, but more severe at the emergency departments. Nurses in the emergency departments are working on the front lines of violence. This study aims to examine risk of violence among nurses in the emergency departments and to find out the association between nurses’ age, years of working in nursing, years of working in emergency departments, work hours, violent events by patients, violent events by coworkers, likelihood of exposure to violence in the future, work environment, intention to leave the job, and risk of violence.

Method: A descriptive predictive study design has been carried out. A non-probability (convenience) sample of (380) nurses from the emergency departments of (12) hospitals in Baghdad city center were selected to participate in the study.

Data were collected through a self-report instrument that includes nurses socio-demographic data, the employment data, general information about the violent events, Intention to Leave the Job Scale, Risk of Violence Scale, Violent Events by Patient Scale, Violent Events by co-workers Scale, Likelihood of Exposure to Violence in the Future Scale and the Nursing Work Environment Scale. The data were analyzed using the Statistical Package for Social Sciences (SPSS) version 26.

The study results revealed that a half of the nurses described the risk of violence they can expose to in the workplace as average. There is a statistically significant inverse correlation between nurses’ age, years of experience in nursing, years of experience in EDs and their exposure to violent event by the coworkers, and risk of violence. The researcher concluded that the younger the nurses, the less the experience they have in nursing, the less the experience they have in the EDs, the greater the exposure to violence by coworkers, and risk of violence.

Keywords: Workplace Violence, Work Environment, Emergency Department, Turnover Intention.

Introduction

More than 5 million United States (US) hospital workers from many occupations are exposed to many safety and health hazards, including violence. Healthcare workers are more likely to be attacked at work than police officers or prison guards(1). Now days, hospital violence against health care providers, especially nurses, is a significant concern in every health care setting in the world(2). World Health Organization (WHO) defines violence as the intentional use of threatened or actual force against a person or a group which may cause physical or psychological trauma(3). There are three forms of violence, emotional violence, physical violence, and sexual harassment(4). Emotional violence comprises verbal abuse, in the practice of punitive words, swearing, talking in a hostile style, or an upraised voice bullying, mobbing, and written or verbal intimidations that do not cause physical harm(5). Physical violence can be defined as every type of assault that has a physical element(6). And involves the use of physical strength against another
individual (7). Sexual harassment as any unwanted, unwelcome and unreciprocated act of a sexual nature that is offensive to the person (8). In the Middle East, workplace violence (WPV) reported variedly according to the type of violence, the verbal threat was the most common forms, with a frequency range between 19.6% and 98.6%, which was three to six times higher than physical violence (9). Additionally, violence is knowingly under reported in a hospital setting, particularly relative to the nonphysical type of violence (10). Many reasons for the under reporting of violence, including an absence of time and refusal to fill in forms (15). The emergency departments (EDs) are typically a stressful environment across the 24-hours of the day and involves a great turnover of nurses (11). Emergency departments nurses’ presence in stressful situations exposes them to more abuse or harsh behavior from patients or their colleagues than other hospital staff (12). Additionally, the risk of violence between nurses in the EDs distribution is not consistent, significant variances are found in relation to age, marital status, kind of service, hospital characteristics, work shift, and position in the profession (13-14). There are many factors making the nursing staff at risk of workplace violence in EDs. These factors are related to the emergency department work environment, nursing staff characteristics, and patient’s condition (16).

Method

A descriptive predictive study design was used in this study from period of December 24th, 2019 to February 23th, 2020. During the study, the total population of interest include (853) nurses who work in the emergency departments of (18) hospitals in the Baghdad City center. Of those, only (380) nurses were selected from the emergency departments of (12) hospitals to participate in the study. The response rate for the study is (76%). A non-probability (convenience) sample was used to recruit study subjects. Data were collected through a self-report instrument that include the socio-demographic data, the employment data, general information about the violent events, the Intention to Leave the Job Scale, Risk of Violence Scale, and Likelihood of Exposure to Violence in the Future Scale, Violent Events by Patient Scale, Violent Events by Coworkers Scale and Nursing Work Environment Scale. The validity of the questionnaire were verified by presenting it to (15) experts. Descriptive and inferential statistics were used to analyze the results of the study using the Statistical Package of Social Sciences (SPSS) version 26.

There are statistically significant inverse correlations between nurses’ age and their exposure to violent event by the coworkers, intention to leave the job, and risk of violence \((r = -.185; \text{at } p < 0.01; r = -.145; \text{at } p < 0.01; r = -.200; \text{at } p < 0.01)\) respectively. On the other hand, there is a statistically significant positive correlation between nurses’ age and their likelihood of exposure to violence in the future \((r = .170; \text{at } p < 0.01)\). There are statistically significant inverse correlations between nurses’ years of experience in nursing and their exposure to violent event by the coworkers and risk of violence \((r = -.137; \text{at } p < 0.01; r = -.202; \text{at } p < 0.01)\) respectively. On the other hand, there is a statistically significant positive correlation between nurses’ years of experience in nursing and their exposure to violent event by the patient work environment, and risk of violence \((r = .193; \text{at } p < 0.01)\). There are statistically significant inverse correlations between nurses’ years of experience in ED and exposure to violent event by the coworkers, intention to leave the job, and risk of violence \((r = -.174; \text{at } p < 0.01; r = -.124; \text{at } p < 0.05; r = -.204; \text{at } p < 0.01)\) respectively. On the other hand, there is a statistically significant positive correlation between nurses’ work hours and their exposure to violent event by the patient work environment, and risk of violence \((r = .134; \text{at } p < 0.01; r = .168; \text{at } p < 0.01; r = .179; \text{at } p < 0.01)\) respectively.

**Discussion**

Concerning the age, the study results revealed that the highest percentage of the study subjects within the age group (19-29) years, this finding consistent with \((17)\) who reported that the highest percentage of the nurses in the emergency departments within age groups (19-29) years. Concerning the gender, the study results revealed that the majority of the study subjects are males. This finding is consistent with that of \((18)\) who reported that the majority of the nurses were males. Regarding the marital status, the study results revealed that the majority of the study subjects are married. This finding consistent with \((6)\) who reported that the majority of the study participants are married. With respect to educational qualifications, the study results revealed that more than two-fifth hold a diploma degree of nursing. This finding is consistent with that \((19)\) who reported that the majority of the study subjects have a diploma degree in nursing. Relating to the years of experience in nursing, the study results revealed that less than a half of the study subjects have 1-5 years. This finding consistent with \((20)\) who reported that less than half of the study subjects have 1-5 years of experience in nursing. Regarding the years of experience in the emergency department, the study results revealed that the majority of the study subjects have 1-5 years of experience in the emergency department. This finding consistent with that of \((17)\) who reported that the majority of the study subjects have 1-5 years of experience in the emergency department. Relating to the work hours in the workplace, the study results revealed that more than a half of the study subjects work for 18-hours. This finding consistent with that of \((21)\) who reported that more than half of the study subjects working for 18-hour. Regarding the work shift in the workplace, the study results revealed that more than a half of the study participants work on the evening shift from 3:00 p.m. -8:00 a.m. This finding supported by that \((20)\) who found that more than half of the nurses work in the evening shift between 3:00 p.m. -8:00 a.m. Regarding the role in emergency department, the study results revealed that the majority of nurses in the ED are clinical nurse. This finding supported by that of \((17)\) who reported that the majority of the study subjects was clinical nurses. The study results revealed that there were statistically significant inverse correlations between nurses’ age and their exposure to violent event by the coworkers. This finding is consistent with \((22)\) who reported that there was a significant inverse relationship between the nurses’ age and the occurrence of workplace violence by coworkers. The study findings indicated that there were statistically significant inverse correlations between nurses’ age and intention to leave the job. This finding is supported by \((23)\) who reported that there was a significant negative correlation between nurses’ age and intention to leave the job. The study findings revealed that there was a statistically significant inverse correlation between nurses’ age and risk of violence. This finding is supported by \((24)\) who reported that there was a significant inverse correlation between nurses’ age and risk of violence. The study findings revealed that there was a statistically significant positive correlation between nurses’ age and their likelihood of exposure to violence in the future. This finding supported by that of \((24)\) reported that there was a statistically significant positive relationship between nurses’ age and their likelihood of exposure to violence in the future. The study findings revealed that there was a statistically significant inverse correlation between nurses’ years of experience in nursing and risk of violence. This finding supported by that of \((26)\) who reported that there was a statistically significant
inverse correlation between nurses’ years of experience in nursing and risk of violence. The study results revealed that there were statistically significant inverse correlations between nurses’ years of experience in the EDs and exposure to violent events by the coworkers. This finding is supported by that of (27) who concluded that there was a significant negative correlation between nurses’ years of experience in the EDs and exposure to violent events by the coworkers. There was a statistically significant inverse correlation between nurses’ years of experience in the ED and intention to leave the job. This finding is supported by (28) who concluded that there was a negative correlation between the years of experience in the ED and the turnover intention of nurses. The study findings revealed that there was a statistically significant inverse correlation between nurses’ years of experience in the ED and risk of violence. This finding is supported by that of (29) who concluded that there was a significant negative correlation between nurses’ years of experience in the ED and risk of violence. There was a statistically significant positive correlation between nurses’ years of experience in the ED and risk of violence. This finding could be explained as that the longer the duration of work the nurses have in the ED, the greater the burnout they may experience. This finding is congruent with that obtained by (30) who concluded that the majority of nurses had reported decreased job satisfaction which was mainly contributed by verbal violence (73%) of participants. There was a statistically significant positive correlation between nurses’ work hours and their exposure to violent event by the patient. This finding is supported by that of (31) who concluded that there was a positive correlation between the work hours and exposure to violence by patients. There was a statistically significant positive correlation between nurses’ work hours and risk of violence. This finding is supported by (32) who concluded that there was a significant positive correlation between nurses’ work hours and risk of violence.

Conclusions

1. The younger the nurses, the less the experience they have in nursing, the less the experience they have in the EDs, the greater the exposure to violence by coworkers and the risk of violence.
2. The younger the nurses age, the less the experience they have in the ED, and the greater the intention to leave the job.
3. The longer the work hours, the greater the exposure to violent events by the patients, and the risk of violence.

Recommendations:

1. It is necessary for the top management in the hospitals to provide as optimal nursing staffing as possible in the emergency departments.
2. Offer training to nurses about predicting, recognizing, and managing assaults, resolving conflicts to increase their ability to deal and manage the workplace violence.
3. Working to improve the security precautions in the hospital; particularly in the EDs to minimize the violent events.

Conflict of Interest: The researchers confirm that there is no any conflict of interest.

Source of Funding: This study is self-funded.

Ethical Clearance: The researchers obtained the ethical approval from the University of Baghdad, College of Nursing.

Abstract

Objective: To assess the quality of lifestyle among asthmatic children.

Population and Method: A descriptive study carried out in Al Noor pediatric hospital in Hilla City, during the period 1/5/2020-30/5/2020, the population was (100) children aged 1-12 years; data were collected by questionnaire through direct interview with the mother or caregiver and the child.

Data analysis by using SPSS, Pearson’s correlation and chi-square were used to find associations between variables.

Results: The highest percentage (34%) of the study samples their age group (4-6, 10-12) years respectively and the age at onset asthma (60%) at (1-3) years. School grade: (68%) of study sample was elementary schools. Family history: (48%) they had history from grand mothers and fathers. Severity of asthma: (46%) of study sample have moderate attacks, the highest mean score for the Asthma attack triggers was (2.45); Change in daily life was (2.14); Family support was (2.71); Satisfaction with daily life was (2.32) and restriction in participating in physical education class was (2.33). significant correlation and severity of asthma with having cough because of sudden change in temperature, disturbance of sleep, unpleasant feeling to be told about asthma and Emergency visit to hospital.

Conclusion: The study concludes asthma has negative Impact on the quality of life style on children at home and school in various ways.

Keywords: Asthma, quality of life, QOLv.3.items.

Introduction

Asthma is a common chronic illness worldwide which increase reaction of the airways to numerous stimuli including allergens and irritants that cause obstructions of the airways. Contracting of muscles around the airway and infection result in swelling of the coating layers and increased secretion of mucous, so, there were difficulty in breathing and coughing. The most common causes of asthma are infection, exercise, allergens, and irritant air pollution. Children with asthma may have wheezing, coughing, shortness of breath, and chest tightness [1].

Asthma cannot be cured, but could be controlled. Asthmatic children have negatively impact of Health-related quality of life (HRQL) they are required to modify their mode of living to avoid its complications, and have negative impact on their psychological and social well-being.

The strongest risk factors for developing asthma are exposure, especially in infancy, to indoor allergens as domestic mites in bedding, carpets and stuffed furniture, cats and cockroaches; a family history of asthma [2]. Children have smaller airways than adults, which makes asthma especially serious for them. Children with asthma may experience wheezing, coughing, chest tightness, and trouble breathing, especially early in the morning or at night. In the United States, about 9 million children have asthma, which triggers by cold weather,
pet dander, and being around smoke. Pollutants can also make children more likely to have respiratory infections as like colds; pollutants can make the lungs even more sensitive to them \cite{3}. Also, triggers asthma are allergens- mold, pollen, animals, irritants-cigarette smoke, air pollution, weather-cold air, changes in weather, exercise, infections - flu, common cold \cite{2,4}.

**Method**

**Study design, setting, and population:** A descriptive study carried out in Al Noor pediatric hospital in Hilla City, during the period 1/5/2020-30/5/2020, the population was (100) children aged 1-12 years; data were collected by questionnaire through direct interview with the mother or caregiver and the child.

Data analysis by using SPSS (Statistical Package For Social Sciences)

**Study Tool:** By using modified the Quality of Life Questionnaire for Japanese School-aged Children with Asthma Version 3 (JSCA-QOL v.3)items scale.

**Data Analysis:** Descriptive statistics was done. Pearson’scorrelation and P value of ≤ 0.05 was considered statistically significant.

**Results**

The study assess of asthmas’ quality Life style among children aged 1-12 years, the highest percentage (34%) of study sample at age group (4-6,10-12) years respectively, and the age at onset asthma(60%) at (1-3) years. (68%) of study sample was elementary schools,(58%, 44%) of mothers and fathers had primary school and College and above graduate respectively. (48%) they had history from grand mothers and fathers. And Severity of asthma (46%) of study sample was moderate attacks,(Table (1)Table 2: shows the highest mean score for the Asthma attack triggers was (2.45); Change in daily life was (2.14); Family support was (2.71); Satisfaction with daily life was (2.32) and Restriction in participating in physical education class was (2.33).Table 3: shows significant correlation between age at onset asthma with age and Disturbance of sleep; Mother education with being absent from school; Father education with Having cough because of sudden change in temperature; and Severity of asthma with Having cough because of sudden change in temperature, Disturbance of sleep, Unpleasant feeling to be told about asthma and Emergency visit to hospital.

Discussion

Demographics of the Sample: The Age group (years): highest percentage (34%) of study sample their age group (4-6, 10-12) years respectively.

That agree with Iraqi Family Health Survey stated that the prevalence rates increase progressively with age and the age at onset asthma (60%) at (1-3) years. School grade: (68%) of study sample was elementary schools;(58%, 44%) of mothers and fathers had primary school and College and above graduate respectively. Family history: (48%) they had history from grand mothers and fathers and the Severity of asthma: (46%) of study sample was moderate attacks[5]. Also a study mentioned that parents’ educational level and family income were positively related to asthma control status[6].

A study found that parents with low educational levels are associated with medication underuse. Also, studies in the United Kingdom and Germany have revealed that severe asthma is correlated with decreasing socioeconomic status. Also, 61.7% of the patients had history of smoking exposure in their home having poor control asthma[1]. Go to:

Although little is known about the scope to which the age at asthma first began is associated with the presence, frequency, or severity of subsequent respiratory health outcomes [7].
Quality of Life as Assessed by JSCA-QOL v.3: The result of this study revealed that there were high negative impact among quality of life for asthmatic children that agree with study conducted by The American Lung Association, states about the secondhand smoke which estimated 400,000 to 1 million children with asthma and their condition worsened and The Centers for Disease Control and Prevention (CDC) state that children with asthma are more likely to have repetitive visit to hospital, emergency, and urgent care visits than adults with asthma[8].

The study shows significant correlation between age at onset asthma with age and Disturbance of sleep; Mother education with being absent from school; Father education with Having cough because of sudden change in temperature; and Severity of asthma with Having cough because of sudden change in temperature, Disturbance of sleep, Unpleasant feeling to be told about asthma and Emergency visit to hospital.

That result agree with study stated that Asthma influenced the life of the children physically, emotionally and socially and consequences of asthma on peer relationships, the dependence on medication, shortness of breath, cough, limitations in activities and limitations due to the response on cigarette smoke exposure[9].

Also, study mentioned that there were association between severity of asthma and child’s quality of life and between routine burden and quality of life in children with asthma[10].

A study showed that while parents of children with intermittent asthma and parents of younger children presented higher levels of caregiving burden,

Significant negative and positive associations were found between burden measurements and quality of life[11].

Also, study stated that Significantly poorer quality of life was observed in children with uncontrolled asthma (p = <0.001). Children with controlled and uncontrolled asthma were equally affected psychosocially with no relation between asthma control and their psychosocial well-being (p = 0.58)[12].

Children are underestimating the level of disease severity. The accurateness of symptom perception depends on cognitive and emotional state, previous life experiences, attributions, related information, attention and learning processes, and prior asthma attacks, the sensation of unpleasantness related to dyspnea, rather than its sensory strength, all that linked to affecting stimuli[13]. The cohorts study revealed that the average increasing incidence of 19.1%, but it keep on steady among children aged 3 years or older, and increased very quickly only among children over 3 years, from 1.3% (95% CI, 1.2-1.3) to 13.7% (95% CI, 13.5-13.9) (P < .0001)[14].

Conclusion

The findings shows significant correlation between age at onset asthma with age and Disturbance of sleep; Mother education with being absent from school; Father education with Having cough because of sudden change in temperature; and Severity of asthma with Having cough because of sudden change in temperature, Disturbance of sleep, Unpleasant feeling to be told about asthma and Emergency visit to hospital.

Recommendations: This study recommends further researches are needed to study the psychological effect of asthma, study the risk factors leading to poor asthma control.

Availability of data and materials

Available on reasonable request.

Author’s Contributions: All the authors are equally contributed to complete this research.

Acknowledgements: We wish to express our sincere appreciation to all study participants for their help and patience. We also thank and appreciate the nurses staff of Al Noor Pediatric Hospital in Hilla City, for assistant during data collection.

Funding: The authors did not receive any external funding for this work.

Conflicts of Interest: The authors declare no conflicts of interest regarding the publication of this paper.

Acknowledgment: The authors would like to thank all mothers and child who involve in this study.

Ethical Consideration: The researchers obtained an approval from Al Noor Pediatric Hospital in Hilla City. And the verbal approval of the mother’s participants in the research project.
Consent for Publication: Not applicable.

Competing Interests: The authors declare that they have no competing interests.

The Biunik of Isotonic Safety with the Addition of Arabic Gum

Thresia Dewi K.B.¹, Sitti Sahariah R.¹, Sirajuddin¹

¹Associate Professor, Department Nutrition and Dietetic, Health Polytechnic of Makassar, Makassar, Indonesia

Abstract

Background: Endurance sports greatly affect fluid requirements. The exercise that is too heavy will cause a lot of body fluids to come out. Providing sports drinks with carbohydrate and electrolyte content has more benefits for athletes. One of them is an isotonic drink formula with the addition of gum Arabic. The food safety factor in isotonic drink formulas is very important to prevent side effects due to the contamination of food or beverages that can endanger health.

Objectives to determine the food safety of the isotonic drink formula with the addition of gum Arabic.

Method: This study is the pre-experimental. Food safety, which includes microbial and metal contaminants, was analyzed at the Makassar Health Laboratory Center. The results showed that the isotonic beverage formula with the addition of gum Arabic was safe from metal contamination.

Results of the microbial contamination test shows that Biunik (F1) is an isotonic drink formula with the addition of safe Arabic gum, while other formulas still exceed the quality requirements of isotonic drinks in Indonesia based on ISN 01-4452-1998.

Keywords: Gum Arabic, Food Safety, Isotonic Beverage Formula.

Introduction

Performance in sports is the main objective of a competition. Maximum achievement can be obtained if the athlete is in good nutrition. Exercise requires energy that is obtained from nutrients in the food or drinks consumed. So achievement and energy are inseparable. Nutritional needs for adolescent athletes are relatively greater in nutritional needs, because adolescents still experience a period of physical growth and development of very fast behaviors such as lifestyle, eating habits, eating behavior disorders, physical activity, and the frequency and duration of exercise¹,²

that is entered. Dehydration can result in hyponatremia, hypoglycemia, hypokalemia so that athletes feel nauseous, dizzy, tired, and reduce the concentration (performance) of athletes during training or competitions. Sports drinks containing carbohydrates and electrolytes have even more benefits. In addition to providing a sweet taste, carbohydrates such as glucose, sucrose, and fructose are also useful for increasing energy, preventing hypoglycemia (decreased blood glucose), preventing weakness, and reducing stress hormone levels in the body. While the electrolyte content in it such as sodium, potassium, and chloride can prevent muscle cramps.\(^6\)

Food safety is a condition and an effort needed to prevent the possibility of contamination of biological, chemical, and other objects that can disturb, harm, and endanger human health. One aspect of food safety is carried out through food sanitation as an effort to create and maintain food conditions that are healthy, hygienic, and free from the danger of contamination. The food safety factor is very important for a food product, both food and beverage to prevent side effects due to food contamination that can endanger health.\(^7\)

Security dap is defined as a state free from the danger of injury or damage to the wearer. If the security aspect is not considered, then food or drink can turn into a source of disaster, a source of disease and death. There are three important things that can cause contamination in food and beverages. The first is handling food ingredients that do not comply with hygiene requirements. Second, in the processing process and the use of processing equipment and unclean presentation. Finally, when the food or drink is left idle or stored for too long at an inappropriate temperature.\(^8\)

The number of isotonic beverage products on the market has attracted researchers to determine the safety of isotonic drink formulas that use local food ingredients, namely purple sweet potatoes. This isotonic drink formula is a development of Justin’s research results (2019), to produce a sports drink formula based on purple sweet potato, there is still starch deposits in the resulting drink, so the addition of a stabilizer is required in the manufacturing process. One of the stabilizers that meet these requirements is gum Arabic. This study aims to determine the food safety of the isotonic drink formula with the addition of gum Arabic. Food safety in question is metal contamination and microbial contamination.\(^9\)

### Material and Method

This research is pre-experiment with a completely randomized design (CRD) that there are three treatment addition of gum Arabic, which is 0.1%, 0.2%, and 0.3% in the isotonic drink made from 75 grams of purple sweet potato. This research was conducted at the Food Technology Laboratory the Health Polytechnic of Makassar in February-September 2020. The materials used to make samples of isotonic drink formulas are purple sweet potato, sweet orange juice, sugar, table salt (NaCl), water, and gum Arabic. The tools used are a blender, cutting board, knife, sieve, scale, basin, gas stove, pan, squeezer, hand gloves, measuring cup, spoon, covered container, sample glass. Prepare all the ingredients and tools needed in the manufacture of an isotonic drink formula. The purple sweet potato is cleaned, then steamed for \(\pm 30\) minutes, skinned, and weighed as much as 75 grams for each formula. After the blend by adding m strangers each 250 ml mineral water. Sweet potato filtrate was filtered to obtain purple sweet potato juice. The purple sweet potato juice is heated for 1 minute, then cooled. After that, add 25 ml of sweet orange juice, sugar, table salt, and gum arabic. Stir until smooth, using a boxed bottle of plastic and glass bottles.

**Findings:** The safety of isotonic drink formulas is tested from metal contaminants and microbial contaminants to comply with SNI 01-4452-1998 regarding the quality of isotonic drinks. The metal contamination of the isotonic drink formula with the addition of gum Arabic which is done twice for each formula.

**Metal Contamination:** The result of metal contamination analysis using the atomization method in the isotonic drink formula with the addition of gum Arabic showed that the average results were below the ISN for isotonic drinks, namely for arsenic metal a maximum of 0.1 mg/kg, maximum mercury 0.03 mg/kg, maximum zinc 5.0 mg/kg, stannum maximum 40 mg/kg, maximum copper 2.0 mg/kg and maximum lead 0.3 mg/kg.

**Microbial Contamination:** The results of the Total Plate Count (TPC) of bacteria in the isotonic drink formula with the addition of gum Arabic showed that the TPC of bacteria for all formulas decreased from the results of the I test. The results of the TPC analysis for mold/yeast showed that the second TPC of mold/yeast
in the isotonic drink formula decreased the TPC of mold/yeast for the formula. F1 and F3. The increase in mold/yeast TPC was seen in the F0 and F2 formulas in examination II. While the results of the Salmonella Sp examination showed that no Salmonella Sp content was found in the isotonic drink formula with the addition of gum Arabic.

Table 01. Results of Metal Contamination and Microbial Contamination Analysis are appropriate SNI 01-4452-1998 Isotonic Drinks

Discussion

Metal Contamination: The metal content of arsenic (As) in the isotonic drink formula with the addition of gum arabic (biunik). The result of the analysis is still within the recommended threshold in SNI 01-4452-1998, namely Max. 0.1 mg/kg. The concentration of As heavy metal contamination is still accepted in the four isotonic drink formulas with the addition of Arabic gum, making it safe for consumption. The mercury content in the four isotonic drink formulas with the addition of gum Arabic was still within the permissible threshold of <0.0005 µg/g on examinations I and II. The maximum allowable limit of mercury/mercury (Hg) contamination is Max. 0.03 mg/kg. The requirements for isotonic drinks according to the Indonesian National Standard (INS) 01-4452-1998, the maximum limit of Zn metal contamination is Max. 5.0 mg/kg. The results of the analysis show that the average levels of Zn in the four isotonic drink formulas with the addition of Arabic gum are between 0.20 mg/kg to 1.11 mg/kg (< 5.0 mg/kg), meaning that the isotonic drink formula is safe for consumption. The maximum B of Sn metal contamination is max. 40 (25.0 *) mg/kg in isotonic drinks according to INS 01-4452-1998. The analysis showed that the average Sn content in the four isotonic drink formulas with the addition of gum Arabic was <40 mg/kg, meaning that the isotonic drink formula was safe for consumption.

The requirement for isotonic drinks in SNI 01-4452-1998, the maximum limit of Cu metal contamination is max. 2.0 mg/kg. The results of the analysis showed that the average levels of Cu in the four isotonic drink formulas with the addition of Arabic gum were between 0.21 mg/kg to 0.34 mg/kg (< 2.0 mg/kg), which means that the isotonic drink formula is safe for consumption.

Lead (Pb) is a metal that has received major attention in terms of health, because of its impact on a large number of people due to poisoning of food or air contaminated with Pb and has dangerous toxic properties. Naturally, lead can be found in the soil, odorless, and tasteless. The INS 01-4452-1998 set of heavy metal contamination limits for lead in isotonic drinks are consumed by humans is a maximum of 0.3 mg/kg. The average value of lead-heavy metal content in the four isotonic formulas with the addition of gum
Arabic which has been analyzed is within the threshold so that it is safe for consumption.(8)

**Microbial Contamination:** The results of the analysis showed that the total average value of bacteria in the four isotonic drink formulas at examination I ($300 \times 10^5$ Colonies/g) was much greater than the maximum value of TPC for bacteria (Total Plate Numbers) required in SNI ($2 \times 10^2$ Colonies/g).(10) This means that this product is not safe for consumption. This data is the reason for the re-creation of the isotonic drink formula. Unlike the previous one, the formula is made and packaged using glass bottles. Before use, the bottles were sterilized at a temperature of $>100^\circ$ C for 15 minutes. Then, a microbiological analysis (examination II) was carried out at the Makassar Health Laboratory Center. Microbiology laboratory results showed that there was a drastic decrease in Bacterial TPC in all isotonic drink formulas. It is known that Bacterial TPC in F0, F1, and F2 is smaller than the maximum value of TPC for bacteria required in SNI for Indonesian isotonic drinks. This means that the formula is safe for consumption based on microbiological aspects. Bacteria TPC F3 ($3.65 \times 10^2$ colonies/g) has experienced a drastic decline but still exceeded the quality standard isotonic drinks ($2 \times 10^2$ colonies/g) if the review of aspects of microbiology.

This research is in line with the research of Rianti A, et al (2018) which showed that the results of TPC testing in green bean drink (GBD) samples showed that the contamination exceeds the maximum limit of microbial contamination. Meanwhile, the sample of soybean drink (SSD) and red bean drink (RBD) did not exceed the maximum limit of microbial contamination. The difference in the process of making SSD, RBD, and GBD samples lies in the type of material used. GBD samples were made with the addition of *pandanus*, while the SSD and RBD samples did not use these materials.(8)

Research on isotonic drink formulas with the addition of gum arabic in their packaging process is not good, so it can cause the risk of bacterial contamination. In making the first formula, drinks are packaged using plastic bottles that have been washed using soap and clean running water, then dried using dry *tissue*. No sterilization process is carried out on the bottles used. Unlike the second formula, the drinks are packaged using glass bottles that have been washed using soap and clean running water, then sterilized at a temperature $>100^\circ$ C for 15 minutes. The results of the microbiological quality analysis showed that the total fungi/yeast F1 and F3 had met the standards set in INS for Indonesian isotonic drinks. Microbiologically, the formula is safe for consumption. In contrast to F0 and F2, the amount of mold and yeast in the formula exceeds the set standard (maximum 50 Colonies/g). The quality requirements contained in INS 01-4452-1998 require negative isotonic drinks *Salmonella* Sp. The results showed that the isotonic drink formula with the addition of gum Arabic was not contaminated with *Salmonella* sp.(1,11)

**Ethic:** This study has been approved by the Makassar Health Polytechnic Ethics Committee with the reference number:: 0087/KEPK-PTKMS/III/2020

**Conflict of Interest:** The researcher states there is no conflict of interest

**Source of Funding:** Self or other source

Funding from The Health Polytechnic of Makassar,

**Conclusion**

The results of the research show that theBiunik with the addition of gum arabic is safe from metal contamination in accordance with the SNI requirements for isotonic drinks. If assessed based on microbial contamination, F1 is an isotonic beverage formula with the addition of Arabic gum which is safe from microbial contamination.

Association of Genetic Polymorphism of Insulin Receptor Substrate 1 (IRS-1) with Polycystic Ovary Syndrome Pathogenicity in Iraqi Women

Zahraa Fouad Fadhil1, Ban Hoshi khalaf 2, Hassan Mahmoud Mousa Abo Almaali3

1B.Sc. Pharmacy, Candidate of Master of Science in Pharmacology and Toxicology, Department of Pharmacology and Toxicology, College of Pharmacy, Kerbala University, Iraq, 2PhD, Professor in Pharmacology and Toxicology, Department of Pharmacology and Toxicology, College of Pharmacy, Kerbala University, Iraq, 3PhD, Assistant Professor of Genetic Engineering and Biotechnology, Branch of Clinical Laboratory Sciences College of Pharmacy, Kerbala University, Iraq

Abstract

Background: Insulin receptor substrate 1 (IRS-1) is an intracellular signaling adapter protein that integrates and coordinates multiple biologically key extracellular signals within the cell, is also a key central receptor in insulin signaling, and plays a focal role in maintaining essential cellular capabilities, e.g., survival, development and digestion system. IRS1 is essentially found in the cytoplasm but localization in nucleus may occur in some cell types and under certain stimuli.

Materials and Method: A total of 104 healthy control and 215 Iraqi women have Polycystic ovary syndrome (PCOS) aged 20–40 years who was admitted to conducted a prospective clinical study at kerbala gynecology teaching hospital, it was measured the genotype distribution of the rs2943641 T to C substitution of IRS1 and the effects of genotypes on Polycystic Ovary syndrome Pathogenicity in Iraqi women,

Results: Analyses were conducted to assess the association between the SNP rs2943641 [TT (Wild type), TC (heterozygous type), and CC (mutated type)], with the pathogenesis of PCOS according to logistic regression results. This survey demonstrated that there was no significant association between different alleles for this SNP with the pathogenesis of PCOS

Conclusion: Genetic polymorphism with IRS-1 may be associated with metabolic disturbance but not Polycystic Ovary syndrome in Iraqi women.

Keywords: Polycystic Ovary Syndrome, Pathogenicity, Genetic Polymorphism, Insulin Receptor Substrate 1.

Introduction

Polycystic ovary syndrome (PCOS) is highly prevalent hormonal disorder among reproductive-aged women. Its clinical manifestations are heterogeneous(1).

susceptibility to insulin resistance and PCOS, Molecular scanning of the IRS1 gene has showed substitutions of several amino acid\(^3\). Insulin Receptor Substrate 1 (IRS1) polymorphism significantly decrease insulin-dependent receptor tyrosine autophosphorylation and increase Insulin-independent receptor serine phosphorylation markedly\(^3\). These serine phosphorylation inhibit normal receptor signaling and make the primary defects in insulin-stimulated glucose transporters (GLUT4) production\(^4\). Decreased glucose uptake may result from suppressed insulin signaling or impaired glucose transporter (GLUT) 4 trafficking. In adipocytes of women with PCOS that decrease insulin responsiveness\(^5\).

**Materials and Method**

**Sample Collection:** A total of 104 healthy control and 215 Iraqi women with PCOS, aged 20–40 years old have been recorded the PCOS subjects had at least two of the following signs: 1) chronic oligoanovulation 2) hirsutism or increased serum total testosterone levels; and 3) polycystic ovarian morphology at ultrasound, according to the Rotterdam consensus. Conference criteria (6). The protocol was approved by the local Ethics Committee, and all women gave written informed consent.

**Polymerase chain reaction:** The human genomic DNA extracted from whole blood by using genomic DNA extraction kit (G-DEX llb Introne, korea), according to the manufacture company, the purity and concentration of DNA obtaining was determinate by nanodrop apparatus (biobase, china). Polymorphism of IRS1 gene was detected by amplification refractory mutation system (ARMS) polymerase chain reaction (PCR). Nucleotides primers were designed through Primer-BLAST allows users to design new target-specific primers according to the websites (https://www.ncbi.nlm.nih.gov/tools/primer-blast/index.cgi) it is also prepared by (Bioneercom.Korea) company as the following (Table 1)

Optimization of PCR reaction was recorded as initial denaturation for 3 min at 94 °C, followed by 35 cycles consist of second denaturation for at 94 °C 30 seconds, 45 second at 56 °C, first extension 55 seconds at 72 °C, then last extension at 72 °C for five minutes. The amplification of insulin receptor substrate 1 was run electrophoresis in the 1.5% concentration of agarose gel at 70 V for 60 min after stained with 2 μL ethidium bromide, the product size was visualized under Ultraviolet.

**Statistical Analysis:** Statistical analysis were used by software SPSS program version 20, Test for Hardy-Weinberg equilibrium in controls and allelic or genotypic association in cases versus control were evaluated by Chi – square (\(x^2\)) test. This analysis was performed for all genotypes in this study using Hardy-Weinberg equilibrium online calculator. To assess the predictability of PCOS, logistic analysis of SNP was applied, this yielded odds ratio (OR) also the 95% confidence interval of the OR was calculated which is good estimator for the significance of the OR; when the value of “one” included within interval, this is an indicator that the OR is not significant. All statistical procedures and tests were applied under a level of significance (P-value) of less than 0.05 to be considered as significant difference or correlation.

**Results and Discussion**

PCOS is a polygenic endocrine and metabolic disorder. The prevalence of PCOS has grown rapidly. Several genetic polymorphisms have already been enrolled in the pathogenesis of PCOS\(^7\). The IRS-1 gene has been considered to be a candidate gene for the etiology of metabolic diseases such as type 2 DM,
PCOS, and obesity. The presence of polymorphisms of the IRS-1 gene has been documented to be associated with the development of IR. The IRS-1 gene located on chromosome 2q36 is the substrate for the insulin tyrosine kinase receptor, responsible for insulin signaling. The protein is expressed in multiple cells and tissues sensitive to insulin. Binding of insulin to its receptor activates phosphorylation of cytosolic substrates of IRS-1\(^8\). IRS-1 activation is a first step in the insulin signaling pathway, and functional studies of polymorphism in the IRS-1 gene showed weak insulin signals through the PI3-kinase pathway\(^9\).

Analyses were conducted to assess the association between the SNP rs2943641 with the pathogenesis of PCOS according to logistic regression and (Figure 1). This survey demonstrated that there was no significant association between different alleles for this SNP with the pathogenesis of PCOS, (Tables 2 and 3).

The exact cause of PCOS is unknown, but several studies suggest a strong genetic component that is affected by gestational environment and lifestyle factors, or both\(^10\). Thus, numerous genetic variations have been related to the presence of PCOS in different populations\(^11\). In the present study, we investigated the possible association between the single nucleotide polymorphisms (SNPs) (rs2943641) of the IRS1 gene and susceptibility to PCOS in Iraqi women, (TT wild type, TC heterozygotes, and CC mutated form for the two SNPs). The frequencies of SNP rs2943641 variant observed in our study were not significantly different between PCOS and healthy control women (11.5% vs. 12.1%, \(P= 0.368\)) as shown in table (2). Our data revealed that the IRS-1 polymorphism (rs2943641) is not associated with increased susceptibility to PCOS in Iraqi populations. However, we cannot exclude the possibility that other genetic polymorphisms of the IRS1 family are associated with PCOS and might be clinically useful as markers to assess the disease risk, as polymorphism of Gly972Arg that could play a contributory role in the pathophysiology and risk of PCOS \(^12\). But C allele of rs2943641 is associated with increased hyperinsulinemia and impaired insulin sensitivity\(^13\).

Conclusion

Polycystic ovary syndrome is associated with hyperinsulinemia and insulin resistance that affected by insulin receptor substrate 1 (IRS1) protein, this protein is an important intermediate in insulin signaling and plays a key role in maintaining the basic function of the cell, so any polymorphism in IRS1 genes acts as a competitive inhibitor of the insulin receptor. IRS1 rs2943641 polymorphism may associated with susceptibility to insulin resistance but not poly cystic ovary syndrome in Iraqi women.

Assessment the Content of Methanil Yellow and Boraks at Traded Food Market in Makassar

Alfina Baharuddin¹, Suharni A. Fachrin², Nurbaety³, Salma⁴

¹Lecturer of Environmental of Public Health, University Moslem of Indonesia, ²Lecturer of Occupational of Public Health, University Moslem of Indonesia, ³Lecturer Public Health, University Moslem of Indonesia, ⁴Postgraduated Faculty of Public Health, University Moslem of Indonesia

Abstract

The market is one of the public places frequented by the public, thus allowing transmission of the disease both directly and indirectly through vectors such as flies. Market cleanliness must be kept clean so that food contamination is less likely to occur so that the food to be consumed remains good, clean and safe to eat. This research to identify boraks and methanil yellow. The sample is a portion taken from the whole object under study and is considered to represent the population. Sampling in this study was conducted by total sampling for interviews with hawker food vendors. Food samples to see the content of Borax and 3 food and beverage samples to see the content of Rhodamin B. The content of Borax and Rhodamin in street food vendors in the Eggplant Market shows that 6 traders who tested the content of Borax on meatballs obtained negative results, while for 3 traders tested the content of Rhodamin B in food sold obtained positive results or did not meet the requirements for consumption. Hygiene in serving food obtained that 20 (64.5%) hawker food vendors in the Eggplant Market did not meet the requirements. Hygiene and sanitation of sales locations shows that 20 (64.5%) of traders are in sales locations that are not good or have not met the requirements.

Keywords: Boraks, methanil Yellow, Personal hygiene.

Introduction

Food snacks as one of the community services in the field of food, which is often still far from meeting health requirements that cause disease to the community¹. By seeing the potential for such large food and high levels of vulnerability, efforts to monitor the quality of snacks are managed by taking into account hygiene and sanitation rules and health requirements. About 80% of food-borne diseases are caused by pathogenic bacteria. Some types of bacteria that often cause disease include: Salmonella, Staphylococcus, Escherichia coli, Vibrio, Clostridium, Shigella and Pseudomonas Cocovenenous¹²³.

Food outlets and food handlers available in public places should receive special attention from the government in order to present good and safe snacks for consumption. One of the public places where there are traders who provide various snacks is traditional markets such as the Makassar Terong Market Snacks sold in markets are needed considering the activity in the market occurs from morning and even usually happens in the afternoon. Snack food that is often sold in the market is cheap enough so that it is in demand by many people. Noteworthy is not only snacks at low prices but we also need to consider the cleanliness of these foods. Of course we want snacks that are cheap, tasty, also have good nutrition and hygiene and can support the health of the human body⁴⁵⁶.

Snack food is very risky for health such as infection by microorganisms, pathogens, poisoning, cancer risk and others that are not yet known by researchers. This risk can occur because of the lack of knowledge about the safety of snacks. These risks can be minimized if in the presentation, as well as at the time of distribution or sale are considered things that can cause health risks. Noteworthy is not only snacks at low prices but we
also need to consider the cleanliness of these foods\textsuperscript{7,8,9}. Of course we want snacks that are cheap, tasty, also have good nutrition and hygiene and can support the health of the human body. Snack food is very risky for health such as infection by microorganisms, pathogens, poisoning, cancer risk and others that are not yet known by researchers. This risk can occur because of the lack of knowledge about the safety of snacks. These risks can be minimized if in the presentation, as well as at the time of distribution or sale are considered things that can cause health risks\textsuperscript{10,11,12}.

There are quite a number of hawker food vendors in the Eggplant Market considering that the Eggplant Market is a fairly large traditional market and the activity of traders in the market sometimes takes place from morning to evening, it is possible that snacks sold can be contaminated with pollutants, bacteria or germs that can disturb health when consumed by humans\textsuperscript{13,14}. In addition, there are some hawker food traders who trade in places that are not good food at Pasar Terong quite a lot considering that Pasar Terong is a fairly large traditional market and the activities of traders in the market sometimes take place from morning to evening, do not rule out food snacks that are sold can be contaminated with pollutants, bacteria or germs that can interfere with health if consumed by humans. In addition, there are some hawker food traders who trade in places that are not good.

**Method**

The population is Snack food is very risky for health such as infection by microorganisms, pathogens, poisoning, cancer risk and others that are not yet known by researchers. This risk can occur because of the lack of knowledge about the safety of snacks. These risks can be minimized if in the presentation, as well as at the time of distribution or sale are considered things that can cause health risks.

Discussion

Snack food ingredients are materials used in processing snacks. In terms of quality, in addition to containing all the substances needed by the body food must also meet safety requirements. Based on the results of research conducted on 31 respondents in the Terong Market Bontoala District of Makassar City, the results obtained are that most traders use natural ingredients/materials in accordance with the requirements of the Minister of Health Decree No. 942 of 2003. Laboratory test results regarding the content of borax in meatballs traders in the Terong Market, Bontoala District, Makassar, showed that 6 traders whose meat samples were taken as samples and had been examined in the laboratory showed negative results or no borax content in the meatballs.

The results of this study are not in line with research on the identification of snacks containing borax in traders in Semarang City markets. From the research results, it was found that there are 3 types of snacks that positively contain Borax, namely: gendar (100%) positively containing Borax, lopis (50%) containing Borax, and cenil (25%) containing Borax. Other types of snacks, namely: rice cake, sentiling, and putu mayang do not contain Borax. From the overall snacks sample studied, 29% contained Borax.

Laboratory test results regarding the content of Rhodamin B in 2 cake traders and one ice trader in the Terong Market in the Bontoala District of Makassar were obtained that all traders whose food samples were taken and examined in the laboratory showed positive results or contained Rhodamin B. The results of this study are in line with research conducted on the identification of snack foods containing Forbidden Dyes at traders in Semarang City Markets. From the results of the study it was found that 50% of the food samples studied contained dyes that could not be used in snacks, snacks containing prohibited dyes, namely: cenil, centiling, and putu mayang.

Rhodamin B synthetic dyes are found in food products that should be used for textile dyes. Although it has a low toxicity, consumption of large amounts or repeatedly causes cumulative properties of respiratory tract irritation, skin irritation, eye irritation, irritation of the digestive tract, poisoning, and liver disorders. From these results it was found that 24 (77.4%) traders were not tested for their food ingredients, because the tested foods were suspected of containing Borax and Rhodamin B. For testing Borax was taken from 6 meatball traders, while for Rhodamin B was taken from food are red and are thought to contain Rhodamin B. Based on the results of field observations made at the Terong Market in Bontoala District, Makassar City by researchers regarding hygiene in serving snacks, it was found that the majority of traders who served their food openly were 20 (64.5%), this meant that hygiene in serving snacks was served not eligible.

The Terong Market area is located in the middle of the city, where vehicles often pass by which can cause pollution or contamination of snacks sold by traders. Food outlets and food handlers available in public places should receive special attention from the government so that merchants serve good, safe food for consumption. Food contamination can occur due to poor sales locations, close to pollution sources such as high frequency traffic. Based on the results of research that has been done for the variable location of sales obtained that most of the traders maintain the cleanliness of their sales location, while traders who have a sales location are close to polluting sources as many as 20 (64.5%). This data is based on the results of direct observations and interviews, the location of the sales of hawker food...
vendors in Pasar Terong partly located beside the roads that are often traversed by vehicles, those that trade beside used clothing sellers (claws), and are right in front of the garbage dump.

The data illustrates that hygiene and sanitation of merchant sales locations in Terong Market, Bontoala District, Makassar City, the majority (64.5%) are not good or have not met the requirements for good, clean and safe street food sales. The results of this study are in line with the results of research conducted by Pratiwi (2012) on traders in the traditional market area of Kaliyoso Village. From the results of the study obtained a description that all traders (100%) in the Kaliyoso Traditional Market. Food hygiene sanitation in terms of sales location does not meet the requirements.

**Conclution**

1. The content of Borax and Rhodamin in street food traders that 6 traders tested the content of Borax on meatballs obtained negative results, while for 3 traders tested the content of Rhodamin B in food sold obtained positive results or did not meet the requirements for consumption.

2. Hygiene in serving food obtained that 20 (64.5%) hawker food vendors in the Eggplant Market did not meet the requirements.

3. Hygiene and sanitation of sales locations shows that 20 (64.5%) of traders are in sales locations that are not good or have not met the requirements.

Mapping Analysis Distribution of Microplastics at the Tallo River in Makassar

Alfina Baharuddin¹, Muhammad Ikhtiar¹, A. Rizki Syamsul Bahri²

¹Lecturer Department of Environmental Health, Public Health University, Moslem of Indonesia, ²Postgraduated program Magister of Public Health University Moslem of Indonesia

Abstract

This aims of the study to identify spatial microplastic pollution sediments in the Tallo River Makassar City. This type of research is descriptive observational. This research design uses a Geographical Information System (GIS) Statistical analysis using the average abundance of microplastics is presented in tables and graphs, then analyzed descriptively quantitatively at each station. Data showing the mean ± standard deviation were analyzed using SPSS software. Based on the results of research that has been done, the number of microplastics found in the sediments in the Tallo River is 289. The highest micoplastic size found in the Tallo River sediments is 1.00-4.75 mm as much as 167 MP (58%) with an average abundance of 18, 56 ± 30,875 MP/kg. Followed by a size of <1 mm as much as 112 MP (39%) with an average abundance of microplastics 12.44 ± 17.686 MP/kg and sizes> 4.75 mm as much as 10 MP (3%) with an average abundance of microplastics 1.11 ± 2,315 MP/kg.

Keyword: Mapping, Microplastic, sediment, river.

Introduction

One of the results of environmental pollution is the accumulation of garbage. Waste production in Makassar City in 2018 was 1,261 tonnes/day (World Bank Group, 2018). This results in garbage entering the river body and ending up in the marine environment. The type of waste that dominates in the waters is plastic waste¹. In 2019, plastic contributed 60% - 80% of waste in the sea and is a threat to the ecosystem. Plastics that are degraded to MP <5 mm in size known as microplastics can accumulate in sediments and are consumed by marine organisms²,³,⁴.

The highest concentration of microplastics is found in the estuaries of many rivers. Population density, domestic discharge, industrial disposal and urban activities can be a contributor to microplastic pollution in sediments. Wind and currents also act as drivers for the distribution of microplastics. Coastal currents and wind transport can contribute to a higher distribution of microplastics at river mouths and adjacent to shore. Lack of proper plastics management could be a cause of transport and the relatively high abundance of microplastics in river estuaries⁵,⁶,⁷.

Microplastics are susceptible to sedimentation as evidenced by differences in the type and shape of the polymer. Microplastic size decreases with increasing microplastic concentration in water and sediment. Smallmicroplastic particles will take more time to settle than larger ones. Adverse human health impacts from the consumption of micro and nanoplastics in seafood can be caused by the plastic particles themselves or the inherent additives and contaminants such as Persistent, Bioaccumulative, and Toxic Substances (PBTs). Microplastic intake in humans from seafood has been estimated at 1 particle per day to 30 particles per day depending on seafood consumption habits and the organism’s exposure to microplastics⁸,⁹.

Microplastics contain a mixture of chemicals added during the manufacture of plastics which can become contaminated in the environment. These chemical additives include monomers, oligomers, plasticizers, and flame retardants. Meanwhile, contaminants that are
absorbed from the environment include Polychlorinated Biphenyls (PCBs), Polycyclic Aromatic Hydrocarbons (PAHs), Chlorinated Pesticides, and the Persistent Organic Pollutants (POPs) group. Persistent Organic Pollutants (POPs) are classified as Bioaccumulative Toxic Substances (PBTs) which have the ability to accumulate in organisms10,11.

One of the studies conducted stated that domestic discharge, surface runoff, municipal discharge and factory effluent were identified as important contributors to microplastic pollution in sediments. In addition, wind and currents are other drivers in the distribution of microplastics along river flows12,13. This study is consistent with the research that has been found that microplastics are found in the most sediments in the 2.45 and 4.75 size categories because they are influenced by their mass. A similar study was also conducted by Karthik, et.al. (2018), that among all classes, the MP size of microplastics between 1.18 and 2.36 mm shows the highest microplastic abundance in sediments in Indian waters2,4,15.

Effluent without proper treatment from Wastewater Treatment Plants significantly increases the abundance of microplastics in water and sediment. In addition, the activities of the plastics industry directly contribute to the load of microplastics downstream and water bodies. Recreational activities along the river contribute a large amount of plastic waste which is a direct source of microplastic11,14,16.

Tallo River is surrounded by rice fields, fishponds and some residential areas. In addition, along the Tallo River, there are several industries including Steam Power Plant (PLTU). The Tallo River is used as a disposal site for used cooling water, a carrier for industrial waste from households to the sea and as a means of transportation for fishermen, fishpond farmers and industry (Zainal and Awaluddin, 2018). Tallo River is used as a means of transportation and tourism activities, namely mangrove nature tourism, Lakkang tourism village, TirtaBugis Waterpark tourism, M; Tos shopping center, and historical tours of the tombs of the Tallo Kings. Based on this background, the researcher is interested in researching microplastic identification in the sediments in the Telloriver, Makassar city.

**Method**

This type of research is descriptive observational. This research design uses a Geographical Information Systems (GIS) approach. Collecting data using the exploratory method, namely direct sampling. The research was carried out in the Tallo City River in 2020.

The materials used for testing the sediment samples were sediment, NaCl solution, Aquabidest, aluminum foil, 47 mm Whatman Nitrocellulose filter paper, plastic samples, and label paper. Sediment sampling was carried out using a shovel with a depth of 3 cm. The sediment was then put into the plastic sample as much as 1 kg.

**Separation of microplastic particles from sediment is carried out in several steps, namely:**

(a) Drying was carried out in an oven at 75oC until the water content of the sediment ran out.

(b) Reduction of the volume of dry sediment was carried out by sieving (size 5 mm). The sieve sample was put into an Erlenmeyer flask.

(c) Density separation was carried out by mixing a 100 gram dry sediment sample and a saturated NaCl solution (300 gr NaCl + 1 liter Aquabidest) with an estimate of 3 times the sample volume. Then the mixture was stirred using a Shaker Rotator H-SR-200 for 2 minutes. The sample is then left for 12 hours to form a supernatant.

(d) Filtering was done by filtering the supernatant using Whatman Nitrocellulose 47 mm with the aid of a vacuum pump.

(e) Visual sorting. Microplastic particles were sorted visually using a stereo microscope and microplastic observations were made.

**Result**

The proportion of the number of microplastics contained in the sediment samples at each station is as follows.
Figure 1 Proportion of Microplastic Data in the Sediment

Based on Figure 1 shows, the proportion of the number of microplastics in the sediment at station 1 is 0.7%, station 2 is 4.5%, and at station 3 is 94.8%.

The proportion of the amount of microplastic contained in the sediment sample is based on its shape as follows.

Figure 2 Proportion Data of the Amount of Microplastic in the Sediment

Based on Figure 2, the proportion of the amount of microplastics in the sediment in the Tallo River based on its shape is 80% fragment shape, 4% foam, 7% film and 9% line.

Figure 3 Proportion of the Amount of Microplastic in the Sediment
Based on Figure 3 shows that the proportion of the amount of microplastic in the sediment in the Tallo River based on its color is white 14.9%, red 4.5%, transparent 36.0%, green 11.4%, blue 31.1%, black color 1.0%, 0.7% brown color, and 0.3% pigmented color.

Based on Figure 3, it shows the distribution of microplastic pollution in the sediments in the Tallo River, namely at station 1 point 1 as much as 1 MP (0.3%), point 2 as much as 1 MP (0.3%) and point 3 microplastics are not found. As for station 2, point 1 is 4 MP (1.4%), point 2 is 1 MP (0.3%) and point 3 is 8 MP (2.8%). Meanwhile, at station 3, point 1 is 38 MP (13.1%), point 2 is 107 MP (37%) and point 3 is 129 MP (44.6%).

**Discussion**

Based on the research results, the forms of microplastics found in sediments are fragments, foam, film, and line. The shape of the fragments is a form that is found more in the Tallo River compared to other forms, namely as much as 231 MP (80%) with an average abundance of microplastics $25.67 \pm 40.811$ MP/kg.

This study is in accordance with the research microplastics found around Kupang and Rote are dominated by fragments. Fragments are pieces of plastic that have strong synthetic polymers such as drinking bottles and other plastic food packaging. That fragments contribute to the majority of microplastics in sediments and are followed by line shapes both at high tide and at low tide. The distribution of the size and shape of the microplastics in the sediments can be caused by various factors such as the source of the plastic, the quality of the debris, the degradation of macroplastics, the wind currents and the sinking rate of the plastics and the relative susceptibility to microbes $^{2,6,17,18}$.

Fragment microplastics are microplastics that come from anthropogenic activities such as household waste. Fragments can come from bottles, plastic bags and pieces of pipe pipe. Fiber microplastics come from synthetic fabrics, fishing boat waste and fishing gear such as fishing nets and fishing lines. This type of fiber can also be called a line. This type of film comes from food packaging. Meanwhile, fragments came from large plastic fractures. Fragments are microplastics derived from pieces of plastic products with strong synthetic polymers. Fiber or line comes from washing clothes, namely the residue of clothing yarn and plastic rope that is degraded and is also affected by fishing activities that come from fishing rods and nets. Films are microplastics that come from the cut and degrade of plastic bags $^{10,19,20}$.

Although foam forms have a lower number than fragments, lines and films, this shape also needs attention. A special structure with many cavities in it and is often
used for sound insulation, heat insulation and impact avoidance. This foam is widely used in packaging, auto components, clothing, and building equipment. Its brittle nature and low density make it easier to enter and float in water. The results of identification in this study, the color of the microplastics found in the Tallo River sediments are white, red, transparent, green, blue, black, brown and the color of the pigmentation results. The most dominant plastic color in the Ofanto River is transparent (56%), followed by black (35%). Microplastics can inherit color from the parent plastic product, but the color can change due to photodegradation and residence time in water. This shows the degree of fragmentation. Microplastic with a transparent color is the initial identification of the type of Polypropylene (PP) polymer and indicates the length of time the microplastic has been photodegradable by UV light. The black color can indicate the amount of contaminants absorbed in the microplastic and has the ability to absorb high pollutants which can affect the texture of the microplastic.9,14,18.

The high level of microplastics in the sediments illustrates that the microplastics originating from land are also high. In this study, the sediment sampling was carried out at three points per station. Based on the research results, at station 1 point 1 and point 2 it was found that each 1 MP (0.3%). Community activities at points 1 and 2 are still insufficient and far from residential areas. At point 1 is the Nipa-Nipa Regulated Reservoir Gazebo where the existing activities are only fishing activities for the surrounding community. Point 2 is to the east of the Nipa-Nipa Sewage Treatment Plant, which is under the Nipa-Nipa intersection. At this location it is still far from activities and residential areas. Whereas point 3 is a location very far from residential areas and is in the middle of a very large agricultural land. So that no microplastics are found at point 3 because there is no resident activity that produces plastic waste8,22.

At station 2 point 1, 4 MP (1.4%) was found which came from anthropogenic waste. Point 1 is located in a residential area so that the resulting waste is the result of resident activities. At point 2 it is found that 1 MP (0.3%) is lower than point 1. This is because the sampling location in point 2 is a location far from residential areas. The activities around point 2 are fishing activities and river transportation. Meanwhile, at point 3, Lakkang Island, the number of microplastics is higher than points 1 and 2, namely 8 MP (2.8%). This is due to the confluence of the pampang tributaries and tributaries of PT. KIMA so that plastic waste accumulates at point 3. In addition, Lakkang Island is a residential location that does not have a Final Disposal Site (TPA) so that the resulting waste is dumped directly into the river.

**Conclusion**

The number of microplastics found in sediments in the Tallo River was 289 particles. The microplastic forms identified were fragment, foam, film and line. The colors of microplastics identified were white, red, transparent, green, blue, black, brown and pigmented colors. The microplastic sizes identified were <1 mm and 1.00-4.75 mm and> 4.75 mm.

Assessment of Nursing Care Provided to Hospitalized Children Burn Patients at Burn and Plastic Surgery Center at Kirkuk City

Aram Najat Abdulrazzaq¹, Hewa Sattar Salih²

¹MSc Student, Pediatric Nursing Department, College of Nursing, University of Sulaimani,  
²Assistant Prof., Community Health Nursing, Nursing College, University of Kirkuk, Iraq

Abstract

Background: Burns are the foremost important causes of a child’s injury that lead to a considerable health problem; social, functional, and psychological weakness. They are the leading reason of hospitalization and are associated with significant morbidity and mortality.

Objectives: This study aimed to assess the quality of nursing management and to find out association between nurses’ sociodemographic data and quality of nursing management provided to admitted children Azadi Teaching Hospital in Kirkuk city-Iraq.

Method: A descriptive design (quantitative approach) was carried out from January 1st to 20th of October 2020. A non-probability (purposive sample) sampling technique utilized to collect data from (48) nurses working in burn and plastic surgery center in Azadi teaching hospital in Kirkuk city. A questionnaire was designed and constructed for the purpose of the study. Statistical analysis was performed using (SPSS) software (V.26). Comparison was carried out using Chi-square (X²) and T test for determination of the P. value.

Results: The study sample revealed that the majority of the sample were in age group (21-30) years old represent (47.9 %), and (60.4 %) of the participants were female. The most striking results emerged from the data is that the majority of the participants have a good level of the practices in relation to nursing management of major burns at admission (54.17%). The results also show a significant association between the nurses’ practices at admission and their age, gender, number of courses training.

Conclusion: Training courses have significant effects on nurses’ practices at admission. Further studies are required to find the effectiveness of intervention that involve nurses’ practices for children with burn injuries.

Keywords: Children, Burn, Nursing Management, Plastic Surgery, Quality.

Introduction

Burns are some of the foremost devastative injuries a child can have. These traumas occur when there’s skin contact with hot liquid: hot surfaces/objects, chemicals, radiation or electricity and skin damage can furthermore results from cold and friction injures. Burn injuries are ranked fourth among acute injuries within the world. The majority of burns are being minor (<10%) total body surface area (TBSA). However a big number of kids sustain burns >15% (TBSA), leading to the initiation of the systemic inflammatory response syndrome. These patients require resuscitation. Delays in resuscitation may result in increased complications and mortality.

World Health Organization definition of quality of management is “the extent to which health care services provided to individuals and patient populations improve desire health outcomes. In order to perform this, health
care must be safe, effective, timely, efficient, equitable and people-centered”.

Pediatric nurses have provocation and responsibility to give assistance to burn children efficaciously. Care of burnt children classified into prehospital care (first aid and transportation to burn unit) and hospital care (wound care, prevention of complication and nutrition support likewise the rehabilitation and psychosocial counseling). Primary assessment of patients with acute burns starts with airway patency and cervical spine protection, assess breathing, circulation, and cardiac status; stabilize any disability, deficit, or gross deformity; and assess the extent of burns and concurrent injuries. The secondary assessment must not begin until the primary assessment is complete. This assessment includes a whole history, instance information about the burn injury, head-to-toe physical examination, accurate calculation of the percentage (TBSA) affected, fluid resuscitation requirements, and wound care. To found the percentage of (TBSA) involved in a burn injury, as this value is use for fluid resuscitation, transfer decisions, further management, prognosis, and research. The useful method of estimation of burned (TBSA) are palm method, rule of nines method, and the Lund and Browder (LB) chart.

Material and Method

A descriptive design (Quantitative approach) was carried out from January 1st to 20th of October 2020 in burn and plastic surgery center. This study aimed to assess the quality of nursing management provided to admitted children Azadi Teaching Hospital in Kirkuk city-Iraq. Burn and plastic surgery center is the only main center for burns that received patients inside and outside of Kirkuk city.

A non-probability (purposive sample) sampling technique utilized to collect data from (48) nurses working in burn and plastic surgery center. (10) Nurses sample for pilot study were included. They were selected according to certain criteria, which include at least one year of experience and worked at burn centers in the hospitals that have such facilities to provide burn nursing.

A questionnaire was designed and constructed for the purpose of study. It is composed of two parts. Overall variables (42) items.

Part I: Socio-demographic Data of Nurses: This part of questionnaire is includes eight variables for the socio-demographic characteristics of nurses who working in burn and plastic surgery center.

Part II: Nursing Management of Child with Major Burn at Admission to Burn and Plastic Surgery Center: This part of questionnaire form is observation checklist which contains information about nursing management for children with burn when admission to burn and plastic surgery center. It is composed of (34) items and this part rated on (2) levels dichotomous scale which are indicated by score (2) for yes and score (1) for no. The total score ranged between (34-68). Therefore, the levels are poor practices when score (≤ 45.33), the levels are fair practices when score between (45.34 - 56.66), and the levels are good practices score (≥ 56.67).

Statistical Analysis: was performed using statistical package of social sciences (SPSS) software (V.26). Comparison was carried out using Chi-square (X²) and T test for determination of the P. value (P< 0.05 significant) and (P< 0.01 highly significant).

Result

The study sample revealed that the majority of the sample were in age group (21-30) years old represent (47.9%), (60.4%) of the participants were female, and (50%) of nurses were graduated professional diploma nursing degree. Plurality of the sample were the monthly income is between (601,000-900,000 ID per month) and (62.5%) of the participants had less than (5) years of experience at burn and plastic surgery center. (70.8%) of the sample were not participated in any courses of special training and (92.9%) of them participated in courses the number of courses is between (1-3) and the located inside of Iraq. Furthermore (62.5%) of the participants had less than (5) years of experience at burn and plastic surgery center. The present result disagree with Hassan (2015)\textsuperscript{10}, who mention (72%) of his sample are in age more than (30) years old and most of the nurses (80%) are male. Additionally, result of study agree with Hassan (2015)\textsuperscript{10}, accounted of (56%), in nurses’ burnout reports that the majority of the study sample have (2-6) years of experience.

The present study disclose the nurses’ practices regarding items of nursing management for a child with the major burns at admission in burn and plastic surgery center. (54.17%) Items in the table 2 is a high mean score that agrees with results of the study done by Youssef, & et al., (2019)\textsuperscript{11}, which found that (74%) of them had a competent level of practice regarding nurses’ care of pediatric burn. The study done by Lam, & et al., (2018)\textsuperscript{12}, found regarding fluid resuscitation method53.5% of nurses provided the correct answer which agree with current study.

The nurses practice regarding pain management is incommensurate in present study table 2 which agree with a study was done by\textsuperscript{13}, their found the minority of the staff regarded pain management as sufficient during dressing changes and after nursing care\textsuperscript{14} mentions in their study children are often exposed to painful procedures during hospitalization. The study illustrate result of association between nurses’ practices and participate in courses training of burn there was statistics high significant association which account the p value is 0.005. The outcome of the study disagree with previous study done by\textsuperscript{15}, there was no correlation found between total knowledge/practice score and number of seminars (r = 0.033, 0.144) respectively.

---

Conclusion

Majority of the sample were in age group (21-30) years old represent (47.9 %), and (60.4 %) of the participants were female. Also (70.8%) of the sample were did not participated in any courses of special training and (92.9%) of them participated in courses the number of courses is between (1-3) courses and the located inside of Iraq. Majority of nurses practices regarding nursing management for a child with the
major burns at admission in burn and plastic surgery center were on good level that accounted (54.17%).

There is statistical significant association between the nurses’ practices at admission and their age, gender, number of courses training and location of courses. Training courses have significant effects on nurses’ practices at admission. Further studies are required to find the effectiveness of intervention that involve nurses’ practices for children with burn injuries.

COVID-19 Infection and its Relation to Preterm Delivery in Pregnant Women

Mohammed Ismael Dawood¹, Rasha Shakir², Mohammed H. Alwan³

¹,²,³Lecturer, College of Medicine, University of Al-Fallujah, Iraq

Abstract

The study aims to find the relationship between COVID-19 virus infections and early births in women infected with this virus in Al-Fallujah city. The prospective study was conducted in Al-Fallujah city during the period between February 1, 2020, and September 1, 2020, at Al-Fallujah Teaching Hospital. Through the study, 100 pregnant women were received, complaining of Covid-19 infections, which were diagnosed in Al-Fallujah, and now Real Time PCR was confirmed through nasopharyngeal swabs that were taken from Al-Fallujah Teaching Hospital. The study also included measuring the level of blood pressure, sugar and C-RP in those women during the fifth to eight week, where we were infected, and then in the 12th week of pregnancy took place, where communication was made, and a level was measured, and as a result, these women who completed the period with a pre-term labor, miscarriage before the 24th week of pregnancy or those completed the period with successful pregnancy. In this study, 33% of COVID-19 pregnant women were within the age group 24-30 years followed by 30% in the age group 31-38 year. In this study, 10% of COVID-19 pregnant women suffer from hypertension, 13% were with Diabetes, 35% with UTI while 70% were suffered from fever. When reaching 24th week of pregnancy, and as shown in Table 3. The study showed that 40% COVID-19 pregnant women experienced completed the period with a pre-term labor, 10% was with miscarriage before the 24th week of pregnancy, while 50% of them completed the period continued the pregnancy. In this study, 82.5% of COVID-19 pregnant women with preterm labor were suffered previously from fever comparing with 55% of COVID-19 pregnant women without preterm labor. The study showed the highest mean of C-reactive protein was present COVID-19 pregnant women with preterm labor (22.5±2.14 mg/ml), fan lowest mean was in women who without preterm labor (14.6±2.11 mg/ml) (P<0.01).

Conclusions: The study showed a significant relation of COVID-19 infection with pregnant women who pre-term labor especially who have high body temperature.

Keywords: COVID-19; Preterm delivery; pregnant women; C-reactive protein.

Introduction

New Corona virus infections are considered one of the most deadly diseases in society these days, especially people who kill countries affected by the virus, and recent studies have indicated that there is a strong relationship between the high level of infection with Corona virus 19 failure to respect global health laws and follow the instructions that my son and use sterilizer and wash treatment With among people (¹). It is worth noting that one of the diseases associated with Virus Corona is chest infections and coughing that exacerbate cases of Covid 19 in society(²). As the Covid 19 virus is considered one of the most important diseases that have appeared in society and that do not affect all ages and genders, regardless of their living condition, but the role of immunity has a great role in expelling the virus or keeping it in a state that can multiply and affect a person’s health(³). There is no doubt that Corona injuries may lead to medicine for people, as the study indicated that Corona injuries are major problems, problems of pregnant women, which deal with miscarriage or early childbirth associated with high blood sugar or high blood...
pressure\(^{(4,5)}\). High temperatures in people with Covid virus 19 are tormented by one of the most important causes of respiratory disorder due to the high level of cytokinins like Interleukin 1 and Interleukin 6 and the C-reactive protein, which adversely affects the health condition through the cytokinin A storm in infected people \(^{(6,7)}\). Which may lead to health problems, especially in pregnant women, which may lead to abortion or premature labor in pregnant women\(^{(8)}\). The study aims to find the relationship between Covid 19 virus infections and early births in women infected with this virus in of Al-Fallujah city.

**Materials and Method**

The study was conducted in the city of Al-Fallujah during the period between February 1, 2020, and September 1, 2020, at Al-Fallujah Teaching Hospital. Through the study, 100 pregnant women were received, complaining of Covid-19 infections, which were diagnosed in Al-Fallujah, and now Real Time PCR was confirmed through nasopharyngeal swabs that were taken from Al-Fallujah Teaching Hospital. The study also included measuring the level of blood pressure, sugar and C-RP in those women during the fifth to eight week, where we were infected, and then in the 12th week of pregnancy took place, where communication was made, and a level was measured, and as a result, these women who completed the period with a pre-term labor, miscarriage before the 24th week of pregnancy or those completed the period with successful pregnancy.

**Results**

In this study, 33% of COVID-19 pregnant women were within the age group 24-30 years followed by 30% in the age group 31-38 year(Table 1).

### Discussion

In this study, 33% of COVID-19 pregnant women were within the age group 24-30 years followed by 30% in the age group 31-38 year(Table 1). Consistent with what our study has reached, many studies also found that most of the ages affected by the Corona virus here are pregnant women were less than 30 years old[6,7]. This age period is considered the most vulnerable to premature birth, as was proven in previous studies[8,9]. In this study, 10% of COVID-19 pregnant women suffer from hypertension, 13% were with Diabetes, 35% with UTI while 70% were suffered from fever.(Table 2). There is no doubt that among the most important problems that pregnant women face is high blood level, high level of diabetes, and also UTI[10]. Where previously conducted studies mentioned that most women with urinary tract infection are pregnant, and as the study indicated that most pregnant women with Coronavirus suffer from high levels of temperature due to infection with the Corona virus, which leads to high temperatures, coughing, shortness of breath, muscle and bone pain[10,11]. When reaching 24th week of pregnancy, and as shown in Table 3. The study showed that 40% COVID-19 pregnant women experienced completed the period with a pre-term labor, 10% was with miscarriage before the 24th week of pregnancy, while 50% of them completed the period continued the pregnancy. On the level of similarities, recent studies conducted this year indicated that most of the women infected with the Coronavirus, who were there during pregnancy, had suffered from pregnancy specialization disorders, including premature birth and abortion, as well as the problem of premature birth at least 40% of these women[12,13]. A study conducted in Wuhan stated that women infected with Coronavirus are more likely to have early labor due to the worsening of the health condition in pregnant women and due to elevated levels of cytokines that affect the baby health (2). In this study, 82.5 % of COVID-19 pregnant women with preterm labor were suffered previously from fever comparing with 55% of COVID-19 pregnant women without preterm labor, Table 4. From previous studies and from the information accumulated by everyone that repeated infections with the COVID-19 include high temperatures in infected people as well as other respiratory symptoms. They complain of high temperatures compared to women who are not enough in the asymptomatic infections[14,15]. Other scientists have instructed similar studies on high temperatures in patients with Covid 19 virus that may result from an elevated level of interleukin-16, CRP and TNF alpha[16,17]. The study showed the highest mean of C-reactive protein was present COVID-19 pregnant women with preterm labor (22.5±2.14 mg/ml), fan lowest mean was in women who without preterm labor (14.6±2.11 mg/ml) (P<0.01), as shown in Table 5. There is no doubt that the level of the reactive protein, a type that is high in infections and viral on the limit of the reactive protein, the type of disease of people with Covid 19 virus is a sign of the task of secondary bacterial infections in the respiratory, upper and lower system of people, the virus, especially since the infected are pregnant women, and pregnant women are known to suffer Those who have
it and the bacteria that infect them as a result these circumstances (18).

Conclusions

The study showed a significant relation of COVID-19 infection with pregnant women who pre-term labor especially who have high body temperature.

Emergency Traumatic Patients, Study & Analysis in Nineveh Province in Iraq

Mohammed Salih Abdullah Ali¹, Zainab Saud Abdulaziz², Sara Raad Lahoob³, Azzawi M. Hadi³

¹Consultant General Surgeon MBChB. CABS, Head of Department of Surgery, Nineveh College of Medicine, ²MBChB, Resident in Nineveh Health Directorate, ³Consultant Urologist MBChB. FIBMS, Department of Surgery, Nineveh College of Medicine

Abstract

Trauma is the medical problems associated with physical injury. This was a cross section study involve 250 trauma cases admitted to Alsalam and Aljumhoory teaching hospitals of Nineveh province Iraq, from November 2018 to April 2019. The study was aimed to highlight the epidemiological parameters of these cases, determine most common causes and the management as well outcome for them. Males are more affected than females, and 56% of patients belong to the age groups from 10 to 39 years, we found that Slips and falls (or same level falls) are the most common mechanism of injury specially among elderly people, while bullet and blast injuries form a small percentage of injuries with 4% & 1.6% respectively. Limb injury is the most common type of injury, followed by head injuries. Most of these injuries were treated conservatively but about quarter of them require surgery, while abdominal injuries which represent about 5.6% of all injuries, were treated by surgery with exception of 21.4% treated conservatively.

Keywords: Trauma, Accidents, RTA, Injury.

Introduction

Trauma is the medical problems associated with physical injury. There are many types of physical injuries that can affect the human body including thermal, chemical and ionizing radiation but the most common type is the mechanical injury. Trauma usually affect younger age group. Those their age below 40-year-old, and it is the main cause for their mortality and morbidity all over the world (1). It’s traditionally seen as a disease of the young, with in particular, young males involved in motor vehicle accidents and interpersonal violence. Training of those involved in the management of patients suffering trauma has often concentrated on these aspects of injury (2).

In 2006 more than 42.5million of injured patient was evaluated and treated in emergency department in USA, and it account about 36% of all patient visit emergency department (3). Although the main mechanism of injuries is unintentional falls (20.3%), followed by motor vehicle accident (9.5%) but the death due to motor vehicle crash is more than due to falls. It is 43,000 deaths from 179,000 deaths due to all trauma, while only 21,000 death was due to fall from this number (3).

Injuries sustained are predominantly due to high energy blunt trauma such as a fall from height, road or workplace trauma (4). Abdomen remain the 3rd most commonly injured region, with surgery required in about 25% of civilian cases (5).

Patients and Method

Two hundred fifty of traumatic patients admitted to the emergency department of Al-Salam and Al-Jumhoory teaching hospital in Nineveh province/Iraq, during the period extended from November/2018 to April/2019 were involved in this study, the data were collected from the patient’s relatives the questioner included the gender, age, mechanism of injury, type of injury, investigation done for the patient and the provisional diagnosis according to the clinical examination and investigation’s results. These data have been analyzed to represent the trauma in Nineveh province.

The mechanism of injury, the patients are classified into bullet injury, blast injury, road traffic accident (RTA), fall from height (FFH), slips and falls, fall of heavy objects on the patient like wall, blocks, or other heavy objects, and injury by sharp objects like knives,
glass or others. The injured patients classified according to the part of the body affected into head injury, chest injury, abdominal injury, limb injury and those who have combined injuries. Conservative treatment included pain management, cleaning, suturing and dressing in case of wounds, closed reduction of fractures and follow up of patients for possible complications. Patients who required surgical intervention, have been followed, but we focused on the surgeries performed for patients with abdominal injuries to know what is the most frequently injured organs and how they are treated.

Results

During the study period we collected 250 cases of trauma patients affected mainly by mechanical trauma from the emergency department of Nineveh province/ Iraq. Table 1 shows age and sex distribution of trauma patients in Nineveh province, it shows that the highest age group affected was those below 10 years, followed by those in the third decade. The least affected age group was those over 70 years.

Mechanism and Type of injury (according to the part of the body involved) of trauma patients in Nineveh province was demonstrated in table 2, it shows that the highest insult was road traffic accident followed by fall from height, while the least cause of injury was blast injuries. The most insulted part was the limbs, followed by head, while the least was the chest.

Discussion

Although trauma is very common in all societies, this is the 1st study in our city to highlight the prevalence of traumatic injuries, their causes and treatment. Male preponderance in our study is corresponding to similar studies in Pakistan (6), Ghana (7) and Tanzania (8), in all injury types, there were more males injured than females (9), this could be related to traditions that obligate many females to stay home unless it is very important to go out.

About the age 56% of patients belong to the age groups from 10 to 39 years which means that young people are mostly affected by trauma among population, this result is also seen in similar studies in Iran (10, 11, 12, 13). Injured men were significantly younger than women in general. (14)

Slips and falls (or same level falls) are the most common mechanism of injury specially among elderly people, it’s commonly occur during daily activities. Older adults are five times more likely to be hospitalized due to falls than to injuries from other causes (15). Road Traffic Accidents (including car accidents, motor cycle accidents and pedestrians) are the most common mechanism of injury in young people, this is mostly due to reckless and speedy driving of the vehicles, not obeying or following traffic rules (16).

Fall from heights is a common cause of injury in children, it’s mostly from terraces, tables, windows and ladders and most frequently have a tendency to occur in homes followed by playgrounds and schoolyards (17).

Injury by sharp objects is also a common mechanism of injury according to this study, it’s mostly caused by glass pieces and other sharp objects specially occur during work time. Injuries caused by a fall of heavy object on the patient form about 7.2% of injuries, it’s caused by fall of blocks during building jobs, wall or even TV or other heavy devices on the patients specially children.

Bullet and blast injuries form a small percentage of injuries with 4% & 1.6% respectively. Limb injury is the most common type of injury, it mostly results from slips and same level falls, it includes injuries to all components of limb architectures such as bone, nerve, blood vessel, soft tissue and skin which makes for prompt and precise evaluation and management for optimizing functional outcome (18). The 2nd most common type of injury, result
from road traffic accidents and fall from heightis head injury, traumatic brain injuries presents in various forms from mild head injury that cause alterations of consciousness to sever head injury that cause comatose state and death (19). CT scan though it is very valuable in trauma, it was the least performed test, because it is not always available in our hospitals, same thing is for FAST.

Most of the injuries in this study treated conservatively with 24.4% require surgery. Abdominal injuries form about 5.6% of all injuries, most of these injuries treated by surgery with only 21.4% treated conservatively. The pre-operative and postoperative diagnosis are nearly compatible specially in suspected liver & splenic injuries and most of the bowel injuries. Nine percent of the abdominal injuries cases that require exploratory laparotomy the result was negative. Most of the patients who underwent abdominal operations didn’t develop complications with approximately third of the patients developed complications of wound infection, bleeding and paralytic ileus.

Wound infection occur more commonly than other complication, higher risk of infection was found in the older age group, patient having colostomy due left colonic injury, taking blood transfusion and having multi organ injury (20). The outcomes of this study show that the majority of patients recovered while 2.8 % died. Head injury specifically intracranial hemorrhage is the most common cause of death.

Conclusion

Young males are the most common group of people exposed to trauma. Limb injury is the most common type of injury while head injury is the commonest cause of death. Most of the patients treated conservatively with pain management, wound’s cleaning, dressing and suturing. Bowel is the most common intra-abdominal organ affected.

Screening for Cervical Polyp among Women Attending Salah-Aldin General Hospital

Atyaf A. Hameed¹, Nabella K. Yakoob²; Marwa Thair Abass¹

¹M.B.Ch. B., Gynecologist, Salah-Aldin General Hospital; ²Prof. Department of Obstetrics and Gynecology, Medical College, University of Tikrit, Iraq

Abstract

Background: Cervical polyps are the commonest cervical lesions, affecting up to 10% of women, with a reported recurrence rate of 6.2%, they arise from the endocervical canal or, less frequently, from the ectocervix, and vary in size from 5 mm to 50 mm. Symptomatic polyps are significantly more frequent in the premenopausal women, while asymptomatic polyps are significantly more common in post-menopausal women.

Aim of the Study: Screening for cervical polyps among women attending Salah-Aldin general hospital.

Patients and Method: A cross sectional study conducted in outpatients clinic and obstetrical ward in Salah El-Din general hospital at the period from the 1st of March 2018 to the end of August 2018. Simple random sample of (200) women in different ages were included.

Results: 200 women were enrolled in this study with the mean age of them were (27.30±6.8 years), the BMI mean of the patients with polyp was (30.2±2.1),4(40%) in age group between 26-35 years. Patients with polyps have ≥ 1 parity 9(9%) and 1(10%) in nulliparous.

Conclusion: The frequency of cervical polyp was 5% with no relation to the age, and 60% of the patients were healed.

Keywords: Cervical polyp; women; Salah-Aldin general hospital.

Introduction

Cervical polyps, affecting up to 10% of women(1), with a reported recurrence rate of 6.2%(2). They arise from the endocervical canal or, less frequently, from the ectocervix(3), and vary in size from 5 mm to 50 mm(4). They are commonly cherry red to purplish red in color, soft, pliable, fleshy, pedunculated, friable and readily bleed when touched(5).

It is hypothesized that they result from chronic inflammation causing focal hyperplasia, reaction to foreign bodies, a localized congestion of cervical vasculature and/or an abnormal local response to estrogen stimulation.

Cervical polyps may present with intermenstrual bleeding, postcoital bleeding, postmenopausal bleeding bleeding after trauma (e.g. gynaecological examination or coitus), vaginal discharge(5) which may be white or yellow mucus, dyspareunia which may be deep or superficial, symptomatic polyps are significantly more frequent in the premenopausal women, while asymptomatic polyps are significantly more common in postmenopausal women(6).

There is still a widely held view that all cervical polyps should be removed and subjected to histological examination to identify an unsuspected malignancy, and that further investigation (ultrasound scan and/or hysteroscopy) should be performed to identify endometrial polyps or other pathology(7), so only about 2.5% of polyps develop neoplastic changes and about 0.4% become frankly malignant. Malignancies include adenocarcinomas, squamous cell carcinomas, and Mullerian adenosarcomas. Malignancy cannot be distinguished by polyp size or appearance; hence, all cervical polyps should be removed completely and submitted for histologic evaluation. Most patients who
have malignant cervical polyps also have an associated cervical malignancy. It is unclear whether the malignancy arises first in the polyp or in the cervix. Patients with a malignant polyp should be examined carefully with colposcopy (8).

Patients with cervical polyps may have one of several types of associated endometrial lesions. These include endometrial polyps, hyperplasia (simple, complex, or atypical), adenocarcinoma, and adenosquamous carcinoma. Endometrial polyps are also common in women who are on tamoxifen therapy. Most women who have endometrial carcinoma associated with cervical polyps have symptoms that include bleeding or leucorrhea (white, thin, sticky vaginal discharge). Patients with both cervical polyps and associated symptoms have a much higher incidence of premalignant or malignant endometrial lesions than those who are asymptomatic. Up to 25% of symptomatic postmenopausal women also have associated endometrial pathology (9).

**Aim of the Study:** Screening for cervical polyps among women attending Salah-Aldin general hospital.

**Patients:** Across sectional study conducted in Salah Al-Din general hospital from first of march 2018 to end of August 2018, which included 200 married women attending obstetrical ward and gynecology and obstetrics outpatients clinic during study period sample selected simple random sampling method. The study included 200 married women in their reproductive age and their parity between 1-6, while Exclusion criteria as adolescent, menopause, unmarried and pregnant women were not included in this study.

**Data analysis:** By using manual statistical analytic method.

**Results**

The current study included 200 women and found 10 patients had cervical polyp.

Discussion

Cervical polyps arise from the endocervical canal or less frequently from the ectocervix (10). Polyps are predominantly gland-like structures with a fibrous core and can be composed of columnar or squamous epithelium similar to the cervical tissues depending on the location of origin. The etiology of these lesions are largely unknown however, it is hypothesized that they result from chronic inflammation, from a localized collection/congestion of cervical vasculature or from an abnormal local response to hormonal stimulation(10,11,12). Cervical polyps have been shown to have a significant association with endometrial hyperplasia and endometrial polyps suggesting that high levels of estrogen may be an etiologic factor(13).

Cervical polyps are a common, and usually benign, finding of the cervix. Prior data suggest that 2%–5% of women develop cervical polyps, and in one analysis of benign tumors of the cervix, (76% were found to be cervical polyps)(14). This is in agreement with the current study when the prevalence of polyp was found in 10 (5%) of the studied group.
In this study the polyps were present in different age group, which means that it happened without age bearing. This is in accord with (15) who mentioned that patients’ age and polyp size did not have any bearing on the results.

In current study the BMI of the patients with polyp were 30.2±2.1 which means it is obese, which is same that found in Mustafa G et al., (16) 2016 who revealed that women with cervical polyp had higher body mass index than the controls, but the difference was not statistically significant.

Symptoms attributable to polyps include intermenstrual bleeding, post coital bleeding, heavy menses, postmenopausal bleeding and vaginal discharge (5). In this study the main symptoms were vaginal discharge, then post coital bleeding.

According to Neri et al., (17) while symptomatic or asymptomatic cervical polyps in premenopausal years do not indicate the need for subsequent D & C, symptomatic cervical polyps in postmenopausal years must be excised with mandatory subsequent D & C since they are associated with a statistically significant incidence of severe pathological conditions. Asymptomatic simple polyps in postmenopausal women on the other hand do not indicate the need for subsequent D & C since they are not associated with malignant changes of endometrium. Other hands do not indicate the need for subsequent D & C since they are not associated with malignant changes of endometrium. In the current study, it was found that (60.0%) of the patients were healed and (40.0%) were relapse (not healed).

Conclusions

The frequency of cervical polyp was 5% with higher frequency at 26-35 years old. So vaginal discharge and postcoital bleeding is the most common sign and symptoms of cervical polyp.

Conflict of Interest: None

Source of Findings: None

Ethical Clearance: The study was approved by the ethical committee of the Ministry of health scientific council and Tikrit Medical College. The purpose and procedures explain to all participants and were give the right to participate or not, verbal consent was taken with reassurance that interpret gained will be kept confidentially and not to be used for other research object.

Microdebrider Assisted Inferior Turbinoplasty: The Evaluation According to the Pathological Causes of Hypertrophied Turbinates

Salim Hussain Ibrahim¹, Qaad Khudhair Abbas²

¹Assist. Prof. Department of Surgery-Otorhinolaryngology Head and Neck Urgery/Medical College/Tikrit University/Iraq, ²Physician, F.I.C.M.S.ENT Department of Otorhinolaryngology, Salah-elddeen General Hospital, Tikrit

Abstract

Background: Hypertrophied inferior turbinates are the frequent cause of nasal obstructions. Microdebrider is one of recent advances in technology used for reduction of hypertrophiied turbinate to improve nasal breathing.

Objective: To evaluate and compare the effectiveness of microdebrider assisted inferior turbinoplasty on nasal breathing, turbinate size and complications according to the pathological causes.

Patients and Method: Aprospective case study of 45 patients with chronic nasal obstruction and hypertrophied inferior turbinates underwent microdebrider assisted tubinoplasty. At Salah-elddeen General Hospital and private practice in salah-elddeen governorate, Iraq. During the peroid from June 2016-June 2018. The patients were classified according to the cause of turbinate hypertophy and follow up at 1,3, and 12 months post operatively for nasal bereathing and turbinate size.

Results: The preoperative turbinate size was grade III (48.5%) and grade IV (51.5%). At 1,3,and 12 months post operatively, the grade I and II was (87%). (90%), and (84%) respectively better in compensatory hypertrophy. The subjective patient’s satisfaction grade I(relieved) and II(improved)) at 1,3, and 12 month after surgery was (100%) (97%) and (89%) respectively more satisfaction with compensatory hypertrophy.

Conclusion: The therapeutic success of microdebrider turbinoplasty for improvement of nasal obstruction and turbinate size, according to the causes . In early postoperative period was almost equal, but long-term follow-up (one year) found it was greater in compensatory hypertrophy and chronic rhinosinusitis and less in allergic and nonallergic rhinitis. There is no significant association between the cause of turbinate hypertrophy and type of complications.

Keywords: Nasal obstruction, Inferior turbinate hypertrophy, Inferior turbinoplasty, Microdebrider turbinoplasty.

Introduction

The turbinates are the portion of nose that warm and moisten the inspired air. The most common turbinates that affect airflow are the inferior turbinates, where enlargement can obstruct nasal breathing, especially the anterior tip of the inferior turbinate is located in the nasal valve region and hypertrophy leads to impingement on the nasal valve, and increase nasal resistance. The enlarged turbinates are the second most frequent cause of nasal obstructions after nasal septal deviation that compromise quality of life. Turbinate hypertrophy can be treated medically or surgically depending on the size and response to medical management, and correction of the causes is important. There were at least 13 basic
surgical techniques described to shrink the size of the inferior turbinates, but the ideal treatment method is currently undetermined. Microdebrider which is one of more recent advances in technology for reduction of inferior turbinate volume and was first reported by Davis and Nishioka in 1996. The significant advantage of this method is removal of submucosal vascular stromal tissue, while preserving overlying respiratory mucosa.

The aim: To evaluate and compare the effectiveness of microdebrider assisted inferior turbinoplasty on nasal breathing, turbinate size and complications according to the pathological causes.

Patients and Method

A prospective case study of 45 patients presented with chronic nasal obstruction and hypertrophied of inferior turbinates underwent Microdebrider assisted inferior turbinoplasty under general anesthesia during the period from June 2016-June 2018 at Salah eldeen General Hospital and private practice in salah-elden governorate, Iraq. Male were 24 patient (53%) and 21 (47%) were female. age ranging between 18-55 years, and the average 29 years.

A detailed history was taken regarding nasal obstruction, discharge, sneezing, itching, smell, and headache. Full ENT examination, nasal endoscopy, and CT-scan of the nose and paranasal sinuses when indicated. All patients did not respond to medical treatment. Mulberry posterior end of inferior turbinate was reduced by extraturbinate microderbrider was excluded from this study.

The patients were classified according to the cause of inferior turbinate hypertrophy in to the following:

1. Patients with allergic rhinitis.
2. Patients with non-allergic rhinitis includes vasomotor rhinitis, hormonal, irritant.
3. Patients with compensatory hypertrophy due septal deviation.
4. Patients with chronic infective rhino sinusitis.

The size of inferior turbinate was graded according to inferior turbinate classification system, by measuring the horizontal percentage of total airway space from the anterior aspect of the inferior turbinate (lateral) to the nasal septum (medial) in to four grads. Grade 1 (0%–25% of total airway space), Grade 2 (26%–50%), Grade 3 (51%–75%), Grade 4 (76%–100%).

The subjective sensation of patient about his or her postoperative nasal breathing was assessed by using the questionnaire applied and divided patients in to four grades. Grade I=Relieved (cured) of nasal obstruction, Grade II=Improved nasal breathing, Grade III=Same as before surgery, IV=Worse.

For assessment of peroperative bleeding (during surgery), the patients were classified in to:

1. Patients with accustomed bleeding (means that the bleeding stopped spontaneously with sugicel).
2. Patients with prolonged bleeding (means that the bleeding continued and stopped using cautereization or suturing the incision or the accidental mucosal tear.).

The patients were followed about the size of inferior turbinate and nasal breathing at one, three, and twelve months postoperatively.

Surgical Procedure: Microdebrider inferior turbinoplasty was performed under general anesthesia.

It was carried out after completing the septoplasty, septorhinoplasty or FESS, when the operation has been accompany with it. The patient is prepared for a standard endonasal procedure using an 0° endoscope 4-mm diameter, injection of 1% Lidocaine with 1:100,000 Epinephrine into the anterior aspect of the inferior turbinate with xylometazoline 0.1% nasal spray. An incision made along the anterior tip of the turbinate at its lateral insertion. Create a submucosal tunnel with a Freer elevator along the medial conchal bone. The turbinate microdebrider blade is inserted into the pocket created and excise submucosa with or with bone excision out a of the inferior turbinate. The incision site can be cauterized or sutured if significant bleeding occurs from the mucosal edge or accidental mucosal tear. Silastic splint, and surgicel placed.

Results

Forty-five patients with inferior turbinate hypertrophy underwent microdebrider turbinoplasty. The compensatory hypertrophy and hypertrophy due to chronic rhinosinusitis was common in male (72%) and (71%) respectively, but turbinate hypertrophy in allergic and non allergic rhinitis was common in female (72%) and (80%) respectively (Table 1). Microdebrider turbinoplasty was performed in combination with septoplasty with or without FESS for 33 patients (73%) and microdebrider turbinoplasty alone for 12 patients (27%).

*$\chi^2 = 22.4,$ d.f. = 3, P-value = <0.05, correlation = 0.057., Strong (significant) association between causes and side of inferior turbinate hypertrophy.

The preoperative turbinate size was as follows grade III 33/68 turbinate (48.5%) and grade IV was 35/68 turbinate (51.5%). At month after surgery the turbinate size was grade I (28%), grade II (59%) then and grade III(13%). At 3 months post operatively grade I was (46%), grade II was (44%) then grade III(10%). In compensatory hypertrophy grade I and II were 20/20 (100%)and in allergic rhinitis were 25/29 (85%).

After one year, grade I was 22/68 (32%), grade II 35 (52%),and grade III 8 (12%). In compensatory hypertrophy Grade I and II were 18/20 (90%) and grade III was 2/20 (10%),which is better than In allergic rhinitis where Grade I and II were22/29 (76%), Grade III was (17%) and grade IV was(7%).(Figure 1).

*Synchia and Atrophic change had not been observed;* $\chi^2 = 0.8,$ d.f. =3,P-value =<0.05, correlation =0.2., No significant association between causes and type of complications.
Subjective improvement of nasal patency after the surgery was as follows: After one month grade I (relieved) was 29/45 patients (64%) and grade II (improved) was 16/45 (36%). No (grade III) nor (grade IV) were reported. After 3 months relieved was 30 (67%), improved was 13 (29%), and same was 2 (4%). After 12 months (49%) were relieved, (40%) were improved and (11%) were same. In compensatory hypertrophy the grade I and II at one month, 3 months, 12 months postoperatively were (100%), (100%), and (94.5%) respectively, more than allergic rhinitis that was (100%), (93%), and (80%) respectively. (Figure 2).
Regarding the complications, the peroperative prolonged bleeding was 6/68(10%) common in patients with chronic rhino-sinusitis were 2/11(18%), then with non-allergic rhinitis 1/8(12.5%). Accidental mucosal tear in 6/68(9%) more in chronic rhinosinusitis was 2/11(18%). Postoperative complications includes secondary bleeding was 2/68(3%) more in non-allergic rhinitis 1/8(12.5%), nasal crustation 7/68(10%), nasal dryness was 4/68 (6%), no synechia or atrophic rhinitis reported (Table 3). No case of synechia and Atrophic change had been reported.

Discussion

The inferior turbinate hypertrophy is a common cause for nasal obstruction. It is prevalence in patients with severe nasal obstruction is (77%)\(^7\). Compensatory hypertrophy of inferior turbinate due to nasal septal deviation is a common cause of nasal obstruction\(^8\). Patients who had compensatory hypertrophy correction of nasal septum deviation (septoplasty) has been performed for all patients accompanied with microdebrider turbinoplasty. Septoplasty has an effect on reduction of turbinate size. There are several studies was found that septoplasty reduce the size of hypertrophied inferior turbinates even without turbinate surgery for size reduction\(^9,10\). (Chieh-Feng Lee, et al.2004) Found that there is excellent out comes in improving nasal patency when microdebrider turbinoplasty is adjunct to septoplasty and endoscopic sinus surgery which lasts for a long time\(^4\), although in rhinomanometric assessment had been found that improvement was greater in turbinoplasty only than combined surgery, but the authors attributed this to undercorrection or residual deviation might exist\(^4\). In the current study found that patients with compensatory hypertrophy of the inferior turbinate had a good therapeutic success rate after 12 months period, regarding turbinate size Grade I and II was (90%) (Figure 1), and for nasal breathing the Grade I and II was (94.5%) (Figure 2).

Allergic and non-allergic rhinitis are the most common causes of inferior turbinate hypertrophy\(^11\). The study found that nasal breathing and turbinate size reduction in allergic and non allergic rhinitis after one year was (80%) which less than that for compensatory hypertrophy was (94.5%)\(^4\). The reasons for this may be that the allergic and vasomotor rhinitis regarded as the most frequent causes of mucosal dysregulation that affect outcomes of turbinate reduction\(^12\). In addition, the method used in this research is intra-turbinate microdebrider inferior turbinoplasty where the submucosal vascular stromal tissue is removed with preservation of turbinate respiratory mucosa\(^13,4\) these will affect the long-term relief of allergic symptoms. Several studies found that extra-turbinate microdebrider is more effective than intraturbinate microdebrider turbinoplasty in allergic rhinitis\(^14,8\).

Previous studies have been conducted that majority of patients (90% -100%) gets subjective improvement of nasal obstruction after reduction of turbinate, but effectiveness often reduced over time\(^15\). A study found that the failure in turbinate surgery is due to persisting pathology for mucosal membrane dysregulation and less due to operating technique\(^12\). For long term follow-up of patients with allergic rhinitis who underwent inferior turbinate reduction, one study found that the improvement of nasal obstruction after one year was (80%)\(^16\). Other study found that improvement after 5 years was (70%)\(^17\).

The turbinate is very vascular structure as it composed of the an extensive plexus of venous capacity vessel (sinusoid) and respiratory mucosa\(^1\). Current study found that peroperative bleeding (during surgery) was accustomed bleeding that it stopped spontaneously with sugicel, because the author used local infiltration of epinephrin with careful handling the shaver results in avoidance damage and protection the turbinate mucosa, all reduce the occurrence of accidental mucosal tear, bleeding and crustation. In this current study excessive primary bleeding was (9%) common in non-allergic rhinitis and infective rhinosinusitis due to hyperemic engorged turbinate that occurrence of accidental mucosal tear increased bleeding. Secondary bleeding was two patients (3%) one on the fifth and the second on seventh day after the operation, they are mostly as a result of infection, that leads to hyperemia and increased friability of the turbinate mucosa. Postoperative bleeding has been reported with a frequency of(3.4%- 10%) in various studies\(^3,18\) one study has been reported postoperative bleeding was (27%)\(^13\). Mucosal tear usually due to aggressive resection, it occurs in (9%) more in chronic rhinosinusitis was (18%) and in non allergic rhinitis (12.5%). Study by another author was found that occurrence of mucosal tear was 7.5%\(^19\). Crustation occur in (10%) with accidental mucosal tear all was resolved with use a saline nasal spray within 3 weeks postoperatively. Atrophic rhinitis were not observed because the mucosa and its neurovascular supply were preserved. Despite the differences in the incidence rate...
of complications with the cause of turbinate hypertrophy (Table 3), but statistically there are no significant association.

Limitations that in this study the turbinate reduction was accompanied by septoplasty, septorhinoplasty or FESS in (73%) of the patients, this makes difficult to accurately evaluate the effect of microdebrider turbinoplasty as an isolated procedure on nasal breathing and to accurately calculate the amount of blood loss from the procedure.

**Conclusion**

The study found that microdebrider assisted inferior turbinoplasty procedure is a safe and effective method for turbinate reduction. The therapeutic success rate for improvement of nasal breathing and turbinate size according to the cause was almost equal in early postoperative period (one and three months), but long-term follow-up (after one year) found that success rate was greater in compensatory hypertrophy and chronic rhinosinusitis and less in allergic and non-allergic rhinitis. There is no significant association between the cause of turbinate hypertrophy and type of complications.

1Student, 2Lecturer, 3Assist. Prof., 3Anesthetist, Department of Anesthesia, College of Health and Medical Technics, Middle Technical University, Baghdad, Iraq, 4MB.Ch.BIFICMS Anesth and IC, Al-Imam Ali General Hospital

Abstract

The present study was carried out on a period between December 2019 to February 2020 on 50 healthy patients, their ages ranged from eighteen to fifty years. They were 26 males and 24 females. These healthy patients were attending Baghdad Educational Hospital, Al-Harriri Hospital, and Al-Diwaniyah General Hospital in order to perform various surgeries. And after all tests are done. Then they were admitted to the operating theater. In this study used the general anesthesia method. And they were given drugs of anesthesia, during each step; the values of blood sugar levels (Mg/dl) were measured. Such as pre induction, post induction, after incision, after fluid, and recovery. To know the effect of general anesthesia method on blood sugar levels in different times of operation on gender and age groups.

This study showed that total numbers of patients were 50 including males about 26 (52.0%) and females about 24(48.0%), their age of all individuals ranged from less than 20 years old (<20-29) which number and percentage 22,44.0% to 50 years old 7 (14.0%). Also there are no significant difference was observed in the blood sugar levels changes (Mg/dl) in both males and females (gender) before and after the operation or surgery, also no found any differences between blood sugar levels changes (Mg/dl) at the age groups and the general anesthesia method, after and before the operation in different times of surgery. So in this study summarized the mean and stander deviation values according to the levels of blood sugar (Mg/dl) among different times of surgery, and then show the mean of pre induction period about 83.84, While mean of values of blood sugar at post induction time at general anesthesia method about 104.94.

Aims and Objectives: This study was investigated the influence of general anesthetic drugs that effect on the blood sugar level changes of patients with surgery. This was done with the following objectives:

- To administer general anesthesia by using a different combination of drugs.
- To assess and compare the blood sugar level changes of the patients at different time intervals.
- Complications, if any were observed and noted on patients at different time intervals.

Keywords: General Anesthesia; Blood Sugar; Times of Operation.

Introduction

Anesthesia was not known prior to 1846 although the anaesthetic properties of ether already described by Faraday in 1818 .the use of ether in 1846 by W.T.G mortan opened up anew era of painless surgery with the help of drugs.Presently there are various anaesthetic agents ether still stand out as the most commonly used anesthetic agent in our country[1]: the primary goal of anesthesia is to provide patient comfortt and safety during surgery or to facilitate the surgical procedure itself. Anesthesia can be general, regional, and local, depending on the needs of the patient and surgeon. General anesthesia is a reversible drug induced state of unconsciousness with hypnosis, amnesia,analgesia and elimination of the patient response to the painful stimuli sometimes accompanied by paralysis[2].

Glucose the main conversion product of carbohydrate food enters the blood from the intestine. Glucose is distributed fairly uniformly throughout the body fluid both extracellular and intracellular. Maintenance of
blood sugar at a constant level is a balance between production and loss[1]. Blood glucose concentrations in normal healthy individuals are normally maintained at ~90 mg/dl. Abnormal concentrations of glucose in plasma result in deleterious effects at the whole organism level. Glucose is the main energy source for the brain and decreased plasma glucose levels (hypoglycemia) can lead to impaired brain function and death. Conversely, increased plasma glucose levels (hyperglycemia), a major clinical symptom of diabetes[3]. The key hormones which regulate glucose homoeostasis include insulin, glucagon, epinephrine, norepinephrine, cortisol and growth hormone (GH)[4]. Surgeries are considered to be the combination of multiple factors including tissue damage, fasting, blood-loss, effect of medication and temperature changes from a metabolic point of view. Combinations of all these factors give rise to stress response. The stress response to surgery is characterized by increased secretion of pituitary hormones and activation of the sympathetic nervous system. The ultimate effect of these various endocrine changes is increased catabolic activity by increased secretion of catabolic hormones like cortisol and glucagon. The effect of these endocrine and metabolic changes ultimately leads to increased neoglucogenesis and hyperglycemia. So this stress response may be quantified by the incidence of hyperglycemia.

The metabolic changes appear to be proportional to the severity of the surgical trauma with plasma cortisol and blood glucose concentration rising slightly during minor surgical procedures but significantly during major operations[5]. Regulation blood sugar levels in the use of general anesthesia needs to be considered carefully. Some induction agents for general anesthesia have the side effects of increasing blood sugar level[6]. Anesthetic drugs will basically have a sympathomimetic effect and affect the endocrine system in the human body, especially the regulation of blood glucose levels. The mechanism for increasing blood glucose levels is very complex. One opinion held is that anesthetic drugs directly suppress pancreatic beta cells through the release of catecholamines and result in decreased insulin production[7]. All the intravenous agents and volatile anesthetics in normal doses have minor influence on the endocrine and metabolic function. Severity of surgery and the type of anesthesia influence the magnitude of the counter regulatory response which is evidenced by increase in circulating catecholamines, cortisol and glucagon concentration and blood glucose as well[5].

Materials and Method

The current study was done in Baghdad Educational Hospital, Al-Harriri Hospital and Al-Diwaniyah General Hospital during the year 2019-2020, with the aim to study the effect of general anesthesia on blood sugar level in patients undergoing surgery. The study recruited 50 adult patients, all the patients were of physically fit belonging to A.S.A. grade I or II, between the age of 18 to 50 years who were ASA I and ASA II patients of both sexes presenting for elective surgeries.

Anesthetic Technique: In the operating room, the standard anesthetic machine check was done prior to commencement of any procedure every morning. All patients had baseline blood glucose measurement performed immediately prior to the start of any things. The patients were cannulated using 18 or 20 or 22G cannula and an infusion of normal saline or normal saline with glucose was initiated. Non-invasive blood pressure cuff, ECG and pulse oximeter probe were then connected to the patient and initial blood pressure and heart rate readings were then obtained. All patients were premedicated with 1 mg midazolam I.V, ranitidine 50 mg I.V, fentanyl 2 mcg/kg I.V, metoclopramide 10 mg I.V and dexamethasone 8 mg I.V, 3 minutes prior to induction. Pre-oxygenation was done during these three minutes after which, induction of anaesthesia using I.V. propofol 2-3 mg/kg, I.V. ketamine 1-2 mg/kg was done. For the ETT, muscle relaxation for intubation was facilitated by the use of injection rocuronium 0.6 mg/kg or atracurium 0.5 mg/kg.

Patients were then ventilated with 100 percent oxygen for a period of 1 minute prior to intubation with the aid of Macintosh laryngoscope. Endotracheal tubes of size 7/7.5 for female and 8/8.5 for male patients were used depending on body weight. Anaesthesia was maintained using oxygen and sevoflurane or isoflurane. Adequacy of ventilation was monitored clinically by assessing chest expansion, auscultation of the lung fields and the epigastric region. Surgery or any other manipulations were not allowed to commence until the study was completed i.e. for ten minutes after intubation/insertion.

Before end of the operation in a short time, the patient is given paracetamol 1000 mg to relieve pain after the operation.

Study Tools: During the operation, blood sugar is measured 5 times for the patient by using electronic
blood glucose meter, the first time is measured pre-induction of anesthesia, the second time is measured post induction of anesthesia, the third time after surgeon begin the operation, the fourth time after stop the fluid and the fifth time is measured in the recovery room. Method of measurement by applying a drop of blood to a chemically treated, disposable ‘test-strip’, which is then inserted into an electronic blood glucose meter. The reaction between the test strip and the blood is detected by the meter and displayed in units of mg/dL or mmol/L.

Results

The demographical picture of studied groups in table 1, for this study showed that total numbers of patients were 50 including males about 26 (52.0%) and females about 24(48.0%), their age of all individuals ranged from less than 20 years old (<20-29) which number and percentage (22,44.0%) to 50 years old (7, 14.0%). There are no significant difference was observed in the blood sugar levels changes of both males and females (gender) before and after the operation or surgery, also no found any differences (not a statistically significant difference) between blood sugar levels at the age groups and the general anesthesia method, after the operation in different times of surgery.

Table (1): Distribution of group study according to the gender and age groups (year)

But the results in table 2, summarized the mean and stander deviation values according to the levels of blood sugar (Mg/dl) among different times of surgery, that show the mean of pre induction period about 83.84, but the stander deviation for this period about 13.610. While the mean of values blood sugar at post induction time at general anesthesia method about 104.94. Also in this table show increase the values of blood sugar in other periods at general anesthesia method such as after incision, and after fluid, that was about 128.66, 137.56 respectively, but in recovery time the mean of value of blood sugar reached to about 125.94.

Table (2): Mean and Std. Deviation values of Blood sugar (Mg/dl) among different time

<table>

Then the table 3, shows the compare between values levels blood sugar (Mg/dl) changes at pre induction and other times. This table show great differences between the two times that were pre induction and post induction. This means found highly significant between the two means values blood sugar (Mg/dl) at pre induction and post induction for general anesthesia method. So above applies to pre induction and other times at general anesthesia method under probability level (P<0.01).

Table (3): Compare between values of Blood sugar (Mg/dl) at Pre induction and other times

From the present study we concluded that in comparison of muscle relaxant ether causes much more hyperglycemia during general anesthesia which is very highly significant rise. But in case of muscle relaxant the change in blood glucose level is just significant. There are because the glucose concider as the main conversion product of carbohydrate food enters the blood from the intestine. Glucose is distributed fairly uniformly throughout the body fluid both extracellular and intracellular. Maintenance of the blood sugar at a constant level is a balance between production and loss\[9]. While this result dis agree with Kouzegaran et al\[10], when reached to the patients had no taken or were not diagnosed with any diseases affecting blood sugar levels. They found no significant difference observed in the blood sugar levels of both groups before and after the operation, but the group which had utilized the general anesthesia method reported with lower levels of blood sugar than the spinal anesthesia group after operation with a significant difference (p < 0.05). A difference has been observed in the levels of blood sugar 2, 12 and 24 hours after the operation in both groups, but it was not a statistically significant difference. As the results indicate, both the general and spinal anesthesia are effective method to reduce the serum level of blood sugar in patients undergoing caesarean. However, none of mentioned method had any influence on reduction of blood sugar levels during the recovery or the period after it. However, none of the mentioned method had any influence on reduction of blood sugar levels during the recovery or the period after it. While the compare between values levels blood sugar (Mg\dl) at pre inductionand other times. There are great differences between the two times that were pre induction and post induction. This result agree with the study of Maitra et al.,\[11], that was undertaken to observe the effect of different maintenance-fluid regimen on intraoperative blood glucose levels in non-diabetic patients undergoing elective major non-cardiac surgery under general anesthesia. That stress induced-hyperglycemic response in patients undergoing major non-cardiac surgery is common in non-diabetic population. Maintenance-fluid therapy by dextrose containing solution as opposed to Ringer’s lactate solution increases the incidence of hyperglycemia. To achieve normoglycemia by intravenous bolus dose of human regular insulin, significantly higher doses are required in patients receiving dextrose containing saline as maintenance fluid. However, they did not mention their intraoperative fluid protocol. Both Saringcarinkul and Kotrawera \[12], found a progressive increase in the
blood glucose values in patients receiving 5% dextrose during surgery.

**Conclusion**

1. The levels of blood sugar (Mg/dl) changes among different times of surgery in general anesthesia method, that show increase the values of blood sugar in other periods at general anesthesia method such as after incision, and after fluid.

2. Found highly significant differences between means values blood sugar (Mg/dl) at pre induction and post induction and between the pre induction - after incision, pre induction - after fluid, and pre induction - recovery for general anesthesia method. Also found highly significant differences between the two means values blood sugar (Mg/dl) at post induction and after incision for general anesthesia method. These because increase the stress hormone, nervous tension, and psychological tension, fear, and terror during the surgery. so found significant differences between two means values blood sugar (Mg/dl) at after fluid and recovery for this general anesthesia method. Because the fear and terror from the idea of performing the operation. To increase the stress hormone specialized in stress factors on the body, which makes the body alert attention to what happens to him whenever occur a surgical incision.

Abstract

Background: One of the most prevalent chronic diseases is Diabetes mellitus that have adverse effect on the health, and the goal today being placed on disease prevention, controlling and screening.

Aim: To assess knowledge, attitude and Practice of periodic screening of DM among teachers in Tikrit city.

Subject and Method: The study is a cross-sectional study that had conducted from 1st of November 2018 until 30 of March 2019 on teachers in Tikrit city primary and secondary school using a questionnaire.

Results: The knowledge regarding the diabetes and its screening a 24% were good and 46% were accepted regarding the disease symptoms and about its control 84% mention that diet modification is the best way then exercise and medication in lower percent while regarding complications 68% (much of them) knowledge were bad, About the importance of periodic screening the great percentage was yes.

Conclusion: There was 93.3% who have knowledge about diabetes mellitus screening among school teachers. Teacher’s method for controlling diabetes mostly are diet modifications 84% then exercise 42.5%.

Introduction

Improvement of the population health depend on disease prevention which is now consider as a superior strategy to decline the morbidity and mortality of most types of diseases[1]. Diabetes mellitus Type 2 has become wide epidemic with marked deformity, premature death and many medical problems[2]. DM is a non-infectious disease of public health importance which have a great effect on the life quality. Prevention and control can be obtained by improving the knowledge[3]. The aim of screening is to discover asymptomatic individuals who are likely to have diabetes. The prevalence of diabetes type 2 is raised strongly[4,5].

DM considered dangerous and life-threatening problems, but may be treated by proper managing and prevention. Diabetic self-care training and education consider important in the controlling of DM[6]. Non-controlled diabetes may end with blindness, limb removal, kidney problems, and vascular and IHD. Screening test to the patients before features appearance may lead to early detection and control, as the same time have no role in reduction of end-organ damage rates[7]. Many studies on (KAP) of diabetes have been support the needs for prevention, detection, and controlling of diabetic risk factor[8]. Good education and healthprogrammers development can lead to improvement of the patients knowledge and alter their practice[9,10]. Cross-section study about the KAP of DM in Saurastha region, India revealed that poverty, low level of education have theresponsibility of low level knowledge about DM[11].

Daily researches about diabetics in India have been find meager levels of education and awareness about diabetes and very bad self-care method\cite{12}[13]. Thus, the elevated number of undetected cases, as well as the low level of knowledge and practices, has direct effect in increasing sudden deaths, costly complications, and financial burdens\cite{14,15}.

**Aim of the Study:** This study was conducted to assess the knowledge, attitude, and practice of periodic screening of diabetes mellitus among teachers in Tikrit city.

**Objectives of the Study:**

1. Identify the knowledge of teachers about importance of periodic checking and the source of their knowledge.
2. Clarify the knowledge about diabetes mellitus and its complications.
3. Demonstrate the practice of teachers for checking their blood sugar levels.
4. Identify the changes in life style among diabetic patients.

**Subjects and Method**

*Ethical and Approval Consideration:* Permission was taken from the teachers to fill the information and they were assured regarding the confidentiality of their responses.

*Type of Study:* The study is a cross-sectional study that had conducted from 1st of November 2018 until 30 of March 2019. The study was performed among teachers in Tikrit city primary schools (Al Kansa’a School and Al Noor School) and secondary schools (Al Motamizat School, Al Motamizen School, Al Safa School, Science City School and Al Forqan School). Sample:- Sample was chosen by clustered sampling then simple random sampling and the sample include 120 teachers from Tikrit city.

*Questionnaire and Interview:* The questionnaire used for data collection was designed in Arabic language. It include demographic characteristics of teachers, followed by close ended and open questions related to their knowledge, attitude and practice of periodic screening for diabetes mellitus. It was administered by the teachers themselves.

**Presentation and data analysis:** All data management and analysis done by manual statistical method. Data was represented by suitable tables and figures which was designated by computer programs.

**Results**

Knowledge of the teachers about the importance of screening of diabetes mellitus a show higher percentage 93.3% of them show very good knowledge while 6.66% were not well fig (1). The teachers knowledge regarding the disease itself and its symptoms, the results was the following, 25% were good, 45.83% were accepted and 29.16 were bad fig (2). Good knowledge about importance of testing they mention that the source of their knowledge was by doctor counseling 46.66%, media 29.16%, internet 36.66% and 2.5% were by attending a seminar about the disease fig (3). Teachers knowledge about the complications of the diabetes 14.16% of the results of their responses were good which is very small percentage, about 17.5 were accepted and 68.33 were bad fig (4). The result of performing of their periodic screening test of diabetes came as 48% performing the screening test while 52% not which is a high percent, About the method or the test types they used to check their blood sugar, 65% respond with laboratory tests, 42.5% with home devices and 12.5% show that they don’t do tests. The teacher’s attitude toward the best method of controlling diabetes were 42.5% by regular exercise, 84.16% by diet modifications, 24.16 by medication, and 2.5% show that they don’t know fig (5). Regarding the counseling and its role in raising the importance of knowledge about the periodic screening of diabetes mellitus, In the table (1) show the general knowledge of the teachers about the disease and its aspects of treatment and the results came with variable responses.

Discussion

The knowledge of the teachers in Tikrit city about the importance of periodic screening have higher percentage 93.3% of them show very good knowledge while in DebreTabor town, Northwest Ethiopia 20.8% were strongly agreed and 32.1% were agreed, a total of 52.9%, that people should be examined for diabetes mellitus, this showing better knowledge of teachers in Tikrit than in Ethiopia[16]. Tikrit teachers mention that the source of their knowledge was by doctor counseling 46.66%, media 29.16%, internet 36.66% and 2.5% were by attending a seminar about the disease. In India...
patients believed that they can get information regarding diabetes through Books/Periodicals 28.57% and 10.72% got information by internet and television, 3.57% by other sources while majority of patients 57.14% were not interested to get information\[17\]. Teachers knowledge regarding the disease itself and its symptoms, the results was the following, 25% were good, 45.83% were accepted and 29.16 were bad, in comparison with Galle discrete in southern Seri Lanka \[16\] around 37% of the participants was categorized as having good level of knowledge \[18\]. Teachers knowledge about the screening and its benefits for the improvement of patient outcomes when detecting the disease earlier 40% were agreed and in West Bengal, India \[19\], 46.5% of diabetics patients and 35.5% of non-diabeticconsider that diabetes can be preventable, but 31.9% of diabetics patients and 14.1% of non-diabeticconsider that DM can be controlled not treat, indicating that early detection can help with the prognosis. Teachers knowledge about the complications of the diabetes 14.16% of the results of their responses were good which is very small percentage, about 17.5 were accepted and 68.33 were bad, while in study from Tabuk City, \[20\] about information of teachers about DM complications, the teachers had good knowledge and more appropriate answers.

The practice of teachers in Tikrit city about the performing of their periodic screening test of diabetes and the results was 48% performing the screening test while 52% not which is a high percent after that asked the teachers about the method or the test types they used to check their blood sugar, 42.5% with home devices and 12.5% show that they don’t do tests\[21\]. The teacher’s attitude toward the best method of controlling diabetes were 42.5% by regular exercise, 84.16% by diet modifications, 24.16 by medication, and 2.5% show that they don’t know while in Study conducted in in DebreTabor Town, Northwest Ethiopia \[16\] state that insulin treatment (57.3%), healthy diet (56%) and oral tablets were the main ways of management of diabetes mellitus and regular exercise (32.5%).

About the general overall view of teachers toward the disease and its controlling ways, asked some questions to assess their point of view and by comparing this with other countries results we found that in teachers of Tikrit city 50% of teachers showed by their answers that diabetes cannot be treated, while 51.3% of people in DebreTabor town \[21\], Northwest Ethiopia were agreed that diabetes mellitus is not curable disease, nearly same percentage of knowledge regarding the disease. Regarding comparison of results about the knowledge regarding diet 67.5% of the Tikrit teachers were agreed that diabetes can be treated by diet modification, while 56% of the people of DebreTabor town, Ethiopia \[16\] were agreed that practicing healthy diet is beneficial for controlling diabetes. In another study, 78% of population in Pakistan \[18\] was agreed that controlling sugar will control diabetes. Showing better results of knowledge in Tikrit than Northwest Ethiopia, but Pakistan results were the best. And regarding exercise, in our study 75% were agreed that it can control diabetes, in Pakistan population 73% thought that exercise is helpful to prevent diabetes, thus the results are nearly the same \[18\]. The knowledge regarding treatment in comparison with other studies 63.3% of them thought diabetes is treatable with medications (tabs and injections) while 57.3% of DebreTabor town, Ethiopia \[16\] people thought Insulin is petter for management of DM and 33.2% consider tablets are better for management of diabetes mellitus.

## Conclusion

1. A high percentage 93.3% of teachers know the importance of the periodic screening of diabetes mellitus and their knowledge mostly 46.6% by doctor counseling.

2. The percentage of teachers who perform the periodic screening of diabetes is 48% and 65% of them do the screening in the medical laboratories.

3. Teacher’s method for controlling diabetes mostly are diet modifications 84% then exercise 42.5%.

Abstract

Background: This study aimed to provide basic data for the development of COVID-19 infection management educational programs by confirming the factors that affect the performance of COVID-19 infection management administration in general hospitals.

Method: Data was collected from administrative staff at 192 general hospitals by means of a structuralized questionnaire, and SPSS Ver. 21.0 software was used for data analysis.

Conclusion: The extent of knowledge and execution of COVID-19 infection management processes by administrative staff in general hospitals was positively correlated with the extent of educational demand for COVID-19 infection management, with explanatory power of 16.7%. It is necessary to include factors including COVID-19 transmission route, transmission prevention, and staff safety in COVID-19 infection management educational program administration. In addition, it is essential also to performance COVID-19 infection management education.

Keywords: COVID-19, Knowledge, Importance level, Educational demand, Performance.

Introduction

The outbreak of COVID-19(1) that began in Wuhan, China in December 2019 resulted in the first confirmed case in Korea on January 20, 2020. From that point on, it proliferated explosively in venues of communal life including religious organizations, clubs, mental hospitals, nursing hospitals and nursing homes, and call-centers(2). In particular, since patients with underlying diseases and degraded immunity tend to be hospitalized at medical institutions, mass infection at medical institutions imparted enormous effects not only on patients and guardians but also medical staff, administrative staff, and medical technicians. At the time of the outbreak of Middle East Respiratory Syndrome (MERS) in Korea in 2015, the proportion of medical health staff infected among total cases was 18%, with 30 confirmed cases from a total of 186 (3).

Since the outbreak of MERS in 2015, there have been studies conducted on nurses regarding the actual status and awareness of MERS infection management(4), assessments of the knowledge, intention for infection management activities, and extent of educational demand for respiratory diseases among nurses (5) and studies of infection management prevention knowledge and extent of performance of said management prevention among nursing aids, care workers, and caregivers(6). The majority of these studies have focused on nursing personnel, who generally had the longest period of close contact with patients. In addition, level D practical education on how to put on and take off quarantine gowns properly has been conducted for medical staff working at medical institutions throughout the country since the outbreak of MERS. However, the majority of
such education is aimed at medical staff, with inadequate education provided for administrative staff.

In order to prevent infection at medical institutions, it is essential for all constituent members including physicians, nurses, medical technicians, and administrative staff to comply strictly with the infection prevention guidelines, including directions regarding hand hygiene, personal protective devices, and environmental management[7]. Workers at medical institutions represent the key channel for outbreaks of medically related infections. Since the extent of infection management performance will be elevated with higher awareness of infection management among such workers, infection management education is very important[8,9]. The administrative staff at medical institutions constitute personnel who provide the necessary support for patient treatment and care, including materials and system resources, and are the first to come in contact with patients during visits to medical institutions. All patients need to register with the accounts department before receiving treatment and care. Since it is difficult to assess the state of patient respiratory infections at this time, administrative staff are confronted with very high possibility of being exposed to infection. Nonetheless, there has not been any study that investigated the actual state of the respiratory infection management knowledge among administrative staff until now.

Accordingly, this study aims to provide basic data for the development of educational programs customized for administrative staff by assessing COVID-19 infection management knowledge, importance level, extent of educational demand, and extent of performance among administrative staff members working at 4 general hospitals in the D Region. Study data was collected over a period of approximately 3 weeks from November 4 to 25, 2020. After extracting data from 4 general hospitals in the D Region, the researcher personally visited these institutions to carry out a survey after first explaining the purposes and methods of the study and acquiring the consent of the administrative staff. Minimum numbers of subjects necessary for statistical analysis were calculated using G*power 3.1 Program. Computed with a significance level of $\alpha=0.05$, scale effect of $d=0.15$, test power of 0.95, and 12 prediction variables, the minimum number of subjects was 184. A total of 200 questionnaires were distributed in consideration of the response rate and drop-out rate. Data collated from a total of 192 questionnaires retrieved after excluding 8 questionnaires filled in inappropriately were used for analysis.

A measurement tool was developed by the researcher in accordance with the study goals by making reference to the guidelines to cope with COVID-19 issued by the Korea Centers for Disease Control and Prevention. The questionnaire consisted of a total of 73 questions, comprising 11 questions on general characteristics, 20 questions on knowledge of COVID-19, 20 questions on the importance level of COVID-19, 8 questions on the extent of educational demand for COVID-19 infection management, and 14 questions on the execution of COVID-19 infection management. The final questionnaire was prepared after its content was verified by the administrative managers at the 4 general hospitals, 2 nursing college professors, and 3 nurses specializing in infection management. The Content Validity Index (CVI) exceeded 0.80.

1. **COVID-19 Knowledge:** The survey tool for assessment of COVID-19 knowledge was composed of a total of 20 questions, with each question to be answered with either ‘Yes’, ‘No’, or ‘Don’t know’. 1 point was allocated for each correct answer, while 0 points were allocated for wrong answers and ‘Don’t know’ responses. As such, the total score for each subject ranged from 0 to 20 points, with higher scores signifying that subjects had higher knowledge of COVID-19.

2. **Importance Level of COVID-19:** This section was composed of 20 questions with a 5-point Likert scale applied to each question. Higher scores
signified higher importance placed by the subject on COVID-19. The reliability of the questionnaire as a tool of assessment was secured with a Cronbach alpha value of 0.94 in this study.

3. Extent of Educational Demand for COVID-19 Infection Management: This section was composed of 8 questions with a 4-point Likert scale applied to each question and a range of scores from 1 point for ‘Not important at all’ to 4 points for ‘Very important’. Higher scores signified a higher extent of educational demand for COVID-19 infection management. The reliability of the questionnaire as a tool of measurement of the extent of educational demand for COVID-19 management was indicated by a Cronbach alpha value of 0.83.

4. Performance of COVID-19 Infection Management: It is composed of 14 questions with 4-point Likert scale applied to each question with the range of scores of 1 point for ‘Not performance at all’ to 4 points for ‘Always performance’. Higher score signifies higher level of execution of COVID-19 infection management. The reliability of the questionnaire as the tool for the measurement of the execution of COVID-19 infection management was secured with Cronbach’s alpha value of 0.84.

Method

The data collected was analyzed by means of the SPSS Ver. 21.0 program, employing the following analysis methods. Characteristics of study variables were analyzed by means of descriptive statistics, while differences in the study variables in accordance with general characteristics were analyzed using the t-test and ANOVA. Follow-up analysis was verified with the Duncan test, while the correlations among the study variables were analyzed with Pearson’s Correlation Coefficient. In addition, Multiple Regression Analysis was used to analyze the factors affecting execution of the infection management by study subjects.

Results and Discussion

General Characteristics of Study subjects: The general characteristics of the study subjects are given in Table 1. There were 112 males (80%) and 80 females (41.7%) with an average age of 36.86±9.56 years. Regarding their employment positions, team members were most numerous at 157 (81.8%), while the average period of work experience was 10.78±8.76 years. There were 110 subjects working in departments that come in direct contact with patients (57.3%) and 128 subjects underwent respiratory infection management education during the last 1 year (66.7%). 54 subjects came in contact with patients suspected of COVID-19 (28.1%), while 6 subjects came into contact with confirmed COVID-19 cases (3.1%).

COVID-19 Knowledge, Importance Level, Extent of Educational Demand, and Infection Management Performance: The levels of COVID-19 knowledge, importance, extent of educational demand, and infection management performance by general hospital administrative staff are illustrated in Table 2. The average score for COVID-19 knowledge among administrative staff was 14.54±2.69 out of a possible 20 points, while those of the subordinate domains including epidemiology and infection management were 7.72±1.37 and 6.88±1.94 points, respectively. The average score for importance level was 4.09±0.88 out of a possible 5 points, while those of the subordinate domains including epidemiology and infection management were 4.10±0.85 and 4.09±0.98 points, respectively. The average score for the extent of educational demand was 3.66±0.34 out of a possible 4 points, while those of the subordinate domains including characteristics of disease, diagnosis, and examination, treatment methods, transmission route, transmission prevention, putting on and taking off of personal protective devices, isolation guidelines, lifting of patient isolation, and staff safety were 3.64±0.79, 3.60±0.53, 3.53±0.59, 3.84±0.36, 3.71±0.49, 3.70±0.50, 3.47±0.62 and 3.78±0.43 points, respectively. The average score for the performance of infection management was 3.40±0.58 out of a possible 4 points, while those of the subordinate domains including hand hygiene, personal protective devices, environmental disinfection, respiratory etiquette, and infection management by staff were 3.22±0.34, 3.55±0.86, 2.73±1.21, 3.63±0.64 and 3.70±0.59 points, respectively.

Differences in Study Variables in Accordance with General Characteristics: There were statistically significant differences in the performance of infection management in accordance with general characteristics depending on the department in which the subjects worked ($t=2.076, p=.039$), with those working in departments with contact with patients displaying higher levels of performance of infection management in comparison to those working in departments with no contact with patients (Table 3).

Correlations Between COVID-19 Infection Management Knowledge, Importance Level, Extent of Educational Demand, and Performance: The correlations between COVID-19 infection management knowledge, importance level, extent of educational demand, and performance are given in Table 4. The level of execution of COVID-19 infection management had a positive correlation with knowledge of \((r=.19, p=.007)\) and extent of educational demand for \((r=.3, p<.001)\) COVID-19.

Factors Affecting Execution of COVID-19 Infection Management: In order to analyze the factors that affect performance of COVID-19 infection management by administrative staff at general hospitals, multiple regression analysis was executed, with the departments in which subjects work, COVID-19 infection management knowledge, and extent of educational demand as the independent variables. Analyzing the tolerance limit and Variance Inflation Factor (VIF) confirmed the multicollinearity of the independent variables tolerance limit to be in the range of 0.913~0.981, while the VIF value was in the range of 1.019~1.096, thereby demonstrating that no variables were affected by multicollinearity. Analysis results demonstrated that the factors relating to the performance of COVID-19 infection management included the extent of educational demand \((\beta=.372, p<.001)\), with explanatory power of 16.7% (Table 5).

Discussion

This study aimed to provide basic data for the development of infection management educational programs to stop the spread of COVID-19 by assessing the factors that affect the performance of COVID-19 infection management, with administrative staff at general hospitals as the subjects. 66.7% of subjects received respiratory infection management education during the previous year at the time of the outbreak of the COVID-19 pandemic, with 28.1% coming in contact with patients suspected of COVID-19 and 3.1% with confirmed COVID-19 cases. Although it is difficult to make comparisons due to the lack of preceding studies, it can be seen that not only are medical staff coming in contact with suspected or confirmed COVID-19 patients, but also administrative staff. Therefore, it is necessary to provide infection management education for administrative staff at the time of outbreak of new infectious diseases such as COVID-19.

The average score for COVID-19 infection management knowledge of general hospital administrative staff was 14.54±2.69 out of a possible 20 points. Although the respective study subjects and infectious diseases differed, the results of surveys of nurses’ knowledge of SARS and MERS\(^{(6)}\) were 13.46±2.97 out of a possible 20 points, which is similar to the results of this study. However, in a study of nursing college students\(^{(10)}\), the average score for the extent of the knowledge of personal protective devices to be used against acute respiratory infectious diseases was 17.83
out of a possible 20 points, which is higher than the results of this study. Accordingly, it is thought that the level of knowledge of administrative staff is similar to that of nurses, since COVID-19 infection management education was executed for all staff at the medical institutions, and information regarding COVID-19 ceaselessly conveyed through mass media. The importance placed on COVID-19 infection management had an average score of 4.09±.88 out of possible 5 points. Although it is difficult to make comparisons due to lack of preceding studies, it is deemed that administrative staff also consider COVID-19 infection management to be important at the time of the current COVID-19 pandemic. The average score for the extent of educational demand for COVID-19 infection management was 3.66±.34 out of a possible 4 points, with the highest score for the extent of educational demand for the transmission route and transmission prevention of COVID-19, followed by staff safety, and the putting on and taking off of personal protective devices, while the score for the extent of educational demand on lifting of patient isolation was the lowest. In the study of the extent of educational demand for SARS and MERS information among nurses (5), the scores were in the order of treatment and nursing, isolation method, clinical symptoms, and method of putting on personal protective devices, thereby displaying differences to the results of this study. That is, the medical staff displayed a higher extent of educational demand in the domains of treatment and nursing, since patient treatment and nursing are their main roles. On the other hand, since the roles of administrative staff include allocation of hospital rooms and supply of goods for patients rather than treatment, the scores for the extent of educational demand for transmission route and transmission prevention were the highest. In addition, while nurses displayed lower scores for the extent of educational demand on the use of personal protective devices, since they use these frequently, it is thought that administrative staff displayed higher scores for this domain since they use protective devices only during special situations. The average score for the performance of COVID-19 infection management was 3.40±.58 out of a possible 4 points, with higher scores for the subordinate domains in the order of infection management by staff, respiratory etiquette, and personal protective devices.

There were differences in the scores for the execution of COVID-19 infection management depending on the department that the administrative staff worked in, with the staff working in departments with contact with patients displaying higher scores. It is thought that the frequency of execution of the guidelines for COVID-19 infection management would be higher in the case of more frequent contact with patients. In terms of the correlations among COVID-19 infection management knowledge, importance level, extent of educational demand, and extent of performance, the extent of performance of COVID-19 infection management was found to be higher with higher levels of COVID-19 knowledge and extent of educational demand. According to the results of this study, 28.1% of the administrative staff came in contact with COVID-19-suspected patients. Accordingly, COVID infection management needs to be executed for administrative staff, and it is anticipated that the spread of infectious diseases within medical institutions can be stopped more quickly and easily if the level of the execution of infection management were to increase through more extensive acquisition of accurate COVID-19 infection management knowledge. A factor affecting performance of COVID-19 infection management was the extent of educational demand, with explanatory power of 16.7%. It was found that the level of execution of COVID-19 infection management is higher with a higher extent of educational demand. Therefore, it is important to assess the extent of educational demand of administrative staff regarding infectious diseases other than COVID-19, since there is very high possibility of such future outbreaks.

Conclusion and Acknowledgements

This study was significant in that it assessed COVID-19 infection management knowledge and the extent of educational demand among general hospital administrative staff, providing basic data for the development of COVID-19 infection management education programs for administrative staff by analyzing the factors that affect the performance of COVID-19 infection management. The extent of educational demand was the factor imparting the most significant effect on the execution of COVID-19 infection management by general hospital administrative staff. The extent of educational demand for the domains of transmission path, transmission prevention, and staff safety against COVID-19 was high. Therefore, it is necessary to include the domains of transmission method, insolation guidelines, and staff infection management of COVID-19 at the time of the development of COVID-19 infection management educational programs in the future.
This study has several limitations and the recommended directions for future studies to supplement these limitations are suggested below. First, general hospitals in a single region with easier accessibility were selected in consideration of the response range of the questionnaire. Accordingly, there could be limitations in terms of generalizing the results of this study to all general hospital administration staff throughout the country. Second, it is important to review and confirm the subordinate domains of extent of educational demand in order to increase execution of infection management. Accordingly, it would be necessary in future to execute a follow-up study for the verification of effects after developing individual educational programs for each of the subordinate domains.

1Lecturer, Department of Public Health, Faculty of Veterinary Medicine, University of Kufa, Iraq, 2Lecturer, Dr, Department of Public Health, Faculty of Veterinary Medicine, University of Fallujah

Abstract
This experiment was conducted on 120 unsexed Cobb chicks of one day old for 28 days. Chicks were randomly divided into 4 groups (30 chicks each) and each group consists of two replicates (15 chicks each). All groups was fed using a basal diet, but the first group drunk water from the tap as a control, while the other drunk water with extract of Eruca Sativa leaves (0.25, 0.50 and 0.75ml/Liter) respectively. This study aimed to determine the effect of extraction of Eruca sativa leaves on broiler performance, some blood parameters and immune response to Newcastle virus. The result showed that the supplementation of the broiler diet with extraction of Eruca sativa especially of levels (0.25 and 0.50ml/L) significantly improve the final body weight (P≤0.05). The weight gain also significantly improved (P≤0.05) but, there were no significantly changes in the weight of internal organs and blood pictures (WBCs, RBCs, Hb and PCV respectively). The antibody titer against the Newcastle virus found to be significantly increased (P≤0.05).

Keywords: Eruca sativa, broiler, performance, immunity.

Introduction
Using of antibiotics in animals feed as growth promoters have been implemented in poultry diets recently. Many studies attempted to find of alternative solutions which would provide positive effects on broiler growth and feed conversion ratio (FCR) (1). Henceforth, essential oils have appeared as a possible alternative to antibiotics in the feed of animal (2). Eruca sativa (Rocket seed meal) locally known in Iraq as “Jarjeer” is containing vitamin C, carotenoids, some flavonoids (like luteolin and appin) and glucosinolates (the precursors of isothiocyanates and sulfaraphene) (3). The Jarjeer is also contain Cu, Zn, Fe, Mn, Mg and other elements which are proposed as elements that enhances the immune system and the reproductive performance(4). And as well as, increases plasma IgG concentration (5). Additionally, Bendich,et al.,(6) reported that Eruca sativa has a role in the enhancing of both T and B lymphocyte proliferative responses and increase the production of certain interleukins .examples of some positive effects of essential oils are improving the feed conversion ratio (FCR) through increase the digestive enzymes secretion, appetite, positive stimulation of the immunity, increase vitality, antiviral and antioxidant activities, regulation the normal micro-flora in the intestine and finally, exhibit antimicrobial properties (7,8). The essential oil (Eso) of Eruca sativa has therapeutic and medicinal properties (9) It has been found that the extract of Eruca sativa exerts a prophylactic and a therapeutic role against oxidative stress by increasing the levels of antioxidant enzymes and antioxidant molecules (10, 11). The E sativa plays important role as antifungal and antimicrobial activity (12,13). The aim of this study is to light the effects of adding Eruca sativa to the diet of the broiler by measuring the performance of the broilers, blood parameters and finally, immune responses of the Eruca sativa fed broiler to Newcastle disease.

Material And Method
A total number of 640 of unsexed broiler chicks (Cobb) aged 28 day-old were weighed and grouped randomly to 4 groups., Each group was additionally subdivided into two equal sub groups with 4 replicates (20 bird per each replicate). All the chickens were fed
using similar starter (day 1-18 of age) and grower (day 18-28 of age) diets in a pellet form (Table 1). Only the water was enriched with the extraction of Eruca sativa and the broiler was irrigated as the following:

1. The first group was given ordinary water to be cosider as a control group.
2. The second group was irrigated using water with 0.25 ml/litter of the extraction of Eruca sativa (0.25 ml/litter).
3. The third group was given water with 0.50 ml/litter of the extraction of Eruca sativa.
4. The fourth group was given water with 0.75 ml/litter of the extraction of Eruca sativa.

All the treatments (diets) were prepared and monitored daily. A vaccination against Bronchitis- virus was administrated to all the broiler on the first day (in drinking water), and a vaccination against Newcastle virus was also applied directly into the drinking water at 1st, 9th, 19th and 28th days of the experimental period. Finally, a vaccine against the Gumboro disease was also given by drinking water at the day 14th of the experiment. At the day 29th of age, three birds per group were randomly selected, weighed and postmortem examined by decapitation to collect some organs that are linked to the weights of the bird such as thyme, spleen and bursa of fabricius (to be used in analyzing the live body weight). Blood samples were collected from the heart directly at 1st, 9th, 19th and 28th days and stored in anticoagulant tubes (contain citrate sodium 3.6% solution). Following a centrifugation (5000 rpm) for 7 min, the serum was separated and at the consequent antibody-titer of Newcastle and Bronchitis disease viruses were measured using the ELISA technique.

### Results and Discussion

**Broiler performance:** The results of Table 2 showed the effect of extract of Eruca sativa on live body weight. Interestingly, chicks that irrigated by a water supplemented with the extraction of Eruca sativa 0.25ml/L had a significant higher body weight once they reached the third week (p≤0.05) while there were no significant differences between groups at 1st, 2nd and 3rd week respectively compared with control. The current results showed the growth performance was improved in broiler that irrigated by a water containing different levels of essential oil especially the concentration 0.25 ml/L. Possible explanation could be that the extraction of the Eruca sativa may enhances the secretion of digestive enzymes which result in improving the digestion rate. Furthermore, many studies indicated that the essential oils stimulate the activity and secretion of pancreatic enzymes such as amylase, lipase, chymotrypsin and trypsin reported that the essential oils of medical plants stimulate the digestion of proteins, fat and cellulose.

Table 3 showed the effect of extraction of Eruca sativa on weight gain of broiler, the main observation was the significant differences (p≤0.05) at 4th week between all treatments and control as well as accumulative weight body gain. This could be due to high concentration of Eruca acid that contributed to antimicrobial activity(13). Thus, it was expected that the essential oils could have an effect on the gastrointestinal microflora by lowering the number of Escherichia coli and Clostridium perfringens and increased the number of Lactobacillus species.

Tables 4 and 5 showed significant effects of Eruca sativa on feed intake of broiler and feed conversion ratio from 3rd and 4th weeks at 0.50 and 0.25ml/L respectively. Indeed, there were no significant effects of the extraction of Eruca sativa (p≤0.05) at 4th week on feed intake. This could be explained by present more than one active ingredient in the herb and the effects are cumulative. Botsoglou et al., 2002 (20) reported that the different levels of essential oil (20-200 ppm) in poultry diets. Positive effects like, weight gain and feed intake were increased whereas feed conversion ratio decreased as compared with control and this is corresponding to (0.25 and 0.50ml/L) these results are agreed with(7,21) that found that the effect of essential oils can be positively through improve feed conversion ratio through increase digestive enzymes secretion, appetite, stimulation of immunity, increased vitality, antiviral, antioxidant activity, regulation of the intestinal microflora and, they exhibit antimicrobial properties.

**Internal organs and antibody titer:** There were no significant differences in thyme, spleen and bursa percentage of chick irrigated with the extraction of Eruca sativa at 0.25, 0.50 and 0.75ml/L (table 6). However, there were significant differences in antibodies titers at 9th and 28th days of broiler given a water with 0.75ml/L of the extraction of Eruca sativa at 9th and 0.50ml/L at 28th. The negative effect in internal organs might be attributed to high concentration of essential oil and may be a great part of the components are metabolized and then precipitated in the chicken meat. These results agreed those obtained by (24) and (24). Both paper reported that the relative weight of some organs such as bursa and spleen, and also antibody titration against Newcastle virus had no significant differences between some herb extract and control. The enhanced in antibody titer may be result of the mineral content of Cu, Zn, Fe, Mn, Mg and other elements which may enhance the immune response and the reproductive performance (4). Finally enhancing of both T and B lymphocytes responses and interleukins have been reported by (6).

Anesthetic Potency of Ketamine in Caspian Terrapin, Freshwater Soft Shell Tortoise and Rat Snake Collected from Bahar Al Najaf District, Al-Najaf Province

Ayad N.D. Alhakim

Abstract

The study was carried out during April 2012. Twelve Caspian terrapins, twelve freshwater soft-shell turtles and 6 rat snakes were collected from Baher Al-Najaf by professional reptiles collectors from Al-Rafidin association for hunting and environment protection, the present study include 3 separated experiments. The terrapins placed in 6 glass aquariums (couple per aquariums) the maintenance conditions controlled after adaptation for one week, all terrapins distributed equally into 3 groups. The animals of group 1, 2 and 3 were injected intramuscularly with 40, 60 and 80 mg ketamine. The anesthetic levels were assessed. Freshwater soft-shell turtles experiment, this experiment was same to previous experiment. The rat snakes placed in 2 plastic containers distributed into 2 groups, the maintenance conditions. The snake of 1.2-and 3 group were injected with 40, 60 and 80 mg/kg intramuscularly. The anesthetic levels were assessed. We note in Table 1 that when ketamine was injected at a dose of 40, 60 and 80 mg/kg of body weight, the minimum onset time for doses was (15, 7, 5), while the most time was (17, 10, 5) respectively. While we noticed the minimum a loss of the right reflex, deep anesthesia, recovery right reflex and completed recovery was (21, 12, 8), (47, 58, 76), (87, 120, 140) and (18, 24, 64). We note in Table 3 that when ketamine was injected at a dose of 40, 60 and 80 mg/kg of body weight, the minimum onset time for doses was (4, 4, 3), while the most time was (12, 5, 5) respectively. While we noticed the minimum a loss of the right reflex, deep anesthesia, recovery right reflex and completed recovery was (8, 4, 5), (50, 40, 74), (290, 260, 290) and (62, 70, 70). Therefore, the best dose is 80 mg/kg for Caspian terrapin, while for freshwater soft shell tortoise it is 80 mg/kg. As for rat snake, the ketamine dose of 80 mg/kg of body weight was the best according to the study.

Keywords: Anesthetic potency, Caspian terrapin, Rat Snake, Bahar Al Najaf district etc.

Introduction

The necessity of researches about reptile’s medicine and surgery has been increasing in recent years, either due to considering reptiles as pet animals or for conservation point (1). The reptiles are difficult to handling and the chemical restrain are necessary to clinical examination, minor surgical operation and biometry recording (2). Ketamine was originally developed for human use as cheap, injectable and safe anesthetic, these advantages were formed a ketamine to use in all primates, many zoological and exotic animals, and in birds and reptiles (3). Mostly, there are no anesthetic has been approved to use in reptiles in addition to variable anesthetic effects between individuals of the same species have been observed in reptile anesthesia studies and have been anecdotally attributed to possible differences in temperature, body size, body condition, sex, stress level, administration route and elapsed time since previous dosing (10). For these reasons the present study was designed to determined the anesthetic effect of ketamine in variant dose scale in three reptiles species including Caspian terrapin (Mauremys caspica), freshwater soft shell turtle (Rafetus euphraticus) and rat snake (Colubridae reptilia) collected from Bahar Al-Najaf district-Al- Najaf province/Iraq.

Materials and Method

Collection and maintenance of reptiles: The study was carried out during April 2012. Twelve Caspian terrapins, 12 freshwater soft-shell turtles and 6 rat snakes were collected from Baher Al-Najaf by professional reptiles collectors from Al-Rafidin association for hunting and environment protection, the present study include 3 separated experiments as followings:

Caspian terrapin experiment: The terrapins placed in 6 glass aquariums (couple per aquariums) the maintenance conditions controlled according to (7). After adaptation for one week, all terrapins distributed equally into 3 groups. The animals of group 1, 2 and 3 were injected intramuscularly (8) with 40, 60 and 80 mg ketamine (5). The anesthetic levels were assessed according (8).

Freshwater soft-shell turtles experiment: This experiment was same to previous experiment. Rat snake experiment: The rat snakes placed in 2 plastic containers distributed into 2 groups, the maintenance conditions (7) approved according to (12,17). The snake of 1.2 and 3 group were injected with 40, 60 and 80 mg/kg intramuscularly in table 3. The anesthetic levels were assessed according (11). All reptiles were released in their natural habit after 2 weeks of experiments.

Results

Discussion

A safe and effective anesthetic protocol for the care of turtles, and in particular of the Caspian Pond turtles, is really important, and unfortunately, there are not enough studies on the clinical anesthetic effects of drug combinations in these animals. It is important to observe the animal for respiratory and circulatory abnormalities and possible clinical signs of sepsis (1). Drugs eliminated by the kidneys such as ketamine are not justified in reptiles with a renal dysfunction. Samples from faeces, aspirates, tracheal fluids or blood can help in making an accurate pre-anesthetic diagnosis. There have been various studies that have evaluated the efficacy and side effects of different drug combinations, such as ketamine in turtle Podocnemis expansa, (4) ketamine in tortoises Gopherus polyphemus, (6) and ketamine in Snapping turtles Chelydra serpentine (7).

Ketamine hydrochloride is an anesthetic and analgesic drug that has been widely used in both human and veterinary medicine, especially in tortoises, (8) and the appropriate dose of the drug for the anesthetization of these animals. The importance of anesthetic and analgesic drugs for the animal medical care has previously been described, (1,2) such as the importance of the studies about the efficacy and efficiency of the drugs on the animals. To select the best anesthetic protocol, for any patient, the key elements are efficacy, safety, and reliability. An effective protocol provides for a rapid and smooth anesthesia induction as well as a fast and optimal recovery. Furthermore, the optimal anesthetic agent has a rapid onset of action and is quickly cleared from the bloodstream and central nervous system.

Ketamine hydrochloride is a general anesthetic agent characterized by analgesia (11, 6), rapid induction, and limited duration of action. The analgesic action of ketamine is due to its ability to bind the N-methyl-D-aspartate subtype of glutamate receptor (16). In snakes, inadequate handling was also reported to induce a fatal myositis (18, 20). In our experiments, we demonstrated, for the first time, on the terrapin that the time needed to reach anesthesia [Table 1, 2, 3], using ketamine hydrochloride. We note in Table 1 that when ketamine was injected 40, 60 and 80 mg/kg of body weight, the minimum onset time for doses was (4,4,3), while the most time was (12,5,5) respectively. While we noticed the minimum a loss of the right reflex, deep anesthesia, recovery right reflex and completed recovery was (8,4,5), (50,40,74), (290,260,290) and (62,70,70).

Furthermore, the measurements of the recovery time followed the same trend [Table 1]. In fact, as summarized in Table 1, the onsets of anesthesia, Loss Right reflex, Deep anesthesia, recovery right reflex, completed recovery were found to be, in animals treated with the ketamine hydrochloride. There was evidence that the measurements of efficacy differed between doses. East African reptiles 40-60 mg/kg I.M. or S.C. < 50 mg/kg ~ sedation > 50 mg/kg ~ anesthesia (11). Monitor lizards 50-100 m/kg I.M. Results from these type of studies are increasingly in bodies (except royal python) Snakes 50-75 mg/kg I.M. Ketamine not sufficient, Chelonians 40-90 mg/kg I.M. surgical anesthesia (19). Therefore, the best dose is 80 mg/kg for Caspian terrapin, while for freshwater soft shell tortoise it is 80 mg/kg. As for rat snake, the ketamine dose of 80 mg/kg of body weight was the best according to the study.

Conclusions

The Caspian terrapin, freshwater soft shell turtles and rat Snakes are an important species of turtles and reptiles, whose conservation status has not yet been evaluated that still needs to be studied under different point of views and for which an anesthetization protocol has to be fully evaluated. This research has shown that the ketamine is the anesthetic with the fastest onset time and shortest recovery time compared to the doses. These results provide new and important information for the medical treatment of an animal species, which is yet to be sufficiently studied. Pertinent due to the effect of climate and environmental changes, currently impacting the worldwide turtle populations.

Conflict of Interests: The authors of this paper declare that he has no financial or personal relationships with individuals or organizations that would unacceptably bias the content of this paper and therefore declare that there is no conflict of interests.

Source of Funding: The authors have no sources of funding, so it is self-funding research.
Ethical Approve: We declare that the study does not need ethical approval.

Correlation of Chemerin with Lipid Profile in Blood Women Polycystic Ovarian Syndrome in Tikrit City

Lolawh J. Falah¹, Asra’a I. Yaseen²

¹MSc Student, ²Assist Prof., College of Education of Women/University of Tikrit/Iraq

Abstract

Background: Polycystic ovary syndrome (PCOS) is the most common endocrine disorder in women of reproductive age, affecting 6%–10% of women worldwide. Objective: The study aimed to assess the relation of serum chemerin level with lipid profile in women with polycystic ovarian syndrome.

Materials and Method: A cross-sectional study was carried out in Salah Al-din City from 10th of October 2019, to 20th of December 2019. The number of polycystic ovary syndrome women under study was 60 women whose ages were between 15 and 36 years old. These women admitted to obstetrics and gynecology unit at Salah Al-din Teaching Hospital. The control group who were matched to the patients studied included 30 women.

Results: The study showed that there is the significant difference between PCOS women and the control group concerning serum chemerin level and lipid profile in PCOS women. This study demonstrates that there was a weak positive correlation between levels of chemerin and cholesterol in PCOS women (r = 0.02) which is mean that cholesterol level is slightly increased with the elevation of chemerin hormone in women with PCOS, There was a positive correlation between levels of chemerin and Triglyceride in PCOS women (r = 0.16) which is mean that level is slightly Triglyceride increased with the elevation of chemerin hormone in women with PCOS, There was a positive correlation between serum levels of chemerin and VLDL in PCOS women, slightly VLDL increased with the elevation of chemerin hormone in women with PCOS. There was a positive correlation between levels of chemerin and LDL in PCOS women, slightly LDL increased with elevation of chemerin hormone in women with PCOS. This study showed negative correlation between Chemerin and, HDL in PCOS women, slightly HDL decreased with the elevation of chemerin hormone in women with PCOS.

Conclusion: Highly significant relation of Chemerin and Cholesterol, Triglyceride, LDL and VLDL in PCOS, While negative correlation between Chemerin and HDL.

Keywords: Polycystic ovary syndrome, Chemerin, Cholesterol, Triglyceride, HDL, VLD and LDL.

Introduction

Polycystic ovary syndrome is the most common endocrine disorder in women of reproductive age, affecting 6%–10% of women worldwide.¹ Polycystic ovary syndrome is characterized by chronic anovulation, hyperandrogenism, and multiple small subscapular cystic follicles in the ovary on ultrasonography.²

Chemerin is a new adipokine of 163 amino acids and a of a molecular weight of 14 kDa.³ Chemerin has been identified as a novel discovered adipocytokine that has been shown to regulate adipocyte differentiation, modulation the expression of adipocyte genes.⁴ Chemerin is found to be highly expressed in adipose tissue and the liver, as well as by cells of the innate immune system, where it modulates the function of innate immune cells. These adipokines are thought to be involved in the development of metabolic syndrome and its related diseases including obesity, T2DM and cardiovascular disease.⁵ Additionally, chemerin levels have been shown to be high in obese PCOS women with insulin resistance.⁶
Materials and Method

A cross-sectional study was carried out in Tikrit City from 10th of October 2019 to 20th of December 2019. The number of PCOS women under study was 60 women whose ages were between 15 and 36 years. The diagnosis of PCOS was based on Rotterdam Criteria: oligo and/or anovulation clinical and/or biochemical signs of hyperandrogenism, and polycystic ovaries in ultrasound, meaning presence of 12 or more follicles measuring 2 – 9 mm in diameter in each ovary and/or ovarian volume more than 10 cm³. In addition the control group consisted of 30 apparently healthy volunteer females with regular menstrual cycles aged between 15 and 36 years. A volume of 5 mls of blood sample was taken by vein puncture from each subject enrolled in this study. Blood samples were placed into sterile test tubes, after blood clotting, the samples were centrifuged at 3000 rpm for 15 min then if a clot was developed, then was removed and re-centrifuged at 3000 for 10 min, and the obtained serum were aspirated using mechanical micropipette and transferred into clean plain tubes with screw which labeled and stored in deep freeze at -20 °C for the biochemical measurement of amylin by ELIZA.

Statistical Analysis: The statistical analysis was performed using Statistical Package for the Social Sciences version 23 (SPSS, IBM Company, Chicago, USA).

Results

This study showed that there was a positive correlations between serum levels of chemerin and cholesterol, triglyceride, VLDL, and LDL as shown in figures (1) (2) (3) (4), while negative correlations between serum levels of chemerin and HDL in PCOS women as shown in figure 5.

![Figure 1: Correlation between levels of Chemerin and Cholesterol in PCOS women.](image-url)
Figure 2: Correlation between levels of Chemerin and triglyceride in PCOS women.

Figure 3: Correlation between levels of Chemerin and S. LDL in PCOS women.
Discussion

Polycystic ovary syndrome (PCOS), is a disorder characterized by heterogeneous clinical presentations including hyperandrogenism, menstrual irregularity, and infertility along with metabolic disturbances manifested by hyperinsulinemia, obesity, hypertension, and dyslipidemia. This study showed that there was a positive correlation between serum levels of chemerin and cholesterol, triglyceride, VLDL, and LDL as shown in figures (1) (2) (3) (4), while negative correlations between serum levels of chemerin and HDL in PCOS women as shown in figure 5. Both visceral fat and insulin resistance are significant determinants for an impaired lipid metabolism. PCOS women are exposed to increased risk for cardiovascular diseases (CVD) through early progression of atherosclerosis and dyslipidemia is an important factor, thus a recent recommendation has been proposed for PCOS women, to assess their lipoprotein lipid profile, in an attempt to prevent CVD. Our data confirms previous reports stating that PCOS women display increased total cholesterol, LDL cholesterol and triglycerides, and low HDL cholesterol, pattern that is usually linked to insulin resistance. Hypertriglyceridemia and low HDL-C are common metabolic abnormalities found in women with PCOS. A study by Aye et al. suggested that
the presence of hypertriglyceridemia could contribute to atherothrombosis via platelet hyperactivation in PCOS.\(^{(12)}\) Chemerin serum levels in this present study were also positively correlated with TG and VLDL in the MetS group. This co-relation was proved also by Bozaoglu et al.\(^{(13)}\) study that was conducted in a large cohort and showed that serum TG was correlated with serum chemerin. Ye et al.\(^{(14)}\) regarding the association of chemerin with HDL-C level, the present study showed that serum chemerin where negatively correlated with HDL-C levels. These results were in agreement with Er et al. found that chemerin levels were negatively correlated with HDL-C plasma levels in Metabolic syndrome.\(^{(15)}\) Although obesity is often associated with metabolic disorders, lean women with PCOS also were found to have hyperinsulinemia and dyslipidemia.\(^{(16)}\)

Hussain found that there were high levels of TG, Cholesterol, and LDL in combination with low level of HDL and with an increase in atherogenic index in women with PCOS.\(^{(17)}\) These data are consistent with prior studies of dyslipidemia in women with PCOS.\(^{(18)}\) Most studies of dyslipidemia and PCOS have reported on cholesterol levels and TG, the lipid profile that is found in women with PCOS consists of elevated TG levels together with low levels of HDL.\(^{(19)}\) Increased secretion of VLDL particles by the liver results in elevated plasma TG concentrations. Subsequently, TG is exchanged for cholesteryl ester by the activity of cholesteryl ester transfer protein. Lipid metabolism in women with PCOS may also be affected by ovarian and-or adrenal secretion of sex-steroid. The effects of sex-steroids on lipid metabolism are complex and involve the actions of both androgens and estrogens. Hyperandrogenism has been associated with increased hepatic lipase (HL) activity. This enzyme, that has a role in the catabolism of HDL particles (partially responsible for the hepatic removal of the HDL particles) exhibits strong dimorphism with exogenous androgens up regulating, and estrogens down-regulating its activity.\(^{(20)}\)

Diagnostic Value of Thyroid Cytology: A Meta-analysis

Aiad Abdullah Abdulrazak
Assistant Professor of Pathology, Department of Pathology, Tikrit College of Medicine, University of Tikrit, Iraq

Abstract

Objective: Thyroid disorders are the most common endocrine disorders worldwide (4-7% of population). Excision of all thyroid lesions is impractical. For rapid diagnosis, Fine needle aspiration cytology (FNAC) is simple, safe, rapid diagnostic procedure. However, indeterminate cases were reported occasionally where the patient cannot be confidently assigned to a manageable category.

Aim: We conducted a systematic review and meta-analysis to evaluate the diagnostic accuracy of FNAC in thyroid lesions and the correlation between cytological and histopathological diagnosis.

Method: A literature search of published studies was conducted using Medline/PubMed, reasearchgate, Scielo (scientific electronic library online), and Google Scholar as international databases, and IVSL (Iraqi Virtual Science Library) and IASJ (Iraqi Academic Scientific Journals) as national databases.

Results: A total of 24 studies are analyzed. The median sample size of the studies included was 100 (range, 20-23). The sensitivity and specificity ranged from 0.38 to 0.98 (pooled sensitivity: 0.81; 95% confidence interval (CI), 0.78-0.83) and from 0.47 to 1.00 (pooled specificity: 0.93; 95% CI, 0.92-0.94), respectively. By SROC curve, the Q-value was 0.883 and the area under the curve (AUC) was 0.945, indicating a high level of overall accuracy.

Conclusion: The recognized accuracy of FNAC in detecting thyroid cancers is applicable only to papillary carcinoma and not to other malignancies. Moreover, FNAC should be considered as a screening rather than diagnostic tool for follicular lesions. Thus, FNAC helps to orientate patient management rather than to provide final definitive diagnosis.

Keywords: Thyroid, cytology, meta-analysis, FNA, fine needle aspiration.

Introduction

Thyroid diseases are the most frequent endocrine disorders globally. In surgical practice, thyroid lesions are seen in 4-7% of population. Moreover, a survey of random patients undergoing neck ultrasonography 20%-76% of adult women was found to have at least one thyroid nodule. The diagnostic challenge facing the clinician is to identify those lesions most at risk and to limit resection of benign conditions as much as is safely possible. Several diagnostic tests, such as radionuclide scanning, ultrasonography, and fine-needle aspiration (FNA) cytology have been used to highlight those patient requiring surgical intervention. FNAC has been used widely because it is safe, and readily doable in outpatient settings. Moreover, Fine-needle aspiration has also been shown to have similar or higher sensitivity and accuracy levels than frozen section examination.

However, there is also evidence of limitations and pitfalls of FNA are those related to specimen adequacy, sampling techniques, the skill of the physician performing the aspiration, the experience of the pathologist interpreting the aspirate, and overlapping
cytological features between benign and malignant follicular neoplasms.\(^{(5)}\)

About one fifth of thyroid nodules with indeterminate cytology found to be malignant after surgery, therefore histopathological examination remains the standard modality of diagnosis.\(^{(6)}\)

**Aim:** we conducted a systematic review and meta-analysis to evaluate the diagnostic accuracy of FNA in thyroid lesions and the correlation between cytological and histopathological diagnosis.

**Materials and Method**

**Search Strategy:** Our study was performed according to the meta-analyses guidelines of diagnostic tests accuracy studies.\(^{(7)}\)

A literature search of published studies was conducted using Medline/PubMed, Reasearchgate, Scielo (scientific electronic library online), and Google Scholar as international databases, and IVSL (Iraqi Virtual Science Library) and IASJ (Iraqi Academic Scientific Journals) as national databases. The study conducted in May 2020.

The database search for eligible studies were made without any restriction (such as (publication date, language, or other restrictions). The search terms included “thyroid”, “cytology”, “FNA” and “fine needle aspiration”. Thereafter, the titles were checked and duplicates were removed, then the abstracts were screened for potentially relevant studies. Full-text articles were then obtained for all potentially relevant studies. Additional references were obtained by checking the reference lists of included studies.

**Inclusion and exclusion criteria:** Candidate studies included in this meta-analysis must conform the following inclusion criteria: (1) studies concerning the diagnostic value of FNAC in thyroid diseases; (2) studies with cytohistopathological correlation. (3) Studies must contain sufficient information regarding true positive, true negative, false positive, false negative or any data from which this information were extractable.

The exclusion criteria were as follows: (1) duplicate articles; (2) case reports, editorials, abstracts, commentaries, (3) lack of essential data and (4) studies without cytohistopathological correlation.

**Data Extraction:** The full texts of all potentially relevant articles were evaluated by the author. Studies were included if they contained extractable data on correlation of cytological diagnosis with histopathological examination of lesions. Data from foreign-language articles (non-English) were extracted from English summary and/or tables. Data extracted from each study included: (1) name of first author; (2) year of publication; (3) number of patients; (4) absolute numbers in TP, FP, FN, and TN, or any data from which this information was derivable.

**Statistical Analysis:** All the analyses were conducted using the following softwares: Statsdirect version 3.2.10, Meta-Disc version 1.4, and Medcalc version 19.3

Statistical heterogeneity was assessed by Cochran’s Q statistic (with a significance level of p ≤ 0.1) and I2 statistic with values of 25%, 50%, and 75% indicating low, moderate, and high degrees of heterogeneity, respectively.

We used random effects model to minimize risk of heterogeneity across studies as diagnostic test accuracy studies are expected to be heterogeneous, making a fixed-effect model inappropriate. Publication bias was assessed using a funnel plot and Eggers test.\(^{(7)}\)

In addition, a summary receiver operating characteristic (SROC) curve was constructed to investigate the impact of thresholds by the Moses-Shapiro-Littenberg method. The AUC was calculated to show the diagnosis authenticity. The closer the AUC was to 1.0, the better the diagnosis authenticity was.\(^{(7)}\)

**Results and Discussion**

**Literature Search:** The process of electronic database search yields 886 potential relevant articles (studies dealing with fine needle aspiration cytology (FNA) for diagnosis of thyroid diseases. An additional 34 eligible studies were identified by scanning references lists of these articles (total records identified n = 920). Title and abstract screening carried out, duplicates and irrelevant studies (studies without cytohistopathological correlation, editorials, case reports) were excluded (n = 858). After reviewing the full-text, we further excluded 38 studies for lacking necessary data (extractable data in the form of true positives, false positives, false negatives, and true negatives). Twenty-four articles are included in the present meta-analysis\(^{(8-31)}\).
Characteristic of the included Studies: The salient characteristics of included studies are outlined in Table 1. The selected studies were published from 1987 to 2019. A total of 24 studies are analyzed. Twenty one of these studies were published in English, one in Arabic and one in Korean. Included studies were from different countries, including India (n=8); Iraq (n=2), Bangladesh (n=2), and one study from each of, Egypt, Iran, Ireland, Korea, Kuwait, Nepal, Saudi Arabia, Syria, Turkey, UK, USA. All included studies compare cytological diagnoses with histopathological ones. Fine needle aspiration cytology (FNAC) was performed and interpreted before histopathology.

1- Role of thyroid FNA and aim of our study: Histopathology examination is the gold standard for thyroid cancer diagnosis. However, this diagnostic process is time-consuming, invasive, and it may expose patients to complications. The quest for simple, safe, diagnostic tool for the initial screening of patients with thyroid diseases deemed rational.

To our knowledge, our study is the first meta-analysis to pool the data regarding accuracy of FNA for the diagnosis of thyroid diseases and provide possible areas of improvement for future studies. Except for one meta-analysis carried out in India and include pediatric patients only. (32)

2- Diagnostic accuracy of thyroid FNAC: At the outset of literature retrieval, we found 24 studies reporting thyroid cases subjected to FNAC and published over a very large period (1987–2019) by Asian, European and American authors. The most significant finding was that the FNAC sensitivity in diagnosing thyroid lesions was noticeably high.

The overall sensitivity and specificity ranged from 0.38 to 0.98 (pooled sensitivity: 0.81; 95% confidence interval (CI), 0.78-0.83) and from 0.47 to 1.00 (pooled specificity: 0.93; 95% CI, 0.92-0.94), respectively. The diagnostic accuracy quantified by AUC was 0.945 (a diagnostic test is considered perfect if the AUC is 100%, excellent if greater than 90%, and good if greater than 80%). All these results demonstrated that FNAC had a considerable potentiality in differentiating thyroid cancers from benign tumors and non-neoplastic lesions. (33)

However, the accuracy of a benign thyroid FNA result is difficult to establish because most patients with a benign result do not have surgery. The false-negative rates reported in the literature reflects only those patients who have their aspirated nodules being surgical excision, and thus the figures may be an undervalue of reality figures. Approximately 18% of patients who have an FNA are actually treated surgically. (34)

3- False-negative: The rate of false-negative results varies from 0 to 22.8% (mean 5%).(9,26) In most series, false negatives are due to inadequate specimens or improper preparation of the smear and, to a lesser extent, to the pathologist’s inability to identify a malignant lesion or to the coexistence of two pathologies. Excluding these causes, the most common errors are due to the presence of a cystic neoplasm, followed by occult lesions and small tumor size. Adherence to strict criteria of specimen adequacy will greatly reduce the number of false negative diagnosis especially, if the benign nodules are followed by a repeated FNA over a period of time, and if ultrasound guidance is used. Large multinodular goiters may represent an important source of false negatives because in 10% of cases, a micropapillary carcinoma may be present. The probability of identifying this type of carcinoma by FNA without US guidance in this gland is practically zero because the aspiration punctures tend to be directed to palpable nodules.(35)

4- False-positive: On the other hand, false-positive diagnoses represent about 0 to 27% of the cases. This figure markedly decline if suspicious malignancies are ruled out, or even nullified in highly skilled hands. Almost false positive diagnoses are due to misinterpretation of hyperplastic nodules and Hürthle cell lesions as papillary or follicular carcinoma.(11-14)

The most common benign lesions giving false positive result are follicular adenoma (including the follicular adenoma with papillary hyperplasia) and hyalinizing trabecular tumor. (34)

5- Study Heterogeneity: We found significant heterogeneity among the 24 studies, so we used a random effect model.

6- Publication Bias: Publication Bias was ruled out from being the potential cause of the heterogeneity in studies. Funnel plot was performed to assess publication bias among the included studies. No publication bias was detected in this meta-analysis, thus heterogeneity cannot be attributed to publication bias. To further confirm the absence of publication bias we did Eggers test (Egger: bias = 3.427 (95% CI = -5.57 to 12.43) P = 0.4381).
6- Summary receiver operator curve (SROC): SROC provides an overall measure of test accuracy. The Q-value, which is the point of intersection of the SROC curve with a diagonal line passing from the left upper corner to the right lower corner of the ROC space and corresponds to the highest common value of sensitivity and specificity for the given test. This point does not indicate the only or even the best combination of sensitivity and specificity for a particular clinical setting, but represents an overall measure of the discriminatory power of a test.

SROC curve demonstrates that the overall area under the curve of 0.945 (standard error: 0.0160). The SROC curve shows the tradeoff between sensitivity and specificity. Our data showed that the SROC curve is positioned near the desirable upper left corner of the SROC curve, and that the maximum joint sensitivity and specificity (ie, the Q-value) was 0.883; while the area under the curve (AUC) was 0.945, indicating a high level of overall accuracy.

7- Conclusion and recommendations: Because of its low cost, relative safety, and rapid sign-out time, FNAC facilitate prompt and appropriate clinical decisions and therapy. However, the recognized accuracy of FNAC in detecting thyroid cancers must be applied only to papillary carcinoma and not to other types of malignancies. Moreover, FNAC should be considered as a screening rather than diagnostic tool for follicular lesions. Thus, the aim of FNAC is to orientate patient management rather than to provide final definitive diagnosis.

Abstract

More than supply the demand for health care usually determines the design of public health services. This is more so when technological developments, including that of information and communication technologies, pierce through the process of utilization of any service by the public. Although prior research papers have focused on the factors that impact on the adoption of information technology, there are limited empirical research works that simultaneously capture technology factors (TAM, TAM2) and end-user development specific factors (perceived technology usage and intention to recommend) helping healthcare professionals to adopt Health Management Information System (HMIS) software in the healthcare environment. To fill this gap, the present paper used the Technology Acceptance Model (TAM), the extended TAM model (TAM2) and identified the important determinants of user acceptance perceived risk and trust. This is specifically undertaken in order to describe ESIC healthcare professionals behavioral intention to adopt HMIS software services. The study was conducted in the Employees’ State Insurance Corporation (ESIC) main hospital and dispensaries in the Tirunelveli sub-region. The required data were collected from 171 ESIC healthcare professionals in the Tirunelveli sub-region. A Structural Equation Model (SEM) approach was used. Convergence and divergence with earlier findings were found, confirming that Perceived Usefulness (PU), Perceived Ease of Use (PEOU), social influence, facilitating conditions and training had significant influence on the intention of healthcare professionals to adopt HMIS software. The study provided a basis for further refinement of technology adoption model. Improving perceived usefulness factor (perceived long-term usefulness) may turn healthcare professionals towards adoption of HMIS.

Keywords: Information Technology, Technology Acceptance Model, Employees’ State Insurance Corporation, Perceived Usefulness and Perceived Ease of Use.

Introduction

In recent years, there has been growing global emphasis on the need for Information Systems (IS) in all sectors. The elementary conditions that enable global competition in the information society are the development of communication technologies and the importance of the administrative information flows and the inter-institutional communication networks. Therefore, more emphasis is placed on flexible and cost-efficient information systems in the competitive presentation of public services. Information systems are one of the means by which public institutions can save economic indicators, such as time and cost. Assuring and promoting quality in health care services continues to be a priority for any health care system. Besides evaluation of health status through morbidity and mortality estimates, there has been equal emphasis...
on quality of care indicators in health systems research. The continuously increasing demand for assessment of quality in the health care system can be attributed to rising costs, constrained resources and evidence of variations in clinical practice. Hospital management information systems provide an institutional framework consisting of different information about the medical, financial and managerial functions of a particular hospital. The first applications of these systems are limited to the recording of patient information and the billing of health services offered. Today, new modules have been added to health management information systems such as appointment over the internet, follow-up patients, and request analysis and display results. Thus, it has become possible for doctors to transmit their requests directly to the laboratories via automation systems and to monitor the results online. In this respect, the main purpose of the study is to define the role of hospital management information system within the functional context. Further, it is crucial to analyze the genuine perception of healthcare professionals’ willingness to adopt these technologies. In order to identify which factors influence on healthcare professional’s intention to adopt HMIS the researcher has merged the existing and empirically validated theoretical models (TAM and TAM2) with perceived benefits and actual use of technology. The study uses constructs from the Technology Acceptance Model (TAM) and the extended Technology Acceptance Model (TAM 2) and integrates the constructs of facilitating conditions and training in the model. Thus, cognitive factors, perceived social forces and intrinsic characteristics are also included in a unified model along with facilitating conditions and training. The study measures intention-to-use health management information system software in the ESIC healthcare environment. Intention to use has been found to be a strong predictor of actual system usage in the available literature. The study uses a quantitative survey method to record ESIC healthcare professionals’ opinions and attitudes. It analyzes the data using a refinement procedure, controlling reliability and validity, and validates the proposed model using Structural Equation Modeling.

**Review of Literature:** IT stress is said to be an important factor and its evaluation techniques are based on the widely used Technology Acceptance Model (TAM). IT stress could be broadly classified into two types. They were Direct IT stress and Indirect IT stress (Raitoharju, 2005). Direct IT stress has always been a hindrance and is caused by the following factors: person’s fear of breaking something, feeling of ignorance, fear of technology, fear about health, fear about anything new and unfamiliar or sense of threat to intellectual self-assessment. Indirect stress is all about time consumption and pressure. Here, the user is an expert in information technology and spends a lot of time in IT related works. Since he spends a lot of time in front of computers, he is unable to complete other tasks properly. This creates unwanted pressure and such a pressure gives way to indirect IT stress. Further, computer anxiety reduced the effectiveness of computerization. Perceived usefulness and Perceived ease of use played an important role in IT acceptance studies. Perceived usefulness encouraged IT usage and thereby resulted in technology acceptance. However, Perceived ease of use did not have any significant effect on Perceived usefulness. While it is important to look at systemic, organizational and professional factors that shape the integration of ICT in health care systems, studying adoption at the individual level is particularly relevant since the ultimate decision to use a new technology is often that of the individual (Hu et al., 2001; Igbaria et al., 1997).

Health Information System (HIS) could be categorized by their complexity and integrity. The HIS could integrate a large variety of medical and administrative information and further, low quality information could have dramatic repercussions on patient healthcare (Ribière, J.LaSalle, Khorrramshahgol, & Gousty, 1999). HIS quality influences the quality of care by capturing, transferring, storing, managing and displaying medical information. Efficient medical decision making, customer satisfaction and reduced health related risks are found to be the prime goals of health information system. System Quality, Information Quality, Use, User Satisfaction, Individual Impact and Organizational Impact were found to be the important dimensions that come under quality of information system. Moreover, adaptation to common tasks and user friendliness could enable increased levels of performance.

Information Technology (IT) increased quality of care indirectly by improving both relational and management continuity of care. Information Technology, through electronic integration, contributed to relational and management continuity as well as to improving quality of care (Pinsonneault, Dakshinamoorthy, Reidel, & Tamblyn, 2012). IT systems should be designed and implemented in such a way so as to motivate patients to
visit a given physician or at least physicians who share important patient record information. The quality of care could be further improved when physicians were electronically integrated with other specialists, retail pharmacies and the health insurance agency.6

The sustainability of Health Information System depended on the technical features and physical infrastructures. Any lack of technical approach would lead to instability of the information system. Socio-technical aspects played an all important role in information system. Integration of such aspects into the organizational structures would lead to stability (Kimaro & Nhampossab, 2007). They would also enable easy execution of routine activities. Health services mainly include curative and preventive activities. These activities are hampered by scarce resources. The main aim of HIS is to overcome the scarcity and bring about better care.4 Further, extra attention should be given to users' needs, evaluation and feedback generation and future improvements. Information generation and sharing of knowledge within the sustainability strategy framework would also add to the stability of health systems.

Large health care infrastructures would always be confronted by the presence of the World Wide Web and electronic commerce. Community Health Information Networks (CHINs) have been defined as: Inter organizational systems (IOS) using information technology(ies) and telecommunications to store, transmit, and transform clinical and financial information.5 This information can be shared among cooperative and competitive participants, such as payers, hospitals, alternative delivery systems, clinics, physicians, and home health agencies. Customers (patients) were often described as ‘by-products’ of the health care delivery system. Economic dimensions, such as reduced risk, lower transaction costs and increased industry knowledge or competencies, were usually considered prior to the adoption stage of implementation (Payton, 2000).

The decomposed TPB model was advantageous to explain physicians’ adoption and intentions to use the Information system (IS). The three antecedent constructs used in the TPB model were attitude, Subjective norm (SN), and perceived behavioral control (PBC). While attitude was decomposed into perceived usefulness (PU) and perceived ease of use (PEOU), PBC was decomposed into personal innovativeness in IT (PIIT), self-efficacy, and facilitating conditions. Perceived usefulness and perceived ease of use had significant impact on attitude of the physicians; perceived ease of use had significant impact on perceived usefulness. Further, Subjective norm could be predicted by interpersonal influence (Hung, Ku, & Chien, 2008). Facilitating conditions is defined as the beliefs about availability of resources to facilitate that behavior. The facilitating conditions had no significant effect on perceived behavioral control.2 This is because, the information infrastructure (eg) internet is already available to most organizations and hence the influence of the facilitating conditions on perceived behavior control gradually decreases.

**Hypotheses Formulation:** This paper proposes a model, which unifies (a) cognitive factors or cognitive instrumental processes, such as job duties, output quality; (b) perceived social forces or social influence processes, such as subjective norm, voluntariness and image; (c) intrinsic characteristics of innovations compatibility, relative advantage, along with (d) computer self-efficacy; and (e) facilitating conditions. Consequently, in the unified model, the following hypotheses are tested:

- **H1a** System Quality may positively impact the perceived usefulness of HMIS.
- **H1b** System Quality may positively impact the perceived ease of use of HMIS.
- **H1c** System Quality may positively impact the perceived behavioral control of HMIS users.
- **H2a** Computer self-efficacy may positively impact the perceived usefulness of HMIS.
- **H2b** Computer self-efficacy may positively impact the perceived ease of use of HMIS.
- **H2c** Computer self-efficacy may positively impact the perceived behavioral control of HMIS users.
- **H3a** Facilitating conditions may positively impact the perceived behavioral control of HMIS users.
- **H3b** Facilitating conditions may positively impact the computer self-efficacy of HMIS users.
- **H4** Users’ perceived behavioral control may positively impact the intention of HMIS adoption.
- **H5a** HMIS perceived ease of use may positively impact the perceived usefulness of HMIS.
H5b HMIS perceived ease of use may positively impact attitudes toward HMIS adoption.

H6a HMIS perceived usefulness may positively impact attitudes toward HMIS adoption.

H6b HMIS perceived usefulness may positively impact the intention to adopt HMIS.

H7 Attitudes toward adopting HMIS may positively impact the intention of adopting HMIS.

H8 HMIS subjective norms may positively impact the intention of adopting HMIS.

H9 Attitudes towards adopting HMIS may positively impact the perceived behavioral control of HMIS users.

**Methodology**

An empirical research study was conducted using a research questionnaire with close-ended questions. Healthcare professionals in the ESIC main hospital and dispensaries in Tirunelveli sub-region have been chosen to be surveyed. The ESIC healthcare professionals were selected using convenience sampling. Among the ESIC hospital staff, there were 171 healthcare professionals in the Tirunelveli sub-region and all the 171 professionals in different departments of the hospital were selected for the study. The questionnaire used in this study was adopted from previous studies. Five point Likert scales were used, ranging from strongly agree to strongly disagree. The questionnaire consisted of 10 parts:

(1) General Information; (2) General System Quality; (3) Computer Self-efficacy; (4) Facilitating conditions; (5) Perceived Usefulness (PU); (6) Perceived Ease of Use (PEOU); (7) Perceived Behavioral Control (PBC); (8) Attitude; (9) Subjective norm (social influence); (10) Behavioral Intention (BI).

A pilot study using an extended questionnaire containing all the scales proposed in the literature review was conducted by administering the questionnaire to 25 ESIC healthcare professionals. Scales and items used in the questionnaire and the analysis have been successfully used in previous studies to measure information system adoption by the healthcare professionals in the hospital environment. These particular scales may not be adequate for measuring attitudes of the particular target group of ESIC healthcare professionals. However, reliability and validity analysis performed hereafter proves that the scales constitute a reliable and valid instrument for measuring information system adoption by ESIC healthcare professionals. For statistical analysis, Structural Equation Model (SEM) approach was used to identify the influential factors to ESIC healthcare professionals’ acceptance of HMIS software in the hospital environment.

**Data and Analysis:**

Table 1: Model Summary (Goodness of fit Index)

<table>
<thead>
<tr>
<th>Model</th>

<td>.973</td>
<td>.946</td>
</tr>
</tbody>
</table>

*Note.* NFI = Normed-fit index; GFI = Goodness-of-fit index; AGFI = adjusted goodness-of-fit index; RMR = Root Mean Square Residuals; RMSEA = Root Mean Square Error of Approximation; CFI = Comparative fit index.

The above table shows the model fit indices for the overall structural model of behavioral intention. The table reveals that the Root Mean Square Error of Approximation (RMSEA) value 0.61 and Root Mean Square Residuals (RMR) 0.074 which is lesser than equal to 0.08 (i.e. the model is mediocre fit (Hans Muller, 2003), the other model fit evaluation method such as Goodness of fit index (GFI) value 0.968, Adjusted Goodness of fit index (AGFI) value 0.945, Normed Fit Index (NFI) value 0.973 and Comparative fit index (CFI) value 0.946 are attained and satisfied the criteria (thumb rule i.e. greater than equal to .90). It is concluded that items perfectly measures behavioral intention model (i.e. an acceptable fit).

This section presents results of hypotheses testing. Table shows sixteen hypotheses represented by causal paths that were used to test the relationships between the latent constructs. The latent constructs used in the proposed theoretical model were classified in two main categories: exogenous and endogenous constructs. Exogenous constructs were the Facilitating conditions.
(p4_tot) and System Quality (p2_tot) while endogenous constructs were the Computer Self-efficacy (p3_tot), Perceived Usefulness (p5_tot), Perceived ease of use (p6_tot), Perceived Behavioral Control (p7_tot), Attitude (p8_tot), Subjective norm (p9_tot), Behavioral Intention (p10_tot). Goodness of fit indices and other parameters estimates were examined to evaluate the hypothesized structural model. Assessment of parameter estimates results suggested that sixteen hypothesized paths were significant. Thus, indicating support for the sixteen hypotheses. These results are presented in detail as follows.

Figure 1: The research model after validation
The table depicts the standardized regression weights (β) which estimate and predict the intention of ESIC healthcare professionals towards HMIS adoption. The SEM result reveals that the hypotheses Self efficacy_ Perceived Usefulness (H2a), Self efficacy_ Perceived Ease of Use (H2b) and Self efficacy_ Perceived Behavioral Control (H2c) were significant. The standardized regression weights of H2a (.280), H2b (.389) and H2c (.246), show that Self efficacy has a direct significant effect on Perceived Usefulness (28%), Perceived Ease of Use (38.9%) and Perceived Behavioral Control (24.6%).

The hypotheses System Quality_ Perceived Usefulness (H1a), System Quality_ Perceived Ease of Use (H1b), System Quality_ Perceived Behavioral Control (H1c) and Facilitating Condition_ Perceived Behavioral Control (H3a) were significant. The standardized regression weights of H1a (.555), H1b (.299), and H1c (.287), show that System Quality has a direct significant effect on Perceived Usefulness (55.5%), Perceived Ease of Use (29.9%) and Perceived Behavioral Control (28.7%). It also reveals facilitating conditions has a significant direct effect on the Perceived Behavioral control(39.9%) and Self efficacy (73.9%).

The hypotheses Perceived Usefulness_ Attitude (H6a), Perceived Ease of Use_ Attitude (H5b) and Subjective Norm _ Attitude (H9) were significant. The standardized regression weights of H6a (.580), H5b (.249) and H9 show that Perceived Usefulness (58%), Perceived Ease Use (24.9%) and Subjective Norm (104.4%) have a direct significant effect on Attitude of ESIC healthcare professionals.

The hypotheses Perceived Usefulness_ Behavioral Intention (H6b), Perceived Ease of Use_ Behavioral Intention (H4), Attitude_ Behavioral Intention (H7) and Subjective Norm_ Behavioral Intention (H8) were also significant. The standardized regression weights of H6b (.227), H4 (.192), H7 (.187) and H8 (.294) show that Perceived Usefulness (22.7%), Perceived Ease of Use (19.2%), Attitude (18.7%) and Subjective Norm (29.4%) have a significant direct effect on Behavioral Intention of ESIC healthcare professionals.

**Discussion**

The results of this study provide support for the research model presented in Fig.1 and regarding hypotheses directional linkage. Findings from the present study suggest that in the presence of both facilitating variables (Computer Self-efficacy, Facilitating Conditions) and operational variables (Perceived Usefulness, Perceived Ease of Use) it is the second set that has a significant effect on intention to use. In more detail: System Quality, Attitude and Subjective Norm, along with Perceived Usefulness and Perceived Ease of Use are the five factors that influence intention to use HMIS. Computer Self-efficacy and Facilitating Conditions, although included in the model, do not significantly affect intention to use. Previously researchers have focused on the factors that impact on the adoption of health information technology; there is a limited empirical research work that simultaneously captures technology factors and user specific factors that help healthcare professional’s adopt HMIS software. Thus, the study has aimed to develop an integrated technology adoption model with TAM and TAM2 model to predict and explain ESIC healthcare professional’s intention to adopt HMIS software and recommend HMIS in ESIC hospital environment. Convergence and divergence with earlier findings were found, confirming that Perceived Usefulness, Perceived ease of Use and social influence (subjective norms) have significant influence in user’s intention to adopt HMIS and these findings are consistent with previous study conducted by Raitoharju (2005). Contrary to the expectation the researcher has found that facilitating condition and computer self-efficacy with intention to adopt HMIS were not valid, these findings are consistent with Hung, Ku and Chien (2008). What the findings of this paper suggest is that along with emphasizing and augmenting technological benefits of using HMIS services, a greater and primary effort should be made in providing efficient and effective HMIS practices. These could satisfy ESIC healthcare professionals and engage them to use HMIS services further. Raising system quality and enhanced training sessions are important steps, but providing results and efficient solutions to ESIC healthcare professionals through HMIS software is more important in raising their intentions to use them. Users find health information systems useful when they relate to their intrinsic characteristics, their interest and their working settings. Users will use health management information systems if they help them to work more efficiently and effectively.

**Conclusion**

This study has limitations that provide the impetus for further research in this field of investigation. First, this research is cross sectional and measures the ESIC
healthcare professional’s intention at one point in time that may be less generalizable as compared with longitudinal study. Second, testing of this newly developed integrated technology model in other developing countries may be useful for the further generalization of this model. The paper made a contribution to the study of adoption of health management information system by applying a model which joins TAM and TAM2. The effort was to measure the contribution of the separate variables in the presence of a multitude of effects. Thus, it is clear from the findings that for the adoption of HMIS by ESIC healthcare professionals, practical and operational issues regarding the efficiency of services should be considered first. This study can serve as a starting point for other health information system adoption researches. The user has to be placed at the center of future developments, thus, the board of members in the governing body of the hospital should take into consideration user needs, established marketing practices to promote the services and provide training to healthcare professionals in order to make the systems attractive to them. Training programs should stress the potential of health information systems and should help users to understand the relative advantage, job relevance and generally the value of them over existing manual systems. The findings can also provide useful recommendations to the development of practices and policies that influence intention to use HMIS services.

Abstract

Diabetes claims millions of lives every year. Diabetes Mellitus is a metabolic disorder that occurs due to the increase in blood sugar level. The blood sugar level control by insulin secreted from pancreas. The diabetes classify as type 1 and type 2 depending on insulin secretion. The type 2 diabetes is more common in people than type 1 diabetes. Traditionally, the blood glucose level estimate with glucometer and blood test. However, the test require invasive blood pricking for blood glucose measurement. The measured blood glucose value also varies due to amount of blood taken for testing, part of blood used for testing, depth of finger pricking, physical activity, stress and underlying illness. Hence, the insulin secretion from pancreas monitor for accurate prediction of blood glucose level. The blood glucose level varies with respect to insulin secretion from pancreas. In this paper, we propose a non-invasive approach to estimate blood glucose accurately through NIR spectroscopy for diabetes control. The NIR spectroscopy signal obtained from pancreas process through Rational Dilation Wavelet Transform to determine the insulin secretion level. The non-invasive NIR spectroscopy method measures glucose level with 90% accuracy compared to lab results.

Keywords: Type 2 Diabetes, RADWT, NIR spectroscopy, Insulin.

Introduction

Diabetes mellitus characterizes by the abnormal increase of sugar level in the blood. When the glucose level in the blood increases, it induces the insulin release from the pancreas. Insulin causes fat cells and muscle to remove glucose from the blood and causes the liver to metabolize glucose and thus reduce blood sugar to normal levels. People with diabetes have high levels of blood sugars ince, pancreas does not produce insulin. The diabetic person have minimal count of β-cells in pancreas which secretes low insulin.

The most general forms of diabetes are type 1, type 2 diabetes, and gestational diabetes. The type 1 diabetes is an autoimmune disorder where, the body attacks the pancreas making it unable to produce insulin resulting in minimal insulin secretion. The type 2 diabetes cause due to factors such as metabolic disorders, age, overweight, obesity, physical inactivity and unhealthy food consumption. The β cell in pancreas produce insufficient insulin coupled with organ resistance to insulin and result in high blood glucose level. The gestational diabetes occurs during pregnancy.

Currently, the blood glucose level control by medication and insulin injection coupled with diet control and physical activity. The blood glucose level determine by blood test or glucometer. The first introduced blood glucose meter was Ames Reflectance Meter. The Ames Reflectance Meter enables diabetic patients to monitor the blood glucose levels themselves. Reffomat is another portable and compact blood glucose meter designed for health care professionals. The Reffomat requires only a small amount of blood to determine blood glucose level. The foresaid meter needs extraction of blood samples through fingertip pricking, ear pricking. The blood glucose monitoring require taking test for up to 4 times every day. Therefore, continuously pricking of finger, ear for blood to determine blood glucose level may cause infection, and calcified nodules. The blood sugar level estimated by glucometer are inaccurate due to damaged blood cells. Further, the frequent skin pricking is uncomfortable, inconvenient and cause skin irritation.
Hence, precise, convenient, safe and comfortable blood glucose measurement method is required.

The blood glucose also measure by non-invasive method. The polarization change is the first introduced non-invasive technique where combination of helium and neon based laser light is coupled to a linear polarizer and the phase matches with the rotation vector is relative to glucose.

Raman Spectroscopy can detect low frequency modes. A Surface Enhanced Raman Spectroscopy (SERS) detects the interaction between glucose molecules and SERS active surface. The monochromatic light on molecule result in photon energy shift. The energy shift of photon is proportional to molecular bond vibration. The molecular vibration have specific Raman spectrum band. The spectrum band features vary for different molecules such as glucose.

Fluorescent spectroscopy is an electromagnetic spectroscopy technique that can analyze a sample’s fluorescence. Fluorescent Spectroscopy utilizes visible light spectrum, to detect energy emitted at different wavelength from glucose molecule. Near-Infrared (NIR) spectroscopy employs near-infrared light of wavelength 780-2500nm. In NIR spectroscopy, glucose level estimates with respect to the variations in the light intensity. Mid-Infrared (MIR) spectroscopy is developed from NIR spectroscopy that utilizes the near infrared light of wavelength 2500-10000nm. MIR spectroscopy is sharper and does not penetrate through the skin effectively. Absorption spectroscopy in the infrared (IR) region is a significant technique for finding unidentified biological substances in aqueous solutions. The technique is based on the process that every molecule has particular resonant absorption peaks. These peaks are caused by molecule’s rotational and vibrational oscillations.

**Literature Survey:** Non-invasive blood glucose monitoring perform through in vitro and in vivo analysis of Differential Continuous Wave Photo Acoustic Spectroscopy (DCW-PAS). The DCW-PAS approach uses amplitude modulation with dual wavelengths of light to identify glucose concentration level. The analysis compares DCW-PAS evaluations including results from invasive blood glucose sensor evaluations of healthy people’s Oral Glucose Tolerance Tests (OGTTs). The blood glucose level estimation from photo-acoustic signal and invasive sensors have good correlation. [1]

The blood glucose level measure with plasmonic sensor made of barium flint glass, gold film and silicon nitride (Si$_3$N$_4$) substrate. The plasmonic sensor rejects infrared wavelength on normal incidence because of coupling between plasmonic wave and incident plane wave. The impact of glucose concentration or ambient refraction analyze for plasmonic structure sensitivity to blood glucose. [2]

A Spoof Surface Plasmon Polariton (SSPP) endfire sensor monitors aqueous glucose solutions and measures on-body glucose. The SSPP endfire sensor radiates an endfire beam into a glucose water solution with minimal effective aperture. At the sensor’s CPW port, a set of triangular ground planes suppresses the side-lobes and limit glucose sensing. The SSPP endfire sensor’s slow wave nature provides the way for measuring glucose concentrations with enhanced sensitivity. [3]

Non-invasive blood glucose monitoring offers an effective solution to diagnose patients with diabetes the glucose response characterize at low Radio Frequency (RF) signals. The relative permittivity and conductivity of aqueous solutions obtain for various glucose concentrations using an impedance analyzer in the frequency range 1 KHz to 1MHz. Further, the blood impedance measure for glucose monitoring the bio-impedance, measure from forearm during cardiac cycle with polygraph at 1000 Hz. The difference in bio impedance evaluate for cardiac cycle. The influence of blood glucose concentration on bio impedance evaluate to remove tissue influence on blood glucose concentration. [4]

The design of a microwave sensor for non-invasive monitoring of blood glucose concentration is presented. Three distinct microwave resonator structures analyze as suitable candidates. The microwave resonator has an open structure to place patient’s finger. The finger’s shape and size should fit in the resonator. The variation in blood glucose concentration alters the tissue’s dielectric properties and changes the structure’s resonant frequency. [5]

A combined millimeter-wave radar system detects various glucose concentration levels of duplicate blood samples made in the laboratory. The mm-wave radar non-invasively monitors blood glucose of patients with diabetes. The mm-wave radar signal with Discrete Time Fourier Transform finds various glucose concentrations in hemoglobin samples. [6]
Thenear infrared spectroscopy non-invasively measures glucose concentration in blood. The infrared light pass through finger and blood glucose concentration evaluate by calculating absorbance through Beer-Lambert law. The infrared absorbance is equivalent to blood glucose concentration and finger thickness. [7]

A sensitive Glucose fringe field Microstrip Line (MLIN), Material under Test (MUT) – glucose as substrate detects concentration of glucose and ports. The electromagnetic field from MLIN interacts with MUT and show variation in $|S_{11}|_{\text{min}}$. The glucose concentration estimate by Single variate, multivariate and multivariate estimation with bin correlation algorithm. [8]

An implanted sensor with telemetry system monitors subcutaneous tissue glucose for long term in diabetic patients. The implantable sensor consist of immobilized glucose oxidase membrane, polydimethylsiloxanemembrane, catalase connected to electrochemical oxygen detection and telemetry system for wireless data transmission. [9]

A planar microwave sensor monitors glucose level continuously. The sensor element contains four different hexagonal-shaped complementary split ring resonators (CSRR) resembling honey-cell pattern. The resonator was fabricated on a FR4 dielectric substrate and connected to planar micro strip with dielectric substrate. The CSRRs were connected through microstrip transmission line to a radar system operating at 2.4-2.5 GHz. The combined sensor system achieves a good sensitivity in detecting the glucose levels that dissolves in the blood similar to aqueous solutions. [10]

A substrate integrated waveguide (SIW) planar sensor’s design measured blood glucose concentration non-invasively. The SIW planar sensor’s structure resembles traditional band stop filter. The SIW planar sensor, yields a considerable and localized field improvement in the sensing region, the inter-digital arms and the slots on the SIW planar sensor cavity’s upper conductor are utilized. Additionally, fingertip is utilized as material under test (MUT) and the effects of finger prints and the finger’s displacement are analyzed. [11]

The ZnO based ultrasonic piezoelectric Micro-Electronics Mechanical Systems (MEMS) receiver monitors blood glucose. The radial displacement and the surface of the ultrasonic piezoelectric MEMS receiver produce voltage due to pressure and stress. The voltage vary with respect to blood concentration level. The simulation analysis of glucose data showed agreeable correlation with glucometer reading. [12]

The blood glucose monitor with RF/microwave technology. The RF sensor measure blood glucose level by detecting dielectric changes of blood. The dielectric variation due to glucose causes the sensor frequency to shift below 8Mhz. The frequency shift also occur due to blood layer, skin, fat, pressure and position of finger. [13]

A wearable, minimum invasive autonomous and pseudo-continuous blood glucose monitoring. This wearable micro system design obtains a whole blood sample from a little lanced skin wound utilizing a new micro-actuator based on a shape memory alloy (SMA) and straightly measures the blood glucose level from the blood sample. [14]

A wirelessly powered implantable electrochemical sensor system monitors blood glucose continuously. The system was powerby 13.56 MHz inductive link and an ISO 15693 radio frequency identification (RFID) standard for telemetric communication. The sensor system comprises awinding ferrite antenna, a RFID front-end, a 10-bit sigma-delta analog to digital converter (ADC), a long-term glucose sensor, an on-chip temperature sensor, a potentiotstandat a digital baseband for controlling and processing protocol. A high frequency (HF) external readerpowers, commands and configures the sensor system directly. The off-chip support circuitry requiresa glucose micro-sensor and a tuned antenna. [15]

**Methodology**

The non-invasive technique of diabetes detection is performed by measuring the blood glucose concentration through NIR spectroscopy. The NIR spectroscopy measures blood glucose concentration by evaluating insulin secretion from pancreas. The NIR sensor is placed on the pancreas region.Figure 1 shows the overview of diabetes prediction with reflected infrared from pancreas.

Pancreas is a gland that is six inches long and located in the abdomen. It is flat and pear shaped, surrounded by liver, small intestine, spleen, stomach. The pancreas’s endocrine cells produce hormones. Hormones are substances that regulate or control particular functions in the body. Hormones are generally formed in one part of the body and passed through the blood to react on another part of the body. The two important pancreatic hormones are insulin and glucagon. The endocrine cells
such as the islet cells present in the pancreas produce and secrete glucagon and insulin in the blood. Glucagon increases the blood sugar level while insulin lowers the blood sugar level. The two hormones function together to maintain proper blood sugar level. The figure 2 shows the structure of pancreas.

Figure 1. Overview of diabetes detection with NIR through RADWT algorithm.

Figure 2. Structure of Pancreas

To find the insulin secretion level from pancreas, NIR spectroscopy is used. NIR spectroscopy is a spectroscopic technique that utilizes the electromagnetic spectrum’s from near infrared region. NIR spectroscopy is used in various medical applications such as pulse oximetry, blood sugar level monitoring, neurology and urology. The NIR sensor is placed on the pancreas region as shown in figure 3. The reflected infrared signal from pancreas acquire with data acquisition tool. The infrared signal from pancreas of normal and diabetic person. The pancreas infrared signal obtain for before meal and after meal condition. The acquired infrared signals processes through Rational Dilation Wavelet Transform (RADWT) to determine infrared variation due to insulin secretion. In RADWT, the Q-factor value change for resolution and subband energy level of pancreas NIR signal.

Rational Dilation Wavelet Transform (RADWT): The Dyadic Wavelet Transform is an effective transformation tool for sparsely representing the smooth signals and it is a constant Q-factor transform and a critically sampled wavelet transform. However, its frequency resolution is poor and has a low Q-factor. The Dyadic Wavelet Transform is not effective for processing NIR signals with oscillatory nature. Some techniques like Cosine Modulated Filter Banks, Short Time Fourier Transform (STFT), wavelet packets are traditionally used for oscillatory type signals rather than using dyadic wavelet transform. The transforms do not have a constant Q-factor. So an efficient transform with constant and high Q-factor and high frequency resolution is required. Another category of wavelet transforms like overcomplete wavelet transform performs efficiently than critically sampled wavelet transforms like dyadic wavelet transform. Overcomplete wavelet transforms extend an N-point NIR signal to a set of M coefficients with $M>N$. Several overcomplete invertible wavelet transforms such as double density wavelet transform, dual tree complex wavelet transform and undecimated wavelet transform exists. These wavelet transforms achieve over completeness through increasing only the temporal sampling in all frequency bands. The frequency spacing between adjacent frequency bands should be reduced to utilize the overcomplete wavelet transform’s redundancy. These overcomplete wavelet transforms are based on rational dilations. The figure 4 represents the Rational Dilation Wavelet Transform (RADWT) where $H(\omega)$ is high pass filter, $G(\omega)$ is low pass filter, $p$ and $q$ are rational dilation factors and $s$ is redundancy factor.
The selection of dilation factor close to one, a wavelet can be dilated from scale to scale and multi-resolution frequency analysis of the NIR signal can be performed. Additionally, the dilation factors $p$ and $q$ and the redundancy factor $s$ enhance the Q-factor and frequency resolution of the NIR signal. The Q factor of the signal resolution depend on the rational dilation factors $q$ and $p$. The filter banks of RADWT is shown in figure 5.

The perfect reconstruction filters for the filter bank shown in figure 5 is derived. The parameters $p$, $q$ and $s$ are positive integers that satisfy $1 \leq p < q$ and $p/q + 1/s \geq 1$. The integers $p$, $q$ are coprime. For perfect reconstruction $p + 1 = q = s$. The only condition for perfect reconstruction filters is

\[
\frac{1}{pq} |H(\omega)|^2 + \frac{1}{s} |G(\omega)|^2 = 1 \quad \text{for} \quad \omega \in [0, \pi] \quad \text{Q(1)}
\]

Finally, the perfect reconstruction filters are given as

\[
H(\omega) = \begin{cases} 
\sqrt{pq} & \omega \in \left[0, \left(1 - \frac{1}{s}\right)\frac{\pi}{p}\right] \\
\sqrt{pq} \theta\left(\frac{\omega - a}{b}\right) & \omega \in \left(1 - \frac{1}{s}\right)\frac{\pi}{p}, \frac{\pi}{q}\right) \\
0 & \omega \in \left[\frac{\pi}{q}, \pi\right]
\end{cases}
\]

\[
G(\omega) = \begin{cases} 
\sqrt{s} \theta\left(\frac{\omega - p\alpha}{p\beta}\right) & \omega \in \left(1 - \frac{1}{g}\right)\frac{\pi}{p}, \frac{\pi}{q}\right) \\
\sqrt{\frac{s}{p}} & \omega \in \left[\frac{p}{q}\pi, \pi\right]
\end{cases}
\]

Results and Discussion

The NIR sensor position over pancreas of diabetic person and infrared signal acquire for before meal consumption and after meal consumption. The infrared signal acquired before meal consumption is shown in figure 6.

The acquired NIR signal decompose up to 11 levels to determine subband signal influenced by pancreas insulin secretion. The NIR signal process through RADWT for multi-resolution frequency analysis. The decomposed subband signal is shown in figure 7. Figure 8 shows the reconstructed subband signal from individual subband.
The multiresolution analysis evaluate for NIR signal subband energy. The RADWT, decomposes the signal and subband energy evaluate for each subband signal. The subband energy level of the NIR signal before meal consumption is shown in figure 9.

In figure 9 the subband energy level is low due to low insulin secretion from pancreas. The low insulin secretion from pancreas cause high blood glucose level. The subband energy level attains a maximum of 24% at fifth subband.

The pancreas NIR signal was obtained from pancreas with NIR sensor after meal consumption is shown in figure 10.
The decomposed signal with RADWT is shown in figure 11. The subband signal reconstructed with RADWT from individual subband is shown in figure 12. In figure 12, the subband energy increases when the insulin secretion level from pancreas increase.
The subband energy level reconstructed NIR signal with RADWT from pancreas after meal consumption is shown in figure 13. In figure 13, the subband energy level increases due to insulin secretion from pancreas. The subband energy level attains a maximum of 28% for fifth subband. The increase in pancreas insulin secretion lowers blood glucose level.

The NIR signal from pancreas of non-diabetic person was obtained for before food consumption and after food consumption scenarios. The NIR subband energy variation was similar to diabetic person. However, the subband energy increased to maximum of 35% at fifth subband before food consumption and increased further to 42% after food consumption due to high insulin response. The subband energy increased proportional to insulin response from pancreas. The high insulin response from pancreas regulated blood sugar level. The table 1 gives information about subband energy, insulin response and glucometer reading of diabetic and non-diabetic person.

**Regression Modeling:** The regression modeling is a statistical procedure used to estimate the linear or straight-line relationship that relates two or more variables. The linear relationship represents amount of change in one variable that relates with change in another variable. There regression modeling also evaluate for statistical significance, to check whether the linear relationship emerge by chance or not. The two variable regression model includes two variables such as an independent variable and a dependent variable. The independent variable causes changes in the dependent variable.

**Linear Regression:** Linear regression model determines relationship between two variables through fitting a linear equation for observed data. One variable is considered as an explanatory variable, and the other is considered as a dependent variable.
The equation of a linear regression line is of the form
\[ Y = a + bX \] (3)
where, 
- **X** is the explanatory variable.
- **Y** is the dependent variable.

The slope of line is **b**, and the intercept is **a** (the value of **y** when **x** = 0). The formula for computing intercept **a** and slope **b** is given as
\[ a = \frac{\sum xy - (\sum x)(\sum y)}{n(\sum x^2) - (\sum x)^2} \]
\[ b = \frac{n(\sum xy) - (\sum x)(\sum y)}{n(\sum x^2) - (\sum x)^2} \] (4)

The blood glucose level of diabetic person obtained from subband energy and lab values is represented by the equation
\[ Y = 14.20X - 159.0 \] (5)
and the blood sugar level of non-diabetic person is represented by
\[ Y = 6.393X - 1.357 \] (6)

**Conclusion**
A non-invasive technique for monitoring blood glucose concentration is presented. The blood glucose level determined with insulin secretion level from pancreas, NIR sensor measures the insulin secretion level in pancreas. The intensity of the NIR light varies according to the insulin secretion level in pancreas. The NIR signal obtained from the pancreas is processed through RADWT to evaluate the insulin level in pancreas. The RADWT subband energy level is relative to insulin secretion from pancreas. The subband energy is low when the insulin secretion level in pancreas is low, before food consumption and the subband energy level is high when insulin secretion level in pancreas increases after food consumption. The subband energy of NIR signal validates with glucometer measurement results.

Visa Regulation of Indonesian Migrant Worker Based on Immigration Control Act of Japan, 2018

Darminto Hartono1*, Lapon Tukan Leonard2

1Lecture at Faculty of Law Diponegoro University, Semarang 50275, Indonesia,
2Lecture at Faculty of Law Diponegoro University, Semarang 50275, Indonesia

Abstract
Japan as a developed country needs a lot of productive labor to fulfill its human resources needs. With the revised Immigration Act of 2018, Japan has opened up to accept many migrant workers, one of whom is Indonesian migrant worker who can fulfill these needs. The purpose of this research is to find out the form of visa regulation for Indonesian migrant workers in Japan based on the provisions of the Japan Immigration Act 2018 and to know the efforts of the Indonesian Government can make in implementing the visa regulations to facilitate Indonesian migrant workers who will work in Japan.

Keywords: Japan, Indonesia, Visa, Immigration, Control, Act.

Introduction
Japan and Indonesia have a mutually beneficial cooperation program on both sides, namely the cooperation of Indonesian migrant workers in Japan. The Japan - Indonesia cooperation program was formed because of the abundance of productive human resources in Indonesia that has been equipped with the ability in the field of verified engineering to be able to work in labor-deprived Japan for the lower middle class. Indonesian migrant workers will be needed to facilitate development in Indonesia and can be a means of cooperation with Japanese medium and small companies in Indonesia. Indonesian migrant workers in Japan are more commonly known as Indonesian Interns or in Japanese called Kenshuusei (practicing while working) and Jishuusei (working while practicing). These workers require a work visa in Japan based on the Japanese company’s employment contract with the individual. For foreign nationals, to enter a country requires an entry permit or so-called Visa.

With the new visa regulations, Indonesian migrant workers are distinguished by Specific Skilled Worker Visas (PBS) and Technical Internship Training Visas (PMT). The new PBS visa was passed through the latest regulations in April 2019 with the aim of meeting the needs of human resources in Japan to work a minimum of 5 (five) years or without the required time span. In addition, PBS also has only 16 jobs that can be applied for visas, in contrast to PMT which has 16 jobs. A very clear difference, PBS visas do not require migrant workers to be training before entering a routine job in Japan, but it does relate to having to pass migrant workers in skill tests and Japanese language tests.

Method
The main purpose is to find answers to various problems that arise in society is to conduct a research. Research in fact reveals something systematically, methodologically and consistently so that the results of the research should be accountable. Research on Visa Regulation of Indonesian Migrant Worker Based on Immigration Control Act of Japan, 2018 legally binding protection provided by the State with the guidance of the regulation. This study uses data analysis approaches and normative juridical method. It uses descriptive analysis method by using literature, documentary studies and field research related to the primary substance of this study. After the data has been collected, the next process is to

e-mail: darmintohartono.undip@gmail.com
identify, clarify and analyses systematically. Finally, all research results are presented in a compiled final report.

**Results and Discussion**

Each country has sovereignty of the country which means the highest power for the state to freely conduct various activities in its interests as long as the activity does not conflict with International Law. An important limitation of a country’s sovereignty is that it is limited to the territorial boundaries of the state and that power ends where the power of another country begins. It is clear that understanding the sovereignty, independence and equality of the above countries does not contradict the concept of an International Society governed by International Law, it can even be said that if it is reasonably understood this sovereignty with two understandings that align with it namely the independence and equality of the degrees of countries is an understanding that has a very important function in realizing an International Society governed by International Law as a reality."}

To safeguard the sovereignty and power of the state within the boundaries of its territory, each country has jurisdiction. The jurisdiction of this country is essentially inseparable from the concept of territorial sovereignty of a country which is one of the essential attributes of the state. Countries exercising sovereignty on their territory will be allowed to make their own laws and regulations legally binding on their residents living on their territory including their owners. State accountability as well as with individuals who may give rise to the country’s rights and obligations to foreigners, nationality, extradition, and asylum, as well as human rights.

All countries have the authority and power to accept or reject foreigners on their territory. If a country accepts the entry of foreigners into its territory, it will grant a visa granted by the country through the embassy of the receiving country located in the country. Through such visas, foreign nationals in the destination country have certain rights and obligations. Foreign nationals obtain the right of acceptance of the destination country followed by obligations to comply with local laws and regulations, so-called provisional compliance terms.

There are several opinions regarding the entry of foreigners to the destination country: All states are obliged to grant permission to all foreigners; A state is obliged to grant permission to all foreigners, provided that it has the right to reject certain groups, such as drug addicts, certain people with certain diseases and other unwanted persons; A state is bound to allow foreigners to enter but may impose conditions relating to their entry permit, and; A state has the right to ban all foreigners according to its will.

In International Law, there is a Theory of Social Contract that states that a person who is in society is outside and regardless of state power. This theory was then applied and analyzed against the state that a country engaged in the association of the International Community, the basic right is not separated from the influence of another country. Further development is influenced by the Natural Law which gives rise to the doctrine of inter-state relations and human relations is the same, namely the right to mutual respect, equality of rights and independence. The American Institute of International Law (AIIL) produced the Declaration of the Rights and Duties of Nations, which was followed by a study of fundamental right and duties of American Republics until the completion of the 1933 Montevideo Convention.

In International Law a country has a standard of treatment of foreigners, i.e.:

a. **National Treatment Standards**: According to national treatment standards foreigners should be treated the same as citizens of the destination country, which if applied consistently would benefit foreigners. International Law does not govern the country’s treatment of foreigners in all activities. The disadvantage of the country’s national treatment standards can certainly treat foreigners inhumanely and justify such treatment on the basis that its citizens can be treated equally.

b. **International Minimum Standard**: According to international minimum standards it stipulates that countries must offer the same treatment of foreigners as their citizens enjoy, but such treatment should not be less than the human rights recognized in international instruments.

In principle each country will be responsible for providing legal protection to every citizen wherever it is and foreigners will receive legal protection under certain restrictions both from the country in which it is located and from its home country. Thus, the nationality status of a person is closely related to the protection of International Law to be given to him, against him, property and his family.

Japan’s 2018 immigration oversight law, which
came into force in April 2019, is a new law that has been passed from several parts of the Immigration and Refugee Control Act. The revised law includes new rules, including visa rules for migrant workers. As part of this framework, Japan established migrant worker visas for the ‘professional skilled workers’ category.

The Life of Foreign Workers in Japan: Foreign workers living in Japan as many as 1.28 million. This is a record after there were 480,000 foreign workers in Japan in 2008. However, the figure is only 1% compared to Japan’s population. Nearly 30% of Japan’s foreign workers come from China with significant populations from Vietnam, the Philippines and Brazil. While in 2019, the number of foreign workers in Japan rose 13.6% from the previous year to 1,658,804 people. China accounted for about a quarter of all foreign workers at 412,327, followed by Vietnam at 401,326 and the Philippines 179,685, according to the Ministry of Health, Labor and Welfare. This increase appears to be due to the government’s promotion of the involvement of highly skilled foreign workers, exchange of students and intern trainees in the workforce, as well as improvements in the overall employment situation leading to more hiring permanent residents and spouses of Japanese citizens.

Indonesian migrant workers alone in Japan recorded 49,982 people living in Japan both legally and illegally. Since 1998, the chairman of the factory association in Oarai has invited Japanese descendants and migrants from North Sulawesi to work in the seafood industry, so it is not new that many Indonesian migrant workers in Japan today. According to statistics from the Indonesian Migrant Workers Protection Agency, Japan received 486 Indonesian migrant workers in 2019. The figure decreased from 538 in 2017, which makes Japan number 13 for the largest Indonesian migrant worker placement country.

Arrangement of Worker Visa under Japan Immigration Control Act 2018: After the Second World War, Japan’s labor management system was
reorganized and new labor laws were introduced along democratic lines. The “Employment Law” includes detailed regulations on the realization of labor relations and modern and democratic labor practices. In the 1960s, the labor market changed significantly. Although agricultural residents flocked to the industrial sector, labor shortages were first seen around 1959. With Japan’s rapid economic development, the slow growth of the production age population in Japan, and the growing number of young people going to high school and university instead of looking for work, the availability of productive people in Japan is very limited.

According to Professor Hiroshi Yoshida, an economist at Tohoku University in Japan published in the Daily Mail on May 13, 2012: “Birth rates are starting to show an alarming decline since 1975. In terms of the number of births, this indicates that the age of children in the current 14-year population reaches 16.6 million, and this number decreases by one (1) person every 100 seconds. Recent studies have shown that Japan’s population is expected to become extinct within 1,000 years if left unchecked.”

To find a solution to the problems facing Japan today, namely the deterioration of the Japanese economy, low competitiveness, reduction of productive labor force, and increasing the number of elderly populations is an interconnected problem. Japan believes that it is necessary to serve the lower middle class immediately. Give me the manpower, by introducing workers from abroad, especially those from developing countries such as Indonesia. Other issues that arise are Japan’s Employment and Employment Law and Immigration Law, which cannot be changed automatically. For the fulfillment of the foreign workforce, the Japanese government adheres to the term apprenticeship program (kenshuusei-jisshuusei). Since 1994 there has been a Memorandum of Understanding (MoU) between the Directorate General of The Ministry of Foreign Affairs and The Association for International Manpower development of Medium and Small Enterprises Japan (IMM).

According to international law, Japan has applied several exceptions to the influx of foreigners, one of whom is poor or has no permanent residence, and can be a burden for the Japanese government or public bodies due to their inability to make a living. Therefore, in accordance with current regulations, any foreign workers with certain professional knowledge can give him the opportunity to stay and work long term in accordance with the period of the contract that can be extended.

Visa arrangements for foreign workers in the latest law make up the difference between interns and workers with special skills. Interns (Kenshuusei) are part of a work training system organized in an integrated way between training in training institutions by working directly under the guidance and supervision of instructors or workers who are more experienced in order to master certain skills or skills. While workers with special skills (Specified Skilled Worker/Tokutei Ginou) are workers who will work in certain fields in accordance with the certificate of expertise or Certificate of Japanese language owned from their country.

The granting of work visas to foreign workers began to be distinguished by the Japanese Government after the revised regulations. Special Type 1 skills are open only to those with adequate technical and Japanese skills. Special Type 2 skills are given to workers working in construction and shipbuilding. Only type 2 visas are allowed to bring their spouses and children to Japan. Information on the rules of residence of foreign workers in Japan, explained article 2-2 of Immigration Control and Refugee Recognition Act (Cabinet Order No. 319 of October 4, 1951) namely:

Article 2-2:

(1) Except as otherwise provided in the Immigration Control and Refugee Recognition Act and other laws, a Foreign National is to reside in Japan under the status of residence (in the case of the status of residence of “Highly Skilled Professional”, including the category of item (i), sub-items (a) through (c) or item (ii) listed in the right-hand column under “Highly Skilled Professional” of Appended Table I (2); in the case of the status of residence of “Specified Skilled Worker”, including the category of item (i) and (ii) listed in the right-hand column under “Specified Skilled Worker” of the same table; in the case of the status of residence of “Technical Intern Training”, including the category of item (i), sub-item (a) or (b), item (ii), sub-item (a) or (b) or item (iii), sub-item (a) or (b) listed in the right-hand column under “Technical Intern Training” of the same table; the same applies hereinafter) associated with that Foreign National’s permission for landing, under the status of residence that the Foreign National has acquired, or under the
status of residence following a change to either of these.

(2) The categories of status of residence are to be as listed in the left-hand column of Appended Table I (in the case of the status of residence of “ Highly Skilled Professional”), including the category of item (i), sub-items (a) through (c) or item (ii) listed in the right-hand column under “ Highly Skilled Professional” of Appended Table I (2); in the case of the status of residence of “ Specified Skilled Worker”, including the category of item (i) and (ii) listed in the right-hand column under “ Specified Skilled Worker” of the same table; in the case of the status of residence of “ Technical Intern Training”, including the category of item (i), sub-item (a) or (b), item (ii), sub-item (a) or (b) or item (iii), sub-item (a) or (b) listed in the right-hand column under “ Technical Intern Training” of the same table; the same applies hereinafter) and II. A Foreign National residing in Japan under a status of residence listed in the left-hand column of Table I may engage in the activities listed in the right-hand column corresponding to that status, while a Foreign National residing under a status of residence listed in the left-hand column of Table II may engage in the activities of a person with the status or position listed in the right-hand column corresponding to that status.

(3) The period during which a Foreign National may reside as set forth in paragraph (1) (hereinafter referred to as “ Period of Stay”) is determined for each status of residence by Ministry of Justice Order; and when the status of residence is one other than that of “ Diplomat”, “ Official”, “ Highly Skilled Professional” or “ Permanent Resident” (in the case of the status of residence of “ Highly Skilled Professional”, limited to those pertaining to item (ii) in the right-hand column under “ Highly Skilled Professional” of Appended Table I (2)), the Period of Stay does not exceed 5 years.

The application processes and documents required to apply for a worker visa with the latest conditions are:

a. Application to the Regional Immigration Services Bureau
   • Applicants must submit a form for issuance of a certificate of eligibility in accordance with the individual’s professional expertise for residency status.

   b. Checks by the Immigration Services Agency

   The examination of requirements is regulated in accordance with Article 7 paragraph (1) of item (ii) of the Immigration Control Act, namely: “ Article 7 (1) When the application set forth in paragraph (2) of the preceding Article is made, an Immigration Inspector must conduct an examination of the Foreign National as to whether or not the Foreign National conforms to each of the following conditions for landing in Japan (with respect to a person who has been granted re-entry permission pursuant to the provisions of Article 26, paragraph (1) or a person who possesses a Refugee travel document issued pursuant to the provisions of Article 61-2-12, paragraph (1), only the conditions listed in the following items (i) and (iv) are to be applied): (i) the Passport possessed by the Foreign National and the visa affixed thereto, if such is required, must be valid.”

   c. Issuance of certificate of eligibility: If the eligibility certificate requirements have been approved, foreign nationals can obtain visas and permission to land smoothly by presenting a certificate of eligibility when applying for a visa.

Conclusion

Japan revised, added and updated the Immigration Supervision Act 2018 primarily on visa arrangements for migrant workers or Foreign Workers who will work in the country. With the revision, other countries including Indonesia also feel the benefits and interest to be able to send migrant workers to Japan. There is a reciprocal interest between Japan and Indonesia; Japan lacks many productive middle-class workers to meet the needs and demands of its companies, while Indonesia has many productive-age workers who are expected to meet Japan’s quotas or the amount needed. This change in Japanese government policy demonstrates an open attitude towards other countries by accepting foreign workers to enter and participate in the development of their country. In the previous law Japan only applied admission to interns (Kenshuusei/Jishuusei) for 3 (three) to 5 (five) years, while the new Immigration Supervision Act applies the provision of residence visas for migrant workers if they fall into the category of skills and meet the conditions mentioned.Efforts can be made by the Government of Indonesia in implementing the new visa
arrangements by Japan, namely by carefully preparing adequate facilities and infrastructure for prospective Indonesian migrant workers. The Government of Indonesia and the Government of Japan, in this case the Japanese Embassy in Indonesia, immediately prepared technically the terms and conditions that must be met for prospective Indonesian migrant workers to Japan. Then the Government of Indonesia is obliged to conduct optimal coaching and supervision to the officers in order to be more professional in handling, educating and training prospective Indonesian migrant workers to comply with the applicable terms and conditions in Japan (Receiving Country).

**Conflict of Interest:** There is no conflict of interest.

**Source of Funding:** This research was funded by the Diponegoro University Faculty of Law Research Grant Fund for the 2020 Fiscal Year.

**Ethical Clearance:** Ethical clearance from the institutional ethical committee obtained for the study.

Abstract

Background: Contraceptive uptake remains a public health concern in Cambodia. Therefore, the aim of this study was to determine the modern contraceptive use pattern and its associated factors among women of reproductive age in Cambodia.

Method: A cross-sectional study used the data from the Cambodia Demographic and Health Survey. This survey adopted a two-stage stratified random sampling process to select respondents to respond a structured questionnaire interview. The multiple logistic regression was applied to determine the association.

Results: Of the total 7,606 women, 51.04% used modern contraceptives. The multivariable analysis indicated the use of modern contraceptives was strongly associated with fertility preferences, ideal number of children, number of living children, husband’s desire for children, age at first marriage, number of induced abortions, and marriage to a first birth interval. Health service factors including sources of family planning information, visited health facilities, inaccessibility to health service as well as sociodemographic factors such as women’s age, occupation, and geographical regions also significantly associated with modern contraceptive use.

Conclusions: About half of women in Cambodia used modern contraceptives. Reproductive, health service and sociodemographic factors were essential for modern contraceptive utilization.

Keywords: Determinants, modern contraceptives, women of reproductive age.

Introduction

Contraception has helped millions of people to control their fertility. The adoption of effective contraception can lower the burden of obstetric complications during childbirth and pregnancies, mitigate the number of abortions, prevent undesired pregnancies, and reduce infant and maternal mortality. Globally, an overwhelming majority of reproductive age women are using various contraceptive method, with more than one out of ten in-union or married women were not practicing any contraceptive method but wanting to halt and delay their childbearing. More than 90% of all contraceptive users, modern contraceptives were practiced by approximately 55% of married reproductive age women in almost all territories in the world in 2000, with a marginal increase of roughly 58% in 2017.

Contraceptive use can prevent approximately 54 million unplanned pregnancies, a million infant deaths, and 79,000 maternal mortality. In 2019, approximately 842 million reproductive age women used any kinds of modern method, constituting female sterilization (24%), male condom (21%), IUD (17%), and pills (16%). Around 225 million women in developing nations averted the contraceptive utilization despite wanting to postpone or stop their motherhood. There were approximately 213 million pregnant women, of which 85 million (40%) were undesired pregnancies, with the highest proportion in the Latin America and Caribbean zones and the lowest in Africa.
Extensive research has been studied to identify factors influencing modern contraceptive utilization. In particular, a wide of determinants including residence site, religion, education level, parity, financial status, access to media, number of living children, age at first marriage, age at first sexual intercourse, and perceptions on contraceptive uses. Other possible associated factors were women’s fertility preference or partners’ desire for children, employment status, counseling about family planning by healthcare providers, and couple’s discussion concerning contraceptive utilization.

Cambodia, one of the least developed nations in Southeast Asia, has only about 16 million population. Cambodia had an extremely low modern contraceptive coverage rate despite a considerable rise in contraceptive uptake from 24% in 2000 to around 51% in 2010 among married reproductive age women. Cambodia still faces many significant challenges affecting contraceptive utilization among women. The findings of the 2014 Cambodia Demographic Health Survey showed that opportunities to meet women’s family planning need have not been well improved and the number of nonusers remains high, which will place a burden on the economy and the welfare of the country as a whole. Hence, the understandings of factors influencing modern contraceptive utilization become incredibly crucial to inform policymakers to select appropriate and tailored interventions to mitigate adverse effects of reproductive health and expand the coverage of contraceptive uptake among women. Few studies have explored information regarding characteristics and related factors of modern contraceptive uptake in Cambodia. Thus, this study aimed to describe the modern contraceptive coverage and identify the association between modern contraceptive use and other factors.

Materials and Method

Study Design: This analytical cross-sectional study used the data retrieved from the 2014 CDHS. The 2014 CDHS was conducted between June 2nd and December 12th, 2014. Further details can be seen in the 2014 CDHS report.

Dependent Variable: The outcome was modern contraceptive uptake of married or in-union women of reproductive age (15-49 years old). Modern contraceptive use was defined as married/in-union reproductive women or her husband/partner used at least one of the contraceptive method including condoms, emergency contraception, pills, injectables, female sterilization, male sterilization, implants, and IUD coded as 1. Those who did not use any contraceptives (either coitus interruptus, rhythm method, or folkloric method) were coded as 0. The responses were then created and categorized as a dichotomous variable (Yes/No).

Independent variables: A set of explanatory variables was selected for the analysis.

Statistical analysis: All analyses were performed by using the Stata program version 14.0. The baseline characteristics and other variables were analyzed and presented as frequency and proportions for categorical data and mean, standard deviation, median, maximum, minimum for continuous data. The data was analyzed considering complex sampling design of the CDHS data.

A simple logistic regression was used to identify the association of each independent variable with modern contraceptive uptake. The independent variables that had p-value<0.25 were processed to the multivariable analysis. The multiple logistic regression was utilized to determine the strength of the association between modern contraceptive use and other variables, adjusted all confounders, and showed adjusted OR, 95% CI, and p-value. In the final model, the significance level was considered at p-value less than 0.05.

Results

Sample Characteristics: Out of 7606 women of reproductive age, 87.27% resided in rural areas, 43.62% were in Central plain, and 43% were poor. The women average age was 32.99 years old, 56.29% of women and 47.88% of husbands attained primary education. The highest proportion (42.38%) were self-employed in the agricultural sector. The mean age of husband was 35.88 ± 9.02 years old.

The mean age at marriage was 19.50 ± 3.76 years, 34.38% got married between the age of 18 and 20 years old, 55.97% had first sexual intercourse before the age of 20 years.

Most of the respondent had two or more parities (73.41%), 83.14% never had induced abortions, 41% had three or more living children, 47.20% had 12-24 months first birth interval after marriage. Majority did not want any more children (55.42%), 64.10% of the couples desired the same number of children and 31% had not want more than 2 ideal children.
More than half (55.77%) heard about family planning from family and friends, 48.36% from TV, 47.37% from billboards or posters, radio (36.33%). A quarter 25% got the information from community councils and 21.26% from local campaign. More than half (51.13%) of women visited health facilities during the past 12 months, 24.22% were visited by family planning staff, 24.75% experiencing inaccessibility to health services. Only 51.04% (49.19%-52.88%) of the women of reproductive age used modern contraceptives, of which 25.08% of all respondents used oral pills, followed by injection (13.09%), IUD (6.37%), and Norplant (3.13%). Only 2.99% used condoms and 0.38% used other method.

**Bivariate Analysis:** The bivariate analysis indicated that potential associated factors with contraceptive use (p-value<0.25) were: women’s age, women’s education, women’s occupation, geographical region, husband’s age, husband’s occupation, parity, age at first marriage, age at first sexual intercourse, number of living children, number of induced abortions, marriage to first birth interval (months), media exposure to family planning from TV or newspapers, sources of family planning information, perceived problems in accessing to health services, fertility preferences, husband’s desire for children, and ideal number of children. These variables were employed to the multiple variable analysis using multiple logistic regression.

**Multivariable Analysis:** The multivariable analysis indicated that the modern contraception was significantly more likely to be used among women who wanted children after two years (adj.OR=5.35, 95%CI=4.09-7.00), despite unsure timing (adj.OR=4.40, 95%CI=2.75-7.04), and undecided (adj.OR=2.97, 95%CI=2.32-3.82); had 2 ideal children (adj.OR=2.65, 95%CI=2.09-3.37), 3 ideal children (adj.OR=1.91, 95%CI=1.55-2.35); and 4 ideal children (adj.OR=1.48, 95%CI=1.19-1.83); had two living children (adj.OR=2.22, 95%CI=1.82-2.70), and more living children (adj.OR=2.55, 95%CI=1.96-3.31); husband desired for fewer children (adj.OR=1.71, 95%CI=1.23-2.38), more children (adj.OR=1.49, 95%CI=1.18-1.88), and the same number as his wife (adj.OR=1.45, 95%CI=1.18-1.79); first birth interval less than 12 months after marriage (adj.OR=1.64, 95%CI=1.37-1.96), one year to two years (adj.OR=1.39, 95%CI=1.20-1.60) respectively. Health education especially received family planning information from community councils (adj.OR=1.24, 95%CI=1.06-1.45) as well as visiting health facilities (adj.OR=1.23, 95%CI=1.09-1.38) and had accessibility to health services were also associated factors. Other significant factors were socio-demographic characteristics including women aged <25 years (adj.OR=2.03, 95%CI=1.70-2.44), 25 to 29 years (adj.OR=1.85, 95%CI=1.52-2.26), and 30 to 34 years (adj.OR=1.34, 95%CI=1.04-1.74); worked as manual workers (adj.OR=2.49, 95%CI=1.94-3.22), agricultural sector’s self-employed (adj.OR=1.91, 95%CI=1.60-2.28), professional and other jobs (adj.OR=1.79, 95%CI=1.46-2.19) (Table 1).

Discussion

Our study identified the factors associated with the use of modern contraceptives among women of reproductive age in Cambodia. The result showed that about half (51.04%) of respondents used modern contraceptive method. It was in line with the uptake rate in a study conducted in Rwanda (50.40%). However, this finding was lower than a study in Kenya (58.8%). The possible discrepancy might be because our study covered both urban and rural areas. Women residing in rural areas of Cambodia have limited access to modern contraceptives from socioeconomic condition as well as health service system.

A significant relationship between women’s age and modern contraceptive use was observed in this study. The use of modern contraception decreased with increasing age of the respondents. This might be due to the fact that women often think they may be too young or immature to take good care of a child and may have to drop or suspend their education; therefore, they used contraceptives to avert pregnancy. This finding is in line with a study in Spain. It is commonly known that late adults in their menopausal phase tend to use contraceptives less due to decreased sexual activities and fertility. A study showed that age was negatively associated with contraceptive utilization.

Women with less stable and paid job were more likely to use contraceptives. The economic constraints might force women to use contraceptives for fear of child rearing burden. Women who had two or more living children were much more likely to use modern contraceptives than those with one or no child. It was consistent with a study in Ethiopia, revealed that as the use of modern contraceptives raised, the number of living children also raised. Generally, this might be influenced by the fact that women with more living children could satisfy their family size and minimize a substantial financial burden in their daily life.

A study in Uganda reported that women desired to have children after two years were more likely to utilize modern contraceptives than those desired children within two years. The main reasons for this delayed childbearing were that women could have more involvement on the labor market including higher education and career engagement.

The finding indicated that women whose husband desired few children were more likely to use modern contraceptives compared to those who did not know whether their husband preferred more, less or the same children. One of the possible explanations was men have been considered as the head of the family and responsible for all expenses and making a final decision in the family in Cambodian context. This study, in agreement with other findings, elucidates that a husband’s desire for fewer children was found to be significantly correlated with contraceptive use. This study also found a significant relationship between the ideal number of children and modern contraception. When the ideal number of children decreased, the odds of women’s use of modern contraceptives increased. This is probably a reflection of the fact that women may not reach their desired family size or prefer to discuss with their spouse after having one child. However, women are more likely to use contraceptives to avert pregnancy. This result is in line with other studies in Ethiopia and Zimbabwe. Sources of family planning information and accessibilities to health services also increased the odds of contraceptive uses. This might reflect the better coverage of services and access to modern contraceptives in the areas.

Limitation: The major strength of the study is this survey covered all areas of Cambodia with a large sample size. However, as a cross-sectional study, a causal relationship between modern contraceptive use and other explanatory variables could not be established. Future study should be a longitudinal study with the aim of identifying relevant trends and patterns of contraception over a long time period.

Conclusion

About half of women used modern method in Cambodia. Factors strongly associated with modern contraceptive utilization were number of living children, fertility preferences, husband’s desire for children, and number of ideal children as well as sociodemographic, health services and health information. Recommendations are to raise awareness of family planning services to both genders. Policy makers, communities, and partitioners should establish multi-sectoral collaboration for integrated family planning programs to improve the access to health education and family planning services. Promoting income-generating activities and creating more employment opportunities are essential for vulnerable families that faced inaccessible to health services and other essential resources.
Ethical Considerations: This study was approved by the KhonKaen University Ethics Committee for Human Research based on the Declaration of Helsinki and the ICH Good Clinical Practice Guidelines (reference number HE632199).

Acknowledgement: The authors would like to express our sincere appreciation to the CDHS for the data and the Faculty of Public Health, KhonKaen University, Thailand for funding.

Conflict of Interest: No conflicts of interest to declare.

Results of Renogram and eGFR in Assessing Kidney Function of Chronic Kidney Disease Patients

Desery Randanan Pakiding¹, Sugiarto Suwito², Hari Basuki Notobroto³

¹Student, Department of Radiology, Faculty of Medicine, Universitas Airlangga, Dr. Soetomo Teaching Hospital, Surabaya 62085, Indonesia, ²Lecturer in Department of Radiology, Faculty of Medicine, Universitas Airlangga, Dr. Soetomo Teaching Hospital, Surabaya 62085, Indonesia, ³Lecturer in Department of Biostatistics and Population, Faculty of Medicine, Universitas Airlangga, Dr. Soetomo Teaching Hospital, Surabaya 62085, Indonesia

Abstract

Background: The ability to assess kidney function properly has important health implications. Glomerular filtration rate (GFR) is still accepted as the best measurement index of kidney function. The formula of the Modified of Diet in Renal Disease (MDRD) is currently widely used by the medical community to estimate GFR (estimated GFR or eGFR). The renogram with radiofarmaka I131-Hippuran is considered to have an inherent accuracy of inulin cliren as the gold standard of GFR measurement.

Objective: To determine the description of renogram and eGFR’s results in assessing kidney function of CKD patients.

Method: This study was a retrospective observational that used medical records from 113 CKD patients undergone renogram examination at Dr. Soetomo General Hospital Surabaya in 2012. eGFR was calculated based on the serum creatinine, age, and sex of the patient. Data of renogram and eGFR examination were presented descriptively.

Results: We obtained male of 63% and female of 37% with age range between 20-69 years. The highest percentage in the age range of 50-59 years. The CKD cases in this study were mostly caused by urinary tract stones of 44%. The most common renogram results were 2 kidney failure by 48% and the highest eGFR was <15 ml/min/1.73m2 score of 73%.

Conclusion: There were no normal results of renogram or eGFR. The most renogram results with 2 kidney failure were found in 48% of all subjects with eGFR of <15 ml/min/1.73m2.

Keywords: Chronic Kidney Disease, Renogram, eGFR

Introduction

Chronic kidney disease (CKD) is a world public health problem with a high incidence rate that is progressive and associated with disadvantageous outcomes. The prevalence of CKD in the United States increased from about 10% in 1988-1994 to 13% in 1999-2004¹-². The US renal data system stated that the incidence of ESRD has continued to increase over the last 15 years, from 142 cases/million in 1987 to 308 cases/million in 2000². There were 2.131 cases of CKD with hemodialysis in Indonesia (1995) which increased to 6.314 cases in 2004³.

GFR (glomerular filtration rate) is the best global index for renal function. GFR describes the flow rate of fluid that is filtered through the glomerular capillaries into Bowman’s capsule per unit of time. The normal range of GFR is adjusted for body surface area of about 100-130 ml/min/1.73m2 in male and female. GFR is measured with inulin clearance of about 110 ml/min/1.73m22 until the age of 2 years and then decreases. GFR decreases progressively by about 0.4-1.2 mL/min per year at the age of >40. The available GFR calculation was eGFR or estimated GFR. The equation was obtained by using the regression technique to model the association...
between serum creatinine and GFR measurements in population studies. eGFR provides a substantial increase in serum creatinine examination for clinical assessment of renal function. Although the equations developed in one population are appropriate for its population, evaluation in other populations is needed to indicate the generalization of the observed association. Two creatinine-based equations have been studied and widely applied, namely the Cockcroft-Gault equation study and the Modification of Diet in Renal Disease (MDRD)\(^1\)\(^-\)\(^7\). The Cockcroft-gault formula was developed in 1973 with the equation Ccr = [(140-age)×weight/] (72×Scr)×0.85 (if the subject was female), where Ccr is expressed in ml/min, age in year, body weight in kg, and Serum creatinine (Scr) in mg/dl. It was exceeding GFR estimates systematically because they were not adapted to body surface area\(^8\). The latest formulation developed by The MDRD Study Group(1999)\(^1\)\(^-\)\(^4\) to measure GFR was the “4-variable MDRD” that used four variables, i.e., serum creatinine (mg/dl), age (year), race, and sex. The estimated GFR (eGFR) was adjusted to the surface area of the body with the equation GFR = 186×(Scr)-1.154×(age)-0.203×0.742 (if the subject was female) or ×1.212 (if the race of a subject was black skin). The validated formula of eGFR from Modified of Diet in Renal Disease (MDRD) is a formula that widely used by medical professionals (mainly the United States and the United Kingdom) to estimate GFR\(^9\)\(^-\)\(^11\).

This formula has been validated in CKD patients; however, the usage is still uncertain in healthy patients with GFR >60 ml/min or in patients with acute renal failure. Currently, most laboratories in Australia and the United States calculate and report MDRD-eGFR along with creatinine measurements. Inulin clearance is a gold standard for GFR measurements, but it is less used because of the method of examination and the unavailability of pure insulin. Further development of ciren of several radioisotope materials such as Chromium51-EDTA or Technetium99-DTPA, Iothalamate or Iohexol or I131-Hippuran have an inherent accuracy of insulin ciren, thus they can be used instead of insulin ciren\(^12\)\(^-\)\(^13\). This study was conducted to obtain a description of the results of renal function evaluation of the renogram and eGFR calculation based on serum creatinine values in CKD patients.

**Method**

113 patients with CKD who underwent renogram in Dr. SoetomoTeaching Hospital Surabaya were enrolled in this study from April to December 2012. Renogram was a noninvasive examination to evaluate renal function by using radiofarmaka. CKD was a disease characterized by progressive and irreversible changes or impairment of renal function. Meanwhile, GFR was the volume of filtrate filtered from the glomerular capillaries into the Bowman capsule per unit time. The inclusion criteria in this study were CKD patients with a history of hemodialysis and CKD patients aged between <20 to 70 years old.

This study was a retrospective study by observing the medical record to obtain a description of Renogram and eGFR in assessing kidney function of CKD patients. Patients who have performed a Renogram examination on the Radio-Diagnostic Installation of Nuclear Medicine Division at Dr. SoetomoTeaching Hospital Surabaya were enrolled based on the inclusion criteria. The results of the Renogram examination showed as follows: 2 normal kidneys, 1 kidney obstruction, 2 kidney obstructions, 1 kidney obstruction-1 kidney failure, 1 kidney failure, and 2 kidney failure..

**Results**

113 CKD patients who fulfilled the inclusion criteria consisted of 43 females (38%) and 70 males (62%) with the highest distribution at the age range of 50-59 years by 38 patients (66%) (Table 1).

There were 83 subjects (73%) with eGFR of <15 ml/min/1.73 m2 (CKD stage V), meanwhile two kidney failure was found in 54 subjects (54%) from renogram results (Table 3).

The highest result of eGFR was <15 ml/min/1.73m2 (CKD stage V) in 83 subjects that consisted of 50 males and 33 females with the highest incidence at the age range of 50-59 years by 29 patients (Table 4).

The renogram results found 54 subjects with two kidney failure that consisted of 36 males and 18 females. The most age range was 50-59 years of 16 subjects. There were no normal renogram results as the absence of normal eGFR results (> 90 ml/min/1.73 m2). We obtained most of the renogram results with 2 kidney failure of 54 subjects and the highest eGFR of <15 ml/min/1.73m2 by 52 subjects (Table 5).

**Discussion**

It was in accordance with a previous research, most of CKD was caused by urinary tract stones (obstructive uropathy) by 44% of all subjects\(^\text{14}\). This result was in accordance with a research by Pais VM in 2007. The age range of most subjects was 50-59 years. According to research by Coresh et al, that there was a decrease of progressive GFR about 1 ml/min/1.73m\(^2\) per year after 30 years. It was also associated with the aging biological process that initiated structural and functional changes in the kidneys(8). No normal results of the renogram were found, it was in accordance with the absence of normal eGFR results (>90 ml/min/1.73 m2). The most results of the renogram with two kidney failure were found in 54 patients. Most eGFR was found as many as <15 ml/min/1.73m2 in 52 subjects. The renogram has more benefits because it can assess the kidney function separately.

Renogram results obtained 58 obstruction kidneys both in one kidney and two kidneys. It was in accordance with a research by Taylor AT in 2007 that mentioned the renogram was a non-invasive examination, especially to evaluate patients with suspicion of obstruction. Renogram as reference method had a number of limitations, especially in patients with severe renal dysfunction or patients with severe dilatation of the collecting system. Despite its limitations, this method was chosen because it was a non-invasive optional method in the context of clinical diagnostic impairment of renal function\(^\text{15-17}\).

**Conclusion**

There were no normal results of renogram or eGFR. The most renogram results with 2 kidney failure were found in 48% of all subjects with eGFR of <15 ml/min/1.73m\(^2\).

**Ethical Clearance:** This research is in accordance with ethical clearance, has not been published before and is not being considered for publication elsewhere.

**Conflict of Interest:** There is no conflict of interest in this study.

Evaluation of Depression Symptoms in Students of Dental Medicine

Dewi Natasya Irawan¹, Aryo Dwipo Kusumo²,³, Muhammad Canino Cahya C.¹, Nur Nandini Wirawan¹, Hashfi Hilman¹, Disti Ayulita¹

¹Undergraduate Student, Faculty of Dental Medicine, Universitas Airlangga, ²Graduate Student of Health Administration and Policy, Faculty of Public Health, Universitas Airlangga, ³Department of Dental Public Health, Faculty of Dental Medicine, Universitas Airlangga

Abstract

Background: Mental illness that is often found in daily life is depression. Not many people know that depression is a medical condition with real symptoms. Many factors can trigger psychological illnesses among students such as adjustment to the new school environment, information overload, lack of free time, financial issues, family-related issues and the competition for higher grades.

Purpose: The authors are interested in discussing the evaluation of depressive symptoms among Universitas Airlangga Faculty of Dental Medicine students.

Method: The research design that will be used in this research is descriptive with a research instrument in the form of a questionnaire. The author chose this method because the author want to know the prevalence of students with major depressive disorder in Universitas Airlangga Faculty of Dental Medicine.

Result: The results of this study shows that 34% were in normal condition, 21% experienced mild mood disorders, 11% experienced borderline clinical depression, 28% experienced moderate depression and as many as 6% experienced severe depression.

Conclusion: Based on the results of the study, it can be concluded that the majority of Universitas Airlangga Faculty of Dental Medicine students experience mild mood disorders or mild depression.

Keyword: Evaluation, Depressive Symptomps, Dental Medicine Students, Sociodemographic.

Introduction

Human in the world must have felt sick. Sick is a condition when someone’s health is disturbed. When humans are not in a good condition, humans will be easily infected with a disease. Diseases are divided into 2 types, namely diseases that can be seen and diseases that are not visible to the eye. Visible diseases are common in daily lives, for example, cough, flu, measles, dengue fever, and so on. Different from the visible diseases, diseases that cant be seen was hard to detect, because the patient did not show a specific clinical symptoms. An example of this invisible disease is a mental illness.

Mental health affects the way humans feel, think, and carry out daily activities. Mental health and physical health affect each other. Therefore, like physical health, mental health is also very important. But today, the public awareness of on mental illness is still relatively low as seen from the results of the Basic Health
Research in 2018 which shows the prevalence of mental emotional disorders in adolescents over 15 years old at 9.8 percent\(^3\). This figure increased compared to 2013 which was 6 percent\(^4\).

The most common mental illness that is often found in daily life is depression\(^5\). Not many people know that depression is a medical condition with obvious symptoms. A lot of stigma has been circulating so far but only a few know about the truth. Those who are struggling with depression are sometimes questioned by those around them.

Mental health also affects the ability to learn and achieve maximum professional potential. Depression is a mental health condition that is often found and affects the majority of health care students\(^6,7\). Dentistry schools are known to have a very demanding and stressful learning environment that often results in medical condition such as depression, obsessive-compulsive disorder, psychosomatic activity related to stress and increased mood disorders, and excessive interpersonal sensitivity\(^8\).

There are many factors that can trigger psychological illnesses among students such as adjustment to the new school environment, information overload, lack of free time, financial issues, family-related issues and the competition for higher grades. Therefore, with this paper, the author wants to know the prevalence of major depressive disorder in Universitas Airlangga Faculty of Dental Medicine students. Thus, the purpose of the writing of this paper is to determine the level of depressive symptoms in preclinical students of the Faculty of Dental Medicine, Universitas Airlangga.

**Research Method**

The research design that will be used in this research is descriptive study. The author chose this method because the author wants to know the prevalence of major depressive disorder in Universitas Airlangga, Faculty of Dental Medicine students. This research was conducted in the area of the Faculty of Dental Medicine, Universitas Airlangga. Researchers chose this location because based on observations that shows the awareness of the Dental Medicine of Universitas Airlangga community on mental health is still relatively low. Researchers chose the location with the aim of wanting to know the prevalence of major depressive disorder in the Faculty of Dental Medicine, Universitas Airlangga. The population in this study were students of the Faculty of Dental Medicine who were educated at Universitas Airlangga in 2019. Sampling is based on pre-clinic students who are randomly assigned to each school year with a total of 100 samples.

Variable | Operational Definition | Category and Criteria
--- | --- | ---
Depressive Symptoms (Dependent Variable) | Range of Values from 0-10 | Normal
| Range of Values from 11-16 | Mild mood disorder
| Range of Values from 17-20 | Borderline clinical depression
| Range of Values from 21-30 | Moderate depression
| Range of Values from 31-40 | Severe depression
| Range of Values over 40 | Extreme depression

The research data is collected by filling out the Beck Depression Inventory questionnaire. After all data from the BDI questionnaire is obtained, the number of questionnaire values is calculated. The range of values 0-10 indicates minimal depression (no depression), 11-16 indicates mild mood disorder, 17-20 shows borderline clinical depression, 21-30 shows moderate depression, 31-40 indicates severe depression, and more than 40 indicates extreme depression.

**Results**

In the study conducted using a questionnaire survey of 100 random samples in preclinical students of the Faculty of Dental Medicine, Universitas Airlangga, it was found that as many as 34% of the study samples did not suffer from any depressive symptoms, 21% of the study samples suffered a mild mood disorder, 11% suffered borderline depression, 28% moderate depression, and 6% of the study sample suffered severe depression.

**Discussion**

The results of this study indicate that among 100 students studying at the Faculty of Dental Medicine, Universitas Airlangga, 30 students in the class of 2016 students 9 was normal, 3 students suffered from mild mood disorder, 6 students with borderline depression, 11 students with moderate depression, and 1 student with severe depression. The results of this study indicate that depression among students in the class of 2016 is more on the moderate type.

Then, in 21 students in the class of 2017, 6 was normal, while 6 students suffered from mild mood disorder, 6 students with moderate depression, and 3 students with severe depression. These results indicate that depression among students class of 2017 is more in the moderate type, mild mood disorders, and normal. In class of 2018 3 students was normal, 4 students suffered from mild mood disorder, 2 students with borderline depression, 5 students with moderate depression, and 2 students with severe depression. These results indicate that depression among students in the class of 2018 is more in the moderate depression.

Then, in the class of 2019 16 students was normal, 8 students suffered from mild mood disorder, 3 students with borderline depression, and 6 students with moderate depression. These results indicate that depression in students in the class of 2019 falls into the normal category.

From the results of this study it can be concluded that in the class of 2018 and 2016 more students experienced symptoms of moderate depression than with other class. This can be caused because students are on a temporary transition period from adolescence into adulthood and can be the most stressful time in a person’s life. The process of adapting into the environment on campus, maintaining good grades, thinking about the future, and being away from home are often the cause of anxiety for most students so that they will end up suffering depression⁹.

From the age variable, the results of this study indicate that among 100 students studying at the Faculty of Dental Medicine, Universitas Airlangga, 1 student who was 16 years old suffered mild mood disorder. Then, 3 students aged 17 years 2 of them was normal while the other one suffer a moderate depression. These results indicate that depression among 17-year-old students is more in the normal. Then in 26 students aged 18 year there were 12 students that was normal, 6 students suffered a mild mood disorder, 1 student with borderline depression, 6 students with moderate depression, and 1 student with severe depression. These results indicate that depression among students aged 18 years is more in the normal type.

In 20 students aged 19 years there were 3 students that was normal, 6 students suffered from mild mood disorder, 3 students with borderline depression, 5 students with moderate depression, and 1 student with severe depression. These results indicate that depression among 19-year-old students is more in the mild mood disorder. Then in 21 students aged 20 years there were 10 that was normal, 4 students with mild mood disorder, 6 students with moderate depression, and 1 student with severe depression. These results indicate that depression among students aged 20 years is more in the normal type.

In 20 students aged 21 years there were 3 students that was normal, 2 students with mild mood disorder, 6 students with borderline depression, and 9 students with moderate depression. These results indicate that depression among 21-year-old students is more in the moderate depression. Then, in 9 students aged 22 years there were 4 students that was normal, 2 students with mild mood disorder, 2 students with moderate depression, and 1 student with severe depression. These
results indicate that depression among students aged 22 years is more in the normal type.

In the research results above it is known that students in the 16-22 age category are young adult age categories\textsuperscript{10}. According to the journal it is said that young adults are a transition phase that experiences new challenges, roles and tasks for some individuals. Risk factors for mental disorders in this phase can be influenced by low social life. Mental disorders may make it difficult to transition from adolescence to adulthood so that it will become depressed. This depression can cause distress to an individual in the school environment and in the formation of social relations. Social life is associated with better mental health and is the most influential factor being young adulthood. Detection of depression in young adults becomes very important to get better treatment results and to improve the long-term prognosis of people who initially experience symptoms of depression\textsuperscript{10}.

In the gender variable, the results of this study indicate that among the 100 students studying at the Faculty of Dental Medicine, Universitas Airlangga, of the 23 male students there were 6 students that was normal, 5 students with mild mood disorder, 2 students with borderline depression, 7 students with moderate depression, and 3 students with severe depression. The results of this study indicate that depression among male students is more in the moderate depression. Whereas in 77 female students there were 28 students that was normal, 16 students with mild mood disorder, 9 students with borderline depression, 21 students with moderate depression, and 3 students with severe depression. The results of this study indicate that depression among female students is more in the normal type.

In the original variable, the results of this study indicate that among 100 students studying at the Faculty of Dental Medicine of Universitas Airlangga, of the 31 students from Surabaya there were 12 students that was normal, 7 students with mild mood disorder, 3 students with borderline depression, 8 students with moderate depression, and 1 student with severe depression. The results of this study indicate that depression among students who come from Surabaya is more in the normal type. Whereas 69 students from outside Surabaya assumed that all samples in this variable were overseas students, there were 22 students that was normal, 14 students with mild mood disorder, 8 students with borderline depression, 20 students with moderate depression, and 5 students with severe depression. The results of this study indicate that depression among students who come from outside Surabaya is more in the normal type. In the results of the above study it is known that the origin of the sample does not greatly affect a person’s level of depression\textsuperscript{17}. This is because the prevalence of depression of students from Surabaya and outside Surabaya shows the same results, namely the highest prevalence in the normal category.

Conclusion

Based on the results of the study, it can be concluded that 34\% of Universitas Airlangga Faculty of Dental Medicine students do not suffer from major depressive disorder, but 66\% of Universitas Airlangga Faculty of Dental Medicine students suffer from depression with varying degrees of severity namely mild mood disorders, borderline depression, moderate depression, to severe depression.

Based on this study, the authors suggest to the general public, especially the academic community of the Faculty of Dental Medicine, Universitas Airlangga to improve their knowledge about depression symptoms. This is to prevent excessive mental burden so that it cant endanger the students themselves.

Effect of Job Satisfaction on Empathic Skills among Oncology Nurses at Kirkuk City

Dhiaa Alrahman Hussein¹, Waleed Ibrahim Saad¹

¹Master Degree in Nursing / University of Kirkuk / College of Nursing / Iraq

Abstract

Background: Nursing care delivered to the patients by using physical, mental, social, spiritual and emotional skills. Increasing the level of job satisfaction can promote the level of empathy skills. Thus improving nursing care quality

Objectives: The aims of the study were to assess of the level of job satisfaction and the level of empathy skills, as well as to assess the effect of job satisfaction on empathy skills among oncology nurses.

Methodology: A correlational study (quantitative design) was carried out at oncology and hematology disease center at Kirkuk city for oncology nurses from first of February, 2020, up to the first of October, 2020. A purposive sampling (non- probability) of (56) oncology nurses both males and females was selected. The instrument used in the study was designed by the researchers according to the previous literature to achieve the purposes of the study. The instrument of the study was consisting of four parts: the first part was the demographical data of the participants, the second part was the Occupational data. The third Part was the Job Satisfaction Scale. And the fourth part was the nurses Empathy skills level. The data collection process were utilized by using self-report technique. The data analysis were by using the descriptive statistical analysis (frequency and percentage) and inferential statistical analysis (Pearson correlation).

Results: The results of the study demonstrate that (80%) of the nurses were dissatisfied regarding nursing job, also the results demonstrate that (64 %) of the participants having moderate empathy skill level, (32 %) of the participants having low empathy skills level.

Conclusions: The study concluded that job satisfaction have clear effect on empathy skills among oncology nurses.

Keywords: Effect, Job satisfaction, empathic skills, oncology nurses.

Introduction

Empathy is a broad and complex concept that the person feel of others. In the nursing profession use empathy is important and very necessary for the delivery of integrated care for patients. Empathy is a multi-dimensional concept with cognitive matter as well as emotive matter. Cognitive empathy is an individual’s abilities to understand the perspective of the others about their conditions and emotive empathy is an individual’s issues for the feelings of the others¹. Oncology and intensive care units are distinct areas in terms of interaction and communication with the patients demonstrate passion and empathy skills. To improve patients care, nurses should develop empathy skills. Nurses with enhanced empathic abilities can understand the patient needs. There are general agreements that the positive correlation between empathy, patients’ outcomes and clinical competence; there are still some conflict in the Relationship between empathy and nurses’ well-being². Understanding patients’ needs, feelings, and their situation is the essential nursing tasks and empathy is the basis for this understanding. Therefore, highlight

to this concept, from the perspective of medical and nursing staff is important.

Objective of the study:
1. To assess demographic and occupational data of the study sample
2. To assess job satisfaction level among oncology nurses
3. To assess empathy skills level among oncology nurses
4. To find correlation between job satisfaction and empathy skills

Methodology

A correlational study (quantitative design) was conducted in oncology and hematology disease center at Kirkuk City for oncology nurses from first of February, 2020, up to the first of October, 2020. To assess the effect of Job Satisfaction on Empathy Skills among oncology nurses at Kirkuk City. A non-probability (purposive sampling) of 56 nursing staff working in oncology and hematology disease center both males and females was selected. The instrument of the study was designed by the researchers according to the previous literature to achieve the purposes of the study. The instrument of the study was consisting of four parts. The first part was the demographical data of the participants consist of (3) items, the second part was the Occupational data consist of (3) items. The third part was the Job Satisfaction Scale consisting of (15) items. And the fourth part was the Nurses Empathy skills level consisting of (20) items. The data collection process were done by the use of self-reporting technique from the period 1st May 2020 to 1st June 2020. The informed consent was obtained from the nurses to participate in the current study. The data analysis were done by using the Statistical Package for Social Science (SPSS). The data analysis done by using the descriptive statistical analysis (frequency and percentage) and inferential statistical analysis (Pearson correlation). to find the effect of Job Satisfaction on Empathy Skills.

This table shows the Job satisfaction have an obvious effect on Empathy skills.
Empathy skills are essential when care of patients, especially in oncology setting and critical cases. Nursing profession includes the human, emotional, mental and social aspect when providing nursing care to hospitalized patients. Nursing services are not only limited to the physical care, but also the nurse provides physical, psychosocial, and emotional care for patients, especially critically ill patients and cancerous patients. According to Fan et al 2017 which state that psychosocial support included not only disease events but also emotional and supporting family. The nursing profession is affected by several factors, including professional and administrative factors that affect the provision of nursing services by nurses. The study aims to assess the effect of job satisfaction on empathy skills among oncology nurses.

The results demonstrate that most of the nurses were dissatisfied about nursing profession and with the nature of work with other health personnel. may be several reasons leading to dissatisfaction, including the inadequate monthly income compared to several countries and neighboring countries, and there are also professional and administrative reasons that determine the independency of the nurse at work, the nature of the work, and the lack of material and moral rewards for the nursing staff. According to the level of empathy skills of the oncology nurses, the results revealed that most of the nurses had moderate level of empathy skill, and this resulted from job dissatisfaction with the nursing profession. This results is similar with the study conducted on nursing students which indicate that the Participants having moderate degree of empathy skills level. According to Perez et al, Empathy Levels are reflected more in women than in men in general. The study of Elayyan et al concluded that empathetic of healthcare workers responses to patients are correlated and connected to a well-resourced, collegial, professional organizational environment that builds empathy for nurses and doctors. The results of the current study also revealed whenever level of job satisfaction is low, it may lead to less interest in patients and thus less empathy skills of the nursing staff, meaning that job satisfaction has a clear effect on the empathy skills of the oncology nurses. As stated by Buyuk et al that the nurses who chose nursing Willingly had a higher level of empathy skills than those whose families chose nursing for them. Karem et al 2019 indicated that there is a significant effect of Job satisfaction on nurses’ skills. Study of Karem et al 2019 indicates if the nurses have high beliefs, and support the current value by the hospital, have the readiness to provide much effort for the hospital, and working with a high level of commitment.

Conclusions

Job satisfaction have an obvious effect on empathy skills, Most nurses working 30-40 hour/week, and most of them working in day and night shift, The majority of the participant were dissatisfied about nursing job, Most participant having Moderate empathy skills.

Acknowledgement: The authors would like to acknowledge the nursing staff who took part in this study and to Kirkuk health directorate and Deanship of Nursing College at University of Kirkuk for their endless assistance.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: Official approval was obtained from directorate of health in Kirkuk city to conduct the study and data collection. Informed consent was obtained from the oncology nurses.

Successfully Tracheostomy and Monobloc Advancement with External Frontofacial Distraction Followed by Simultaneous Adenoidectomy, Conchotomy, and Septoplasty in Severe Late Crouzon Syndrome

Diar Mia Ardani¹, Magda Rosalina Hutagalung², Irwan Kristyono³

¹Medical Staff, Pharyngeal Larynx Division, Department of Otorhinolaryngology–Head and Neck Surgery, Faculty of Medicine, Universitas Airlangga–Dr. Soetomo General Academic Hospital, Surabaya, Indonesia, ²Medical Staff, Department of Plastic Reconstructive and Aesthetic Surgery, Faculty of Medicine, Universitas Airlangga–Dr. Soetomo General Academic Hospital, Surabaya, Indonesia, ³Medical Staff, Department of Otorhinolaryngology–Head and Neck Surgery, Faculty of Medicine, Universitas Airlangga–Dr. Soetomo General Academic Hospital, Surabaya, Indonesia

Abstract

A 10-year-old male patient presented with Severe Late Crouzon Syndrome, with turri-brachycephaly, and severe exorbitism of both eyes, visual loss, beaked nose and maxilla hypoplasia. The head circumference was 54 cm and 90 percentile. Patient had a high arched palate, tonsil hypertrophy and type III malocclusion. From the multidisciplinary meeting, in the first stage it was decided to first secure the airway with Tracheostomy then immediately followed by Monobloc Advancement with External Frontofacial Distraction. Then in the second stage, after removal of the rigid external distractor, by 9 months after first surgery, the patient underwent a simultaneous procedures of Adenoidectomy, Conchotomy, and Septoplasty. Thus, after patient got stable in follow-up, Nasendoscopy and Tracheostomy devices was removed. After 11 months follow-up. Visual function still not getting better. However turri-brachycephaly, exorbitism of both eyes, beaked nose and maxilla hypoplasia, head circumference, arched palate, tonsil hypertrophy and the malocclusion were getting much reduced, and the patient getting happier and more active.

Keyword: Adenoidectomy, conchotomy, septoplasty, crouzon syndrome.

Introduction

Crouzon syndrome is a congenital abnormality in the fetus in the womb during organ formation and is a dominant autosomal disorder. This disease was first described by neurosurgeon Octave Crouzon from France in 1912. This syndrome is classified as a group of syndromes that are rarely found with the main characteristic of craniosinostosis. Craniosinostosis is a condition in which one or more fibrous sutures on the babies cranium merge and harden prematurely, thereby changing the pattern of cranial growth. In the case of Crouzon syndrome organ formation does not develop properly, especially in cranium sutures that close prematurely so that when the head forms it becomes imperfect (1-4).

The four main physical findings that are characteristic of Crouzon’s syndrome are exorbitism, retro maxillary, inframaxillism, and paradox retrognathia. The manifestations of Crouzon syndrome that can be found in the oral cavity, namely mandibular prognathy, crowded teeth in the maxilla, maxillary atresia, crossbite anterior

Diar Mia Ardani
Pharyngeal Larynx Division, Department of Otorhinolaryngology – Head and Neck Surgery, Faculty of Medicine, Universitas Airlangga – Dr. Soetomo General Academic Hospital, Jalan Mayjen Prof. Dr. Moestopo no. 6-8, Airlangga, Gubeng, Surabaya, East Java 60286, Indonesia
e-mail: diarmiaia@gmail.com
with posterior open bite, curvature of the maxillary jaw and cleft palate. Crouzon’s syndrome accounts for 4.8% of all cases of craniosinostosis, with an incidence of 1: 25,000 to 1: 65,000 births and an autosomal dominant disorder. This pathological variation is believed to be caused by the mutation of the Fibroblast Growth Factor Receptor 2 gene (FGFR2) on chromosome 10q26(3, 4).

Children with craniosinostosis syndrome including Crouzon syndrome are prone to obstructive sleep apnea (OSA) syndrome with an estimated prevalence of between 40 and 85%. The cause of OSA is mainly caused by anatomical midfacial hypoplasia. Premature stitch fusion causes midfacial hypoplasia, increased nasopharyngeal resistance, and narrowed oropharyngeal space, all together contributing to OSA. Continuous positive airway pressure (CPAP) and surgical techniques are the two main OSA therapies for adults. Children with Crouzon syndrome are faced with more complicated problems including corneal exposure, craniofacial abnormalities, and malocclusion. Surgery for osteogenesis and craniomaxillofacial disorders seems to be a better choice for these children because it can relieve or even complete OSA by correcting midfacial hypoplasia and improving facial profiles (5-7).

The diagnosis of Crouzon syndrome is done by history, physical examination, oral cavity, functional and radiographic analysis. In general, before the treatment of orthodontic anomalies, surgery is needed first. The treatment of Crouzon syndrome patients requires several stages. The first stage involves treating craniosinostosis by correcting its frontal-orbital abnormalities in the sagittal direction. Next stage is reconstruction of the face and so on until it reaches the final stage of reconstruction which is a class III dental malocclusion treatment (8, 9).

Case Presentation: Patient was referred from a social organization and presented with turri-brachycephaly, severe exorbitism of both eyes, visual loss, beaked nose and maxilla hypoplasia (Figure 1). The head circumference was 54 cm and 90 precentile (figure 2). Patient had a high arched palate, tonsil hypertrophy and type III malocclusion. Ophthalmologic review revealed decreased vision in both eyes to light perception. Funduscopic examination was not able to be performed due to patient’s agitation. Neurosurgical review supported monobloc surgery and based on MRI showed Arnold Chiari malformation type 1. Paediatric review revealed obesity and good development based on IQ, PEDSQL and PSC-17. ENT review revealed adenoid hypertrophy through nasoendoscopy, septal deviation, severe bilateral conductive hearing loss. Psychiatric review showed IQ scored 90. Polisomnography revealed Sleep Apnea (central sleep apnea, obstructive sleep apnea and mixed apnea with severe AHI 74x/hours).

From the multidisciplinary meeting, in the first stage it was decided to first secure the airway with tracheostomy by head and neck surgeon then immediately followed by monobloc advancement with distraction. Then in the second stage, after removal of the rigid external distractor, ENT would do an adenoidectomy, septoplasty and conchotomy. In the final stage, after re-evaluation by ENT and Head and Neck surgeon. Monobloc advancement with RED was strongly indicated due to severe OSA, increased ICP and threatening blindness. It is a standard protocol for Crouzon beyond 8 years of age. We performed the surgeries in stages and only after securing the airway with a tracheostomy. Adenoidectomy was done nine months after the monobloc.

The tracheostomy was removed only after ENT review indicated no contraindication and weaning was successful. He recovered uneventfully. He became active and happy, breathing spontaneously, sleeping well, and his eyes were fully healed even though the visual acuity remained at light perception and mastication became more effective. Details of patient development from the beginning to the end of treatment can be seen in figures 3-4.

Figure 1. The patient’s condition on pre-surgery (A) and post-surgery (B)
Discussion

Sleep apnea syndrome is a syndrome with the discovery of episodes of apnea or hypopnea during sleep. Apnea can be caused by a central disorder, obstructive airway, or a mixture. Obstructive apnea is the cessation of air flow to the nose and mouth even with breathing efforts, while central apnea is the cessation of breathing which is not accompanied by an effort to breath due to the absence of breath stimulation. Obstructive hypoventilation is caused by partial obstruction of air flow which causes hypoventilation and hypoxia. The term obstructive hypoventilation is used to indicate the presence of hypopnea, which means a reduction in air flow (7, 10).

The term OSAS is used in total or partial airway obstruction syndrome which causes significant physiological disorders with variation clinical impacts. The term primary snoring is used to describe children with snoring habits that are not related to obstructive apnea, hypoxia or hypoventilation. Guilleminault et al. Defined sleep apnea as apnea episodes 30 times or more in 8 hours, for at least 10 seconds and occurred both during the sleep phase of rapid eye movement (REM) and non rapid eye movement (NREM). There are terms of apnea index (AI) and hypopnea index (HI), namely the frequency of apnea or hypopnea per hour. Apnea or hypopnea index can be used as an indicator of the mild severity of OAS (7-9).

Risk factors for OSAS in children include the result of adenoid and tonsillar hypertrophy, craniofacial disproportion, obesity. Adenoid and tonsillar hypertrophy are the conditions that most often cause OSAS in children. Adenoid and tonsil size is not directly proportional to the severity of OSAS. There are quite large children with adenoid hypertrophy, but OSAS that occurs is still mild, other children with mild adenoid enlargement show severe OSAS symptoms. Adenoid and tonsil hypertrophy can also cause complications in children with basic bone disorders. Although in most OSAS children it improves after adenotonsillectomy, a small portion will remain after surgery. In one study a small proportion of children with OSAS who had been successfully treated with adenotonsillectomy surgery then experience recurrence of symptoms during adolescence. Children with craniofacial anomalies that experience a marked narrowing of the airway structure (micrognation and midface hypoplasia) will experience OSAS. In children with craniofacial disproportion can cause airway obstruction even without adenoid hypertrophy (7, 10).

Another cause of OSAS is obesity. In adult obesity is the main cause of OSAS whereas in obese children it is not the main cause. The mechanism of the occurrence of OSAS in obesity because there is a narrowing of the upper airways due to accumulation of fat tissue in the muscles and soft tissues around the airways, as well as external neck and jaw compression. Determination of obesity can be done by counting body mass index (BMI) and measurement of neck circumference. For OSAS determination, the more important is the neck circumference compared to BMI. It is well known that
large neck circumference or obesity in the upper area is associated with an increase in cardiovascular disease, as well as allegedly associated with snoring and OSAS. It is suspected that the accumulation of fat in the neck area can make the upper airway more narrow. Another possibility is that obese patients with large necks have velofarings that are more prone to collapse so that it can facilitate the occurrence of upper airway obstruction at bedtime (7, 10).

The most common clinical manifestations are difficulty breathing during sleep, which usually progresses slowly. Before symptoms of breathing difficulties occur, snoring is a symptom that initially arises. Snoring in children can occur continuously (every sleep) or only in certain positions. In OSAS, children generally snore every time they sleep with loud snoring coming from outside the room and see episodes of apnea that may end with body movements or wake up. A small number of children do not show classic snoring, but in the form of grunting or breathing, noisy breathing. Breathing efforts can be seen with retraction. The position during sleep is usually on his stomach, half sitting, or neck hyperextension to maintain airway patency (7, 10).

On physical examination can be seen mouth breathing, adenoidal facies, midfacial hypoplasia, retrognation, micrognation or other craniofacial abnormalities, obesity, failure to thrive, allergic stigmata such as allergic shiners or horizontal nasal folds. The patency of the nasal passages must be assessed, note the presence of septal deviation or nasal polyps, tongue size, integrity of the palate, orofarings, redundant palatal mucosa, tonsil size, and size of the uvula, may be found pectus excavatum. The lungs are usually normal on auscultation examination. Examination of the heart can show signs of pulmonary hypertension such as increased pulmonary component of heart sound II, right ventricular pulsation. Neurological examination must be performed to evaluate muscle tone and development status (7, 10).

OSAS management in children is divided into two major groups, namely surgical and medical (non surgical). Surgical measures performed are tonsillectomy and or adenoidectomy and correction of craniofacial disproportion, while medical therapy can be a diet in obese children and nasal use of CPAP (Continuous Positive Airway Pressure) (7, 10).

Many experts argue that the action of tonsillectomy and or adenoidectomy is a necessary action because the benefits are greater. The rate of recovery of this action in children is around 75%-100%. In children with etiology of adenoid hypertrophy and tonsils alone the success rate is high but if accompanied by other risks such as obesity and craniofacial disproportion then postoperative OSAS will still occur. However, because OSAS occurs due to the size of the structure of the upper respiratory tract components relative to the absolute size of the tonsils and adenoid, the experts believe that tonsillectomy and or adenoidectomy is still needed in the above conditions. Post tonsillectomy and or adenoidectomy polysomnographic monitoring is needed as a follow-up. Sometimes symptoms persist and within a few weeks they disappear. Other non-medical treatments such as handling obesity are still carried out despite tonsillectomy and or adenoidectomy (7, 10).

Conclusions

One of the rare cases of Crouzon syndrome which is handled in a multi-disciplinary manner by the person in charge of the reconstructive plastic surgeon, is consulted to the otorhinolaryngology – head and neck surgery with a diagnosis of obstructive sleep apnea. The interventions given were adenoidectomy, conchotomy, and septoplasty which were able to improve the quality of life of patients.

Digitalization of Criminal Proceedings in the Context of the Coronavirus Pandemic (Covid-19) in Uzbekistan

Dilbar Suyunova1, Behruz Shamsutdinov2

1Acting Professor; 2Lecturer, Department of Criminal Procedural Law, Tashkent State University of Law, 35 Sayilgoh, Tashkent, 100047, Uzbekistan

Abstract

The widespread introduction of modern technologies in all spheres of life, including in the activities of the judiciary, has made it possible to make justice accessible to citizens. This became especially obvious due to the negative impact of the COVID-19 pandemic on the administration of justice, including the legal regulation of public relations in the field of criminal justice. The consideration of criminal cases in the mode of videoconferencing in the context of the pandemic contributed to the acceleration of the use of digital technologies in judicial activities. The goal of the research is to consider some issues related to the use of digital technologies in criminal proceedings, especially in the context of the spread of coronavirus infection and the introduction of quarantine measures.

Keywords: Criminal justice, digitalization, videoconferencing, electronic document management, rights and freedoms of citizens, coronavirus pandemic, COVID-19.

Introduction

It should be recognized that the introduction of information and communication technologies into judicial activity was not an innovation when it became known about the COVID-19 pandemic as a global challenge to the entire world community. By this time, the courts of many states, including Uzbekistan, used in criminal proceedings the experience of conducting court proceedings in the mode of videoconferencing (VKS), automatic distribution of cases, fixing the course and results of investigative actions with audio and video recordings, publishing court decisions on the Internet, sending executive documents for compulsory execution in electronic format, etc.

The use of digital technologies by courts in Uzbekistan dates back to the adoption of the Resolution of the Cabinet of Ministers of the Republic of Uzbekistan “On measures to introduce modern information and communication technologies into the activities of courts” dated December 10, 2012, which was the basis for the provision of interactive services and the introduction of electronic document management into the judicial system. Since 2013, Uzbekistan has developed and launched the National Information System of Electronic Judicial Proceedings “E-SUD”.

By the Law of the Republic of Uzbekistan dated May 23, 2019, amendments were made to the criminal procedure legislation regarding the use of videoconferencing in criminal proceedings. This computer technology has made it possible to conduct trials at a considerable distance when the court and the convicted person are far from each other. Positive aspects can be noted when considering a criminal case in the videoconferencing regime: the possibility for witnesses, victims who are outside the territory where the trial is taking place, to save their money, to participate in court and give evidence at the place of residence, the likelihood of interrogating additional witnesses in court to establish truth in the case, reduction of the time for consideration of cases.

With the onset of the COVID-19 pandemic, the relevance of remote court hearings has increased, the highest judicial body of Uzbekistan explained to the courts about the need to take measures to timely consider criminal cases using videoconferencing1.

It should be noted that to protect the rights and freedoms of citizens, ensure openness and transparency of the courts, the leadership of Uzbekistan is taking all necessary measures, including those aimed at introducing modern information and communication
technologies into the judicial system. On September 3, 2020, the President of Uzbekistan signed the Decree “On Measures to Digitalize the Activities of the Judiciary”, which defines the tasks of digitalizing the activities of the judicial authorities, namely: ensuring the openness and transparency of the activities of the judicial community by introducing special information programs; expanding the possibility of remote participation in court sessions, including through mobile devices and other forms of electronic interaction, as well as creating conditions for the parties to receive court decisions online; recording of court sessions in all courts using audio recording based on the petition of the parties in the case and with the consent of the presiding judge, as well as the formation of court records using the system of automatic generation of court documents, the development of a mobile application that provides an opportunity to participate in court sessions in the mode of videoconferencing and much more².

Method

The article uses general scientific research method, the method of system analysis of the theoretical foundations of the task, the practice of using digital technologies in Uzbekistan and some foreign countries.

Findings: The digitalization of the activities of the courts will undoubtedly ensure openness and transparency in the consideration of criminal cases, increase the level of citizens’ access to justice, and facilitate effective interaction of courts with the bodies of inquiry, preliminary investigation to promptly consider criminal cases. In Uzbekistan, the country’s leadership and its government have taken appropriate decisions regarding the digitalization of the activities of the judiciary. In the country’s law enforcement practice, the procedure for considering criminal cases via videoconferencing is successfully applied.

Discussion and Results

In different countries of the world, procedures related to the introduction of remote justice have both similarities and differences. In many countries, before the outbreak of the COVID-19 pandemic, laws and regulations on the organization of videoconferencing in court sessions had already been passed. However, it was the coronavirus pandemic and the quarantine measures taken by the states that became a kind of the impetus for the mass use of communication technologies by courts.

Professor Richard Susskind, a member of the Computer and Law Society of Britain, has dedicated an entire book on the active implementation of modern technology in the judicial system³. Under his leadership, the Internet project “Remote Courts Worldwide” was implemented, which allowed all the judges of the world to share their experience for the development of remote justice⁴.

Videoconferencing is being conducted by UK courts via Skype for Business at HMCTS. To join these video conferences, a free Skype meeting application has been developed. Each participant in the criminal case receives instructions and a link to go to the hearing as a “guest”. The issue of communication between a lawyer and his client in the UK was resolved by introducing an independent system, outside of interaction in the criminal process, through which a lawyer and his client can communicate for an unlimited time⁵.

Besides, the UK Courts and Tribunals Service is expanding its cloud-based video platform to enable remote hearings for any courtroom that has the technology and the right equipment. Participants in the process can access such a meeting through any laptop or video device. There are video points in courts, prisons and police stations. The instruction dictates that on the day of the hearing of the case, all participants must be in a closed, quiet place where they cannot be overheard. They should be prepared to take on a challenge during the meeting An employee of the Courts and Tribunals Service helps to connect to the system. He also records the hearings and ensures its storage.

Since 1995, the Court Call company has been operating in the United States, providing the remote presence of the parties at court hearings. During a pandemic, the company’s employees not only connect the parties and the courts by phone, but also organize court sessions in the videoconferencing mode, as well as check the appearance and identity of persons participating in court sessions, and monitor the quality of communication to help the judges⁶.

Professor Michael Legg of the University of South Wales in Sydney, Australia, in his article “COVID-19 Pandemic, Courts and Online Hearings: Maintaining Open Justice, Procedural Fairness and Impartiality”⁷, pointed out that “even in a pandemic, the courts must function under their institutional role and its main characteristics”. This article uses the unique
circumstances of the pandemic to consider how courts can use technology while still upholding the core or substantive demands of the court and identifies the three core characteristics of courts - open justice, procedural fairness and impartiality”.

In July 2020, Judge Lee Seyu Kin was one of the first to conduct a virtual trial in Singapore. Subsequently, the state took appropriate measures to transfer almost all courts online, which gave positive results. We learned about how Singapore’s judicial system quickly switched to remote hearings during the COVID-19 pandemic in an article by Aaron Jung, Secretary of the Supreme Court of Singapore. In particular, the author indicated that the adopted “Law on COVID-19” provided for the conduct of trials and proceedings in the Sharia court using remote communication technologies. However, the accused or witness may testify via live video link or live TV broadcast approved by the Chief Justice. Appearances and other testimonies given through remote communication are accepted in the same way as they were given in the courtroom.

In Spain, on 28 April 2020, Royal Decree-Law 16/2020 was issued on procedural and organizational measures to combat COVID-19 in the area of administration of justice. The provisions of the Law provided for the possibility of carrying out procedural actions (including court sessions) in telematic presence, provided that the courts, tribunals and prosecutors have the necessary technical means at their disposal.

The Bulgarian parliament has allowed courts to use videoconferencing in administrative, civil and criminal proceedings. Persons involved in the case may request participation in the court hearing through the HQS if they cannot attend in person. In this case, the trial must be held in a regional court equipped for videoconferencing.

In Germany, in addition to conducting court sessions in the videoconferencing regime, an electronic dossier is created with digitized materials of the criminal case, and to reduce the time for acquaintance with the materials of the criminal case, the defender receives its electronic materials through his special e-mail box.

An analysis of the practice of courts on the use of information technology in the administration of justice has shown that during the period of restrictive measures associated with the coronavirus pandemic, most countries of the world have transferred legal proceedings to a remote format to prevent the threat of the spread of coronavirus infection.

At the same time, the increase in the volume of criminal cases, the consideration of which is carried out in the videoconferencing regime, the conduct of electronic document management has revealed some features of information technology. The analysis of the remote court session showed the following:

- In areas remote from the centre, there is still a problem with connecting to a single Internet network;
- Not all citizens acting as victims, witnesses can use new technologies, the trial and interview of its participants in most cases takes place in court buildings, which can put pressure on victims and witnesses when they give evidence;
- Network insecurity, i.e. conducting a public court session via the Internet can give wide publicity to the participation of a citizen in court and cause a violation of his honour and dignity;
- The participation of the accused in custody in the court session in the videoconferencing regime and giving testimony to them raises some doubts about their veracity since the interview procedure is carried out with the participation of employees of the remand prison;
- It is noted that the conduct of the court session in the videoconferencing regime limits the rights of the defender and the accused to talk with each other, correct their testimony and formulate questions;
- Lack of legislative regulation of the court session in the format of the videoconferencing.

Conclusions

The introduction of digital technologies in the activities of courts, the holding of court sessions in the videoconferencing regime, especially during the COVID-19 pandemic, helped to solve the primary tasks of the state in the administration of justice. But still, given the specifics of criminal proceedings, the following factors should be taken into account, requiring an early decision.

1. When working with electronic documents, legislative protection against unauthorized access and prevention of changes in their content to documents is required. Digitalization must meet the requirements of criminal proceedings, its features,
including those related to the confidentiality of the testimony of victims, witnesses and other participants in the process.

2. During the height of the COVID-19 pandemic, the likelihood of its second wave, there is a need to develop a unified digital platform for courts with an increased level of channel protection, through which the information of persons involved in the case is transmitted, as well as an independent server for storing information on each specific case ... It is pertinent to note the specifics of cases in which offline court hearings would be held in closed court sessions (crimes against sexual freedom, in cases involving state secrets, etc.) since this issue should be regulated separately in the law.

3. Conducting court sessions in the videoconferencing regime should in no way violate the rights of participants in criminal proceedings. The accused must be allowed to communicate with his defence lawyer in unlimited time, victims and witnesses must give their testimony in court freely, without any pressure from the organizers of the videoconferencing process. At the same time, ensuring the safety of all participants in a trial is a fundamental element of a fair trial.

4. All participants in the process should be guaranteed the right to defend both the accused and the victims and witnesses. As a rule, the defender needs to provide a separate room with an established Internet network or Skype, to communicate freely with his client in an unlimited period. In this context, the accused should also be ensured his right to an objective, a free narration of the events of the crime, since the accused in custody participates in the court session in the videoconferencing regime in the presence of the staff of the institution for the execution of punishment and is under their supervision.

5. Of course, we cannot completely replace real litigation with digital technologies. However, today’s events related to the coronavirus pandemic have forced the judiciary to use the power of videoconferencing in judicial activities, and thus exercise their functions of administering justice.

Therefore, our task is to use new technologies only with the condition of guaranteeing the rights of citizens participating in criminal proceedings. Besides, it should be borne in mind that when assessing the evidence collected in the case, the court must check their reliability, taking into account the quality of the image, sound and other factors that may subsequently be important for deciding whether a person is guilty or innocent.

The danger of the spread of coronavirus infection obliged judges to promptly consider criminal cases using digital technologies. It is necessary to thoroughly analyze the current practice of the courts in the consideration of criminal cases in the mode of videoconferencing and develop the necessary legislative mechanisms to regulate the use of digital technologies. This process should in no way violate the rights and freedoms of citizens guaranteed by the Constitution.

Correlation of Pharyngeal Residue with Penetration-Aspiration in Post-Radiotherapy Nasopharyngeal Carcinoma Patients with Oropharyngeal Dysphagia

Dionisia Vidya Paramita1, Sri Herawati Juniati2, Achmad Chusnu Romdhoni3

1Resident, Department of Otorhinolaryngology Head and Neck Surgery, Faculty of Medicine, Universitas Airlangga – Dr. Soetomo General Academic Hospital, Surabaya, Indonesia, 2Professor, Department of Otorhinolaryngology Head and Neck Surgery, Faculty of Medicine, Universitas Airlangga – Dr. Soetomo General Academic Hospital, Surabaya, Indonesia, 3Associate Professor, Department of Otorhinolaryngology Head and Neck Surgery, Faculty of Medicine, Universitas Airlangga – Dr. Soetomo General Academic Hospital, Surabaya, Indonesia

Abstract

Background: Nasopharyngeal carcinoma (NPC) ranks first for head and neck malignancies, and radiotherapy is a recommended treatment. Most post-radiotherapy NPC patients experience oropharyngeal dysphagia that results in pharyngeal residue. Pharyngeal residue is thought to be a risk factor for aspiration-penetration.

Objective: Examining the correlation between pharyngeal residue and penetration-aspiration in post-radiotherapy NPC patients.

Method: Participants have been identified since 2018 to find out the total number of NPC patients. In the period January-October 2019, identification of NPC patients was performed according to participant criteria. Participants were examined for fiberoptic endoscopic evaluation of swallowing (FEES), pharyngeal residue using the Yale Pharyngeal Residue Severity Rating Scale (YPR-SRS), and penetration-aspiration using Penetration-Aspiration Scale (PAS). Statistical tests were used Spearman correlation test with \( p < 0.05 \).

Results: The highest participant’s pharyngeal residue appeared in vallecula when given soft bolus (96.55%), and in pyriform sinus when given thick liquid bolus (72.41%). Most participants with soft bolus had the highest negative penetration (72.59%) and positive penetration in thick liquid bolus (51.72%), while most had negative aspirations with the lowest value (89.66%). There is aspiration in 10.34% of patients when given a dilute liquid. There was a significant correlation between pharyngeal residue in vallecula and pyriform sinus with penetration-aspiration (\( p < 0.05 \)). There was a positive association with the use of soft bolus (\( r = 0.623 \)), thick liquid bolus (\( r = 0.631 \)), and dilute liquid bolus (\( r = 0.891 \)).

Conclusions: There is a significant association between pharyngeal residue and penetration-aspiration in post-radiotherapy NPC patients.

Keywords: Nasopharyngeal carcinoma, radiotherapy, pharyngeal residue, penetration-aspiration

Introduction

Nasopharyngeal carcinoma (NPC) is a squamous cell carcinoma originating from nasopharyngeal epithelium. This carcinoma ranks first for head and neck malignancies\(^1\). Radiotherapy is a recommended treatment because of the radiosensitive nature of NPC. Giving radiotherapy in addition to killing cancer cells can also damage normal cells that causes various side
effects. Protection of surrounding organs is difficult to perform when using conventional radiotherapy. Organs such as parotid, tongue, pharyngeal mucosa and pharyngeal constrictor muscle are often sacrificed during radiotherapy, resulting in oropharyngeal dysphagia. Oropharyngeal dysphagia can cause reduced food intake, malnutrition, decreased activity, and even aspiration. Aspiration is the most serious complication of oropharyngeal dysphagia because it can lead to aspiration pneumonia to death. Management of oropharyngeal dysphagia in post-radiotherapy NPC patients is still not optimal, so parameters are needed to predict the incidence of aspiration(2-4).

Oropharyngeal dysphagia can result in pharyngeal residue, which is a risk factor for penetration-aspiration. Pharyngeal residue are secretions before swallowing and bolus residue after swallowing in pharynx which cannot be completely cleansed by swallowing(5, 6). The incidence of aspiration increases as a result of pharyngeal residue because larynx has experienced relaxation so that bolus can enter the airway(7). Aspiration occurs when bolus has passed under vocal cords, whereas penetration is the presence of bolus material in larynx that does not pass through vocal cords(4, 8).

Post-radiotherapy NPC patients often experience oropharyngeal dysphagia with a prevalence reaching 75%. Management of oropharyngeal dysphagia is needed to eliminate aspiration which can cause aspiration pneumonia to death. As many as 65.9% of post-radiotherapy NPC patients have aspiration. One risk factor for penetration of aspiration is pharyngeal residue. Patients with pharyngeal residues have a thirty times greater risk for aspiration(5, 9, 10).

The most common procedures for evaluating oropharyngeal dysphagia in head and neck cancer patients are videofluoroscopy (VFS) and fiberoptic endoscopic evaluation of swallowing (FEES). Videofluoroscopy is considered a gold standard for examination of oropharyngeal dysphagia, but its use is limited because of high costs, cannot be removed, and the presence of radiation exposure. The FEES method is currently more widely used because it can be performed at the bedside and allows direct visualization of swallowing structures including nasopharynx, hypopharynx, larynx, and vocal cords(11).

Assessment for penetration-aspiration during ingestion process can use Penetration-Aspiration Scale (PAS). This method consists of eight scales that describe the depth of bolus penetration or aspiration into the airway, the sensation felt by patient to the presence of penetration or aspiration, and the effectiveness in removing bolus from the airway(7, 12). Different parameters can be used to assess pharyngeal residue because there is no consensus on the scale of assessment of the value of pharyngeal residue. Recent research showed that The Yale Pharyngeal Residue Severity Rating Scale (YPR-SRS) has the highest reliability when compared to other parameters(5, 9).

The number of NPC patients in Dr. Soetomo General Academic Hospital, Surabaya, Indonesia, has increased annually in 2017 by 125 patients, in 2018 by 137 patients, and in 2019 (until October) by 101 patients. Thus far, there is no study examining correlation between pharyngeal residue and penetration-aspiration in post-radiotherapy NPC patients at hospital. Based on the description above, the researchers aimed to analyze the association between pharyngeal residue and penetration-aspiration in post-radiotherapy NPC patients.

**Method and Materials**

**Participants:** Participants in this study were NPC patients who had completed radiotherapy that met the inclusion and exclusion criteria. Inclusion criteria were NPC patients aged 18-74 years, had completed radiotherapy using three-dimensional conformal radiation therapy (3D-CRT) techniques for 35 times in accordance with NCCN guidelines(13), had dysphagia complaints, were willing to undergo FEES examination in maximum twelve months after radiotherapy, the Glasgow Coma Scale of compos mentis (456), and can sit. Exclusion criteria included patients having other diseases that can cause dysphagia (stroke, head trauma, brain base tumors, cervical vertebral trauma, meningitis, Guillain Barre syndrome, diabetes mellitus, and goitre), underwent radiotherapy for more than 35 times, used nasogastric tubes, used tracheostomy tubes, respiration rate more than 24 times per minute, and oxygen saturation <94%. Participants first received an explanation of the study details including the benefits, objectives, rights and obligations of the participant. In addition, participants who were willing to take part in the research must fill in the consent form.

**Design:** The study was conducted at the Oncology Poly of Dr. Soetomo General Academic Hospital,
Surabaya, Indonesia, from January-October 2019. This study used a cross-sectional design with consecutive sampling techniques. The number of participants was 29 NPC patients. Participants were assessed for characteristics, pharyngeal residue, and penetration-aspiration after receiving radiotherapy for 35 times. This study had passed ethical test (1031/KEPK/III/2019). NPC stadium referred to the classification of Tumors, Nodules, Metastases (TNM) developed by Union International Against Cancer (UICC) and the American Joint Committee on Cancer (AJCC)(14, 15).

Fiberoptic Endoscopic Evaluation of Swallowing: Participants were examined for FEES by the Otorhinolaryngology Head and Neck Surgery Specialist (Broncoesophagologist consultant). FEES examination used endoscopy (Olympus Evis Exera II, Olympus Medical System, Tokyo, Japan). Patients were seated, and left and right nasal cavity were given decongestant Oxymetazoline HCl spray 0.05%. The endoscopy tip was inserted through nose to nasopharyngeal cavity (between soft palate and top of epiglottis) where the gel was applied first. Prepare three bolus of different consistency (soft, thick liquid, dilute liquid) each ± 5 ml. Participants were asked to swallow the bolus once to see whether there was vallecular residue and pyriform sinus after the white-out period. The white-out period is formed due to changes in tissue position after swallowing reflex. The order of bolus usage was soft bolus, thick liquid, and dilute liquid. Furthermore, the endoscopy was rapidly moved to the area of laryngeal vestibule to evaluate penetration and aspiration.

Pharyngeal Residue Assessment: Pharyngeal residue is secretion before and after ingestion of bolus residue in vallecula and pyriform sinus which cannot be completely cleansed by swallowing. Pharyngeal residual assessment was obtained through FEES examination using the YPR-SRS scale(5). The scale of vallecular residue is divided into five, namely scale 1 (none) if there are no residuals found in vallecula, scale 2 (trace) if the residue only covers vallecular mucosa or fills 1%-5%, scale 3 (mild) if the residue fills vallecula up to a quarter full (5%-25%) with visible epiglottic ligaments, scale 4 (moderate) if the residue fills vallecula to half full (25%-50%) with invisible epiglottic ligaments, and scale 5 (severe) if the residue fills vallecula more than 50% to the upper edge of epiglottis. Pyriform sinus residual rating scale is also divided into five, namely scale 1 (none) if there is no residual pyriform sinus, scale 2 (trace) if the residue only covers pyriform sinus mucosa or fills 1%-5%, scale 3 (mild) if the residue fills pyriform sinus up to a quarter full (5%-25%), scale 4 (moderate) if the residue fills pyriform sinus up to half full (25%-50%), and scale 5 (severe) if the residue fills pyriform sinus more than 50% to reach aryepiglottic folds.

Penetration-Aspiration Assessment: Penetration is the presence of bolus material in larynx which does not pass through vocal cords after swallowing phase. Aspiration is the presence of bolus material that has passed under vocal cords. Penetration-aspiration assessment used PAS, which the rating scale is divided into eight(12). Scale 1 indicates no boluses enter larynx. Scale 2 shows that the bolus has entered larynx, remains above vocal cords, and can be removed from larynx. Scale 3 shows that the bolus has entered larynx, remains above vocal cords, but cannot be removed from larynx. Scale 4 is a condition when bolus has entered larynx, touches vocal cords, and can be removed from larynx. Scale 5 indicates that the bolus has entered larynx, touches vocal cords, but cannot be removed from larynx. Scale 6 shows that the bolus has entered larynx, passes through vocal cords and can be removed from larynx. Scale 7 is a condition when the bolus has entered larynx, passes through vocal cords, but cannot be removed from larynx despite attempts to remove it. Scale 8 shows that the bolus enters larynx, passes through vocal cords, and no attempt to remove it. Scale 1 shows the absence of penetration-aspiration. Scale 2-5 illustrates penetration, while scale 6-8 shows aspiration. Aspiration may not be identified in post-radiotherapy of head and neck cancer patients. Symptoms of aspiration in patients who have undergone radiotherapy are often unclear, and they do not feel anything due to sensory disturbance in the trachea area that is called silent aspiration.

Statistic Analysis: Data obtained in the study were displayed in tabular form, and were analyzed statistically. The association between pharyngeal residues with penetration-aspiration was analyzed using the Spearman correlation test. This research used significance level \( p<0.05 \). Statistical test analysis employed the IBM SPSS Statistics software version 21.0 (IBM Corp., Armonk, NY, USA).

Results

Characteristics of Participants: Most participants belonged to the age group of 46-55 years (37.93%), followed by age group of 36-45 years and 56-65 years (20.69% each). The average participant age was...
48.41±13.20 years, with the youngest age at 18 years and the oldest age at 68 years. Most participants were male (72.41%). All participants did not undergo metastasis to other organs, and most participants had stage-IV NPC (55.17%). Most participants had a T4-type tumor classification (41.38%) and followed by a T3-type tumor (27.59%). T4 is a tumor that extends intracranially and/or involves cranial nerve, hypopharynx, infratemporal fossa, or masticator space, while T3 is a tumor that invades bone structure and/or paranasal sinuses. In addition, most participants had an N2-type nodule (44.83%), followed by an N3-type nodule as much as 27.59%. N2 is categorized as bilateral cervical lymph node, with the largest size ≤6 cm, above Supraclavicular fossa, while N3 is categorized as cervical lymph node >6 cm, and/or towards Supraclavicular fossa. Most participants suffered injuries due to radiotherapy in the range of 3-6 months as much as 51.72% (Table 1).

Participants complained of several problems related to dysphagia, including drooling or saliva coming out of the mouth as much as 2 participants (6.90%), food came out of the lips as much as 3 participants (10.34%), regurgitation or food and drink coming out of nose as much as 5 participants (17.24%), cough when eating or drinking as much as 7 participants (24.14%), choking while eating or drinking as much as 9 participants (31.03%), reduced saliva that leads to difficulty swallowing as many as 29 participants (100.00%), require water to help swallow as many as 28 participants (96.55%), avoiding foods with certain consistency as much as 18 participants (62.07%), require certain portion size as much as 7 participants (24.14%), longer mealtime length as much as 27 participants (93.10%), having the sensation of food getting stuck in the throat as many as 20 participants (68.96%), and changed voice as many as 16 participants (55.17%).

**Pharyngeal Residue:** Most participants had vallecular residue when given soft bolus (96.55%; 3.21±1.01), while 89.66% of participants had the residue when given thick liquid bolus (2.41±0.87). On the other hand, when given dilute liquid bolus, most participants experienced pharyngeal residue in vallecula as much as 68.97% (2.41±0.87). Most participants experienced pharyngeal residue in pyriform sinus when given soft bolus as much as 62.07% (2.41±1.18), thick liquid bolus as much as 72.41% (2.00±0.93), and dilute liquid bolus as much as 62.07% (2.03±1.08; Table 2).

**Penetration-Aspiration:** Most participants had no penetration-aspiration when given soft bolus as much as 72.59% negative penetration and all negative aspirations (2.07±1.25). When given thick liquid bolus, most participants (51.72%) had positive penetration and all negative aspiration (2.07±1.25). On the other hand, when given dilute liquid bolus, most participants had no penetration-aspiration as much as 55.17% of negative penetration and 89.66% of negative aspiration (2.52±1.78). When, we gave a dilute liquid bolus as much as 10.34% of the participants experienced aspiration (table 3).

**Correlation of Pharyngeal Residue with Penetration-Aspiration in Post-Radiotherapy NPC Patients:** Correlation between pharyngeal residue in vallecula with penetration-aspiration in the administration of soft bolus was \( p=0.025 \) with \( r=0.416 \), thick liquid bolus was \( p=0.003 \) with \( r=0.494 \), and dilute liquid bolus was \( p<0.001 \) with \( r=0.807 \). These results indicated a significant association between pharyngeal residue in vallecula and penetration-aspiration. Correlation between pharyngeal residues in pyriform sinus and penetration-aspiration in the administration of soft bolus was \( p<0.001 \) with \( r=0.623 \), thick liquid bolus was \( p<0.001 \) with \( r=0.631 \), and dilute liquid bolus was \( p<0.001 \) with \( r=0.891 \). These results showed a significant association between pharyngeal residue in pyriform sinus and penetration-aspiration (Table 3).

Discussion

Oropharyngeal dysphagia in post-radiotherapy NPC patients is secondary due to nerve and soft tissue damage. This can occur in the short or long term with varying degrees of severity. Changes in swallowing structure can occur due to early and late effects of radiotherapy. Radiation causes axonal injury, demyelination, extensive fibrosis in and around nerves, and ischemia in blood vessels that provide vascularization to nerves. Not all structural changes in swallowing due to radiotherapy can be explained completely. Reduced retroflexion from epiglottis and retraction of tongue base will cause pharyngeal residue in vallecula. Reduction of pharyngeal contraction and relaxation of upper esophageal sphincter results in pharyngeal residue in pyriform sinus. Pharyngeal residue is a risk factor for aspiration after the ingestion phase. Aspiration in post-radiotherapy head-neck cancer patients mainly occurs after swallowing phase, thus pharyngeal residue must be considered as primary symptoms of oropharyngeal dysphagia in this population. Pharyngeal residue can cause penetration-aspiration after swallowing phase because bolus enters airway when larynx has been relaxed (7, 16-19).

Pharyngeal residue is a risk factor for penetration-aspiration in post-radiotherapy head-neck cancer patients. A study found a significant association between pharyngeal residue and penetration-aspiration at each given bolus consistency (\(p<0.05\)) (10). Increased pharyngeal residue in dysphagia patients is directly proportional to the incidence of penetration-aspiration. Penetration-aspiration increases along with the increase in pharyngeal residue in vallecula and pyriform sinus at each given bolus consistency and is statistically significant (\(p<0.001\)) (9). The results of penetration-aspiration in post-radiotherapy head-neck cancer patients mainly occur after the swallowing phase compared to before or when swallowing (\(p<0.05\)) (7).

The location of pharyngeal residue in vallecula or pyriform sinus influences penetration-aspiration although there are still differences regarding the more dangerous location. Some studies mentioned residue in pyriform sinus are more dangerous than in vallecula, while other studies showed the opposite (7). A study found a significant correlation between pharyngeal residue in pyriform sinus and aspiration in post-radiotherapy NPC patients (\(p<0.001\)) (20). Aspiration is more often caused by pharyngeal residue in pyriform sinus compared to vallecula. The greater distance between vallecula to laryngeal anterior chamber than pyriform sinus to laryngeal anterior chamber might result in aspiration due to a large amount of residue in pyriform sinus. Residue in the lower pharyngeal area increase the risk of penetration-aspiration. Vallecular residue are more difficult to enter laryngeal vestibule because of the presence of epiglottis as a barrier, but epiglottic function in head and neck cancer patients can be damaged due to fibrosis, malformations, or tissue damage so that failure continues to prevent residues from entering larynx (7, 21).

This study found a significant correlation between pharyngeal residue in vallecula and pyriform sinus with penetration-aspiration, but did not distinguish the more dangerous areas between the two. The association between pharyngeal residue in pyriform sinus and penetration-aspiration showed a stronger correlation when compared with residue in vallecula at all given bolus consistencies. The type and consistency of bolus also play an important role in the occurrence of penetration-aspiration. Some studies mentioned that dilute bolus is easier to cause aspiration when compared with thick bolus, whereas other studies showed the opposite results (7, 9, 22, 23). Some studies found a significant association between pharyngeal residue with penetration-aspiration, and the correlation was stronger when given dilute bolus (21, 24). Pharyngeal pressure decreases significantly when given liquid compared to soft bolus. This might be due to liquid viscosity that allows gravity to take over the transfer of flow through pharynx. Liquids are more at risk of causing penetration-aspiration when compared to soft boluses in post-radiotherapy NPC patients who experience pharyngeal contraction disorders. Liquid boluses cannot provide enough stimulation to pharyngeal wall due to interference with nerve function that plays a role in swallowing (3, 25).

Some studies reported a stronger correlation between pharyngeal residue and penetration-aspiration when given soft bolus compared to liquid (9, 10). This might be caused by differences in types of bolus given, which are solid, soft, and liquid. The last fluid bolus given can be overestimated due to residual residues from previous solid and soft boluses. Assessment of repeated swallowing management to clear pharyngeal residues can provide a different interpretation of penetration-aspiration. Fluid boluses can easily flow into the airways, but are also easier to cough out. Thick bolus is difficult to enter the airway, but it is not easy to be removed again after entering so that it can cause airway obstruction. Assessments made after repeated swallowing will cause
soft boluses to appear to be more likely to result in aspiration than liquid boluses \(^{(9, 26)}\).

This research did not distinguish which type and consistency of boluses that are more dangerous for penetration-aspiration. A stronger correlation between pharyngeal residues and penetration-aspiration was obtained when given dilute liquid bolus compared to thicker bolus on vallecula or pyriform sinus. This study proved that there was a significant association between pharyngeal residue and aspiration-penetration in post-radiotherapy NPC patients, so that pharyngeal residue could be used to predict penetration-aspiration in post-radiotherapy NPC patients.

**Conclusions**

Most post-radiotherapy NPC patients have oropharyngeal dysphagia, which can lead to penetration-aspiration. FEES examination is performed to assess penetration-aspiration and pharyngeal residue, while YPR-SRS is used to pharyngeal residue scoring and PAS is used to penetration-aspiration scoring. There is a significant correlation between pharyngeal residue and penetration-aspiration in post-radiotherapy NPC patients. The correlation between pharyngeal residue and penetration-aspiration in the administration of dilute liquid bolus shows the strongest results. There is a strong association between pharyngeal residues in pyriform sinus and penetration-aspiration in the administration of liquid bolus.

**Conflict of Interest:** The authors declare they have no conflict of interest.

**Funding:** None

**Informed Consent:** Informed consent was obtained from all individual participants included in the study.

**Ethical Approval:** All procedures performed in studies involving human participants were accordance with the 1964 Helsinki Declaration at the ethics committee in Dr. Soetomo General Academic Hospital, Surabaya, Indonesia (1031/KEPK/III/2019).

Effect of Supportive Care Activities on Negative Emotional Feelings of Children with Nephrotic Syndrome

Doaa Mahran¹, Iman Ibrahim Abd El-Moneim², Hyam, R. Tantawi³

¹Researcher; ²Professor of Pediatric Nursing, ³Professor of Pediatric Nursing, Pediatrics Nursing Department, Ain Shams University, Cairo, Egypt

Abstract

Nephrotic syndrome is a collection of symptoms due to kidney damage. This includes protein in the urine, low blood albumin levels, high blood lipids, and significant swelling. Other symptoms may include weight gain, feeling tired, and foamy urine. Complications may include blood clots, infections, and high blood pressure.

Aim of the study: This study was aimed to assess the effect of supportive care activities on negative feelings of nephrotic syndrome children. Setting: The study was carried out at medicine department of children’s hospital affiliated to Ain Shams University Hospitals. The subjects: The subject of this study was purposive sample composed of (50) children were attended to the previously mentioned setting and accompanying mothers. Tools of data collection: An Interviewing Questionnaire, Children’s Assessment of Participation and Enjoyment (CAPE), multidimensional Scale of Perceived Social Support (MSPSS).

Results: Less than half of the studied children having negative Emotional Feelings.

Conclusion: The study concluded that the studied children with Nephrotic Syndrome have negative feelings need Supportive Care.

Recommendations: This study recommended the importance of Encourage use of Supportive care activities programs to help them to prevent the negative feelings of Nephrotic syndrome children.

Keywords: Children, Emotional, Supportive, Negative, Nephrotic Syndrome.

Introduction

Nephrotic syndrome may occur when the filtering units of the kidney are damaged. this damage allows protein normally kept in the plasma to leak into the urine in large amounts, which reduces the amount of protein in your blood. Since the protein in the blood helps keep fluid in the bloodstream, some of this fluid leaks out of the bloodstream into your tissues, causing swelling, called edema.¹⁴

Nephrotic syndrome is a problem where too much protein called albumin is released from the body into the urine. it means that one or both kidneys are damaged. the kidneys contain many coils of tiny blood vessels. each of these is called a glomerulus. glomeruli filter substances from the blood into the urine. nephrotic syndrome occurs when the glomeruli stop working normally.¹⁰

Glomerular disease may be caused by an infection or a drug it may be caused by a disease that affects the entire body, like diabetes or lupus. Many different diseases can cause swelling (inflammation) or scarring (sclerosis) of the glomerulus. Sometimes glomerular disease is idiopathic, meaning it happens without any cause that can be found, the glomerular diseases that cause nephrotic syndrome generally can be divided into primary and secondary Nephrotic Syndrome.¹⁶
Primary nephrotic syndrome is known as idiopathic nephrotic syndrome. It is associated with glomerular disease without an identifiable causative disease or drug. Idiopathic nephrotic syndrome includes multiple histologic types such as: minimal change disease, mesangial proliferation, focal segmental glomerulosclerosis. Secondary nephrotic syndrome refers to an etiology extrinsic to the kidney. Approximately 10% of children with nephrotic syndrome have secondary nephrotic syndrome.

Childhood nephrotic syndrome is a group of symptoms that occur because of damage to the kidneys. Nephrotic syndrome can occur in children at any age, but usually is found in children between 18 months and 5 years of age. You should check with your child’s pediatrician or a pediatric kidney disease specialist if your child has signs of nephrotic syndrome.

Supportive care is an important aspect of managing children with nephrotic syndrome. Patient and parent education is adequate information about the disease, associated complications and the expected course should be provided. Parental motivation and involvement are essential in management of a child with nephrotic syndrome. Measures are emphasized such as urine examination for protein at home, maintain a diary showing proteinuria, medications received and intercurrent infections, ensure normal activity and school attendance.

Negative emotional for children with Nephrotic syndrome has biological, behavioral, and social manifestations that have implications on the mental health, social and personality development of the child, and family coping. Nephrotic syndrome in children has a significant impact on intellectual functions and behavioral aspects, including anxiety and depression. Parents of children with nephrotic syndrome are more likely to develop psychosocial problems, have less social adjustment, and have a poorer quality of life compared with parents of healthy children.

The Role of the nurse is very important to aiding mother in acceptance of their child’s condition, encourage the mother to know diagnosis and teach them how they can support their children by living normal life and accept negative emotion feelings, nurses should provide educational classes for the mothers and their children about nephrotic syndrome to elevate their level of health awareness about disease and its care. As well provide children and their mothers with useful source of information at home, in addition to mass media should provide educational mass media programs for such diseases.

Significance of the study: Pediatric Nephrotic syndrome is the most common renal disorder, in childhood and adolescences; pediatric Nephrotic syndrome prevalence is 4-5% worldwide and in Egypt ranged from 11-12%. (National Center of Biological Information’s NCBI., 2017). Also no one provide supportive care for children with Nephrotic syndrome at pediatric care setting.

Aim of the Study: This study aimed to assess the effect of supportive care activities on negative emotional feelings of Nephrotic syndrome children

Subjects and Method

I. Research Design: A quasi-experimental design was used to conduct this study.

Study Setting: The study was carried out at medicine department of children’s hospital affiliated to Ain Shams University Hospitals.

Subjects: The subject of this study was purposive sample composed of (50) children were attended to the previously mentioned setting and accompanying mothers.

II. Technical Design: Tools of data collection: Data were collected through use of the following tools:

I. Interview Questionnaire:

1. An Interviewing Questionnaire: It was designed by the researchers after reviewing the related literature:

(1): Characteristics of children

(2): Characteristics of mothers of children and their knowledge.

Scoring System: Scores used to evaluate Mother’s knowledge regarding nephrotic syndrome. The correct answer was taken score one and for the incorrect answer was taken zero scores. The total knowledge score interpreted as follows:

- Satisfactory knowledge was considering from 60 to 100%
- Unsatisfactory knowledge less than 60%
II. Children’s Assessment of Participation and Enjoyment (CAPE): It was designed to examine how children and adolescence participate in everyday activities outside of their school classes. It measures children’s participation in recreation and leisure activities outside of mandated school activities.

Scoring System: Scoring system was done by allocating to each sentence a score (0) for No and (1) Yes. The score of items was summed-up and the total divided by a number of the items, giving a mean score of the part. These scores were converted into a percent score was classified as the following:

- < 60% Not participated in activity from zero < 33
- ≥ 60% Participated in activity from 34 – 55

III. Multidimensional Scale of Perceived Social Support (MSPSS), it was used to measure perceived social support.

Scoring System: Scoring system was done using three points Liker scale ranging from Zero to 2 respectively as (0) Rarely; (1) Sometimes; and (2) Always. The score of items was summed-up and the total divided by a number of the items, giving a mean score of the part. These scores were converted into a percent score was classified as the following:

- < 50% Low perceived social support from zero <12
- 50 %< 75% moderately perceived social support from 12 <18
- ≥ 75% highly perceived social support from 18 – 24

III. Operation Design: The operational design for this study consisted of three phases, namely preparatory phase, pilot study, and fieldwork.

Preparatory Phase: The researcher reviewed the literature and prepared the data collection tools including the socio-demographic and clinical data parts, as well as children’s emotional negative feelings scale, children’s assessment of participation and enjoyment and multidimensional scale of perceived social support among children having nephrotic syndrome. This was served to develop the study tools for data collection. During this phase, the researcher also visited the selected place to get acquainted with the personnel and the study settings. Development of the tools was under supervisors’ guidance and experts’ opinions were considered.

Pilot Study: A pilot study was carried out in the first half of July 2018, before data collection. The pilot study included 10% of the study subject fulfilling the previously mentioned criteria; it was conducted to evaluate the simplicity, practicability, legibility, understandability, feasibility, validity and reliability of the tool, it was also used to find the possible problems that might face the researcher and interfere with data collection to estimate the time needed to fill in the sheets. According to the results of the pilot study, no modifications were done in the tools. Those who shared in the pilot study were included in the main study sample.

Fieldwork: Once permission was granted to proceed with the study, the researcher visited the study setting and met with mothers/children having nephrotic syndrome who fulfilled the inclusion criteria. The purpose of the study was explained to mothers/children. The researcher started the interview with the mothers/children individually using the data collection tools. The researcher read, explained the steps of the study and choices were recorded for illiterate mothers, while educated mothers read and full the questionnaire by themselves.

The time consumed to fill out the full questionnaire ranged from 35 to 45 minutes for one questionnaire, each Saturday, Monday, and Thursday from 9:00 am to 12:00 pm in previously mentioned sitting.

IV. Administrative Design: An official letter requesting permission to conduct the study was submitted from the Dean of Faculty of Nursing, Ain Shams University to obtain permission from the general director of children’s hospital affiliated to Ain Shams University Hospitals to collect the data of the study. The agreement of each relative was obtained after explaining the aim and nature of the study.

Ethical Considerations: Approval was obtained from the ethical committee to conduct this study. The researcher explained the study aim in a simple and clear manner to be understood by eligible mothers/children. Verbal consent was obtained by each participant before collecting any data. Participants were informed about their right to withdraw from the study at any time without giving any reason. Data were considered confidential and not be used outside this study without mothers approval.

V. Statistical Analysis: Data collected from the studied sample was revised, coded and entered using PC. Computerized data entry and statistical analysis.
were fulfilled using the statistical package for social sciences (SPSS) version 20. Data were presented using descriptive statistics in the form of frequencies, percentages. Categorical data were tested with the Chi-square test (X2) for qualitative variables and independent sample t-test for quantitative variables. Statistical significance was considered at p-value <0.05.

**Results**

Table (1) shows that, near to two thirds (64.0%) of the studied children were males, 32.0% of them their age ranged between 8<10 years old with mean± SD 8.1±1.4. Regarding to educational level, nearly to two thirds (60.0%) of the studied children were in primary school.

Table (2) shows that, more than one third (40%) of the studied children were fathers age ranged between 35<40 years old with mean± SD 37.1±2.9, while nearly to two thirds (60.0%) of the studied children fathers were age ranged between of 40<45 years old with mean± SD 42.6±2.4.

Table (3) shows that, more than one third (38.0%) of them were had illness for 2<4 years with mean± SD 2.3±0.8, near to three quarters (70.0%) of the studied mothers were discovered disease through signs and symptoms and the majority (94.0%) of them were treated with immunosuppression.

Table (4) shows that, nearly to half (42.0%) of the studied children were overweight, 46.0% of them were shorter than normal, 56.0% of them had normal head circumference, while 34.0% of them were had large arm circumference than normal.

Table (5) clarifies that, there were statistically significant differences between the studied mothers regarding their knowledge in relation to meaning, causes and signs & symptoms of nephrotic syndrome throughout the pre and post intervention respectively (p<0.05).

Table (6) clarifies that, there were statistically significant differences between the studied mothers regarding their knowledge in relation to treatment & precautions of nephrotic syndrome throughout the pre and post intervention respectively (p<0.05).

**Discussion**

Nephrotic syndrome is a problem where albumin is released from the body into the urine. It means that one or both kidneys are damaged. The kidneys contain many coils of tiny blood vessels. Each of these is called a glomerulus. Glomeruli filter substances from the blood into the urine. Nephrotic syndrome occurs when the glomeruli stop working normally. A child with nephrotic syndrome may have: (very high levels of protein “albumin” in the urine, low levels of protein in the blood, tissue swelling all over the body “edema” especially in the belly “ascites”, weight gain from excess fluid, high cholesterol levels in the blood and less urine) 2.

The most common type is called Minimal Change Nephrotic Syndrome (MCNS). With MCNS, a child has times when symptoms get worse (relapses). But the condition can be managed over time. In rare cases, a child may develop kidney failure and need dialysis. Most children with this problem have idiopathic nephrotic syndrome. Idiopathic means that it occurs with no known cause. 18

In rare cases, a nephrotic syndrome may occur in the first week of life. This is called congenital nephrotic syndrome. It is inherited by an autosomal recessive gene. This means that boys and girls are equally affected. A child inherits 1 copy of the gene from each parent, who are carriers. Carrier parents have a 1 in 4 chance of having a child with this syndrome with each pregnancy. The outcome for this type of nephrotic syndrome is very poor. 8

This was supported by 5, who studied “Nephrotic syndrome in childhood” mentioned that, one third of the studied children were in the age group (8-10 years old), were the first child in their families and two thirds of them were males.

But this was not in accordance with 6 who conducted a study about “Psychiatric adjustment in children with nephrotic syndrome” showed that, one third of the studied children were in the age group (6-8 years old) and were males.

The current work mentioned that, more than one third of the studied children mothers were in the age group (35<40 years old), while two thirds of their fathers were in the age group (40<45 years old). As regards their education level it was found that, less than half of them had secondary educational level. Also two thirds of the studied children mothers were working and the majority of their fathers were working (table 2).

This was in agreement with 15 whose study was about “Long-term outcome of children with steroid-sensitive idiopathic nephrotic syndrome” clarified that, regarding the educational level of the studied children parents less than half of them had moderate educational level, the majority of their fathers were working while two thirds of their mothers were working mothers.

In the study of 20, which was about “Treatment of idiopathic nephrotic syndrome: regimens and outcomes in children” showed that, two thirds of the studied children were shorter than normal and it was clear from this study that there was significant correlation between the growth retardation and nephritic syndrome.

Having knowledge and health related practice regarding chronic illness such as nephritic syndrome improve child and family health outcomes by promoting recovery, speeding return to school, promoting health behavior, and appropriately involving the child on his
or her own care decisions. Important strategies for helping child to cope include providing information within the child’s cognitive ability, and helping parent to understand what choices they have.

This was in accordance with whose study was about “How mothers perceive their children with the nephrotic syndrome” mentioned that, there was statistically significant difference between knowledge of mothers about nephrotic syndrome in relation to treatment, complications and follow up pre and post intervention.

This was supported by, who conducted “A study about knowledge of mothers of children with nephrotic syndrome toward recurrence of disease” clarified that, there was statistically significant difference between mothers of the studied children regarding their total knowledge in relation to nephrotic syndrome.

The study of, which was about “Assessment of mothers’ practices toward children with steroid-sensitive nephrotic syndrome at pediatrics hospitals in Baghdad city college of nursing, university of Baghdad” showed that, there was highly statistically significant difference between perceived social support to nephrotic syndrome children in relation to (there is family that tries to help, have friends with whom can share joys and sorrows and can talk about problems with friends) pre and post intervention.

This was in agreement with whose study was about “Psychological status of both children with the nephrotic syndrome or acute glomerulonephritis and their parents” clarified that, there was statistically significant difference between the studied children regarding their self-improvement activities in relation to (reading and doing homework) and their physical activities in relation to (performing activities and team sports).

This was supported by who studied “Health-related quality of life and psychosocial adjustment in steroid-sensitive nephrotic syndrome” mentioned that, there was statistically significant difference between the studied children regarding their participation and enjoyment throughout the pre and post intervention.

This was supported by, who studied “Correlations between performance on neuropsychological tests in children with nephrotic syndrome “mentioned that, there was statistically significant difference between the studied children regarding their emotional negative feelings pre and post intervention.

**Conclusion**

The result of the present study concluded that Supportive care activities as, social support, recreational Activities, Social Activities, Self-improvement Activities, Active Physical Activities, Skill-based Activities intervention prevent the negative emotional feelings of Nephrotic syndrome children, namely, Emotion liability, Negativity dimension and Emotion Regulation dimension.

**Recommendations**

In the light of the study findings, the following recommendations are suggested:

1. Encourage use of Supportive care activities programs periodically for children with nephrotic syndrome disease and their mothers based upon their actual assessment to help them to prevent the negative emotional feelings of Nephrotic syndrome children.
2. Further studies should be conducted to study risk factors of rapid progression of the negative emotional feelings of Nephrotic syndrome children.
3. Availability of multidisciplinary team of supportive care as well as follow-up out-patient clinic that include pediatric nurses, renal physicians, social workers, dietitian, psychotherapists and physiotherapist to assist children and their families in maintaining near normal lifestyle at highest possible level of emotional feeling.

Abstract

Introduction: Utilization of well-known drug brands in bad faith at this time is increasingly rampant and leads to losses to both consumers and owners of such well-known brands.

Research Objective: The purpose of this study is to analyze and find the political formulation of the law of protection of well-known drug brands from the act of passing off in Indonesia.

Research Method: This research uses a normative juridical research approach because it seeks to examine the legal politics related to Law Number 20 of 2016 on Brand and Geographical Indications.

Research Results: Protection of well-known drug brands in Indonesia based on Law Number 20 of 2016 on Brand and Geographical Indications, consisting of brand scope, actual use, nature of goods, announcements, rights granted, application requirements to obtain brand certificates, transfer and licenses, and brand registration. The politics of the protection of well-known drug brands in the future, that in accommodating the passing off of well-known drug brands in Indonesia, it is necessary to protect holders of well-known brand rights in Indonesia.

Keywords: Legal Protection; Political Law; Famous Drug Brands.

Introduction

In the face of free markets, Indonesia needs various implementations as an action to carry out the plan that has been made. One of the implementations of The Indonesian state and society towards the 2020 free-market era is to become a free open market for goods and services both intellectual creativity of individuals and foreign companies. The trend of increasing trade in goods and services will continue in line with the increasing national economic growth. Like other human intellectual goods and creativity, it is necessary to acknowledge and reward the legal order called intellectual property law. One form of intellectual property rights is a brand specifically regulated in Law Number 20 of 2016 on Brand and Geographical Indications¹.

The use of well-known brands in bad faith at this time is increasingly rampant and leads to losses to both consumers and owners of such well-known brands. The success and high reputation of a company with products and also brands attached to the product often tempts other parties who have bad intentions to deal with in ways that violate business ethics, norms of decency, and the law².

Acts that try to gain profit by brand-blocking so that it can cause deception, misdeeds, or violations of the brand as above is known as passing off. Passing off over a well-known brand today can only be said to be a reputational hitch that leads to fraudulent competition conducted by irresponsible manufacturers³. The form of passing off action can give an idea, among others, the likelihood of confusion, mistake, or deception, namely there is a form of a brand that resembles or has similarities with well-known brands.
The problem that is often encountered in IPR, especially in the field of brands is the emergence of unhealthy business competition. Basically, with Indonesia’s participation in the WTO which includes the TRIPs Agreement, it indirectly means agreeing to a world competition plan in the framework of free trade. One of the consequences of participation is how to prepare businesses in Indonesia to be able to conduct business competition honestly and healthily in the global market. This can only be realized if the government can provide a sense of fairness and legal certainty to unhealthy business competition practices. Unhealthy business competition practices have had widespread impacts in various fields, including imported drugs. This is a very concerning issue considering the provision of drugs is one of the efforts of public health services. Everyone has the right to a level of life that ensures health and good health for himself and his family, including food, clothing, boards, and health services as well as necessary social enterprises, and is entitled to guarantees at a time of unemployment, illness, disability, widows/widowers, the elderly or experiencing other lack of living because of circumstances beyond his control.

An example of a well-known drug brand dispute case is between PT. LAPI and PT. GRAHA FAJAR FARMACEUTICALLABORATORIES. PT. LAPI which has the trademark “LAMESON” with Trademark IDM000234288 (Extension of Number471636) for the type of goods: “Pharmacy preparations, ingredients for hand-feeding/diet tailored for medical use, healthy food/food supplement and herbs” which belongs to the class 5 that filed a lawsuit against PT. GRAHA FAJAR FARMACEUTICALLABORATORIES which has a trademark “FLAMESON” with the number IDM00008448 for the type of goods: “Cleaning cotton, plasters and adhesive tapes for medical purposes, odor removal/neutralizer preparations, air fresheners and air purifiers, anti-parasitic preparations, anti-septic cotton, anti-septic, sterile cotton, medium for bacterial breeding, Hygienic pads, sanitary napkins, wound dressings, blood for medical purposes, blood plasma, camphor and camphor oil for medical purposes, deodorant other than for personal use, sanitary napkins for hygiene purposes, sanitary pads for medicine and surgery, fungal dressings, gases for medical purposes, gauze to bandage, diapers or pants for people who are powerless to withstand urination or large, carbolic, fuel and liquid mosquito repellents, insect repellents, exterminators (materials), disinfectants (ingredients), flea repellents (germs), moss exterminator (material), bandages, insect repellent preparations, preparations to eradicate destructive animals, preparations to eradicate bad plants” which also belong to class 5.

The laws governing passing off specifically in Indonesia to date do not exist because Indonesia adheres to the Civil Law legal system. This legal system uses basic divisions into civil law and public law, both of which are not known in the common law system. Directorate General of Intellectual Property Rights only handles passing off cases that indicate a violation of a brand that has a good intention, such as an equation in essence or whole (using a certain form, look (packaging), or design or logo of a particular brand. Therefore, it is important to make a study on the legal politics of drug brand protection in Indonesia.

Given the study of the politics of law leads to law enforcement, in particular protecting IPR, in this case, well-known brands from brand violations including passing off actions, then it should be legal politics to enforce the protection of well-known brands against the act of passing off against the community needs to be realized. From the above problems, the purpose of this research is to analyze and find the political formulation of the law of protection of well-known drug brands from the act of passing off in Indonesia.

**Research Methodology**

The research approach that will be used in this research is the normative juridical approach, which is carried out based on the main legal materials, which include ways to study the theories, concepts, legal principles, and laws and regulations related to this research. Also, the use of normative juridical approaches related to the purpose of the study that seeks to examine the politics of law relating to Law Number 20 of 2016 on Brand and Geographical Indications along with regulations related to the law related to the act of passing off, such as impersonation or denotation of the reputation of well-known drug packaging that has the insecurity of packaging impersonation.

**Discussion**

According to Article 1 of Law Number 36 of 2009, that drug is an ingredient or alloy of ingredients, including biological products used to influence or investigate the physiological system or state of pathology in the determination of diagnosis, prevention, healing,
recovery, improvement of health and contraceptives for humans.

By the Regulation of the Minister of Health of the Republic of Indonesia Number 917/MENKES/PER/X/1993 concerning Mandatory List of Finished Drugs in Article 1 Part 3 that drugs can be grouped into several groups. Classification intended for increased safety and provision of use and security of distribution consisting of over-the-world drugs, limited over-the-world drugs, mandatory drug pharmacies, hard drugs, psychotropics, and narcotics.

Included in the group above are drugs made with chemicals and/or with materials from plant and animal elements that have been categorized as medicinal ingredients or mixtures/alloys both, so that in the form of synthetic drugs and semi-synthetic drugs, respectively. Herbal medicine/traditional (TR) is not included in this group.

Classification of drugs based on marking on the packaging of the drug consists of First is an over-the-world drug can be purchased freely without a prescription and can be purchased at pharmacies and licensed drug stores to overcome (minor illnesses) that are nonspecific. Over-the-top medicine is relatively safe, can be used to deal with mild symptomatic diseases that are widely suffered by the general public whose treatment can be done alone by the sufferer or self-medication (self-treatment or self-medication). The drug has been used in scientific (modern) drug and is shown to have no risk of alarming harm. Marking on the packaging: dot a green circle with a black border. Examples: Oralite, some analgetic or pain killer (painkillers) and some antipyretics (heat-lowering drugs) such as paracetamol, ibuprofen, aceosal (aspirin), some vitamin and mineral supplements/multivitamins such as vitamin C, and vitamin B complex, antacid DOEN, eucalyptus oil, liniment, outer wound medicine, and so on.

Second, is a limited over-the-free drug also called drug list W (W: Waarschuwing= warning/alert) is a hard drug that can be purchased without a doctor’s prescription but its use should pay attention to the drug information on the packaging. In the sale has a limit on the amount and content level must be accompanied by a warning sign, warning P1 - P6. Restricted can only be purchased at pharmacies or licensed drugstores. Restricted over-the-world drugs are relatively safe as long as they comply with the rules of use.

Third, is hard drugs (Drug list G or “Gevaarlijk”, dangerous) including also psychotropics to obtain it must be by prescription and can be purchased at a pharmacy or hospital. However, there are hard drugs that can be bought in pharmacies without a doctor’s prescription that is handed over by pharmacists called Mandatory Medicine Pharmacy (OWA) such as linestrenol, antacids, salbutamol, bacitracin cream, ranitidine, and others.

All types of drugs require a brand in the process of trading. Brands distinguish products from competitor’s products. The brand will provide identification that a product different from other products. Product identification is also useful when sending and promotions. Adding value to the product, consumers see the brand as a benchmark and add value to a product. Brands can add an image of a product. Consumers also tend to choose branded products because more trustworthy, the origin of the product can be shrinking. The need to manage the brand will be more felt by Small Business entrepreneurs who will open branches. The brand is part of intellectual property rights.

The term Intellectual Property Rights (IPR) was first used in 1790, then in 1793. Fichte says the creator’s property rights are in his book. The property in question is not a book as an object, but a book in the sense of its contents. The term IPR consists of three keywords, namely Rights, Property, and Intellectual. Wealth is an abstraction that can be owned, transferred, bought, or sold. Intellectual Property is the property of all the production of intelligence of thought, such as technology, knowledge, art, literature, song composition, writing, caricature, and so on. IPR is also the right, authority, or power to do something about such intellectual property, leading to the politics of the law (leading to the regulation of applicable norms or laws).

So far there are still various opinions including the mention of the term IPR with Intellectual Property Rights/ Hak Milik Intelektual (HMI). One of them is William Fisher who concluded that there are four approaches related to the regulation of Intellectual Property Rights, including: that the regulation of property rights should be maximized for the welfare of many communities thereby should be optimized the balance between the power of exclusive rights that creators have to encourage creation and discovery, as well as the right of the public to acquire or enjoy a creation. This view was influenced by utilitarians Jeremy Bentham and John Stuart Mill. Furthermore, this view was developed by Posner in the
theory of economic analysis of law (theory of economic analysis of law). This theory is a new theory that has an impact on civil law adherents such as Indonesian law. Through economic principles, Posner hopes to improve legal efficiency including efficiency in improving social welfare (social welfare). In the principle of efficiency, Posner emphasizes “pareto improvement” where the purpose of the legal arrangement can provide valuable input for justice and social welfare. According to Posner sees an optimistic future and believes that judges can create good law/liberal law if they diligently adore social change and external changes with a clear goal, namely the efficiency of the judge’s ruling. Furthermore, the depiction of economic viewpoints on the law gave birth to the behavior of law and economy. This behavioral principle is applied in a plural society, which is impossible to avoid transaction fees. The impact of the rule of law is one of the musts that can provide legal certainty and maintain a sense of social justice in society. These rules can be in the form of contracts and arrangements regarding the limits of ownership and property rights directed at achieving social welfare. This view is based on the proposition that a person who has struggled to pour all his abilities or expertise to create something is naturally entitled to his efforts. This approach is derived from Kant and Hegel’s writings which state that individual property rights are crucial in providing a sense of satisfaction in some human needs. This approach is based on the proportion that property rights in general and intellectual property rights in particular, can and should be established to help promote the achievement of justice and attractive culture.

The development of IPR, one of which is the Brand, until now has not been encouraging, for example, seen from the rampant violations, especially against well-known Brands. Explanation of the Brand is certainly inseparable from goods and services in commodity trading. Commodity trading characterized by the existence of a Brand certainly has a selling value that economically can help the income of the community, individuals, or legal entities in obtaining profit. Traded brands have a variety of shapes and advantages to attract consumers interested in buying them.

The establishment of IPR law, especially the Brand is sought to remain oriented to the interests of the national IPR, although the provisions of Trade-Related Aspects of Intellectual Property Rights (TRIPs) cannot be ignored. TRIPs are an instrument of international law, although TRIPs are not the starting point for the concept of intellectual property rights. Various International Conventions have long been born, and have been changed several times. The main and also significant basis of the concept of Industrial Property is the Paris Convention for the Protection of Industrial Property (Paris Convention).

TRIPs contain four groups of settings. First, that associates Intellectual Property Rights with the concept of international trade. Second, which requires member states to comply with the Paris Convention. Third, set your own rules or conditions. Fourth, which is a provision for things that generally include law enforcement efforts contained in the legislation of member states. Indonesia’s newest Brand Law, namely Law Number 20 of 2016 on Brand and Geographical Indications as a modifier of the old Brand Law (Law Number 19 of 1992 on Brands amended into Law Number 14 of 1997 on Brands then changed again to Law Number 15 of 2001 on Brands) has adopted the provisions of trips. The provisions of trips as outlined in the contents of Law Number 20 of 2016 on Brand and Geographical Indications are as follows:

1. **Scope:** The brand includes brands and geographical indications (article 2 paragraph (1)), which are protected consisting of signs in the form of images, logos, names, words, letters, numbers, color arrangements, in the form of two dimensions and/or 3 (three) dimensions, sounds, holograms, or a combination of two or more elements to distinguish goods and/or services produced by people or legal entities in the activities of trading goods and/or services (article 2 paragraph (3)). The brand is used to mark the resulting goods to indicate the origin of the goods (indication of origin). A brand may be regarded as a stamp, mark, spirit, for an item or service. A trademark is any mark or combination of marks capable of distinguishing goods or services from one entity to another. These marks include words, including individual names, letters, numbers, figurative elements, and color combinations, as well as combinations of marks.

Member states may establish registrations based on differences through use if such signs do not sufficiently cause discrepancies in certain goods or services. Even member states can require that the signs be “virtually perceptible”. This provision makes it possible to register shapes (shapes), even smells (smells) as Brand.

2. **Actual Use:** The State may assign registrations
based on actual use, but the actual use of the Brand should not be used as a condition for registration submissions, in other words, the application for registration should not be rejected solely because the planned use is not carried out before the expiration of the three years from the date of application. This is the basis of national regulation, including Indonesia regarding the right to the Brand to be abolished if not used three years continuously.

3. **Nature of Goods**: The nature of the goods or services should not be the reason for the rejection of the registration of the Brand.

4. **Announcement**: The State regulates that before registration, brands are published or announced in advance (article 14) to provide opportunities for other parties wishing to submit objections (disclaimer) to the application for registration of the Trademark as set out in article 16. This provision is the implementation of the principle of openness, as a balance of exclusive rights enjoyed by rights holders.

5. **Rights Granted**: As in other areas of intellectual property rights, the owner of the Brand has exclusive rights to prevent others, without his permission to use identical (identical) or similar (similar) Brands for trade purposes, and in such case, a likelihood confusion shall be presumed, so the key is identical, similar, and likelihood of confusion.

6. **Application Requirements for Obtaining a Brand Certificate**: Each party may apply for an official passage of a registered Brand certificate by paying a fee. In the case that the issued Brand certificate is not taken by the owner of the Brand or its Agent within a period of not later than 18 (eighteen) months from the date of issuance of the certificate, the registered Brand shall be deemed withdrawn and abolished.

7. **Transfer and License**: The right to registered Brand may be transferred or transferred due to inheritance, wills, endowments, grants, agreements, or other reasons justified by law (article 41 paragraph (1)). Registered Brand Owners may grant Licenses to other parties to use the Brand either in part or all types of goods and/or services (article 42). Registered Trademark Owners who have granted licenses to other parties as referred to in Article 42 paragraph (1) may still use themselves or grant licenses to third parties to use the Brand unless otherwise promised.

The State may set the terms of Trademark transfer and the licensor shall be requested to register it with the Minister at a cost. Mandatory licensing has occurred in the United States in the case of Rea Lemon about business competition policy. Defendant company is a company that owns a well-known Brand and controls 75% of the market for the goods. Parodying with a mandatory license on patents, and to achieve healthy competition in the field of lemon juice order, the Federal Trade Commission (FTC) requires the company to give the Rea Lemon Brand for ten years to others with an open offer to interested parties. The FTC sets royalty at 11½%. Apart from this mandatory license, the WTO does not accept the concept.

8. **Brand Registration**: The Brand cannot be registered if: contrary to state ideology, legislation, morality, religion, decency, or public order; similar to, relating to, or simply mentioning the goods and/or services requested for registration; contains elements that may mislead the public about the origin, quality, type, size, sort, the purpose of use of goods and/or services requested for registration or is the name of protected plant varieties for similar goods and/or services; contain information that is not following the quality, benefits, or efficacy of the goods and/or services produced; has no differentiating power; and/or; and is a common name and/or publicly owned emblem.

Constitutive principles (important elements) required the registration of a brand for a person or legal entity to obtain legal protection and recognition of the rights to the brand. Registration is carried out at the Directorate General of Intellectual Property Rights through the examination stage until it arrives at the stage of granting rights to the brand in the form of issuance of brand certificates (registered in the General List of Brands). However, the registration of this brand does not escape the possibility of registration without rights made by certain parties who have bad intentions (bad).

Unlicensed registration often occurs in well-known brands because well-known brands are usually attached to a reputation that makes certain parties with bad intentions try to make a profit by dosing or tarnishing the reputation of a well-known brand. This reputation even though intangible is a valuable asset for brand owners as well as for the law so it needs protection.

The registration of this bad-faith brand is often followed by the filing of a lawsuit in the form of
cancellation of the registration of the brand by the owner of the rights to the original brand. The existence of poor-faith registration and claims of brand cancellation by the original brand owner became the basis for the need to research to see the suitability of the application of the procedure of granting rights to the brand in the Directorate General of Intellectual Property Rights with the brand law governing it.

As it is known that in the business world the main goal is to make a profit, then many industries that do not understand the importance of the relationship between entrepreneurs, consumers, and society will behave profit-oriented solely regardless of other aspects but more concerned with their interests regardless of the interests of the other parties and who encourage them to do so is the availability of consumers who use their products.

Businesses that see it as one of the business opportunities will try to profit through unworthy shortcuts by creating or marketing goods or products by counterfeiting or imitating well-known brands and for consumers is a prestige when using such well-known brands.

Pseudo prestige factor from consumers who feel proud to use well-known brands, especially products from abroad (label minded) is also very affecting and at the same time beneficial for counterfeiting brands, because it gets the opportunity to satisfy the desire of the public through original but fake brands or brands similar to well-known brands, by producing products that are often deliberately tailored to the purchasing power of consumers who want to wear well-known brands but cannot buy them so that they buy original but fake brands as long as they can still prestige. This triggered businesses to make a reputation for selling goods with well-known brands.

The regulation regarding passing off (passing off) in Law Number 20 of 2016 on Brand and Geographical Indication is not yet visible. This is because in Indonesia’s literature previously the act of passing off is not widely known either the definition or in detail the description of the form of action. While this is concluded is that passing off is an act of hitchhiking on a well-known brand. In contrast to the common law system countries, such as the United States, United Kingdom, Singapore, Malaysia, or former colonies of the British empire has first known and regulated what is meant by passing off as a form of unfair completion (unfair completion) in the field of trade.

In accommodating the passing off of well-known brands in Indonesia, it is necessary to protect well-known brand rights holders in Indonesia. Such protections are in the form of regulation of laws banning monopoly and unhealthy business competition or antitrust laws or more specifically in the law on brands by the Government of Indonesia. Unfortunately, in Law Number 5 of 1999 on Prohibition of Monopoly and Unhealthy Business Competition the rules on passing off have not yet appeared and are regulated rigidly. The regulation in Law Number 5 of 1999 concerning Prohibition of Monopoly and Unhealthy Business Competition, implies the main point that the existence of antitrust regulations is intended only to ensure that there are adequate clauses on business competition in the market openly or closed on goods or services and prevent a business entity from becoming strong through monopoly practices, monopsony, market mastery, and conspiracy. Therefore, it is necessary to note for the Government of Indonesia in the future so that passing off is regulated also in it.

Related to the act of passing off of a well-known brand is illegal and if the brand that carried out the defection is registered with the Director-General of Intellectual Property will also be rejected because it is considered as a brand that has similarities in essence. The basis of its rejection is contained in Law Number 20 of 2016 on Brand and Geographical Indications, Article 21 paragraph (1), plus paragraph (3) if the registration is done in bad faith

Furthermore, it is also necessary to add to existing laws, among others, philosophical elements at the time of the registration process. The philosophical element is given as the intent of resistance from bad faith. Businesses should be able to give a sign labeling a product as a representation of the reputation of the product. This is done considering that giving a brand name to a product is not easy. Especially when giving a brand name to the creation of his work made with energy, time, mind, and capital that is not a little. Another consideration is that a brand is not allowed to have a multi-interpretation of the understanding of a well-known brand and similarities in essence or its entirety. The law on brand and geographical indications in the future should be able to provide certainty to the Judge about the extent to which a person can provide proof of public knowledge, vigorous promotion of the
brand, evidenced by anything and not providing a period of limitation of proof of brand registration.

The provisions of Article 21 above actually implied almost the same meaning as the act of passing off on a brand by a business person or business entity. The act of passing off itself is an act that undermines the reputation of a well-known brand. This is because well-known brands are already known to the general public for goods and services. Therefore the act of passing off can be analogized as an equality clause in essence. In the old law, this was regulated but clarified again in Law Number 20 of 2016 on Brand and Geographical Indications. However, the law is still unclear in explaining the passing off. Therefore it is expected that the upcoming brand laws regarding the elements of passing off actions, philosophical elements, and the existence of multi-interpretation of well-known brands and similarities in essence or whole can be detailed in detail and clearly.

The use of products with certain brands in addition to the goodwill owned by the brand itself in addition to the fanatical nature of consumers towards the brand is considered to have the advantages or advantages of other brands. The fanatical nature of consumers is not only to meet the needs, but there is also a priority of prestige and gives the impression of the wearer so that by using their perception is a “symbol” that will give rise to a new lifestyle.

There are differences in perceptions in society about brands giving rise to various interpretations, but even so means that the actions of people who produce an item by taking the fame of others can not be justified just like that, because by allowing irresponsible actions it indirectly produces and justifies someone to deceive and enrich themselves dishonestly. The act of using well-known brands owned by others, as a whole is not only detrimental to the owner or holder of the brand itself as well as the consumers but the broader impact is detrimental to the national economy and more broadly also harms international economic relations.

**Conclusion**

A drug is an ingredient or alloy of ingredients, including biological products used to influence or investigate the physiological system or state of pathology in the determination of diagnosis, prevention, healing, recovery, improvement of health, and contraceptives for humans. Drug brands in Indonesia are protected by Law Number 20 of 2016 on Brand and Geographical Indications as a modifier of the old Brand Law (Law Number 19 of 1992 on Brands which was amended into Law Number 14 of 1997 on Brands then changed again to Law Number 15 of 2001 on Brands) has adopted the provisions of TRIPs. Brand laws include brand scope, actual use, nature of goods, announcements, rights granted, application requirements for obtaining brand certificates, transfer and licensing, and brand registration. The politics of the protection of well-known drug brands in the future, that in accommodating the passing off of well-known drug brands in Indonesia, it is necessary to protect holders of well-known brand rights in Indonesia. Such protections are in the form of regulation of laws banning monopoly and unhealthy business competition or antitrust laws or more specifically in the law on brands by the Government of Indonesia. Furthermore, it is also necessary to add to existing laws, among others, philosophical elements at the time of the registration process.

Factors Associated with Disaster Response Competency of Nursing Students in Graduation Years

Do-Young Lee¹, Gie-Ok Noh²

Abstract

Background: This study was conducted to provide the basis for the disaster nursing curriculum through grasping the degree of disaster preparedness attitude and disaster response competency of the senior nursing student.

Method: Data was collected through a questionnaire for senior nursing students from five universities in South Korea. A total of 168 data were analyzed through the IBM SPSS 25.0 program.

Finding: Disaster response competency were most strongly predicted by “satisfied” major satisfaction, followed by “average” major satisfaction, “realization of good deeds” motivation, “yes” experience of disaster education. The explanatory power by these variables was 19.7%.

Conclusion: The results of this study suggested that the experience of disaster education is important to improve the disaster response competency of nursing students. In preparation for disasters that are unpredictable and lead to serious resource shortages, nursing colleges will have to make efforts to provide sufficient education and training.

Keywords: Disaster, Graduation, Nursing students, Preparedness attitude, Response competency.

Introduction

Disasters result in numerous human and property loss, and even extreme stress and health problems for contemporaries who experience them indirectly¹. In Korea, the establishment of a national disaster management system since 1995 has led to a multi-disciplinary interest in disaster-related research, which is no exception in the field of nursing², ³. Disaster education in Korean nursing began in 2005 at the Armed Forces Nursing Academy, and disaster nursing is also operated with a large proportion⁴. There are also survey items on disaster management in the certification assessment standards of medical institutions, and we strive to improve nurses’ disaster nursing competency by conducting regular disaster training and training on our own⁵. However, disaster preparedness education for nurses is partially conducted, and disaster preparedness education for nursing colleges is insufficient⁶. Disaster nursing is the systematic use of professional knowledge and skills to provide the nursing activities required by the subject to reduce the risk of life and health caused by the disaster⁷. In the event of a disaster, the need for medical workforce increases, so there should be a vast and diverse workforce suitable for the response system according to the magnitude of the damage⁸. In this respect, nurses should have attitudes and competency to various possible disasters. In order for nurses to be able to prepare for disaster situations, the nursing curriculum needs to include disaster competency training⁹, but most universities still address disaster nursing partially in
some subjects such as emergency care and community care.

Nurses play a very important role as severity classification and first aid providers, care providers and mental health counselors at a time when there is a growing demand for health care due to many patients in the event of a disaster. However, nurses were reported to have insufficient experience in disaster-related education and low disaster response competency. Because disasters occur unexpectedly and cannot be learned directly from experience, disaster response competency requires systematic education and training in advance, which is necessary from nursing students when basic education begins.

Therefore, this study aims to provide basic data for the development of disaster nursing education courses and programs by identifying disaster preparedness attitude and disaster response competency for the senior nursing students and identifying factors affecting disaster preparedness.

**Method**

**Study Design:** This study is a correlation survey study attempted to identify the disaster preparedness attitude and competency of the senior nursing student and to identify the factors affecting the disaster response complication.

**Participants:** The subjects of this study were students in the fourth grade (graduation grade) who were attending the nursing department of five domestic universities. The number of samples was calculated as significant level .05, power .95, effect size 0.15 and predictors 8, referring to the preceding study of disaster experience and disaster preparedness of nursing students. Using the G*power 3.1.9 program, the minimum number of samples required for regression was 160.

**Measurements:** The disaster preparedness attitude was measured by a tool developed by Moabi. This tool consists of a total of 11 items, and four negatives were reversed. The higher the score on the Likert 5-point scale, the better disaster preparedness attitude. The time of tool development, the reliability of Cronbach’s α was .82 and the reliability of the instrument as assessed by Cronbach’s alpha was .78 in the study. The disaster response competency was measured by Huh as well as the contents provided in ICN Disaster Nursing Capacity Framework and the nurse’s disaster response tool developed by An et al. The tool consists of four sub-regions: disaster prevention (6items), disaster response (7items), disaster copy (10items), and disaster rehabilitation and recovery (3items) total 26 items. The higher score on the Likert 5-point scale, the higher the disaster response competency. In Hu’s study, the reliability of Cronbach’s α was .92, and in this study the reliability of Cronbach’s α was .96.

**Data Collection:** Data were selected from September 10 through October 15, 2020. For data collection, the purpose, procedures and method of this study were first explained to the director of the nursing college and then the survey was approved. Using the online questionnaire, we explained the purpose and method of the study and collected data from those who agreed to participate in the study. Online questionnaires were distributed in the form of access URLs via SNS of senior nursing students from five universities who had obtained consent to the survey. An anonymous questionnaire was used that did not include identifiable personal information.

**Statistical Analysis:** The data was analyzed using IBM SPSS 25.0. Of the 177 questionnaires returned, 9 questionnaires were excluded for having missing data. General characteristics, disaster preparedness attitude and competency were analyzed using frequency, percentage, mean, and standard deviation. The differences in disaster response competency according to characteristics were analyzed using independent t-tests or one-way ANOVA with Scheffé test for post-hoc analysis. The correlations between disaster preparedness attitude and disaster response competency were analyzed using Pearson’s correlation coefficient. The factors associated with disaster response competency were analyzed using a step-wise multiple regression analysis.

**Results**

**Characteristics and disaster response competency of nursing students in graduation years**

Female students accounted for 87.5% and 79.8% of those under the age of 25, with 96.4% showing more than average major satisfaction. Because of the good employment, nursing was the most common choice of department, and 69.0% said they were healthy. 85.7% had experience in disaster education, and most (97.0%) were aware of the need for disaster education (Table 1).

Disaster response competency has been found to be significantly high for those who show satisfaction with
their majors (F=14.12, p<0.001), those who have chosen nursing for their Realization of good needs (F=3.29, p=0.013), those who have experience in disaster education (t=2.80; p=0.006), and those requiring disaster education (t=2.45, p=0.016).

Table 1: Characteristics and disaster response competency of participants (n=168)

**Disaster preparedness attitude and disaster response competency of participants:** The disaster preparedness attitude of the graduate nursing college student was confirmed to be 38.77±3.95 points on average on a scale of 44 points. The disaster response competency averaged 84.73±16.70 points on a total score of 130 points. In the lower section, the competency for disaster rehabilitation and recovery was found to be the highest level (Table 2).

Factors associated with disaster response competency: In order to identify the factors influencing the disaster response competency of the senior nursing student, multiple regression analysis was conducted by injecting significant variables among the characteristics of the target and disaster preparedness attitude. The variables for Major satisfaction, motivation for choosing the department of nursing (motivation), experience of disaster education, need for disaster education, and need for disaster education were converted to dummy variables and statistical analysis was conducted. There were no problems with the autocorrelation (Durbin-Watson=1.742) and the multicollinearity (tolerance=0.15–0.99; VIF=1.01–6.82) in the implementation of multi-recursive analysis.

The regression model was significant (F=11.29, p<0.001), and average to satisfied major satisfaction, choosing nursing major for realization of good deeds, experience of disaster education were found to be significant predictors of disaster response competency. The adjusted R2, indicating the model’s explanatory power, was 19.7%. Disaster response competency were most strongly predicted by “satisfied” major satisfaction (β=0.97), followed by “average” satisfaction (β=0.77), “realization of good deeds” motivation (β=0.18), “yes” experience of disaster education (β=0.18) (Table 4).

Discussion

In this study, in order to provide basic data on disaster preparedness, the disaster response competency and disaster preparedness attitude of the senior nursing student were identified and the influencing factors were presented. As participants in this study were fourth-grade nursing students ahead of graduation, their experience in disaster nursing education was confirmed by 85.7% who were higher than the preceding studies. In addition, most (97%) of those surveyed were aware of the need for disaster education. This is believed to be COVID-19, reflecting the present time in the infectious disaster situation, and to have shown a higher perception than the preceding studies.

In this study, the disaster response competency according to general characteristics was found to be significantly higher if disaster education experience was present, if disaster education was required. In the preceding study, disaster response competency was high if disaster-related education was received. Therefore, in order to enhance competency, it will be necessary to continuously provide disaster education.

In the disaster response competency of the senior nursing student, the competency for disaster rehabilitation and recovery was identified as the highest level in the sub-item. The study by Ann & Kim said that in order to demonstrate disaster preparedness, one needs to be confident about one’s ability through professional and
specific education. A study by Huh & Park suggested the need for various aspects of education in disaster nursing subjects, including trauma treatment, severity classification, and the use of protective equipment. Therefore, the training of disaster response competency will require more enhanced training for those areas by first identifying insufficient capabilities. The higher the level of disaster preparedness attitude of the senior nursing student, the higher the level of disaster response competency. This supports the results of a prior study that presents factors affecting the ability to perform disaster nursing as a perception of disaster.

Finally, Disaster response competency were most strongly predicted by “satisfied” major satisfaction, followed by “average” average, “realization of good deeds” motivation, “yes” experience of disaster education. This is consistent with the presentation of the need for disaster education in many preceding studies to enhance disaster response competency. Based on the research results, it can be suggested that disaster education be implemented as a realization of good needs through active participation and experience in nursing curriculum.

Although this study is meaningful in that it presents factors for improving disaster response competency, it is limited in generalizing the results because it involves limited participants. Further research is also required to verify additional variables affecting the disaster response competency, with the explanatory power of the variables identified in this study being low at 19.7%.

Conclusion and Recommendations

This study is meaningful in that it identifies the attitude and competency of the senior nursing student to prepare for disasters and presents the factors that affect the disaster response competency. Based on the results, I propose an integrated education program of theory and practice that can improve the disaster response competency of nursing college students. It also suggests attempts for qualitative research about the awareness, demand and satisfaction of disaster education of nursing students.

The Implementation of *Hypnobirthing* Effect on Pain Relief in the Intrapartum Period at Klinik Pratama Rakyat Hospital Makassar

Een Kurnaesih¹, Nia Karuniawati², Siti Fatimah Azahrah³, Sundari², Alfina Baharuddin⁴

¹Associate Professor, Department of Midwifery Faculty of Publik Health, Universitas Muslim of Indonesia, ²Lecturer Department of Midwifery Faculty of Publik Health, University Muslim of Indonesia, ³Practitioners Psikolog Kuningan Jawa Barat, ⁴Lecturer Department of Public Health, University Muslim of Indonesia

**Abstract**

The pain of childbirth is one of the factors that causes a mother to become anxious even to the point of despair, so mothers tend to choose a shortcut to speed up their childbirth, either by requesting an operation, or by taking a remedy to relieve the pain by taking an analgesic drug, whereas pain caused during childbirth is pathological because of the effects of changing uterus that creates pathways or openings.

The type of research is experimental quantitative research using *Quasi Experimental* method, namely experimental design with the observation design (measurement pain intensity) before and after treatment (*Hypnobirthing treatment*) which consists of the two group, namely the intervention group (*Hypnobirthing*) and the control group. Sampling was taken from June to August 2020 with the number of samplings intervention group (*Hypnobirthing*) as many as 20 respondents and the control group as 20 respondents. Data analysis method uses Univariate and Bivariate with t-test using SPSS Computer Program.

The results were obtained with the average of pain intensity in childbirth after being given *Hypnobirthing* had a decrease in pain while the control class was upgraded. The results of statistical test are presented *ρ valua* by 0.000 at the mistaken rate of (α) 5% or 0.05 (trust 95%) so value is ρ < α. The data indicated that there was a significant (apparent) of *Hypnobirthing* treatment in childbirth relief. The conclusion of this research was that there was a significant *Hypnobirthing* effect on the treatment of childbirth at Klinik Pratama Rakyat Hospital. That was expected for midwife duty at Klinik Pratama Rakyat Hospital to adopt the method of *Hypnobirthing* to assist the mothers with normal childbirth.

**Introduction**

The delivery process is a series of events that begins with the expulsion of the baby at term or near term, accompanied by removal of the placenta and fetal membranes from the birth canal. Problems that occur in the process of childbearing often have an impact on the death of both mother and fetus. The Maternal Mortality Rate is an indicator to see the degree of women’s welfare and the target set in the Millennium Development Goals (MDGs) development goal 5, namely improving maternal health, which targets to be achieved by 2015. The number of maternal deaths or 102/100,000 births life, therefore efforts to achieve these targets still require commitment and continuous hard effort¹,²,³,⁴.

In the process of childbirth, of course, many things happen to the mother’s body and to the fetus’s body, one of which happens during childbirth is the pain that is felt...
by the mother, this is a normal or natural occurrence but many mothers do not understand that pain is good during childbirth, this is due to changes in the body, especially in the uterus, due to the influence of hormonal work that occurs during childbirth. There are many things that can be done by mothers to cope with feelings of pain during childbirth, including by adjusting the breathing patterns that are often taught during ANC but recently there are relaxation methods that can be done by mothers to overcome pain, one of which is “Hypnobirthing”\(^5,6,7\)

This childbirth relaxation method called “Hypnobirthing” was developed by a midwife named Lanny Kuswandi through Fr. Jacson in Australia who made her realize that women are very special human beings and in Indonesia this method began to spread. Hypnobirthing is a therapeutic method that uses hypnosis as a means to reach the client’s subconscious mind, so that the client can be directed to thoughts that are guided by the person who hypnotized them, so that the pain felt by the client can be channeled through a pleasant imagination and will reduce feelings pain that is being experienced. Pain during the intranatal period/delivery period is physiological pain or normal pain because the pain felt by the mother is pain caused by widening the birth canal or cervix, this is very necessary in the delivery process\(^8,9,10,11\)

**Material and Method**

The research design was a quasi experiment with a pretest design with a control class. In this design, the research was conducted 2x, namely before the experiment (pretest) and after the experiment (posttest). The sample in this study were 40 people, 20 intervention groups and 20 control groups. In the experimental group, a pre-test was carried out, then hypnotherapy was carried out then a post-test was carried out. Whereas in the control class only IEC was given to overcome labor pain without being given hypnotherapy and carried out a post tes

</table>
The pain experienced by the mother during childbirth is due to changes in the physiology of the birth canal, where the uterus undergoes changes that occur in its muscles, especially the cervical area, which was originally thickened at the bottom of the cervix to become thin or begins to open, the muscles of the uterus, namely the upper and lower segments of the uterus are quite clear but with the effect of the contraction, the corpus and the service eventually change, namely the opening of the cervix which causes pain. The literature that supports this theory is the opinion that labor pain is caused by the process of cervical dilation, uterine ischemia and stretching of the lower uterine segment and compression of the nerves in the cervix\textsuperscript{12,13,14}.

That pain depends on the work and the large and small nerves that are in the root of the dorsal ganglion. The stimulation of the large nerves will increase the mechanism of the activity of the substance gelatinosa which results in the closing of the door of the mechanism so that T cell activity is inhibited and causes the delivery of stimuli to be obstructed. Stimulation of small fibers will inhibit the activity of the substance gelatinosa and open the door to the mechanism, thereby stimulating T cell activity which in turn will deliver pain stimuli\textsuperscript{15,16}.

In this study, the pain intensity of the respondents varied both in the intervention group with hypnobirthing and in the control group that was given counseling, meaning that hypnobirthing was not done. Based on table 5.1 above, in this study before hypnobirthing was carried out, respondents who experienced moderate pain and severe pain were aged respondents, it was found that respondents with age <20 years were the intervention group, namely 2 (10%) respondents while the control group was 0 (0%) respondents with 20-30 years of age in the Intervention group were 17 people (85.0%) and the control group were 20 people (100%) and from the age group over 30 years the intervention group was 1 person (2.5,%). produced in Magfiroh’s (2012) research in Adam and Umboh (2015) that the age of mothers who are <25 years old feels more severe pain than those aged 25-35 years. This is because a young person does not have enough experience with labor and pain, so they perceive pain to be heavier than older people. In addition, young people have a more intense pain sensory than mothers who have an older age. Youth tends to be associated with an unstable psychological condition that triggers fear and anxiety so that the pain you feel is getting stronger. Age is also used as a factor in determining tolerance to pain,\textsuperscript{5,9,12,17}

The hypnobirthing method is an attempt to naturally instill positive thoughts or give psychological suggestions or subconscious thoughts during childbirth and preparation for labor based on the belief that every woman has the potential to undergo a normal, calm and comfortable birth process. The basis of hypnosis is the use of our ability to directly access the subconscious. Usually we are only aware of the thoughts that are in our conscious mind. We are consciously focused. to something in front of our eyes, we consciously speak and say words, or consciously we try to remember what we have done. But when doing these things, the conscious mind collaborates with the subconscious, our thoughts are carried or directed by a thought guide who performs Hypnosis in women who experience pain when facing childbirth by diverting thoughts (Kartasis) until they want to follow the commands direct it\textsuperscript{8,9,11,15}.

Measurement of pain intensity in labor begins during the active period, namely starting the IV opening and is assigned as a pre test. Hypnobirthing treatment was carried out at the VII opening and every time the mother felt pain until the VIII opening and was determined as a post test. For the control group the pain scale was measured before and after the mother was given counseling/IEC\textsuperscript{8,11,14}.

The hope of the Mother of Surakarta, that the majority of maternal pain levels before being given hypnobirthing (pretest) were severe pain as much as 70.0% and after being given hypnobirthing (post test) the level of maternal pain was moderate pain as much as 90%. Test results with. Based on the explanation above, it can be concluded that the use of the hypnobirthing method can reduce the intensity of pain during labor\textsuperscript{18,19}. There is a decrease in labor pain after hypnobirthing is done because this method brings respondents to integrate with the natural body movements and rhythms during childbirth, allowing the body and mind to work, Wilcoxon obtained a value of $\rho$ value = 0,000.

**Conclusion**

Hypnobirthing techniques can minimize labor pain because with hypnobirthing, mothers are required to achieve a very relaxed and comfortable condition during labor. The influence of the hypnobirthing method on pain management during childbirth is because this method teaches natural relaxation techniques, so that the body
can work with all nerves in harmony and with penu cooperation.

Loss of Value *Bundo Kanduang* in the Attention of Parents Who Affect Stress in Young Stunting

**Eravianti**¹, Delmi Sulastri², Adang Bachtiar³, Yantri Maputra⁴

¹Doctoral Program in Public Health Sciences, Andalas University–Indonesia, ²Professor of Biomedical Science, Andalas University–Indonesia, ³Professor Association in Public Health Sciences, Indonesia University–Indonesia, ⁴Professor Association of Psychology, Andalas University–Indonesia

**Abstract**

Research goals to know the stress and stress risk factors of a parent’s attention to the loss of value *Bundo Kanduang*. Sampling techniques by purposive sampling. Data collection is conducted in the in-depth interview, observation of participation, and secondary data. The Number of subjects 5 people. The research was conducted in March 2020. The subject of youth research stunting Padang. The attention of parents is the dominant factor in causing stress. Based on the results of qualitative research of 5 informants. If parents’ attention is good then low child stress levels For example children can control emotions, control themselves, be calmer when facing problems, easily socialize with the surrounding environment as well as vice versa. The loss of the value of *Bundo Kanduang* in the attention of parents greatly affects the stress experienced by teenagers. From qualitative analysis, 5 informants say the parents’ attention to risk factors related to stress.

**Keywords:** Stress, attention of parents, family, stunting, padang.

**Introduction**

Teenagers are the ages at which someone wants to try new things. So everything about the Internet can attract attention. With a big interest, then the desire to explore itself will be great too. The desire to be known and noticed by many people through the Internet. This can lead to negative behaviours. For example, writing something that belongs to someone else’s privacy, uploading someone else’s inappropriate images, can even make fun of your friends in social media. Dismissive behaviour, insult, or misled someone on the internet is included in cyberbullying or violence in cyberspace (Internet)¹.

Technology contributes to adolescent mental health. The use of social media is one cause of stress in teenagers. The prevalence of stress and depression continues to increase among adolescent generations. The prevalence of emotional mental disorders in teenagers over 15 years old amounted to 9.8%. This figure increased compared to 2013 by 6%. In West Sumatera Province, 4.5% of adolescents experienced emotional mental disorders. Emotional disorders occur in the form of stress, anxiety, and depression. As many as 25% of teenagers experience mild depression and 7% of teenagers with growing depression have attempted suicide attempts².

Poor mental development such as easy stress on teenagers is exacerbated by stunting. Nationally, the stunting prevalence of 2018 years of stunting in Indonesian adolescents decreased to 25.7% (7.2% very short and 18.5% short) in groups of aged 13–15 years and 26.9% (4.5% is very short and 22.4% short) in groups of age 16–18 year. The prevalence of stunting in adolescents in West Sumatra in 2018 the prevalence of stunting is almost equal to the national number of 25.6% (very short 7.2% and short 18.4%) In the age group of 13–15 years and 26.8% (very short 3.7% and short 23.1%) In the age group of 16–18 years³.

Young stunting is more stress-prone than not stunting. Stunting sufferers are significantly less happy, depressed, and frustrated. Stunting has associations with...
Increased cortisol concentrations. According to study in Jamaica in children aged 8–10 years showed that the concentration of saliva cortisol was higher than that of normal children. Family roles and support are crucial in overcoming stress. If teenagers don’t get the attention of parents, a problem is easy, because there is no telling of the youth.

Many factors are causing stress on adolescents, one of which is a factor of parental attention. Pressure in the family is one source of the stress of teenagers. The need for parent and adolescent cooperation in assisting the youth faced by teenagers, parents’ attention is very main in addressing adolescents’ problems especially stressing the quality Improvement Program of education through the improvement of high intensity–enriched curriculum, longer formal learning period, more school assignments and the necessity of becoming a leading centre has been stressful among adolescents. Young people suggest that they experience stress due to the lack of attention to parents. Research is conducted to find out the stress and stress risk factors in the family in stunting adolescents.

Method

Research is done to 5 informants. Data retrieval was conducted in March 2020. The scope of research is included in the youth health sphere. This research is a qualitative study with a descriptive approach. Qualitative method can make it easier for researchers to describe the parents’ attention factors affecting young stunting stress. This research sample is the teenage stunting of Padang City which meets the criteria of inclusion. The study subject chosen by the Purposive sampling method chosen is not random but is based on a particular consideration made by the researcher himself, i.e. by the criteria of the inclusion of the established researchers. The number of subjects is 5 informants, students, parents, teachers, psychologists, and Bundo Kanduang. The free variables in this study are stressful. The Variables tied in this study are the concern of parents. Variables of parents’ attention are obtained through a direct interview in-depth interviews with the informant. Each informant is interviewed from a validated researcher’s question. Data analysis is done along with the data collection process. The data analysis process begins with collecting all the interviews and observation data directly.

Results

Qualitative analysis results are aimed at knowing the parental attention factor as a risk factor for adolescent stress. Qualitative data collection is done with an in-depth interview with some informants. In this qualitative study obtained the total informant of 5 persons in Table 1 below.

Source: Data analysis, 2020.

The attention of parents is the most dominant factor in causing stress based on qualitative research results. If parents’ attention is good then the child’s stress levels are low for example the child can control emotions, control themselves, be calmer when facing problems, not alone, easily socialize with friends and surroundings. Likewise, conversely if parents’ attention less then the stress of a high child that means children are difficult to hang out like to be alone, often cry, do not concentrate on learning, easy emotions, often daydream, feel worthless, and so forth.

Based on information from students it is known that the attention of less or too excessive parents can cause stress such as the following statements “But yes, sometimes there is good and not good. Too much attention is also not good, to the point that when I want to take an exam I am told to study continuously, sometimes I get tired myself, I want to take a break first. But it’s better to do it so that the enthusiasm for learning. It’s a pity for those whose parents are too ignorant, but it’s good to be in the middle (in terms of parental attention), who are just doing it. Being watched but not restrained (Inf-1)”.

Table 1: Characteristics of qualitative research informant
The same information is also stated by parents that the child’s attention should be reasonable and not excessive, by the following statements “Attention is important. Sometimes these mothers pay attention too much or are sarcastic, but that includes that attention, more like organizing it also includes attention. It’s just that later the children won’t be independent, that’s all they need attention. It needs that attention to a reasonable degree (Inf-2)”.

The same is stated by teachers that parents’ attention affects the child’s learning process, such as the following statement “There’s no way a child can get good grades if the parents don’t pay attention to the learning process ... indeed a child gets attention from parents, then their parents’ background also has the education, then their economy is stable, the child is better (Inf-3)”.

The attention that parents give to their children must be sufficient and reasonable. Excessive attention makes the child depressed and unnoticed to make the child feel uncherished. It by the statements of students and parents as follows “In my opinion, the attention is sufficient, not excessive and insufficient. Also not restrain so the child feels depressed. Parents must know the nature of their respective children, right? So, just adjust how the attention is (Inf-2)”.

Teenagers are the time of transition from children towards adults up to their young people as a story of telling them, the attention of good parents will make the child feel comfortable and open to tell his problems. The children are not guided in patience not by being haunted or divided with problems that occur. It suits the following statements “Parents have time for their children, not too busy just to work because children also have problems that cannot be solved by themselves. Parents pay attention, not in the form of yelling, but what guides the child to better understand what the parents mean (Inf-1)”.

At the Minangkabau community, the attention of a good mother is closely associated with the values and the role of the Bundo Kanduang. Minang people are not familiar with the figure of Bundo Kanduang as the first Madrasah child in the family than the father figure. Bundo Kanduang is a figure of educators and observers in the family even broadly for his people according to the following statements “Bundo Kanduang is closely related to women. The role of Bundo Kanduang in the family is of course inseparable from how to educate children, even to the extent of educating their families. Not only their biological children, to their families too. In a brief sense, Bundo Kanduang is a mother figure who not only educates her children but can also educate her people (Inf-3). “The values adhered to by Bundo Kanduang are like guiding children with love (Inf-4)”.

Bundo Kanduang is a symbol of indigenous women in Minangkabau. Bundo Kanduang is a designation for the mature Minangkabau woman and understands the customs. The following are the opinions regarding the Bundo Kanduang according to the following statement “If there are mothers who are considered to be able to protect, not from their families, usually, it is determined from the community, it is agreed by the community who becomes Bundo Kanduang who can solve problems, who can be asked for advice (Inf-2)”.

Now the role of Bundo Kanduang is necessary for educating the child, the attention of good parents according to the teachings of the Bundo Kanduang according to the following statement “Women as direction/advisors, women become the upstream and estuary of the problems of their people. Because this principle states that parents are a place for everything, a place to ask questions, to tell stories and to educate and guide children (Inf-5)”.

Bundo Kanduang plays an important role in educating the child, but not just the mother in the house but has an important role in the community, but the role and values of this Bundo Kanduang Bundo have begun to disappear. Today mothers are busy working and leaving cultural values that should be retained according to the following statement “Parents are sometimes busy alone, children too. No more communication (Inf-2)”.

Every Minang woman has the role of being a Bundo Kanduang in educating the child. In addition to mothers, children can be educated by their grandmother and challenge who also know the sublime values of Bundo Kanduang. In ancient times children lived in large families so much attention was received, but at present, there was only a core family consisting of mother and father alone. So the less attention of parents will be very influential to the child’s stress. This corresponds to the following statement “Previously, the name of educating children was inseparable from the mother alone, there were her grandmothers, grandparents, her mother. If now they have lived alone (Inf-3)”.
Here is the opinion of the informant to revive the role of the *Bundo Kanduang* in addressing the child’s problem, according to the following statement “The concept of Bundo Kanduang has been running for a long time and has been implemented in West Sumatra P2TP2A, PUSPAGA and other educational organizations. This concept should also be applied in PAUD schools, kindergartens and other formal schools (Inf-4)”.

Based on information from students it is known that the attention of less or too excessive parents can cause stress. The same information is also stated by parents that attention to the child should be appropriate and not excessive. The same is stated by teachers that parents’ attention affects the learning process of children. Adolescent depression can be triggered by events that are often associated with family problems and conflicts. Stressful events and lack of social support from peers and family can also trigger the emergence of depressive conditions in adolescents.

The presence of social support, especially from parents, will provide physical and psychological comfort for children. Families can act as social support providers that help individuals when a problem arises. Individuals who gain high social support will be more optimistic and more able to adapt to stress. The support that families can provide can be emotional, award support, tool support, and informative support. This research is in line with research as the effect of the parent’s attention towards student stress levels that there is a parental concern with a student stress level of 2017 with a P-value of 0.000 and a correlation value of coefficient 0.549 included in the moderate relationship level.

As a parent should pay attention to his children, such as preparing breakfast, providing learning facilities, giving motivation, giving guidance to the child because in the childhood children began to grow and the child began to seek his identity, then the need for support and motivation from parents. Busy parents tend to be more concerned with the work than to gather with their children and do not give more attention to their children then the child will feel uncared for. As young children desperately need the attention and affection of their parents, it makes them more meaningful and more confident to actualize themselves. From interviews with teachers and parents it is known that attention is important and needed by the child, but because the condition of a busy parent with work makes parents’ attention to the child become not optimal. Interviews with teenagers are also known that they need parents’ attention to encourage them to learn.

The attention of parents is good then low child stress levels For example children can control emotions, control themselves, be calmer while facing problems, not alone, easily socialize with friends and surroundings. And vice versa if the attention of parents less then the stress of a high child that means children are difficult to hang out like to be alone, cry, do not concentrate on learning, emotions, often daydream, feel worthless and so forth.

The attention of parents in terms of the *Bundo Kanduang* is greatly reduced, because of the current aspects of the *Bundo Kanduang* administration, its nature to help guide the child in the Minangkabau region. So, it’s the attention of parents is also reduced because of the teachings of the *Bundo Kanduang* that do not cling anymore to parents. The interview results from 5 informants, especially in terms of the role of *Bundo Kanduang*, have been greatly applied outside the home or inside the house, especially when teenagers are now influenced by modern culture and the use of gadgets and the world of the internet.

**Conclusions**

Qualitative analysis obtained statements from 5 informant says that the risk factors of parental attention are related to stress.

**Acknowledgements:** The author says with a big thank you to the intellectual association “Bundo Kanduang” Padang City who has appointed me as the team leader and provided assistance in the research of “Loss of value *Bundo Kanduang* in the attention of parents who affect stress in young Stunting”.

The Effect of Family-Based Empowerment on Adolescent’s Nutritional Status in Tana Toraja

Erni Yetti R.1,  Zadrak Tombeg2, Anto J. Hadi3, Saskiyanto Manggabarani4

1Lecturer of Health Promotion and Behavioral Science, Akademi Kebidanan Sinar Kasih Toraja, Tana Toraja, Indonesia, 2Lecturer of Mother and Children Health, Akademi Kebidanan Sinar Kasih Toraja, Tana Toraja, Indonesia, 3Lecturer of Public Health, Fakultas Kesehatan, Universitas Aaufa Royhan, Padangsidimpuan, Indonesia, 4Lecturer of Nutrition, Sekolah Tinggi Ilmu Kesehatan Pertamedika, Jakarta, Indonesia

Abstract

Adolescent’s nutritional status is one of the problems of public health nutrition. Adolescents or teenagers are a group that is sensitive to nutrition which has an impact on increasing the prevalence of degenerative diseases due to excess nutrition. This study aimed to analyze the effect of family-based empowerment on the teenager’s nutrition status in Tana Toraja. The research design used a quasy-experiment with a pre-test and post-test design with a control group design. It was carried out on 64 overweight students consisting of 32 intervention groups and 32 control groups as well as simple random sampling and data analysis using Hotelling’s T² test. The results showed that family-based empowerment was significant in reducing overweight case due to adolescent’s nutritional status against obesity prevention with a value of p = 0.000 <0.05. The conclusion of this study is that there is an effect of family-based empowerment on the adolescent’s nutritional status in Tana Toraja. It can be a reflection for teenagers who have experienced an overweight nutritional status so they can adopt a healthy diet. This study shall performed further in public nutritional status.

Keywords: Nutritional Status; Adolescent; Empowerment; Family.

Introduction

The increased prevalence of obesity in adolescents is placed as a risk factor for degenerative diseases among youth. Risk factors for obesity include an energy-dense diet, high consumption of sugary drinks, a diet such as snacking and high sedentary behavior level. The case are also worse with the number of low physical activity level intake, especially in daily basis. Research reports show that obesity is associated with a high intake of energy dense, low in foods such as soft drinks, savory chips, sweet biscuits and sweets, and also an increase in the time spent in their association(1). Based on the 2013 South African National Health Report and Screening Survey (SANHANES-1), the number of participants who aged 18-24 were reported to be inactive and over-nourished (50.2%)(2).

WHO warns that obesity and overweight cases are the fifth leading risks of global death (3). Cardiometabolic risk factors in obese adolescents in Kuwait have a poor quality of life and health compared to adolescents with healthy weight, this can be seen in cultural differences between western and Kuwait societies (4). The increasing occurrence of obesity has also reported in developing countries such as Indonesia. Basic Health Research or Riset Kesehatan Dasar (Risksdas) Indonesia in 2013 shows that nationally the prevalence of fat among adolescents aged 13-15 years in Indonesia is 10.8%, consisting of 8.3% overweight and 2.5% obesity. The province with the highest prevalence of overweight and obesity was DKI Jakarta (4.2%) and the lowest was West Sulawesi (0.6%) (5).
South Sulawesi Province is one of 16 provinces whose population experiences less activity above the national prevalence, namely 49.1% (<150 minutes per week) and eating less fruits and vegetables 93.7% (<5 servings per day)\(^6\). The same thing happened to Riskesdas (2013), namely the less active activity of the age group ≥10 years by 31%, exceeding the Indonesian average value of 26.1%. Based on Riskesdas (2013) in numbers, the prevalence of overweight in South Sulawesi province according to BMI/U age 13-15 years is 6.8% fat and 2.4% obese, and in Tana Toraja Regency as much as 10.5% fat and 2.3% obesity \(^5\).

Changes in dietary habits in adolescents, based on previous research, if not attempted to improve it will bring the influence of the quality of society towards. As one of death factor, this research focused on the occurrence of overweight and obesity in adolescent in Indonesia. The recent cases of obesity has a put the problems of obesity in the next generation afterwards. Otherwise, it is necessary to seek information and treatment in a form of intervention regarding adolescent obesity through family-based empowerment models \(^7\).

The findings about the incidence of overnutrition are the result of unhealthy eating behavior and less physical activity, therefore it is necessary to improve behavior and increase the physical activity of adolescents so as to reduce prevalence and prevent excess complications and obesity. With empowerment based on family nutrition education, it is used to improve diet so that it can reduce the nutritional status of overweight adolescents to normal. The purpose of this study was to analyze the effect of family-based empowerment on the nutritional status of adolescents in Tana Toraja.

**Material and Method**

**Research Design:** A method to be used in this study was taken to quasi-experiment approach. As the research design, pretest and post-test with control group design was elaborated to determine before and after treatment. The study group in this study was divided into 2 (two) groups consisting of 1 (one) treatment group and 1 (one) control group. The first group was given intervention in a form of health education through family empowerment with modules, the second group (control) was given health education with modules and family mentoring without role playing.

**Population and Sample:** The population and sample in this study were some of the parents and overweight adolescents in grades 7 and 8 at the Junior High School in Tana Toraja. The sampling technique in this study was simple random sampling method, namely selecting a sample among the population by drawing lots. The samples number was 32 for the treatment group and 32 for the control group. The number of 32 obtained in the calculation of the sample size above is obtained by entering the data on the number of populations, the expected error rate, the range of the level of accuracy/accuracy and the desired level of confidence into the Sample Size Determination (SSD) in Health Studies.

**Data Collecting:** The anthropometric assessment of adolescents was carried out using the Camry brand digital scale as a measuring tool for children’s body weight with an accuracy of 0.1 kg and a capacity of 150 kg and Microtoise as a measuring device for height with an accuracy of 0.1 cm and a capacity of 200 cm. Then the anthropometric index used was body mass index per age (BMI/A) WHO Anthropus software 2007 reference standard for school age children 5-18 years and nutritional behavior was assessed by a questionnaire consisting of 15 question items.

**Data Analysis:** Analysis we have done was taken into the determination of test significance as well as the determination of the difference in the mean of research variables. The data was collecting between before and after the intervention. If the data distribution was normally distributed, the independent t-test or paired t-test was used based on the group, while the non-normal distribution used the Mann-Whitney non-parametric test and multivariate analysis by using Hoteling’s T² test to see the difference between the two test groups (treatment group and control group). Each of which contains at least two or more variables and will be analyzed simultaneously together.

**Results**

**Adolescent’s Characteristics:** The location of this research was Makale City Junior High School, Tana Toraja Regency, South Sulawesi Province. The data is processed and analyzed according to the research objectives. Data results analysis are presented in tabular form equipped with the following explanation. The distribution of adolescent’s nutritional status can be seen in Table 1.
Table 1. Distribution of Adolescent’s Nutritional Status

<table>
<thead>
<tr>

</tbody>
</table>

Table 1 shows that all adolescent’s nutritional status of research measurement during the pre-test had overweight nutritional status. After the post-test, 16 adolescents (50%) had normal nutritional status in the treatment group and 21 adolescents (65.6%) had also normal nutritional status. The differences then were analyzed by Mann-Whitney test.

Changes in Adolescent’s Nutritional Status:

*Mann-Whitney

Table 2 shows that the results of the Mann-Whitney test. It shows that the change in respondents’ nutritional status (BMI) were recorded at post-test. The difference was quite significant compared to pre-test. This shows that there is a difference in BMI in the pre-test and post-test in both the treatment and control groups. The decrease in BMI was more significant (higher in number) in the treatment group than in the control group.

Multivariate Analysis Results:

*Hotelling’s T

Table 3 shows that the results of statistical tests with Hotelling’s T test. It was obtained that the value of $F = 8.472$ and $p = 0.000$ ($p < 0.05$). This means that there are differences in the nutritional status of adolescents who receive family-based empowerment. Family-based empowerment affected nutritional status of adolescents as family members ($p < 0.05$).

Discussion

In line with the existence of a high-calorie diet, the low frequency of physical activity and lots of free time activities have contributed to an increase in the prevalence of overweight and obesity among adolescents as the research objective in this study. The results showed that the results of the Mann Whitney
test showed that there was a change in nutritional status during the post-test compared to the pretest. This shows that there is a difference in body mass index (BMI) in the pretest and post-test in both the treatment and control groups. The decrease in body mass index (BMI) was higher in the treatment group than in the control group. For counterfeit analysis, the research of Tuah et al. (2011) that the use of the Stage of Change (SOC) on Transtheoretical Model (TTM) in maintaining the obesity weight management programs supported our findings. The supported sideway was taken as if the SOC was effective for weight loss in adolescents(8).Johnson et al. (2008) has conducted the research related to adult obesity. The research focused on respondents with BMI ranged from 25-39.9. The number of respondents in the research were 1277. Under multiple behavior interventions, this study shows the patterns on results due to ability of TTM. TTM tends to be effective in improving healthy eating patterns, holding exercise schedule of respondents, managing emotional distress, changing behavior and maintaining body weight (9). Multiple behavior interventions have been proven to elaborate the impact in this research. In this study, we found that the results were three times better than single behavior interventions. Health promotion in the proper community agenda or obesity prevention programs held by formal health practitioners together with the government and/or mentors are quite effective. The results from previous study found that health promotion was able to prevent an increase in BMI. In addition, it can also lead to reducing snacks intake by respondents, cutting soft drinks consumption off or limiting respondents from eating desserts after meal course so that the improvement can be achieved(10).

Multicomponent intervention, according to Foster, is also significant to uphold. The method whatsoever is proven to prevent the development of obesity cases, especially in children in grades 4-6 located in urban elementary schools (11). Based on need-based analysis, community-based partnership have been provoking to integrate health, education, environment, government and business services altogether. Golan & Weizman (2001) developed the research model in the form of family-based conceptual model. It emphasizes two main points, namely healthy lifestyle and weight loss (12). According to Watson in Potter (2005) to improve health is to return the client to his healthy condition and prevent pain(13). Furthermore, parental caring behavior will bring the influence as if it is very important in preventing the effect of the certain diseases on children and in this study children who are overweight and obese are being the main focus. A program to hold and uprise African American students’ awareness on obesity and overweight cases. It was conducted to preserve the risk of heart disease and diabetes towards(14). Jones et al (2010) revealed the beneficial sides of the health information technology (IT) and health literacy (HL) programs. The effectiveness of the two health promotion methods was determined to raise awareness about the health risks of obesity among African American students (15).

The regular measurement conducted in this study found various changes in body mass index (BMI) in respondents. Both groups experienced a decrease in BMI at the sixth month based on pretest and post-test measurement. The decrease number of BMI in the treatment group was 90.3%. The result number was higher than the control group that was only getting into 21.2% of threshold value. Balanced healthy menu based on age was given as one of interventions. The other interventions given were one-hour physical activity on a daily basis and the maintained children’s healthy behavior. The interventions in our study adopted and developed from Barlow (2007). The research done by Barlow has been recommending children and families to maintain food intake, physical activity and relaxing habits; or in this case is sedentary behavior. Mushtaq et al. (2011) found two of independent predictors of obesity of school-aged children in Pakistan were physical activity and daily lifestyle. Daily lifestyle included watching television, working on computers and playing video games. The three parameters showed a significant association with a high BMI and the risk of being overweight and at risk of health disease with the OR score of 1.60 in children without normal BMI. Based on the nutritional status of adolescents we elaborated in this study, there were reported that overweight adolescents the treatment group tend to have normal nutritional status after the intervention. This study proves that family-based empowerment played a huge role as health intervention as it greatly affected adolescent’s BMI reduction. It also influenced the changes in better and normal adolescent nutritional status. Due to deep analysis in pilot study comparison, the module content we developed is equipped with information on healthy lifestyles and youth monitoring sheets. It can help families to be the role of culture care repatterning so that they can control the family member’s physical activity and food intake afterwards. Families also believe that they are able to carry out a healthy lifestyle in children with good family self-efficacy.
Changes in BMI in adolescents are motivation for adolescents to change their lifestyle into healthy behaviors. The way and steps they spend per day in losing weight motivation in adolescents is the key to success as it turns to be motivation to shape the confidence in public appearance. This is because school-age children begin to gain the ability to sequence a number of events and actions, children become physically mature, children became curious and asked a lot about health\(^{16}\). Thus, the role of the family in controlling the lifestyle of adolescents by doing good physical activity as many as 32 adolescents has an impact on changes in adolescent BMI, which decreased by 31 (97.3%) in the treatment group. This can be happened after the implementation of family-based empowerment.

The decrease in BMI in the treatment group showed an increase in knowledge, attitudes, behavior, family culture, physical activity of adolescents from month to month accompanied by adequate calorie intake of children along with the decrease of sedentary activities. Thus, the family is able to control overweight adolescents which has an impact on decreasing the body mass index (BMI) of adolescents. The change in BMI has an impact on the psychosocial development of adolescents according to Erickson in Wong (2009) that if adolescents cannot resolve conflicts or problems, they will become inferior. A decreased BMI will have a positive impact on adolescents, namely adolescents are more confident with their body size. A decrease in BMI in adolescents is a change in the positive energy balance to a negative energy balance through biochemical changes, physiological changes, and anatomical changes. Positive energy balance is excessive intake and under exercise in overweight adolescents before the intervention. After the application of the family-based empowerment model, there was a change in BMI, namely a decrease in BMI in the treatment group. This decrease in BMI is the result of a process of anatomical changes that can be measured through anthropometry including adolescent nutritional status based on BMI and adolescent age.

Research by Nayak and Bhat (2010) in which multicomponent intervention was given for one month to 269 children, an amount of 13 (4.8%) were overweight and 7 (2.6%) were obese \(^{17}\). Sedentary activity after school hours such as watching television for a longer duration on Sundays and weekdays, decreased physical activity, skipping meals, the influence of the media in choosing food, parents offering food as gifts, frequent consumption of fried and junk food, and frequent drinking carbonated drinks is an important factor in influencing the incidence of overweight and obesity \(^{18}\). There was a significant reduction in the body mass index (BMI) of the intervention group at the end of the fourth week.

**Conclusion**

Family-based empowerment has an effect on decreasing body mass index of adolescent family member (BMI) or adolescent’s nutritional status. There was a decrease in the BMI of adolescents in the treatment group but there was an increase in the BMI of adolescents in the control group. We need to monitor adolescent’s nutritional status and provide counseling to adolescents regarding healthy eating patterns from an early age.

**Ethical Clearance:** The results of this study found that eating culture in the local area can affect eating patterns due to geographic conditions, thus impacting on food and energy use so that it affects changes in weight of obese teenagers.

**Acknowledgement:** The authors thank all the Public Health students who helped in the collection of the data. Tana Toraja Regency Government, Health Service, Head of Community Health Center who has granted research permit. Respondents who have been willing to spend time in the interview process.

Protection of Public Interests in the Process of the Indonesian Proprietary

Etty Susilowati¹, Paramita Prananingtyas¹, M Fauzi²

¹Lecture at Faculty of Law, Universitas Diponegoro, Indonesia,
²Lecture at Faculty of Law, Universitas Mulawarman, Indonesia

Abstract

Protection of public interests in the bankruptcy process is regulated in the Indonesian Bankruptcy Law. However, the implementation of this provision raises problems both in the concept design of the public interest itself and in its protection mechanisms. The bankruptcy law provides at least three concepts of public interest, each of which can be identified with the interests of the wider community as creditors, the interest in the stability of the financial services sector, and the interests of state finances. The three concepts of public interest are protected with exclusive and prerogative powers on the regulators and supervisors as the authority of each field. Such protection mechanisms have so far only blocked the path of creditors and debtors, and provided immunity to special debtors, as the majority of authorities do not want to file bankruptcy requests and prefer to exercise their public powers.

Keywords: Bankruptcy, public interest, legal protection.

Introduction

Bankruptcy institutions are needed as a special debt settlement mechanism. When debtors experience problems in completing their obligations to creditors, it can be generally assumed that the debtors are experiencing financial difficulties. This situation can encourage each creditor to try in various ways to get payment for assets that are assumed to be far below the value of all liabilities (common pool problem). If this situation is not properly facilitated, the resolution will result in problems leading to injustice, both for the debtor itself and the creditors. Some creditors may receive payment, even full payment while other creditors may get nothing. The position of debtors is getting more difficult because in addition to facing financial difficulties, debtors are also faced with claims from creditors who each want their receivables to be paid in full and prioritized over other creditors.

Bankrupt institutions cannot only be seen narrowly as a mechanism for settling debts and receivables between debtors and creditors. The complexity of transactions and the number of parties related to their interests, either directly or indirectly, also influence the dynamics and development of the bankruptcy institution. The various interests involved in a debt settlement process demand that bankruptcy institutions be encouraged to take into account other interests affected by the bankruptcy process. Both creditors and debtors are not only bound by one legal relationship. As an economic being as well as a social being, both creditors and debtors certainly have rights and obligations to other parties or other roles in the social system of society. If the settlement of these debts and receivables is not carried out properly, it can be ascertained that both third parties and the wider community will more or less be affected. If one of the creditors does not get payment, it is possible that the creditor cannot pay the salaries of his employees or even has to close his business, so that it will impact on the family welfare of the employees. Likewise, if it turns out that the debtor’s business sector is urgently needed by the community, unstructured collections that unilaterally only pursue the settlement of accounts receivable can result in cessation of meeting the needs of the community, which was originally only supplied...
by the debtor's business. It must be acknowledged that in certain situations the bankruptcy process and decision has an impact and influence on the interests of other parties and society in general, either directly or indirectly. The interests of other parties are directly harmed if the bankruptcy process results in the cessation of fulfilling the interests of that party, including if a bankruptcy decision is imposed on an entity/company whose products or services are used by the wider community. The bankruptcy process and decision can also harm the interests of other parties, indirectly, if the bankruptcy process affects and or hinders the fulfillment of the interests of the party, which, among other things, if the bankruptcy process causes anxiety and panic in the community.

This paper is based on nondoctrinal legal research that uses the standpoint of participants with inductive reasoning that empirically conceptualize law. This research examines social realities in the form of the behavior of parties related to the protection mechanism of the public interest in bankruptcy and the relationship between these various symptoms as real legal manifestations. The paradigm used is the post-positivism paradigm which ontologically sees that the reality of the public interest does exist but can never be fully understood (critical realism). Likewise, the public interest protection mechanism as outlined in legislation as a set of norms imposed on society, its enforcement will be greatly influenced by other factors (law as it is in society).

Public Interest in the Indonesian Bankruptcy Law: The settlement of accounts payable in the bankruptcy process is essentially taken over and controlled by the state through a panel of judges in the Commercial Court and curators. There are at least two possible purposes for the state’s presence in the bankruptcy process. The first objective is to ensure that the settlement of accounts payable between debtors and creditors is carried out fairly. The next objective is to ensure that the settlement of debt and credit problems between creditors and debtors is not detrimental to wider interests. This is because the state in its position as administrator of the public interest also has an interest so that the settlement of rights and obligations between the debtor and its creditors does not interfere with the bigger interest. Thus, it is natural that the interests of the state in safeguarding the public interest are also considered in the process of settling these debts and receivables so that bankruptcy institutions not only protect the interests of debtors and creditors but also protect public interests.

The Indonesian bankruptcy law regulates several bankruptcy mechanisms which are intended to protect interests outside the interests of debtors and creditors. Various interests outside the rights and obligations between creditors and debtors are protected in the bankruptcy process through public policy and authority and are given priority over individual interests, the authors assume, as the public interest. This special mechanism gives authority to the Attorney General’s Office, the Ministry of Finance and the Financial Services Authority (OJK) in submitting bankruptcy statements against certain debtors. Article 2 paragraph (2) of the Bankruptcy Law authorizes the prosecutor (public prosecutor) to file a bankruptcy application in the public interest when the requirements as referred to in Article 2 paragraph (1) have been met and no application for bankruptcy has been filed by another party. The concept of public interest in the explanation of these provisions is the interests of the nation and the State and or the interests of the wider community. This interest can arise when the debtor is not cooperative, embezzles assets or runs away. The public interest also arises when the debtor’s debt is a fund that comes directly or indirectly from the wider community and/or SOES. The AGO has discretionary power in assessing the existence of other public interests. The public interest is essentially the main concept that underlies the birth of every statutory regulation. Likewise, the bankruptcy law carries the concept of public interest which is tried to be protected in the bankruptcy process. There are at least three concepts of public interest presented in the bankruptcy law. The public interest regarding the authority of the prosecutor’s office in bankruptcy is the accumulation of the interests of many creditors. This is because the prosecutor’s position is only as a substitute for creditors in filing a bankruptcy statement.

Public Interest Protection Mechanism in the Bankruptcy Law: Based on the provisions in the Bankruptcy Law mentioned above, it can be concluded that there are 2 types of bankruptcy mechanisms, namely bankruptcy in general and bankruptcy with restrictions on the rights of debtors and creditors to apply for a bankruptcy statement. The differentiation of the bankruptcy mechanism is based on the type of interest being protected. A special mechanism in the form of limiting the rights of debtors and creditors to apply for a bankruptcy statement is provided to protect the public interest by taking into account the characteristics of the
debtor who is filed for bankruptcy\textsuperscript{8,9,10}. Based on their characteristics, debtors are grouped into three groups, namely debtors in general, debtors who are SOEs, and Debtors who are banks, insurance companies, reinsurance companies and pension funds, securities companies, stock exchanges, clearing and guarantee institutions, depository and settlement institutions.

This limitation is used as a counterweight considering the bankruptcy requirements based on the provisions of Article 2 paragraph (1) of the Bankruptcy Law are very simple and only require debt to two creditors, where the debt is due and can be collected, the debtor can be easily bankrupt through the trial process and brief evidence without the insolvency test. Such loose bankruptcy provisions are considered to be very dangerous to the interests of the wider community, especially if the debtors who are bankrupt are financial institutions and SOES. On the basis of these considerations, limiting Creditors’ rights to file bankruptcy applications against specific debtors is considered a necessity to protect the larger public interest\textsuperscript{8,9,10}. The concept of the Constitution states that such restrictions on rights can be established by law, on the condition that the limitation, although it looks as if it is imbalanced, but fulfills a rational balance. The fulfillment of the principle of balance in question is that the limitation is intended to protect the greater interest. In addition, for the party affected by the restriction, there are other alternative legal remedies that allow the party to fight for their rights.

Protection of public interest in bankruptcy has rational grounds and objectives. However, the concept and operationalization of the protection of public interests in bankruptcy still raises several fundamental issues, especially in relation to the concept of public interest which is the object of protection, whether the interest is an interest in bankruptcy or an interest outside bankruptcy, whether these interests are interests that already exist, do not exist, or only possible interests. This limitation of the concept of public interest is important because it becomes the basis of legitimacy for its protection efforts. Without clear evidence that there is a public interest there, there is no need for special protection measures that override the bankruptcy mechanism in general. Moreover, the Indonesian bankruptcy law has used an authoritative instrument in the form of restricting (revoking) the right to apply for a bankruptcy statement as a form of protection for the public interest.

The Indonesian bankruptcy law has used an authoritative instrument in the form of restrictions on who can file applications as a form of protection for the public interest. Limitation of this right can be interpreted as revocation of rights because in fact it has made the party that should have the right to apply for it not entitled to apply. Although the limited rights related to protection for the public interest are the rights of creditors in the field of formal law (procedural law) and on the other hand, the civil rights of creditors in the form of claims are legally recognized, guaranteed, and protected, however the construction of bankruptcy with this special mechanism is very different from the initial concept of bankruptcy as a debt settlement institution that gives creditor and debtor authority as parties who have rights and interests based on a civil law relationship\textsuperscript{15}. The Minister of Finance and OJK as the authorities may have more adequate data and knowledge regarding the impact of bankruptcy status on financial institutions and SOEs so that they can take more appropriate policies and steps, but both basically have no interest and right to apply for a bankruptcy statement.

The number of requests for bankruptcy statements, submissions for judicial review to the Constitutional Court and the reluctance of the authorities given the authority to submit requests for bankruptcy statements are evidence that the protection system for public interest in bankruptcy with restrictions on the rights to file bankruptcy statements has not been a fair and effective solution. The resolution of the issue of protection of the public interest in bankruptcy cannot be done only by limiting the right to file a bankruptcy statement. If all issues of protecting the public interest in bankruptcy are carried out with restrictions on the right to apply for a bankruptcy statement, then it can be ascertained that the right to apply for a bankruptcy statement against all debtors will be with public institutions because aspects of the public interest will arise in all fields along with the increasing number and level of dependency society towards certain products and services.

Conclusion

The public and private dichotomy may have begun to fade as a result of the domination of the role of the state in all aspects of life. The role and interests of the state in bankruptcy to protect public interests cannot be avoided. However, the concept of public interest given by the bankruptcy law still raises several problems. Likewise, the exclusive and prerogative protection
mechanism removes control over the use of this power by public institutions. Both resulted in unclear protection of interests in the private area and on the other hand created moral hazard from debtors who indirectly received immunity from bankruptcy. Along with the development of guarantee institutions for both public savings and policy guarantee institutions (which will soon follow), an evaluation of the authority of public institutions in filing a bankruptcy statement needs to be carried out to assess its urgency and minimize conflicts of interest between the interests of these public institutions as regulatory and supervisory authorities and interests. as the only party authorized to apply for a bankruptcy statement.

How Cultural Competency of Community Health Care Providers Reflects Multicultural Education: A Case Study on Nursing Majors

Eunhyung. Cho
Associate Professor, Nursing department, Seoul Women’s College of Nursing, Seoul, Korea

Abstract

In the current global era, multicultural education is a requisite for those who attain higher education, such as nursing majors working in a community with people from a variety of cultural backgrounds. This study aimed to explore the effect of multicultural education by identifying cultural competency (CC) and multicultural acceptance (MA) among two groups of students and professionals who majored in nursing.

A series of surveys was conducted targeting nursing students and clinical professionals. Out of 189 participants, data from 98 participants with experience of multicultural education and 91 participants without experience of multicultural education was analyzed. Independent t-tests, correlation tests, and regression analysis were conducted to examine the effect of multicultural education, and to identify the correlation between CC and MA and the factors influencing them through the comparison of data from each group. The results demonstrated two major points. First, multicultural education was shown to enhance CC and MA of the participants. Second, cultural knowledge and cultural experience were important factors influencing MA.

These results can be used to provide educational direction regarding cultural competency and multicultural acceptance, ultimately leading to provision of better healthcare services in multicultural communities.

Keyword: Competency, healthcare, cultural competency, culture, diversity.

Introduction

In the current global era, people with diverse cultural backgrounds reside in merged communities and live and work together. Thus, a certain level of cultural competency is required for highly educated groups of adults, such as students and professionals who majored in nursing, to deal with them. Nursing majors are one group of healthcare providers in the community who are generally highly educated. As such, it is necessary to strengthen their vocational abilities to deal effectively with people from diverse cultural backgrounds to whom they provide healthcare services. Knowledge and experience of cultural differences, such as health-associated cultural traits, play a key role in promoting effectiveness of healthcare services1,2. Research literature has labeled these abilities as cultural competency (CC) and multicultural acceptance (MA)1-6. Recent studies on CC and MA have emphasized that multicultural education that provides cultural knowledge, or an experience of various cultures have a positive effect on enhancing these competencies2,5-7. Therefore, there have been attempts to design effective educational programs to enhance these competencies, and many studies have been conducted to examine these competencies and identify the factors which influence the promotion of these competencies2,4-6. In this context, CC is defined as an ability to possess awareness and knowledge of each culture, cultural experience and sensitivity, and cultural
skills. It is also considered a practical skill, including a recognition of the unique characteristics of each culture, such as health-related beliefs\textsuperscript{2-4}, and an imperative ability to understand the sensitivity level of people from diverse cultural backgrounds. These skills are necessary for nursing majors when they provide healthcare services, especially to build therapeutic credibility\textsuperscript{2}. Meanwhile, MA is defined as the ability to understand and accept diverse cultural backgrounds of members who have migrated and settled into the local community. It refers to a universal ability covering cultural awareness and open-minded attitudes toward different cultures, social coexistence, and supporting community members with different cultural backgrounds\textsuperscript{5,6}. This competency is important for nursing majors not only in their role as a global citizen but also as a community member. However, a recent study indicated that multicultural education for nursing majors as well as other groups of highly educated adults is partially stagnant, and identified the need for a plan to improve multicultural education and individualize competency consolidation to reflect group characteristics\textsuperscript{6,7}. Studies on CC and MA have delineated that it is necessary to develop an educational program that reflects the characteristics of each group and employs measures to strengthen those competencies in order to increase the educational effect\textsuperscript{2,6,8-10}. Particularly, they have emphasized the need for educational programs by academic level for nursing college students and clinical professionals, and noted that continuous research through repetitive capacity measurement within each group and between groups is needed to develop effective educational programs\textsuperscript{2,9-11}. For this purpose, some recent studies on CC and MA have consistently conducted research on the factors that affect each competency, and found that acquiring cultural knowledge through regular classes in school, exposure to multicultural information through mass media, personal experiences through contact with other cultures, and educational experiences in other cultures create a positive effect\textsuperscript{11,12}. In contrast, other studies argued that educational programs designed to acquire knowledge regarding different cultures are insufficient to strengthen CC or MA\textsuperscript{2,5,13}, and that frequency of contact with other cultures has no significant effect on either competency\textsuperscript{14}. Therefore, further research on multicultural acceptance as well as cultural competency based on cultural knowledge and experience with CC and MA is extremely necessary. One point of view is that CC and MA are similar concepts in terms of definition. In contrast, another view is that, while CC is considered as a required competency for healthcare workers, MA is a required competency for members of the general society. In recent years, there has been a steady interest in CC and MA of healthcare students and clinical professionals, and related factors which affect these competencies\textsuperscript{15}; however, most studies have been focused on CC and few studies have examined the degree of MA and the correlation between the two competencies from the perspective that both clinical professionals and healthcare students are members of the general society too. Therefore, this study aimed to suggest an educational direction that can strengthen CC and MA of healthcare providers by identifying the effect of multicultural education on nursing majors. The study examined CC and MA in individuals involved in the healthcare field and explored the correlations between the two competencies as well as the factors which influence both competencies. Further, the study identified differences in the factors which effect CC and MA between two groups of participants with and without experience of multicultural education.

The research objectives were as follows.

**Hypothesis 1:** The level and perception of CC and MA of nursing majors and the degree of retention of each competency are different depending on whether or not they have had an experience of multicultural educational.

**Hypothesis 2:** There is a correlation between the CC and MA level.

**Hypothesis 3:** Multicultural educational experience for CC has a positive effect on increasing MA.

**Materials and Method**

**Study Design:** This study employed a comparative survey design to identify the degree of CC and MA, the correlation between the two competencies, and the factors influencing the two competencies in nursing students and clinical professionals based on their experience of multicultural education.

**Subjects:** The number of samples to be surveyed was calculated as 100, with an effect size of 0.90 and \(p<0.05\) using G*power version 3.0; however, the sample size was doubled to obtain universal validity of the study results. A total of 189 valid survey results were obtained out of 200 distributed questionnaires, after excluding incomplete questionnaires. Subsequently, 98 participants
were placed in the group with multicultural education and 91 participants in the group without multicultural education. All participants were Korean nationals; participants included college students enrolled in a 4-year program (N=110), graduates who currently work as a nurse (N=70), clinical professionals (N=8), and an unemployed nurse (N=1). Age-wise, 169 participants were in their twenties, 16 in their thirties, and 4 were aged over forty. The sample comprised individuals who were nursing majors, since they are required to have the ability to recognize and utilize health-related cultural characteristics of healthcare recipients from diverse cultural backgrounds in different communities.

**Data Collection and Analysis:** Copies of self-report questionnaires were distributed to the participants, and the results were collected between June and December 2019. The appropriate measurement tools for the study were selected by the researcher through a literature review between February and May 2019. These tools included a scale for measuring CC by Chae⁴, a scale to measure CC developed by Han¹⁶, and a scale for measuring MA for community members by Ahn et al.⁶ were used. Each instrument used a 6-point Likert scale with possible responses of “strongly agree” (6 points), “agree” (5 points), “slightly agree” (4 points), “slightly disagree” (3 points), “disagree” (2 points), and “strongly disagree” (1 point) for all items. All participants completed the questionnaires after the researcher had distributed them one by one. The SPSS WIN version 24.0 was used to test the validity of the three measurement tools. A series of independent t-tests, correlation tests, and multiple regression analysis were conducted to examine the degree of CC and MA. Further, the factors influencing the two competencies were identified.

**Cultural Competency:** Both, the CC measurement tool for nurses (CCN) developed by Chae⁴ and the CC measurement tool for nursing students (CCNS) developed by Han¹⁶, were used in this study. The CCN targets clinical professionals and includes 33 questions regarding cultural awareness, cultural knowledge, cultural sensitivity, and cultural skills. The CCNS targets nursing students and consists of 27 questions that add cultural experience to the CCN⁴¹⁶. The reliability analysis conducted on the two tools showed a Cronbach’s α value of 0.789 for the CCN and Cronbach’s α value of 0.915 for the CCNS, for the sample group with multicultural educational experience. For the group without multicultural educational experience, Cronbach’s α was 0.818 for the CCN and 0.842 for the CCNS. Therefore, both analyses showed high reliability.

**Multicultural Acceptance:** The MA measurement tool developed by Ahn et al.⁶ was used in this study to assess MA of healthcare workers as general members of society. The MA includes 35 questions regarding perspectives toward culture, national identity, fixed-prejudice and discrimination, expectations of one-sided assimilation, sentiment of rejection and avoidance, willingness to act on interpersonal exchange, underlying evaluation and willingness to act as a global citizen. The reliability analysis of the tool was high, with a Cronbach’s α of 0.861 for the group with multicultural educational experience and 0.879 for the group without multicultural educational experience.

**Results**

**Demographic Characteristics:** The frequency analysis of the participants’ general characteristics is presented in Table 1. 87 participants of the experienced group and 23 participants of the unexperienced groups were college students, and most of all participants were female as seen in Table 1.

Cultural competency and the competency of multicultural acceptance according to experience in multicultural education: An independent sample t-test and correlation analysis were conducted between the two groups on cultural competency and multicultural acceptance. The group with educational experience had higher cultural competency and multicultural acceptance, and significant differences between the groups were detected in the degree of each competency, as seen in Table 2. In addition, there was no significant correlation between cultural competency and multicultural acceptance in the cultural competency tool by Chae in either groups. Conversely, ‘cultural experience’ showed a positive correlation with ‘open perspectives towards culture’ (r=.203, p=.045) in the tool developed by Han for the group with educational experience, and ‘cultural knowledge’ and ‘cultural experience’ showed a negative correlation with the willingness to act as a global citizen, which is a factor for multicultural acceptance (r=-.249, -.223 p=.017, .024).

Next, based on Table 3, multiple regression analysis was conducted to identify the influencing factors between cultural competence and multicultural acceptance. ‘Cultural experience’ was found to have an effect on multicultural acceptance (‘open perspectives towards cultures’) in the multicultural education group, with an overall explanatory power of 28.5%, as shown in Table 4. However, regression analysis of the group without multicultural educational experience showed ‘cultural experience’ and ‘cultural knowledge’ as factors influencing MA (‘willingness to act as a global citizen’). The overall explanatory power was 24.7%, as shown in Table 4.

Discussion

This study aimed to prove the significance and necessity of multicultural education by identifying the level of CC and MA awareness, the degree of the two competencies, and the correlation between the two competencies as well as factors influencing CC and MA in two groups of participants according to their experience of multicultural education. First, participants showed significant differences in their degree of awareness regarding CC and MA according to their multicultural educational experience (Tables 2). The group with multicultural education had a higher awareness of CC and MA than the group that did not have such education (Table 2). Upon examining the degree of CC and MA between groups according to their multicultural educational experience, the CCN, the CCNS, and the MA measurement tool all outlined significant differences between the groups (Table 2). The level of MA among participants in this study was higher than the average score (4.07/6) in a group of highly educated clinical professionals surveyed by Kim et al. Moreover, the CC in the multicultural education group was higher than the 4.14 ± 0.45 score obtained by Choi and Kim, and the 3.9 ± 0.46 score in Han (Table 2). Furthermore, the scores detecting cultural experience as part of the CCNS between the groups with or without multicultural educational experience were higher than the score of 3.85±0.72 points in Choi and Kim and 3.05±0.79 points in Han. The score in the group without multicultural education was also higher than the 3.34±0.70 points in Choi and Kim and 2.54±0.22...
points in Han. These results identifying the differences between the groups with and without multicultural educational experience appear to be meaningful, based on comparison with previous studies. Thus, multicultural educational experience is effective in enhancing CC and MA, and more opportunities to receive multicultural education should be provided to those pursuing higher education, including nursing majors, to enhance CC and MA.

Second, on examining the correlations and factors influencing CC and MA, it was found that among the subcomponents of CC, ‘cultural experience’ and ‘cultural knowledge’ showed a significant correlation with MA (Table 3). In addition, according to the results of the multiple regression analysis, ‘cultural experience’ influenced MA in the multicultural education group, and ‘cultural experience’ and ‘cultural knowledge’ influenced MA in the group with multicultural education (Table 4). These results support the findings of Cho and Sok, which state that the degree of multicultural awareness and degree of CC affect MA. Therefore, education that raises awareness of CC is necessary for nursing majors and clinical professionals to enhance MA. However, cultural experience such as an experience in providing medical services to foreign patients, and cultural knowledge gained in the classroom such as introduction to and explanation of various cultures were identified to have greater impacts on MA. The results of this study are different from results of previous studies that showed that contact with foreigners and exposure to multicultural information through media such as television broadcasts, Internet, and newspapers positively influenced MA. In contrast, in this study, contact with foreigners and exposure to multicultural environments were found to have a negative impact by hindering open perspectives toward people from diverse cultural backgrounds, for the group with multicultural education. This difference in the results was further evident in the group without multicultural education, as such contact and exposure can diminish social support for healthcare recipients by forming a rigid manner of thinking. However, as interest in CC and MA is consistently increasing among healthcare workers, including nursing majors, providing academic or professional level-specific educations is an effective method to enhance CC and MA. In conclusion, multicultural education can enhance CC by considering cultural knowledge and cultural exposure, such as teaching the unique health beliefs of the recipients’ culture; such education may have more effect on groups with multicultural educational experience to enhance the competencies necessary for healthcare providers, as suggested by Chae et al. and Byun and Park. In addition, providing education about multicultural policies in local communities and providing training for healthcare skills tailored for recipients from multicultural backgrounds, as well as providing education to enhance empathy and human rights sensitivity as suggested by Han and Ahn and Noh, is also needed.

**Conclusion**

In this study, the following results were obtained through a comparative analysis of CC and MA between two groups of nursing majors according to their educational experience. First, the degree of awareness of CC and MA varied depending on the experience of multicultural education. Second, CC affected the degree of MA. Specifically, it was confirmed that in the group with experience of multicultural education, cultural experience acted as the main influencing factor for MA, and in the group without multicultural education, cultural experience and cultural knowledge were the main factors influencing MA. Third, the components of multicultural education should be different depending on healthcare providers’ educational experience. Job skills training that utilizes knowledge of each individual’s own culture may be more effective in groups with multicultural educational experience than exposure to information through mass media and contact with foreigners and other cultures. Last but not least, the components of multicultural education must be different depending on the educational experience. For those who have received multicultural education, job skills training based on specific information to provide differentiated services in consideration of the cultural characteristics of recipients from different cultural backgrounds, may be effective. Whereas, for those who have not experienced multicultural education, it is necessary to provide education to improve policy toward foreigners in the community, increase empathy for foreigners, and sensitivity to human rights. However, as this study specifically targeted healthcare providers who majored in nursing, there are limitations to extensively applying the results on broader spectrums, and therefore, follow-up studies are required.

**Funding:** This research received no external funding.

Emergency Obstetric Protocol and its Effect on Practices of Interns Nursing Students

Ezz Ibrahim¹, Shadia Hamido², Sabah Metualy³, Eman Moustafa⁴

¹M.Sc. Technical Institute of Nursing, ²Professor. of Maternity & Neonatal Nursing, ³Professor .of Maternity & Neonatal Nursing, ⁴Professor. of Maternity & Neonatal Nursing, Faculty of Nursing, Ain Shams University, Ezz Ibrahim Fathy Shawer, Master Degree in Obstetric and Gynecological Nursing, Clinical Instructor in Technical Institute of Nursing, Ain Shams, Cairo, Egypt

Abstract

Background: Obstetric emergencies are life threatening medical condition that occurs during pregnancy, labor, or the postpartum period. Moreover, internships offer carefully planned, monitored work experience which allow the opportunity to apply knowledge and skills in a professional setting.

Study Aim: to evaluate the effect of emergency obstetric protocol on the practices of interns nursing students.

Methodology: A quasi experimental study conducted in technical institute of nursing faculty of nursing and in emergency department, intensive care unit and labor unit of maternity hospital Ain- Shams University. A convenient sample of one hundred of all female interns nursing students in the technical institute of nursing faculty of nursing Ain- Shams University from period (October 2019 to March 2020). Tools of data collection: Obstetric triage observational checklist used for assessment of intern nurses’ practices related to triage of obstetric emergencies cases and observational checklists tool for assessment of intern nurses’ practices related nursing management of common obstetrics emergencies pre and post protocol implementation.

Results: Showed statistically significant improvements in intern nurses’ practical skills related to triage process and nursing care of common obstetric emergencies immediately post intervention and in follow up phase.

Conclusion: Implementing emergency obstetric protocol had a positive effect on the practices of interns nursing students.

Keywords: Emergency Obstetric Protocol, Practices, Interns Nursing Students.

Introduction

Obstetric emergencies are life threatening medical condition that occurs during pregnancy, labor, or the postpartum period. Every day around the world, approximately 830 women die from preventable causes related to pregnancy and childbirth (1).

Additionally, there are a variety of obstetric emergencies that can threaten the well-being of both mother and child as, ectopic or tubal pregnancy, abruptio placenta, placenta previa, sever preeclampsia & eclampsia or pregnancy induced hypertension, premature rupture of membranes, amniotic fluid embolism, inversion or rupture of uterus, placenta accreta, prolapsed umbilical cord, shoulder dystocia, postpartum hemorrhage, obstetric shock and postpartum infection (1).

The triage process for women with common obstetric emergencies requires gathering relevant patient information, performing a focused assessment, determining an acuity level, and prioritizing the needs of the women seeking emergency care, all in a time-sensitive manner. Accuracy in problem identification is a crucial component of clinical decision making, especially in the triage encounter, and requires the nurse to establish boundaries of physiological and psychological stability as well as predict the potential trajectory of the patient’s condition (2).
Meanwhile, reducing maternal mortality is a major public health concern and arrived at the top of the health and development agendas and also one of Millennium Development Goals. So, multiple strategies are required to reduce the maternal mortality, one of these strategies is to make emergency obstetric care acceptable, accessible, and available to women and their families(3).

Also, creating protocols regarding obstetric emergencies including triage process are very important to provide the highest quality less cost efficient nursing care and increase satisfaction of clients. Moreover, nurse interns should be highly knowledgeable and well-trained caregivers for the overall safety and wellbeing of women. Building knowledge and practical skills are considered as a powerful tool for performance improvement and to maintain the efficiency of any health care organization(4).

Meanwhile, the mission of nursing education is to produce qualified nurses with the requisite knowledge, attitudes and skills. Moreover, internships offer carefully planned, monitored work experience which allow students the opportunity to apply their knowledge and skills in a professional setting (5).

Also, interns can earn academic credits from their college. During this period nurse interns should acquire the values, attitudes, increases confidence in knowledge and assessment skills, improves clinical skills, decision making, clinical judgment and critical thinking (6).

Materials and Method:

Research design: A quasi-experimental design was utilized to conduct this study.

Setting: The study was conducted in study classes, teaching rooms and in lab of the technical institute of nursing faculty of nursing Ain-Shams University and in emergency unit, intensive care unit and labor unit of maternity hospital Ain-Shams University

Subject:

Type of sample and size: Convenient sample was obtained. All female interns nursing students (100) in the technical institute of nursing, faculty of nursing Ain-Shams University in the period from (October 2019 to March 2020).

Tools of Data Collection: First Tool: Obstetric triage observational checklist. The researcher developed tool after reviewing the current related literature. It consists of nine sentences and it was used to assess intern nurse's practical skills for triage common obstetrics emergencies pre & post-interve

Scoring System: The checklist items was scored (3) for done each step correctly while (2) score was given for done incomplete correctly and (1) score for incorrect or not done. The scores of total practice were considered as ≥ 60% competent practice and < 60% incompetent practice.

Second Tool: Observational checklist developed by researcher after reviewing the current related literature. It consisted of nursing procedures and techniques for clinical practice based on published evidence for management of obstetric emergencies. The observational checklist used to assess and evaluate practical skills of interns nursing students regarding nursing management of obstetric emergencies pre & immediately post intervention and in follow up phase.

Scoring System: The total practice was scored as ≥ 60% was considered competent practice while total practice scored as < 60% was considered incompetent practice. Each item in the checklist was scored as complete correct practice scored as (3), incomplete correct practice scored as (2) and incorrect practice or note done scored as (1).

Data Analysis: The appropriate statistical method and tests were used. Data were analyzed using Statistical Program for Social Science (SPSS) version 21.0. The following tests were done: Chi-square (X2) test, Pearson Correlation (R) and Alpha cronbach reliability analysis of used tools.

P < 0.05 significant (S) *

This table shows that there was statistically significance differences relation between intern nurses’ practice related to obstetric triage, practice related to emergency obstetric post intervention and their qualifications (previous experience & and training program).

Discussion

Regarding practice of obstetric triage; results of the present study revealed that, nearly three quarters of the studied intern nurses had incompetent practice regarding obstetric triage before protocols implementation. Moreover, the present study revealed improvement in intern nurses’ practice of obstetric triage as the majority of studied intern nurses had competent practice related to obstetric triage after protocol implementation and at follow up slightly increase.

The result pre protocol implementation could be explained by intern nurses lack of knowledge regarding triage cases with obstetric emergencies, lack of training courses and workshop about emergency obstetric skills and obstetric triage that affect on their practice.

So this incompetent level of practice before intervention showed the importance of continuous education, teaching protocols and regular updating clinical courses for intern nurses and importance of internship program and focusing on weak points during training to promote knowledge and practice. Therefore, it is important and essential that intern nurses should be well trained and educated on obstetric emergencies and obstetric triage as they have the vital role to play as nurses are primary anchorperson in emergency department and should have proper decision making then begin the initial assessment, triage then offer nursing management of such cases.

This result agrees with (7) who study effect of triage education on nurses’ performance in Diverse in emergency department of obstetrics and pediatric gavernate hospital in Beni Suef, who stated that the studied nurses’ practices related to triage improved throughout the education guideline implementation phases as most of them don’t practice triaging before the guideline implementation. Then this deficient practice greatly improved to reach the majority of them had correct practice immediately after program implementation and at their follow up evaluation.

Also, in accordance with current study findings (8) who conducted study of assessment of staff nurse’s knowledge and performance regarding triage in emergency department of Nasr institute hospital, who mentioned that more than three-quarters of nurses had inadequate performance regarding triage before intervention.
In the researcher point of view, this similarity may be attributed to lack of nurses’ knowledge which reflected on their performance and lack of qualifications.

Furthermore, on investigating practical skills of intern nurses during caring of obstetrics emergencies cases, results of the present study revealed that slightly less than three quarters of the studied intern nurses had incompetent practice regarding management of obstetric emergencies before protocol implementation. Meanwhile, after implementation of the protocol the most of them had competent practice related to obstetrical emergencies.

These above findings are consistent with (3) who illustrated that slightly more than three quarter of nurses had unsatisfactory practices toward emergency obstetrics care before intervention of the nursing management protocol related to EMOC. Meanwhile, after intervention the most of them had satisfactory practices regarding obstetric emergencies.

The current study findings were also in accordance with (9) who mentioned that there was a relation between the availability of guidelines for the management of obstetric emergencies and the higher competency among primary healthcare workers in Mali.

Furthermore, this result is supported by (10) who indicated that regular training of nursing personnel will improve and enhance quality of health care, who made mixed-method study in fourteen Bangladesh government healthcare facilities.

Additionally, this result agrees with (11) who studied the effect of educational program for nurses about pregnancy induced hypertension on their knowledge and practice in Port Said hospitals, who founded that the majority of nurses before training had incorrect practice regarding EMOC and improved post training.

Also, the present study finding showed that there was significant improvement in practice related to EMOC post intervention compared to pre-intervention. The finding of the current study was in agreement with (8) who studied the effect of maternity nursing logbook on internship students’ skills at woman’s health hospital, Assiut Governorate and stated that there was a significant difference between pre and post training related the total score of internship nursing student’s practical skills.

Additionally, this result was consistent with (3) who found that there was significant improvement of nurses’ practice after protocols application compared to before it.

Also, results of the present study revealed that there was statistically significant difference between studied intern nurses’ total practices score related to obstetric triage, EMOC, and their qualifications post intervention.

The current study findings confirmed by (7) who studied assessment of cardiotocography versus intermittent auscultation of fetal heart on admission to labor ward for assessment of fetal wellbeing, who found that there was a highly statistically significant relation between nurses’ performance & their qualifications.

The current study findings confirmed by a study done by (3) who found that there was positive statistically significant correlation between practices related to obstetric emergencies after nursing management protocol and years of experience.

Additionally, this was similar with the finding of with (12) who reported that there was a significant relationship between practice, interpretation of CTG and qualification and work experience of studied sample.

Meanwhile, this result disagrees with who (13) studies assessment of emergency nursing care offered at labor ward in Ain Sham maternity hospital. Who found that there was no statistically significant difference between nurses’ performance and their qualifications. Also, these results disagree with (12) who stated that there was insignificant relation between nurses’ practice and their experiences year and personal characteristics.

In the researcher point of view, the dissimilarity may be related to study subject in second study (nurses) spending a lot of times working in the same department and absence of training program in that time and state of unrefreshment.

Conclusion
Implementing emergency obstetric protocol had a positive effect on the practices of interns nursing students.

Recommendations: Dissemination of emergency obstetric protocol for all internship nursing students in faculties of nursing and nursing institutions this will be effective in improving their practical skills about obstetric emergencies.
Further Researches: Replication of the study on large sample size and in other different institutions for generalizing the findings.

Source of Funding: Self funded “author”

Conflict of Interest: Non to declare.

Ethical Clearance: All experimental protocols were sssapproved under the collage of Nursing – Ain Shams University Cairo. Egypt and all experiments were carried out in accordance with approved guidelines.

Estimation of Stature from Foot Dimensions from Female Population of Rajasthan

Faray Jamal1,2, Rishu Agarwal2, Aditi Mishra2,3, Ulhas Gondhali4

1Assistant Professor, Lovely Professional University, Phagwara, 14441, India, 2M.Sc, Mody University of Science and Technology, Rajasthan-332311, India, 3Research Scholar, RashtriyaRakshaUniversity, Gujarat, India, 4Lecturer, O. P Jindal Global University, 131001, India

Abstract

Background: Analyzing and identifying evidences found at crime scene plays a crucial role in apprehending the offenders and putting them behind bars. Stature Estimation has a significant importance when it comes to narrowing down the list of suspects. At various instances footprints are left behind at the crime scenes as vital evidence and can be utilised for generating the stature of the individual/s connected with the crime scene.

Method: The present study focuses on female population belonging to Rajasthan. Major objective is to determine relation between foot dimensions and stature (n=111). Foot dimensions, mainly foot length and breadth were calculated using standard measurements method. The samples were statistically analyzed; regression equations were generated for length and width of left and right foot.

Conclusion: The predicted R-squared values showed quite significant value of left foot being (0.09) and right foot being (0.04). SEE was calibrated through the regression equations. Width of both the left and right foot were found to be more significant measurements for estimating stature in Rajasthan Population.

Keywords: Forensic science, Anthropometry, Foot length and breadth, Stature estimation, Regression analysis.

Introduction

The application of Anthropology in the field of forensic science is to yield answers to questions that arise due to legal and public concerns. Numerous cases have been reported in the past where, skeletal remains were recovered and identification had to be made. Forensic Anthropometry which was initiated by Alphonse Bertillon back in 1800s was used to record the data of the individuals who were suspects or criminals by taking various body measurements. It still plays an extremely vital role in identifying and reconstructing such events where the death is in question.It becomes even more necessary when we encounter natural calamities such as earthquake, tsunami or a disaster like bomb blasts, air plane crash, where numbers of deceased are uncertain. Countless researches have been utilized in deciphering the gender, ethnicity, age at the time of death and the physical make up or the stature from the recovered fragmented cadaver.

Stature Estimation has been conducted by numerous scholars over the time, the records dates back to 1899; K. Pearson suggested various parameters and equations for evaluating the height and the correlation found among bones and stature. In his memoir it has been mentioned that one equation or a parameter cannot be used to decipher stature of every population that have a different ethnic and ancestral background.

Estimating stature through bones has been accomplished but few studies focus on determining the same using foot dimensions. Being a crucial part of
anthropology they play a decisive role in crime scene investigations. The possibility of their occurrence at a crime scene is uncanny. They can be found in numerous forms, latent, patent as well as plastic impressions. Once located if they are carefully lifted or recorded with correct measurements they can be used to determine the height of the person that was involved at the crime scene. Each print holds great evidentiary value and thus can be aided in narrowing down the investigation. Determining the stature with foot, hand length and breadth was conducted in Turkey on volunteers and the equation derived using foot dimensions yielded more accurate results. Similar studies have been reported in the subcontinent of India, the selected population group being small and restricted to states. Height was estimated using foot measurements in Gujrat Region, Kori Population of Kanpur (U.P) were analyzed on similar body measurement parameters such as full arm length, foot length and breadth, knee length, the accurate measurements were yielded by the foot dimensions. Study conducted on tribal males of Udaipur district of Rajasthan yielded high core relation between the left and right foot length and the stature of the individuals under study. In the present study, the focus is drawn towards stature estimation and determination through human foot of the young females hailing from Rajasthan.

**Materials and Methodology**

Sample collection was conducted at Mody University of Science and Technology, Laxmangarh, Rajasthan. Females who originally hail from the state of Rajasthan were the key targets. A total of 111 samples were collected with the age between 17-23 years, height was calculated using standard measurement criteria; the measuring scale was drawn on a straight wall. The foot prints were taken on plane A4 size sheets. Consent was taken from each individual for maintaining the anonymity and that the data is being collected for the sole purpose of research. Stature was calculated by asking the individual to take off shoes and socks and was made told to stand straight in front of the measuring scale; using a ruler the accurate distance was measured. The foot impressions were drawn with the help of the pen aligning the edge of the skin on an A4 sheet with the support of the flat tile surface. Both the foot were drawn on two different sheets. The length was the foot was taken from the heel to the apex of the toe represented as LFL for Left Foot Length and RFL for Right Foot Length. The breadth was measured from either side of the metatarsals represented as LFW for Left Foot Width and RFW for Right Foot Width. These measurements were brought about on the drawn images of the foot on the piece of paper. (Figure 1)

![Figure 1: Measurements taken of right foot LENGTH (a) and Width (b) of the foot.](image)

**Descriptive Statistics:** Statistical analysis was brought about on the acquired samples. Descriptive statistics result as shown in Table 1. The measurements of the stature of individuals under study had a range between 145-177cms. In order to yield a better correlation between the parameters and the stature, value of p<0.001 was considered. A significant correlation was obtained between stature estimation and Right Foot Width having the value of R=0.02 and Left Foot Width with the value of R=0.03.

Discussion

Numerous studies have been conducted in estimating the stature or height using various body measurements. A significant amount of research reveals that yielding equations using foot dimensions can be extensively used for estimating the stature of various individuals. Literary works conducted nationally as well internationally clearly mention that one single formula and equation cannot be utilized in determining the stature at universal level. Thus every population, tribe, community, locations where people have been living are key research hot spots for conducting these studies. Taneja et al.⁶ in their study of stature estimation of the males of Udaipur, Rajasthan using foot measurements obtained a correlation coefficient between stature and dimensions of the right foot of 0.184 and 0.186 of the left foot. One more study was conducted on KORI population of Kanpur with various body measurements of both males and females.⁵ Thus derived regression equation for estimating the stature of the said population yields a highly significant value while determining stature using foot measurements.

Similar research using foot dimensions for estimating the stature of Gujarat Population was conducted.⁴ They obtained significant values of correlation coefficient between stature and foot length of both male and female. The obtained significant value for male was 0.65 and female was 0.80. Another study was conducted in Mahakauschal region of Madhya Pradesh.⁷ In their study they determined the height from foot dimension, the width and the length being the key parameters and were found to be extremely correlated with stature.

Ozaslan et al.³ conducted the research on Turkish Population for estimating stature using both hand and foot dimensions. In their study they reported that length measurements yield more accurate results as compared to breadth results. Foot dimensions in male yielded a value of r=0.696 and females reported r=0.496. Concurringly hand dimensions in male gave a significant value of r=0.578 contrary to females with r=0.309 value. Moorthy & Khan ⁸ conducted their research on Bidayuhs in east Malaysia using regression equation for estimating stature using footprints. Apart from dimensions they also incorporated gender as an indicator in stature estimating. The result showed that dimension dependent values were found to be more significant than the one that had gender as a parameter in the pooled sample population.

Giles & Vallandigham⁹ used anthropometric measurements on human anatomy for determining the height on Igbo inhabitants of Imo state in Nigeria. Their findings report that foot lengths are more accurate and have high predictability rate as compared to width. Right foot showed accuracy of 50.26% in males and 44.05% in females.

Numerous scholars have predicted various measures of stature estimation that have various parameters involved after from just length and breadth dimensions. The present study conducted on females of Rajasthan population show a more significant role of width in height estimation than length. Analysis conducted on Right foot width produced a value of 0.04 which is extremely significant and on contrary Left foot width produced a significant value of 0.09. Thus it can be concluded that the obtained regression equations can be utilized in estimating the stature from footprints of Rajasthan female population.

Conclusion

Stature estimation or height determination plays extensive role in forensic science. Its extent stretches from narrowing down the suspect list to identifying the individual. India is a large country with diverse communities thus generating a universal equation for stature estimation is not feasible. Thus research conducted on communities sharing ancestral history of location can be brought about for correct estimation of height. These collections can at a large become a database that could be used for identification purpose. Our study conducted on Rajasthan population of females achieved a significant result of equations, where both foot widths are showing highly accurate result for estimating the stature.

Common Hemoglobinopathies for Couples Premarital Individual and its Influence on Hemostasis and Immune State

Fatimah Kadhim Ibrahim AL- Mahdawi¹, Noor Nayyef Oudah², Mazin Razooqi Mohammed³

¹,²Medical Laboratory Technology Department, Bilad Al-Rafidain University College,
³Consultant Doctors, Baqubah Teaching Hospital, Diala Health Directorate, Iraq

Abstract

Before marriage, couples are screened through a procedure known as premarital screening for different genetic, infectious or bloodborne diseases that can be passed from them to their offspring. The aim of our research was to assessment the premarital screening of couples for hemoglobinopathies and undiagnosed cases with suggestive findings of thalassemia or its variants. and evaluation hematology parameters among common Hb hemoglobinopathy. This study contains 228 individuals with hemoglobinopathy, the participants were couples attending primary health centers for regular premarital inquiries in Baquba teaching hospitals, Iraq. α-thalassemia was enrolled in 3 (1.3%) from all hemoglobinopathy individuals, β-thalassemia was enrolled in 255 (98.8%), which include β-thalassemia minor in 226 individuals 88.6%, while β thalassemia intermediate in 5 individuals 2.2% from all individuals with hemoglobinopathy. Others thalassemia was recorded 3 Hb-E 1.1%, 1 Hb-S 0.39, 10 Hb-D 3.92, 13 Hb-C 5.09. Pre-marital examinations are important to determine hemoglobinopathy and limit transmission to offspring, as well as blood tests are important to identify people with haemoglobinopathy and its influence.

Keywords: Hemoglobinopathies, Premarital Individual, hemostasis, immune state.

Introduction

Before marriage, couples are screened through a procedure known as premarital screening for different genetic, infectious or bloodborne diseases that can be passed from them to their offspring(1). Among the most common autosomal recessive disorders affecting humans, haemoglobinopathies are assessed and are characterized by the existence of qualitative and/or quantitative anomalies affecting the globin chains (2).

The most common qualitative anomalies are haemoglobin (Hb)S, which causes Hb-C or Hb-D disease of the sickle cell (SCD) and others, and the most common quantitative anomalies with decreased or absent alpha- or β-globin chain synthesis lead to alpha- and β-thalassemias, respectively(3, 4). These are the world’s most common single gene disorders, particularly in the Eastern Mediterranean Region, including Iraq(5). Premarital screening for thalassemia and sickle cell anemia was required in 2004 by the Third Royal Decree. According to this decree, couples getting married must receive a certificate specifying their thalassemia and sickle cell anemia status from the approved health centers after being checked. Another essential role of this initiative is the therapy of couples at risk (6).

This study aimed to assess the premarital screening of couples for hemoglobinopathies and undiagnosed cases with suggestive findings of thalassemia or its variants, and evaluation hematology parameters among common Hb hemoglobinopathy.

Material and Method

This study contains 228 individuals with hemoglobinopathy. The participants were couples attending primary health centers for regular premarital inquiries in Baquba teaching hospitals, Iraq. By using standard laboratory procedures the hemoglobin electrophoresis on cellulose acetate (at pH 8.6) was
carried out on all (228) samples. The HbA2 level was calculated by alkaline denaturation using elution from cellulose acetate and HbF(7).

β-thalassemia minor was diagnosed by an elevated HbA2, while β-thalassemia major was diagnosed by an elevated Hb-F, and others (Hb-E, Hb-S, Hb-D, Hb-S) trait by a positive test confirmed by Hb band on electrophoresis. α-thalassemia trait was diagnosed by an absence of Hb variants or any increases in Hb A2 or HbF(8), table 1.

**Statistical Analysis:** Statistical analysis was achieved by using SPSS 20.0 software (SPSS, Inc., Chicago, IL, USA). Continuous variables were expressed as the mean ± standard error. Dichotomous variables were expressed as percentages. ANOVA was achieved to estimate the differences in continuous variables between the common hemoglobinopathies groups. P < 0.05 was considered to indicate a statistically significant difference.

**Results**

α-thalassemia was enrolled in 3 (1.3%) from all hemoglobinopathy individuals, β-thalassemia was enrolled in 255 (98.8%), which include β-thalassemia minor in 226 individuals 88.6%, while β-thalassemia intermediate in 5 individuals 2.2% from all individuals with hemoglobinopathy Figure 1 and 2. Others thalassemia was recorded 3 Hb-E 1.1%, 1 Hb-S 0.39, 10 Hb-D 3.92, 13Hb-C 5.09 Figure 3.

![Figure 1: The percentage of β- and α-thalassemia](image-url)
Table 2 illustrated Hb electrophoresis, the mean Hb A0, A1c, A2, F level in α-thalassemia patients was (70.5 %, 9.9%, 1.7 %, 25.3% respectively). And in β-thalassemia minor patients was (80.32%, 5.0%, 4.9%, 6.6% respectively). While in β-thalassemia intermediate patients was (48.8%, 5.1%, 6.8%, 30.1% respectively). Others hemoglobinopathies the mean Hb A0, A1c, A2, F level in Hb E beta thalassemia patients was (64.43%, 4.8%, 25.6%, 0.9% respectively), Hb Sickle disease patients was (58.5%, 5.4%, 3.4%, < 0.8% respectively), Hb D beta thalassemia patients was (54.47%, 5.05%, 5.05%, < 0.8% respectively), and Hb C disease patients was (56.39%, 4.93%, 3.2%, <0.8% respectively).

### Discussion

The premarital screening program is essential for genetic disorders as it dictates the prevalence and potential transmission of these disorders to the offspring.

The most prevalent abnormal finding observed in our study was β-thalassemia minor (88.6%), while the α-thalassemia reached (1.3%). Studies performed in Jeddah (West) and Al-Hassa (East) found that 4.69 percent and 3.4 percent of individuals had β-thalassemia trait(9,10). With an average prevalence of carriers of about 4 percent and an estimated 15,000 registered major/intermediate thalassemia patients throughout the region, β-thalassemia is a common inherited hematological disorder in Iraq. The sickle cells were found in (0.39%) individuals in the studied population. This result is contradictory to the findings of other studies where the recorded prevalence of sickle cell trait β thalassemia is 3.4% and 3.3%(11,12). Hemoglobin E (1.1 %) was found to be a small proportion of the studied population. In Jeddah, the prevalence of hemoglobin E recorded was 0.85% these percentage is low when compared with our result(13).

In our study the platelets showed decrease significantly in β-thalassemia intermediate and increased significantly in in Hb E beta thalassemia when compared with others groups, platelets are activated by free radical from hemoglobin(14,15), RBC phospholipids, thrombin(16), and microparticles(17). Then, after their activation, platelets bind to proteins S and C(11). Release thromboxane A2 (TXA2)(18), and form microparticles of platelets(17). Simultaneously, iron overload is also present in β-thalassemia.] Vitamin C is decreased due to this iron overload, which may result in platelet defect(19).

Several immunological defects can be found in patients with thalassemia, among which the impairment of neutrophils and macrophage phagocytic and killing functions. In our study the white blood cells showed increased significantly in β-thalassemia intermediate and decrease significantly in Hb E beta thalassemia when compared with others groups. In β-thalassemia, The white blood cells defect in thalassemic patients may result from dysregulation of the apoptotic cells death pathway(20).

### Conclusion

Pre-marital examinations are important to determine hemoglobinopathy and limit transmission to offspring, as well as blood tests are important to identify people with haemoglobinopathy and its influence.

**Source of Funding:** Self fund.

**Conflict of Interest:** No conflict of interest

**Ethic Statement:** The researchers already have ethical clearance from all required institution and laboratories.

Abstract

Child sexual abuse (CSA) is a serious and widespread problem in India as it is in many parts of the world today. Objective: The aim of this study was assess the knowledge on child sexual abuse among school children at Kattankulathur High School and to associate the knowledge on child sexual abuse among school children at Kattankulathur High School with their demographic variables.

Method: Quantitative approach and non-experimental descriptive research design was used. The data collection included two parts. Part A: Demographic variables, Part B: A Structured questionnaire to assess knowledge on child sexual abuse among school children. 180 school children who fulfilled the inclusion criteria were selected as samples using non probability convenient sampling technique. The study was conducted at Kattankulathur High School, Kancheepuram dt.

Results: The data were analyzed and interpreted based on the objectives using descriptive and inferential statistics. Among 180 school children 90.6% of them had Moderately adequate Knowledge, 9.4% of them had Inadequate knowledge and None of them had adequate knowledge. The p-values are not significant since they are not less than 0.05 hence we can say that there is no significant association between the demographic variables and the knowledge on Child Sexual Abuse at 5% level. Conclusion: child sexual abuse is an important contributor to psychological and emotional disorders, that some children and adolescents may never overcome.

Keywords: Child sexual abuse, school children.

Introduction

Child sexual abuse (CSA) is defined as the misuse of power and authority, combined with force or coercion, which leads to the exploitation of children in situations where adults, or children sufficiently older than the victim to have greater. Child sexual abuse (CSA) is a serious and widespread problem in India as it is in many parts of the world today. The trauma associated with sexual abuse can contribute to arrested development, as well as a host of psychological and emotional disorders, that some children and adolescents may never overcome. When sexual abuse goes unreported and children are not given the protective and therapeutic assistance they need, they are left to suffer in silence\textsuperscript{(1)}.

Child sexual abuse, also called child molestation, is a form of child abuse in which an adult or older adolescent uses a child for sexual stimulation Forms of child sexual abuse include engaging in sexual activities with a child (whether by asking or pressuring, or by other means), indecent exposure (of the genitals, female nipples, etc.), child grooming, child sexual exploitation or using a child to produce child pornography\textsuperscript{(2)}.

Child sexual abuse can occur in a variety of settings, including home, school, or work (in places where child labor is common). Child marriage is one of the main forms of child sexual abuse; UNICEF has stated that child marriage “represents perhaps the most prevalent form of sexual abuse and exploitation of girls”. The effects of child sexual abuse can include depression, post-traumatic stress disorder, anxiety, complex post-traumatic stress disorder, propensity to further victimization in adulthood, and physical injury to the child, among other problems. Sexual abuse by a family member is a form of incest and can result in more serious
and long-term psychological trauma, especially in the case of parental incest(3).

The global prevalence of child sexual abuse has been estimated at 19.7% for females and 7.9% for males. Most sexual abuse offenders are acquainted with their victims; approximately 30% are relatives of the child, most often brothers, fathers, uncles, or cousins; around 60% are other acquaintances, such as “friends” of the family, babysitters, or neighbors; strangers are the offenders in approximately 10% of child sexual abuse cases. Most child sexual abuse is committed by men; studies on female child molesters show that women commit 14% to 40% of offenses reported against boys and 6% of offenses reported against girls(4).

The Magnitude of the Problem:

Global Level: In 2017, the WHO estimated that up to 1 billion minors between the ages of 2 and 17 years of age have endured violence either physical, emotional, or sexual. Sexual abuse (from groping to rape), according to some UNICEF estimates from 2014, affected over 120 million children, representing the highest number of victims. In 2017, the same UN organization reported that in 38 low and middle income countries, almost 17 million adult women admitted having a forced sexual relationship during their childhood(5).

According to the report on crimes in India for 2016, released by Indian Home Minister Rajnath Singh in Delhi, 106,958 cases of crimes against children were recorded in 2016. Of these, 36,022 cases were recorded under Pocso (Protection of Children from Sexual Offences) Act(6).

Unfortunately, many people feel that talking about childhood sexual abuse is taboo, even though we know it happens and know that it’s a crime. Some survivors are cut off from supports like family, friends and community members when they talk about their experiences(7).

Nurses should educate children and young people about healthy relationships and how to stay safe online. These foundations can be laid from a young age. Simple way to teach younger children how to stay safe from abuse may help to prevent them from sexual abuse.

Method and Materials

Quantitative approach and non-experimental descriptive research design was used. A total of 180 school children who fulfilled the inclusion criteria were selected as samples using non probability convenient sampling technique. The study was conducted at kattankulathur High School, Kancheepuram dt. The data collection included two parts. Part A: Demographic variables, Part B: A structured questionnaire to assess knowledge on child sexual abuse among school children. The Study variable was knowledge among school children on child sexual abuse and the Demographic variable were Age, education, mother education, father education, mothers occupation, fathers occupation, Type of family, Number of Children in the Family, other maids in the house and another family member living/always visiting your house.

Ethical Consideration: Formal approval was obtained from the Institutional Review Board and Institutional Ethical Committee of SRM IST, Head of the Department of Obstetrics and Gynaecology, SRM General Hospital, Kattankulathur. In addition, the participants were informed of their right to withdraw anytime during the study.

Instruments: The Demographic and the Structured Questionnaire was developed by the investigator based on the review of literature, discussion with experts and investigators personal experience. The tool consists of 2 sections. Part -A deals with demographic Variables and Part-B consisted of 15 questions to assess the knowledge on child sexual abuse among school children.

Scoring Key: Each question was given 4 options. Each correct answer was awarded score 1. Each incorrect answer was awarded score “0”.

Scoring Interpretation:

<td>68 to 100</td>
</tr>
</tbody>
</table>

Method of Data Collection: The formal permission was obtained from the head of the kattankulathur High School. The investigator explained the objectives and method of data collection to the school children. Verbal concern was obtained from the samples. The samples was chosen through non probability Convenient sampling technique. A total number of 180 school children who met the inclusion criteria were selected. The investigator explained the purpose of conducting
the study and reassured the client that the collection will be kept confidential.

On selection of the subject, a self introduction was given. Consent was obtained and confidentiality of the response was assured. The investigator assessed the Knowledge of child sexual abuse and it was assessed by Structured Questionnaire. In case of any doubts the investigators clarified the doubts.

The investigator collected information regarding section-A [demographic data] and section-B [knowledge assessment tools] and the responses marked simultaneously. It took around 15 minutes from each sample to obtain the necessary data. The investigator thanked the participants for extending their fullest cooperation.

### Statistical Analysis:
The information collected from the study participants was scored and tabulated. The data were entered into the master coding sheet and saved in Microsoft Excel. Statistical analysis was conducted using Statistical Package for Social Sciences-16. Mean, percentage, and standard deviation were used to explain the demographic variables, and Chi-square test was used to associate the demographic variables with level of knowledge on child sexual abuse among school children.

### Results

</table>

*Significant at 5% level, **Significant at 1% level

**Result**

The p-values from the above table are not significant since they are not less than 0.05 hence we can say that there is no significant association between the demographic variables and the knowledge on Child Sexual Abuse at 5% level.

**Discussion**

The major consequences of Sexual abuse in childhood is known to be a major risk factor in the development of long-term psychological and social adjustment problems that can carry over into adulthood and affect married life and parenthood. The most common effects of sexual abuse in children are symptoms of post-traumatic stress disorder, psychological distress and inappropriate sexual behaviour.

El khoury c et al assessed the prevalence and correlates of experiences of child and post-childhood sexual violence among young MSM residing in Beirut, Lebanon. In total, 226 MSM, aged 18 to 29, were recruited with long-chain peer referrals and administered a survey that included questions on history of being pressured to have sex, as well as specific forms of sexual harassment and abuse, in addition to measures of psychosocial functioning and sexual behavior. Logistic regression analysis was used to examine correlates of child sex abuse and experiences of sexual violence post-childhood; 17.3% experienced sexual abuse as a child (below age 13), while 63.3% experienced any form of sexual violence post-childhood-furthermore, 48.7% had experienced being forced or pressured to have sex during their lifetime, including 32.3% prior to age 18. These findings reveal a high prevalence of sexual
violence among MSM in Beirut, both in childhood and post-childhood(8).

McWhorter KLe et al conducted a study on Traumatic childhood experiences and multiple dimensions of poor sleep among adult women. A large cohort of US women, 35-74 years old, enrolled in the Sister Study from 2003 to 2009. Among 40 082 women, 55% reported a TCE, with 82% reporting betrayal trauma. TCEs were associated with poor sleep in women with greater impact when the perpetrator was regarded as close. More research is warranted to better understand pathways between childhood trauma and sleep health in adulthood to develop effective interventions(9).

**Conclusion**

Child sexual abuse (CSA) is a serious and widespread problem in India as it is in many parts of the world today. Child sexual abuse exploits and degrades children and can cause serious damage to cognitive, social, and emotional development of a child. Society have a collective responsibility to prevent child sexual abuse. To accomplish this, must initiate and support services and policies that enhance children’s development, health and safety and we must advocate for policies and programs to help meet the basic needs of children and families and must also promote research, training, and public education to strengthen protective factors that buffer risk factors for sexual abuse while also directly addressing those risk factors.

A Study to Assess the Knowledge Regarding Gestational Diabetes Mellitus among Pregnant Mothers and Self Care Practice of Gestational Diabetes Mellitus Management among Mothers with Diabetes in Pregnancy Attending Selected Hospitals of Kottayam District

Gesa George¹, T. Sasikala², Remya Chidambaran³

¹PhD Scholar, Rani Meyyammai College of Nursing, Annamalai University, Chidambaram-608002, Tamil Nadu, India, ²Lecturer, Rani Meyyammai College of Nursing, Annamalai University, Chidambaram-608002, Tamil Nadu, India, ³Vice-Principal, Sreesuchendra College of Nursing, Ernakulam, Kerala

Abstract

The study was conducted to assess the knowledge regarding Gestational Diabetes Mellitus among pregnant mothers and self care practice of Gestational Diabetes Mellitus management among mothers with diabetes in pregnancy attending selected hospitals of Kottayam District. The objectives were to assess the level of knowledge regarding Gestational Diabetes Mellitus among pregnant mothers, to assess the self care practice of Gestational Diabetes Mellitus management among mothers with diabetes in pregnancy, to find association between level of knowledge regarding Gestational Diabetes Mellitus and selected demographic variables, to find correlation between knowledge and self care practice of Gestational Diabetes Mellitus management among mothers with diabetes in pregnancy. The research design used in the present study is non experimental descriptive design. The study was conducted among 60 antenatal mothers and 15 mothers with gestational diabetes mellitus by using non probability convenient sampling technique. In the present study it was found that 33.3% mothers had poor knowledge, 33.3% had average knowledge and 33.3% had good knowledge regarding Gestational diabetes mellitus. When comes to practice t 46.7% had satisfactory practices and 53.3% had good practice. There is a positive correlation between knowledge and practice (p=0.04).

Keywords: Gestational diabetes mellitus, Knowledge, Practice.

Introduction

Pregnancy is one of the wonderful and noble services imposed by nature which no women can shrink. It is a period of happiness, excitement, expectancy, anxiety and fear.¹ Some common maternal health condition or problems a women may experience during pregnancy are Anemia, UTI, Mental health condition, Hypertension, Gestational Diabetes mellitus, Obesity and Weight gain, Infection, Hyper emesis gravidarum.²

Diabetes Mellitus is a metabolic disorder that affects carbohydrate, fat and protein metabolism.³ Today the majority of the women have Type 2 diabetes or diabetes during pregnancy. International Diabetes Federation says that the prevalence of high blood glucose in pregnancy increase rapidly with age and is highest in women of 45 in 2017.³

The main cause and risk factor of Gestational Diabetes Mellitus are age > 25 years, pre-gestational obesity or excessive weight gain during pregnancy, family history of diabetes, personal history of poor obstetric outcome such as polyhydramnios, macrosomia, pre-eclampsia, fetal malformation of an ethnic group with a high risk prevalence of diabetes and history of Diabetes Mellitus in previous pregnancy.⁴

Diabetes during pregnancy has been associated with increased perinatal mortality, an increased rate of caesarean sections, significant risk of macrosomia, and other neonatal morbidities, including serious birth
-trauma, hypoglycemia, hypocalcemia, polycythemia and hyperbilirubinemia. Management is therefore directed toward reducing perinatal mortality and morbidity, a goal that may be achieved by maintaining close surveillance of the mother and fetus and stringent glucose control.  

**Need for Study:** Diabetes is a metabolic disorder characterized by resistance to the action of insulin, insufficient insulin secretion or both. Diabetic Mellitus is the most common metabolic disorder that complicates 3-5% of all pregnancies and is a major cause of perinatal morbidity and mortality as well as maternal morbidity.

As the incidence of both obesity and Diabetes Mellitus among women of child-bearing age continue to raise well, so as the prevalence of hyperglycemia in pregnancy. Gestational Diabetes Mellitus develops in 1 in 25 pregnancies worldwide. According to American Diabetic Association, Gestational Diabetes Mellitus is a common condition affecting 7% of all pregnancies. Depending on the population sample and diagnostic criteria, prevalence range from 1-14%.

It is the most common metabolic disorder in pregnant women, associated with serious maternal and neonatal complications. This phenomenon is initially diagnosed during late pregnancy. It is predicted that the number of diabetic patients is projected to double by 2030, which will also affect pregnant women.

A prospective study on the prevalence of carbohydrate intolerance of varying degree in pregnant woman in western India (Maharashtra). On 2005-2007 the sample size were 1225 woman with average age of 25 to 40 years. The result shows that the prevalence of Gestational Diabetes Mellitus was 21.6% and concluded that Gestational Diabetes Mellitus affect one fifth of pregnant female from western India.

From the above studies, it clearly shows that Gestational Diabetes Mellitus drastically increasing year by year now it is a serious complication during gestational period which affect both mother and child. Gestational Diabetes Mellitus is an intense field of research study. It shows that prevalence of Gestational Diabetes Mellitus increases by 45% but still knowledge regarding Gestational Diabetes Mellitus and self care management is very low. Hence the investigator felt that this study would help the antenatal woman to enhance their knowledge regarding Gestational Diabetes Mellitus and self care practice of Gestational Diabetes Mellitus management which in turn would help to prevent complication during pregnancy.

**Statement of the Problem:** “A study to assess the knowledge regarding Gestational Diabetes Mellitus among pregnant mothers and self care practice of Gestational Diabetes Mellitus management among mothers with diabetes in pregnancy in selected hospitals of Kottayam District.

**Objectives of the Study:**

1. To assess the level of knowledge regarding Gestational Diabetes Mellitus among pregnant mothers
2. To assess the self care practice of Gestational Diabetes Mellitus management among mothers with diabetes in pregnancy.
3. To find correlation between knowledge and self care practice of Gestational Diabetes Mellitus management among mothers with diabetes in pregnancy.

**Hypothesis:**

H1: There is a significant correlation between knowledge and self care practice of Gestational Diabetes Mellitus management among mothers with diabetes in pregnancy.

**Methodology:**

**Research Approach:** Non experimental descriptive design

**Research Design:** Descriptive research design

**Variables:** Study variables are knowledge and practice

**Setting:** The study was conducted in Carmel Medical centre, Pala, Marian medical centre Palai.

**Sample:** Sample include 60 antenatal mothers and 15 mothers with gestational diabetes in selected hospitals in kottayam.

**Sampling Technique:** Non probability purposive sampling

**Tool and Technique:** Structured questionnaire is prepared with the help of review of literature, personal experience and discussion with experts. The questionnaire is categorized into 3 sections.
Section 1: Consists of socio demographic data which include age monthly income, education, occupation, religion, previous history of Gestational Diabetes Mellitus etc.

Section 2: It consists of question regarding knowledge regarding Gestational Diabetes Mellitus.

Section 3: It contains questions regarding self care practice of Gestational Diabetes Mellitus management.

Method of Data Collection: The formal permission for data collection was obtained from concerned authority. The actual study was conducted on 11/09/2019 to 11/10/2019. By purposive sampling technique, the investigator identified 60 antenatal mothers and 15 mothers with gestational diabetes based upon inclusion and exclusion criteria. Prior to data collection, purpose of study was explained to the subjects to gain co operation. The written consent was obtained and the investigator requested to to read the instruction on the questionnaire and fill it. The data was collected and was then compiled for analysis.

Table shows the calculated correlation coefficient(r) was 0.880 which indicate that there was a positive correlation between knowledge and practice.

Discussion

In the present study, 73.3% of pregnant women belong to the age group of 20-30 years and 26.7% belongs to the age group of 30-40 years. 41.67% of mothers were Hindus, 41.67% were Christians and 16.6% were Muslims. In the present study it was found that 33.3% mothers had poor knowledge, 33.3% had average knowledge and 33.3% had good knowledge regarding gestational diabetes mellitus. The above findings can be supported by a study conducted among 30 mothers attending antenatal clinics of Mangalore to assess the level of knowledge regarding gestational diabetes mellitus and self care management. The results showed that 26.60% of women had poor knowledge and 20% had good knowledge.10

In the present study 46.7% had satisfactory practices and 53.3% had good practice. The results of this study is contradictory to the study conducted among Diabetes Patients in Dhaka City, Bangladesh in the year 2016 which showed that majority of patients reported regular routine follow up diet and exercise etc. for controlling DM. However, glycemic control was poor among 46.67% of respondents and 62.38% patients never performed self-blood sugar test due to lack of knowledge or lack of the feeling of necessity to do it.11 The present study
shows that there is positive correlation (p=0.04) between knowledge and self care practice of gestational diabetes mellitus management among mothers with diabetes in pregnancy.

**Recommendations:**

1. Similar study can be replicated with large sample in different settings.
2. A cross sectional study can be done to test the effectiveness of the instructional module.

**Conclusion**

Pregnancy is a period of great change for the women in both physiological and psychological aspects. The women should adapt with these changes for the successful outcome of the pregnancy. From the present study the result showed that 33.3% had above average knowledge, 33.3% had average knowledge and 33.3% had below average knowledge regarding the gestational diabetes mellitus and the self care management. The present study shows that 46.7% had satisfactory practices and 53.3% had good practice. There is a positive correlation between knowledge and practice (p=0.04).

**Conflict of Interest:** Nil

**Source of Funding:** Self

**Ethical Consideration:** Ethical clearance was obtained from ethical committee, Govt. Medical College, Kottayam. Informed written consent was taken on the selection of the subjects. Full confidentiality was maintained throughout the study.

Studying and Evaluating the Immune System in Urticaria, Asthma and Rhinitis

Ghanyia Jasim Shanyoor¹, Rawaa Abdul-ameer Abdul-jabbar², Ekhlass N. Ali¹

¹Ass. Prof., ²Lecturer, Biology Department, College of Science, Mustansiriya University, Baghdad, Iraq

Abstract

Background: Diseases related with allergy such as urticaria, asthma, and rhinitis have an effect on autoimmune system.

Objectives: This study was planned and carried out to assess how the immunity affected in patients with allergy and urticaria, asthma, and rhinitis through measuring the total IgE and IL-33.

Materials and Method: A collection of females and males (74 patients) with urticaria, asthma, and rhinitis were chosen in this research, 24 with urticaria, 26 with asthma, and 24 with rhinitis their ages were ranged from 30 to 45 years while their weight ranged from 69 to 92 kg, using immuno sorbent assay (ELISA), the IL-33 and IgE were calculated and evaluated respectively in the patients and the collected data were compared with healthy individuals (control).

Results: The data that was gathered from the blood serum of urticaria, asthma, and rhinitis patients indicates considerable differences in levels of IL-33 which were tolerated from 172 to 185 Ng/l, while the IgE ranged from 321 to 397 Ng/l comparing with healthy individuals (control). Also results of specific IgE signify a existence for one or more inhalant allergens in urticaria, asthma, and rhinitis, especially in rhinitis patients, precisely in Weeds allergens (w6, w9), Tree allergens (t2, t3, t4, t7), and Grasse’s allergens (g6, g12) and it was lower in females than males.

Conclusion: The considerable changes in the IL-33, and IgE in the patients affect the immunity system in the patients due to the chronic inflammatory diseases (urticaria, asthma, and rhinitis) and it will increased in patients with inhalant allergy.

Keywords: Urticaria, Asthma, Rhinitis, immunity, inhalant allergy.

Introduction

Allergens, which commonly are in urban communities as well as in modern societies, are certain materials or animals that cause a certain symptoms in respiratory system and in eyes; the signs may appears in lungs, noise, and eyes. It may also appear in the skin as eczema or red spots, and it affects the blood. Diseases that appear due to allergens such as urticaria, asthma, and rhinitis may cause high sensitivity and disorder which affect the IL-33 and IgE percentages in blood and considered as pathogenic to allergic disease (1-3).

IL-33 (Interleukin-33), associated with the molecular damage and is considered as immune system alert to allergens and usually considered as a IL-1 family member, thus it is an extracellular cytokine, therefore it is support endothelial cell against inflammation, and this enable the scientists and the researcher to consider it as a key factor to discover and characterize the diseases that related to allergy and this could be due to the activation of the immune cells (Th2)(4-6).

IgE (immunoglobulin E) is a protein (antibody) by
which the plasma cells are responsible to synthesize it and it is considered as allergy indicator in the body and used by the immune system in the duration of the defense against some syndrome\(^\text{7, 8}\).

Recent studies assured the relationship and the link between allergy that caused by allergens substances and the level of IgE in the serum, this principle can be applied on urticaria, asthma, and rhinitis patients who suffered from these chronic diseases\(^\text{9, 10}\).

The goal of the current study is to assess how the immunity affected in patients with allergy from certain materials and the patients who have urticaria, asthma, and rhinitis through examining the level of IgE and IL-33 in blood serum.

### Materials and Method

74 patients were chosen in this study, half of them were females while the other 37 were males, and they were classified according to their diseases ((24 Urticaria, 24 Rhinitis, and 26 Asthma). The sera were isolated from the blood samples, and were kept at -70 °C. Healthy 28 individuals’ half females and 14 were males, and they were included in the current study and used their sera for comparison with the 74 patients. Patients and healthy individuals were diagnosed by the special physicians in Allergic Specialized Center/Baghdad.

Immuno sorbent assay (ELISA), were carried out to indicate the levels of IL-33 and IgE and were calculated and evaluated respectively in the patients. The collected data were compared with healthy individuals (control).

Statistical analyses were also carried out using Minitab software for statistics, version 13. The P-value was also calculated using ANOVA.

### Result and Discussion

Levels of IL-33 and IgE that appears from ELISA test were listed in table 1.

<table>

</tr>
</tbody>
</table>

From table 1 it was found that all the patients shows a significant increasing in the level of IgE comparing with control (healthy group), but patients with asthma have higher level of IgE than patients with urticaria, and rhinitis, the age and the weight of the patients doesn’t shows and correlation with the level of IgE.

Table 2 represent the calculated data from inhalant allergies that caused by certain compounds to patients with allergy and urticaria, asthma, and rhinitis.

Results in table 2 indicate the correlation between the allergy that caused by inhalant and the three groups of patients (urticaria, asthma, and rhinitis), as towards animal, the results shows a high correlation between and the highest level IgE and the gender, females shows high inhalant allergy than males, while males affected with weed more than the females\(^\text{11}\).

Many studies confirm the correlation between the allergy toward animal and mite, precisely for urticaria patients, these studies indicates atopic allergies (dermal and respiratory) such as eczema, rhinitis and asthma\(^\text{12, 13}\). Grass and tree allergies are higher in males than females, this conclusion was confirmed also by Cayrol and her team coworkers in 2014 \(^\text{14}\), while for mold the females shows more inhalant allergy than males\(^\text{11}\).

Studies confirm the relationship between the level of IL-33 in patient serum and allergy, the data that were obtained in the current study (represented by table 1, and 2) shows a continuous changes in IL-33 structure due to the activation of many pathways signs as well as the inflammatory cells in asthma patients, this elevation depends on the typep of allergy, type of cellular damage and cellular stress production.

Atrial Fibrillation One of Hidden Causes of Subclinical Stroke: Case-Control Study

Haider Shaheed Mohammed
Lecturer, Department of Internal Medicine, College of Medicine, University of Thi-Qar, Thi-Qar, Iraq

Abstract

Background: Silent cerebral infarction is frequently encountered on various imaging modalities of brain in individuals with atrial fibrillation, its exact relation with atrial fibrillation is still debated.

Objectives: The study was carried out to estimate the link between silent cerebral infarcts with atrial fibrillation, both paroxysmal and persistent types.

Materials and Method: A random sample of 150 were included in the study, 100 with atrial fibrillation 50 case with paroxysmal, 50 case with persistent type, and 50 control, for both cases and control a questionnaire was constructed, physical examination, neurological examination, and magnetic resonance imaging were done.

Results: Mean age was 64.6667. Of the total sample there was 96 males and 54 females. 89 individual of the total sample had silent cerebral lesion while 61 had no lesion. Of those who had lesions, 38 individuals had paroxysmal atrial fibrillation, 41 had persistent atrial fibrillation, and only 10 individuals belong to control group. There was high statistically significant difference between group of cases with atrial fibrillation and group of control in sinus rhythm where p value is 0.0001.

Conclusion: Both paroxysmal and persistent atrial fibrillation is associated with heightened hazard of silent cerebral infarctions.

Keywords: Paroxysmal atrial fibrillation, persistent atrial fibrillation, silent cerebral infarctions.

Introduction

Atrial fibrillation is customarily happened arrhythmic heart disorders in clinical ground [1]. It is think about to be the most continual arrhythmia in older age individuals [2]. World wide its prevalence and incidence is get higher [3], with almost one percent prevalence over the world [4]. Atrial fibrillation is a hazard for recruitment of cardiac failure, health facility consumption, uprising morbidity burden, and fatality [1]. “Paroxysmal atrial fibrillation is defined as an episode of atrial fibrillation that terminate spontaneously or with intervention in less than seven days”[13]. “Persistent atrial fibrillation is defined as atrial fibrillation that fails to terminate within seven days”[13]. Worldwide stroke listed as the second most frequent cause for fatality and the third habitual cause for disability [5]. Stroke is remarkably catastrophic danger in Asia and its danger of death in Asia is more than western nations [6]. Atrial fibrillation is a noteworthy predisposing condition for ischemic stroke by mechanism of thromboembolization and the stroke that is attended by atrial fibrillation is more dangerous, with worse sequelae, greater disablement, higher fatality and massive infarct size than those without atrial fibrillation [7]. Atrial fibrillation heighten the hazard of embolic stroke by five times and the hazard is alternating from one to fifteen percent every year dependent on attendance of comorbid disorders [8]. Atrial fibrillation is not only give rise to symptomatic

DOI Number: 10.37506/mlu.v21i2.2740
Medico-legal Update, April-June 2021, Vol. 21, No. 2

stroke but also asymptomatic one that is brain ischemia in individuals with atrial fibrillation wandering from clinically asymptomatic to catastrophic\textsuperscript{[9]}. Silent cerebral infarction is referred to existing of brain infarction without parallel complaints \textsuperscript{[10]}. Silent cerebral infarction happened in both individuals with atrial fibrillation and those without, but nearly most of studies stated that it is happened with raised occurrence in clients with atrial fibrillation \textsuperscript{[4]}. The prevalence in general public fluctuates correlating to the imaging method implemented, the prevalence of silent cerebral infarction discovered by magnetic resonant imaging in most estimations falling in range of eight to twenty-eight percent, while is approximately forty percent in patients with atrial fibrillation \textsuperscript{[9]}. Silent cerebral infarction is well-recognized to advance to symptomatic stroke \textsuperscript{[4]}, it is not considered silent and harmless as it is linked with indistinct neurological defect, cognitive impairment, psychological abnormalities, clinically manifest stroke, and early fatality \textsuperscript{[4]}. A number of risk conditions are correlated with growing happiness of silent cerebral infarction, the most prominent of which is elevated blood pressure and increasing age \textsuperscript{[10]}. Owing to sophisticated advancement of neuroimaging, greater number of patients with atrial fibrillation ascertained to have tiny ischemic brain lesions, that is because of its higher prevalence in individuals with atrial fibrillation and its greater danger to advance to clinically overt neurological defects it should be considered appreciably while physician assess individuals with atrial fibrillation \textsuperscript{[4]}. Investigators perceives that silent infarctions often confined to cerebral cortex and cerebellum are commonly discovered in patients with atrial fibrillation for which cardiac origin is of paramount role \textsuperscript{[11]}.

**Methodology**

Type of study: this is a case control study.

The study had been long lasting from the beginning of first week of February 2018 to the end of the last week of April 2019.

**Study Population:** The study population comprises an admitted patient in cardiac care unit in Al-Hussein teaching hospital in Al-Nasiriya city. The diagnosis of cases rely on any accessible tests or reports in case file of patients or diagnosed on interview. Total number of patients that were included in the study was (150), with (50) case with paroxysmal atrial fibrillation, (50) case with persistent atrial fibrillation, and (50) controls.

**Inclusion Criteria:** Any case with atrial fibrillation with any predisposing factors whether paroxysmal or persistent was included in the study.

**Exclusion Criteria:**

1. Any patient with implantable heart device had been inserted or any other contraindication to magnetic resonance imaging.
2. Any patients with existing or antecedent clinical confirmation of transient ischemic attack or cerebrovascular accident.
3. Any recognized case of intracranial injury, space lesions, autoimmune, or inflammatory insults of brain that interfere with precise interpretation of radio imaging.
5. Any case of atrial fibrillation due to valve disorder.
6. Any patient with significant carotid artery stenosis more than seventy percent detected by carotid Doppler sonorographic study.

**Sample Size:** was convenient restricted by accessibility of patients and time span of study, but sampling task for control, systematized random sampling procedure was done to collect control.

**Ethical Issue:** An ethical consensus was acquired from Al-Hussein teaching hospital administration. An informed consents also were extracted from all participants.

**Study Appliances:**

**The Questionnaire:** Distinct design of questionnaire was formulated to assemble data and it was revised and reviewed by three subjects matter experts (of community medicine and physician) for examining the validness and the enrichment of questionnaire. The questionnaire is consisted of two sections:

**First Section:** Involve questions regarding identity information, Second section: questions related to past medical history comprising chronic medical diseases, medication history, type and number of medications have been determined for every individual in the sample (cases and control).

**Diagnostic Procedures:** Atrial fibrillation is diagnosed by electrocardiogram. “Atrial fibrillation is
characterized by the replacement of consistent P wave by rapid oscillation or fibrillatory waves that vary in amplitude, shape, timing associated with an irregular frequently rapid ventricular response when (AV) conduction is intact[12]. CHA2DS2-VASc score for stroke risk estimation in atrial fibrillation was calculated for all individuals suffered from atrial fibrillation [14]. Atrial fibrillation type and time span were delineated. A comprehensive physical examination was carried out for all patients, neurological examination was carried out in agreement with Coma Neurological Check [15]. All patients undergone carotid artery Doppler sonographic study to preclude significant carotid artery stenosis greater than seventy percent in agreement with North American symptomatic carotid endarterectomy study ECST, or peak systolic velocity greater than 130 cm/s [16]. All participants were exposed to magnetic resonance imaging (MRI) study. All magnetic resonant imaging reports were interpreted by two expert radiologist senior make unmindful to clinical informations. The image protocols constitute of sagittal T2 weighted-spin-echo sequence, an axial T2-fluid attenuated inversion recovery (FLAIR) sequence, and a diffusion weighted sequence. Most studies defined silent cerebral ischemia as centerpiece, crisply delineated abnormality greater than three millimeter which is hyperintense on T2 weighted image, a small of number of studies implement ancillary specifications to discriminate silent cerebral infarctions from the quite tiny lesion called leukoaraiosis which is hardly to be categorized as silent infarction, the most pivotal of these specifications is size greater than three millimeters [9]. All control individuals with sinus rhythm are gender, age, educational level, and risk factors matched and exposed to preconstructed inquiry sheet of questionnaire comprised of identity informations as for cases, past medical history and chronic medical illnesses including cardiovascular disorders, drug history including antithrombotic. All control subjects are exposed to physical and neurological examination with magnetic resonance imaging. Anatomical locality, laterality and number of lesions on magnetic resonant imaging were predetermined for all cases and controls.

Statistical analysis: statistical package for social sciences (SPSS) version 25 had been used for data assessment, descriptive statistics, frequencies, percentages, associations, tests of significance (chi-square, Fischer exact test, T-test, ANOVA test) had been utilized for interpretation of categorical variables, means, and standard deviation were utilized to present data of continuous variables. A p value less than 0.05 was set as statistically significant.

Results:

A total of 150 individuals engaged with in the study, dispersed evenly in three categories (paroxysmal, persistent atrial fibrillation patients and control group) they exhibit no significant statistical difference in their bio-demographic characters, where P value estimated by ANOVA and chi-square to be greater than 0.05, in all categories of comparability as expressed in table 1 and 2.

Discussion

In our study we establish high percentage of silent cerebral ischemia in the analyzed specimen, 59.3% of all persons engaged in the study were affected by the lesion, 76% of paroxysmal atrial fibrillation, 82% of persistent atrial fibrillation while only 20% of controls were affected by lesions with significant statistical difference between both cases of paroxysmal and persistent atrial fibrillation with control where P value 0.0001. Shadi et al^[9] metaanalysis states that silent cerebral lesions are habitually catch by magnetic resonant imaging in individuals with atrial fibrillation. In current study, Two-sided lesions were observed in 60.5% of cases with persistent atrial fibrillation while they were observed in 31.6% of cases with paroxysmal atrial fibrillation. Control subjects have the least percent of two-sided lesions (3%). Our findings are in accordance with Fiorenzo et al^[18] that demonstrate silent cerebral ischemia is more predominant in cases of atrial fibrillation than in non-atrial fibrillation persons (p value 0.001) and
persistent atrial fibrillation have had greater percentage of lesions and more bilateral lesions than paroxysmal type. The higher percentage of silent cerebral lesion (46%) in the control group found by Fiorenzo et al[18] in comparability of 20% in our study probably linked to difference in the baseline properties of control side in the two studies. But this detection is in accordance with Jonathon et al[19] a population-obtained studies that displayed prevalence of these lesions of ten to twenty percents. Our study implying that atrial fibrillation is a crucial hazard for silent cerebral ischemia as a cardinal detection, according to Shadi et al[9] atrial fibrillation is accompanied by double fold heighten hazard of silent cerebral infarction. In our study the persistent atrial fibrillation have their lesions located more in frontal lobe bilaterally. This major detection in our study is in line of Fiorenzo et al[18] study and highlight the method of cardio embolization that is accountable for higher prevalence of silent cerebral infarction in atrial fibrillation which is quite tiny, widely distributed bilaterally principally in frontal lobe[20]. Regarding bio demographic characters of the study cases and controls were crossly fit to keep away from selection bias so there was no significant statistical association between cases and controls with bio demographic properties. Though there is significant statistical difference between cases and controls regarding anticoagulant use and Fiorenzo et al[18] determine identical finding P value <0.01), but there is inadequate usage of anticoagulant among cases in our sample, 47% of paroxysmal atrial fibrillation cases and 44 % of cases with persistent type are mandatory to use anticoagulants according to CHA2DS2VASc score, while only 37% of paroxysmal and 21% of persistent atrial fibrillation are undergone anticoagulation, preceding studies point to decreased utilization of warfarin[17].

**Conclusion**

Atrial fibrillation is associated with heightened hazard of subclinical cerebral infarction.

**Conflict of Interest:** None

Perceptions and Attitudes of Men towards their Wives’ Menopausal Transition Period

Hanan J. Alzein¹, Samira Habashneh¹, Husam Al Khatib¹, Rabia S. Allari¹

¹Faculty of Nursing, Al-Ahliyya Amman University, AlSult, Jordan

Abstract

Background: Menopause is a natural process that occurs in women’s life as a part of normal aging. Recognition of women’s needs during menopause is considered important and required to maintain good quality of life.

Objective: This study aims at exploring the perceptions and attitudes of men towards their wives during menopause in Jordan.

Method: This study used the descriptive approach. 104 men were randomly chosen, for data collection, the Attitude towards Menopause was adopted in this study.

Results: Study results concluded that the men’s perceptions and attitudes toward their wives experiencing menopause in Jordan, ranged from (1.83– 1.30), where the whole dimension scored a total mean of (1.55), which is of a medium level. The study also concluded that there is no relationship at level of (0.05) between men’s perceptions and attitudes toward their wives experiencing menopause in Jordan and age, nationality, educational level and marry year. And the results showed that there are no statistically significant differences in the men’s perceptions and attitudes according to the age, and nationality in Jordan. While, there are statistically significant differences in their perceptions and attitudes with the Marry year in favor of 1-10-year category.

Conclusion: Advising men to engage in various activities with his wife during menopause can positively affect their attitudes, improve their body image.

Keywords: Attitudes of men, Experience, Menopause, Perceptions, Transition period, Wives.

Introduction

Menopause is a natural process that occurs in women’s life as a part of normal aging. The average age of menopause is between 51 and 52 years, and most of women live about one third of their life after menopause[1]. And the majority may experience hot flushes and night sweating. For some women, the climacteric symptoms are troublesome, therefore a varying percentage of women look for medical advice due to symptoms related to the menopausal transition period.

It is a challenging duty for health care providers to improve management of menopausal women[2]. Hormone therapy has been considered as a safe and well-established treatment of menopausal symptoms[3]. Since the 1960s, hormone therapy has been established as a treatment of menopausal women and has been used by women. The usage of hormone therapy has increased for around 7% in the 1980s among 53 to 54 years old women to more than 40 % in 2017[1].

The increase of hormone therapy use was probably justified by the confidence in the results from several
observational studies in 1980s and 2017s which reported beneficial effects of continuing hormone therapy use. Results from several large-scale randomized clinical trials published after 1998 did not find proof for those long-term benefits of hormone therapy, and these new results attracted attention from media, and hence appeared to have a major impact. The new results headed to a dramatic change in the treatment guidelines, and in the use of hormone therapy among women\[4, 5\].

Mental perception is a reflection of things or indicators or events that a person has already realized. It is a psychological and mental skill that can be acquired and learned. Perception can be further considered as an outcome of mental processing and a rational source that codes a person’s brain in order to respond according to this programming process. The perception mechanism depends on retrieving past experiences of things, events, or manifestation [6].

Recognition of women’s needs during menopause is considered important and required to maintain good quality of life. Studies looking at men’s conception and perception toward menopause revealed that men form a critical source of support in helping their women to cope with menopausal changes and challenges [7]. Understanding of men for the changes experienced by menopausal women fosters the development of a better emotional support for their wives that help to improve the quality of marital relations [8]. This study aims at exploring the perceptions and attitudes of men towards their wives during menopause in Jordan.

**Literature Review:** Revision of previous studies related to menopause highlighted that with increased age women in general are exposed to significant physiologic changes during menopausal period which reflected on social, psychological and emotional changes. Women spend nearly 1/3 of their lives in menopause and the period after menopause due to prolonged life span. In this period, women live a lot of change in their family, work and social lives besides some roles and responsibilities as wife, mother, business woman, grandmother and friend [9].

One study by Parish, et al. (2019) aimed to assess the men’s awareness and their understanding of their partner’s menopausal transition. Results showed that men are aware of their partner’s menopausal transition and may influence decisions relating to symptom management such as, difficulty sleeping, and lack of energy. Most men in the same study reported they were negatively impacted by the previous symptoms. They engaged in discussions with their wives regarding menopausal symptoms and believed they were influential in their wives decision to seek treatment [10].

Furthermore, Santoro, Epperson & Mathews (2015) aimed in their study to identify menopause in both women and men, as well as the social, psychological and health consequences of menopause on women and men and how to face the negative effects of it. The study used the descriptive approach in which focus groups where employed. The researcher interviewed six groups of women at menopause stage to ask them about this stage [11]. The researchers further required information about the women’s husbands who entered the stage of menopause and what implications this had on them. It concluded to a number of results which included social, psychological and health effects of menopause. The most significant social effects of menopause included: a change occurred in the quality of the overall life (e.g., social disturbances, loneliness, absence of active role, and the distance from social and recreational activities). The psychological negative effects covered depression, anxiety, mood swings, insomnia and nervousness. The health effects comprised a number of symptoms like hot flushes, night sweats, osteoporosis, fatigue and general tiredness, decreased libido, concentration and memory problems, and other symptoms [11].

Santoro, et al. (2015) study offered several recommendations, the most important of which are: seeking the doctor or psychologist consultation and support to overcome the causes that may lead to disorders and help achieve psychological and social compatibility [11]. The findings suggested that both spouses should take into account the psychological condition they both experience. The spouses experiencing menopause are advised to develop social networking instead of leaving oneself to social isolation and introversion which is assumed to help them achieve the psychological balance and increase their self-confidence. The spouses further are guided to continue giving others and participating actively in social gatherings that can assist them mingle with people. The results finally recommended conducting seminars to educate men and women about menopause stage and how to cope with its different effects [11].

Ibraheem, Oyewole and Olaseha (2015) investigated the experiences and perceptions of women in menopause,
85% of participants had never heard about menopause and the participants’ major source of information was close relatives. The mean knowledge score for menopause was low with 2.8 ±1.0. And only 28.0% of the participants could state at least one symptom of menopause. 54% who scored above the mean knowledge score had positive attitude towards menopause. 70% of participants had the certainty that sexual intercourse causes sickness for menopausal women. About 60.8% of the participants believed that women should not tell anyone about their menopausal experiences. 83% had experienced at least one symptom out of the 19 common symptoms of menopause. Uncomfortable experiences attributed to menopause included dryness of the vagina, pain during intercourse, and joint pains. Actions that had been taken by participants included self-medication, and adoption of sexual abstinence.

Marahatta’s (2012) study was designed to examine the major health problems in the females’ mid-life, the age of menopause, frequency of menopausal symptoms, and what menopausal symptoms are common among Nepalese women. The results showed that the mean age of menopause found to be 49.9% with urinary tract infection being the major clinical diagnosis and physical menopausal symptoms being the commonest.

Another study done by Rodolpho, et al. (2016) explored men’s perceptions and attitudes toward their wives in menopause. Four themes of experiences were categorized, such as: 1) misconceptions about overcoming menopause through coexistence and recognition of women’s perspectives; 2) recognition of women’s needs and efforts to provide support; 3) coping with changes in marital relations and need to start a new life; and 4) existence of several needs as husbands of women experiencing menopause.

The researchers concluded that a better understanding of the changing experienced by menopausal women can foster the development of a better emotional support for wivesby husbands, which consequently improves the quality of marital interactions. To date worldwide, few surveys have targeted women’s husbands to assess their perception of menopause, and they have been limited in scope. And in Jordan no studies targeted toward women’s husbands therefore, the perception and attitudes of menopause shared by men are still mostly unknown; however, men may influence how their wives cope with and manage their menopausal transition period.

**Objectives of the Study:** This study is designed to examine men’s perceptions and attitudes toward their wives who experience menopause in Jordan. And to explore the difference between men’s perceptions and attitudes toward their wives who experience menopause and some of the demographic information.

**Research Questions:**

1. What is a level of men’s perceptions and attitudes toward their wives who experience menopause in Jordan?
2. Is there a significant difference at level of (0.05) between men’s perceptions and attitudes toward their wives who experience menopause in Jordan and some of the demographic information?

**Materials and Method**

This study used the descriptive approach to suit its purpose that deals with Men’s perceptions and Attitudes toward their Wives Experiencing Menopause in Jordan. The study population consists of Men whose wives experiencing menopause in Jordan. The sample size of (100) participants was estimated for this study using G power analysis computer program developed by Faul and Erdfelder (1992), with a medium effect size 0.15, power of 0.8, and α (the risk of Type I error) at 0.05. Yet, 130 participants were selected to produce better power and more reliable findings and to compensate for uncompleted questionnaires.

**Data Collection:** The research was conducted after institutional review board approval at the university where the researchers work in. Research sample will be recruited from the private out patients’ gynecology clinics. Researchers explained the process of participation in the study and the need to read and approve the informed consent prior completing the designated questionnaires. Study participation was volunteered; the confidentiality and anonymity were assured.

**Study tool (the questionnaire):** The questionnaire used for the study is the Attitude towards Menopause (ATM) which developed by Neugarten et al (1963) and modified later in 2005 by Huffman et al. For this study the adopted ATM is forward and backward translated to Arabic. The goal of this method is that the two scales, the original and the one adapted for the new culture, will attain equivalence of meanings. The translated ATM consists of two sections, which are:
Section One: Demographic Variables including: nationality, educational level, husband work, marital status, wife work, marry year, number of children, chronic disease, husband age, and wife age.

Section Two: Mean’s Perceptions and Attitudes toward their Wives Experiencing Menopause in Jordan, it contains statements (1-19)

In order to verify the validity and reliability of Arabic version of the questionnaire, the researcher has distributed it to academic reviewers and other experts in the psychology field, to take their opinions, and rewording of some paragraphs, and make the required modifications to measure the content validity.

And to verify the reliability of the questionnaire, the researcher used the equation of internal consistency using Cronbach’s alpha test for all statements of the survey, as the value of Cronbach’s alpha was (0.824) and its higher than (0.60).

The research type scale included two Likert scale as follows:

- The Low degree from 1.00- 1.33.
- The Medium degree from 1.34 – 1.67.
- The High degree from 1.68 – 2.00.

Data Analysis: In order to answer the study questions which were formulated, a Statistical Package for Social Sciences (SPSS) (Version- 22) was used to analyze the collected data. The following statistical techniques and tests were used in data analysis: Frequencies and percentages to describe demographical variables. Cronbach’s Alpha reliability (α) to measure strength of the correlation and coherence between questionnaire items. Means and Standard Deviations. These techniques were used to illustrate respondent’s level. Pearson Correlation test was used to illustrate the relationship between the variables. Independent Sample T-test, One Way ANOVA and LSD tests to measurement the study hypothesis.

Results

The researcher distributed (130) questionnaires to Men, (120) of which were retrieved, while (16) questionnaires were excluded from the analysis due to incomplete information, leading to (104) questionnaires valid for statistical analysis, showing the response rate of (80%). (79.8%) of the participants were Jordanian, (96%) were below 50 years old. Majority of the participants’ education was BSC with (35%). Almost (95%) of the participants were working. In addition, (96%) were married. (74 %) of the participants were married for 20 years and above. Majority (47%) had also 4-7 children. Of all participant only (41.3%) had wives with chronic diseases.

Descriptive Analysis of Study Variables:

Q1: What is a level of Men’s Perceptions and Attitudes toward their Wives Experiencing Menopause in Jordan?

The researcher used the arithmetic mean, standard deviation, item importance and importance level to show the level of men’s perceptions and attitudes toward their wives experiencing menopause in Jordan, as shown in Table (2).

</table>

As shown in Table (1) that the means values of (Men’s Perceptions and Attitudes toward their Wives Experiencing Menopause in Jordan), ranged from (1.83–1.30), where the whole dimension scored a total mean of (1.55), which is of a medium level. (A woman’s body may change in menopause but otherwise she doesn’t change much) ranked first with a mean of (1.83), and standard deviation of (0.38), which is of a high level, and (A woman is concerned about how her husband will feel about her after menopause) ranked second with a mean of (1.82) and standard deviation of (1.38), which is of a high level. (Women generally feel better after menopause) ranked last with a mean of (1.30), and standard deviation of (0.46), which is of a low level.

Q2: Is there significant relationship at level of (0.05) between Men’s Perceptions and Attitudes toward their Wives Experiencing Menopause in Jordan and some of the demographic information?

The study used Pearson Correlation test to illustrate the relationship between Men’s Perceptions and Attitudes and some of the demographic information as shown in table (2).
Table (2) Pearson Correlation test

Table (2) showed that there is no relationship at level of (0.05) between the mean score of men’s perceptions and attitudes toward their wives experiencing menopause and the mean scores of age, nationality, educational level and marry year. Pearson Correlation values were (-0.137, -0.036, -0.094 and 0.074) and it’s not significant at level of (0.05). On the other hand, the results showed that there is a positive relationship between men’s perceptions and attitudes and number of children, Pearson Correlation value was (0.329) and it’s significant at level of (0.01).

Study hypotheses test:

H0: There are no statistically significant differences in the men’s perceptions and attitudes toward their wives experiencing menopause in Jordan according to the age, nationality, educational level, and marry year.

Age: The study used Independent Sample T-test to identify the statistically significant differences in the men’s perceptions and attitudes toward their wives experiencing menopause in Jordan according to the age as shown in table (3).

*Significance at level of (0.05)

The results showed that there are no statistically significant differences in the Men’s Perceptions and Attitudes according to the age in Jordan, mean value for (50-60) category was of (1.57) with standard deviation of (0.16) “medium level”, and mean value for (61-70) category was of (1.52) with standard deviation of (0.13) “medium level”, (t) value = (1.394) and the variance between means values not significant at level of (0.05).

Nationality: The study used Independent Sample T-test to identify the statistically significant differences in in the men’s perceptions and attitudes toward their wives according to the nationality as shown in table (4). The results showed that there are no statistically significant differences in the men’s perceptions and attitudes according to the nationality in Jordan, mean value for (Jordanian) category was of (1.56) with standard deviation of (0.16) “medium level”, and mean value for (Non-Jordanian) category was of (1.54) with standard deviation of (0.16) “medium level” also, (t) value = (0.367) and the variance between means values not significant at level of (0.05).

</tr>
</tbody>
</table>

*The mean difference is significant at the 0.05 level.

LSD test result in table (6) showed that the variance in the men’s perceptions and attitudes was in favor of marry year category (1-10 year) then the variance was in favor of (>20 year).

**Discussion**

This study aims to explore the perceptions and attitudes of men towards their wives during menopause in Jordan. The study found that the men’s perception and attitude was medium in level with a mean of (1.55). Many studies revealed that men were aware and understand of their partner’s menopausal transition and showed a positive and medium level of perception toward menopause. Nevertheless, Erbil (2018) study which showed negative perception toward menopause, in addition to other many studies. A woman’s body may change in menopause but otherwise she doesn’t change much which ranked as the highest in importance may due to men’s wives negative perception of menopause, and generally the women’s thoughts about body image and how much it is important for her to stay attractive for her husband so he will be satisfied in his marriage, and this can be assured by the second highest ranked item which is a woman is concerned about how her husband will feel about her after menopause. In addition, many women according to their culture and raising process they think about what other people feel about her forgetting her self-satisfaction and her feel about herself. This is consistent with other studies, women generally feel better after menopause, which considered less important to men and this can be explained by previous paragraph and support the women thought about their husbands feelings and perception toward menopause. Also the constructivist view of the learning process assumes that the individuals build their own knowledge on the base of the knowledge they already have, and therefore, see the world in ways that are acceptable and useful to them from their point of view. In building process of this knowledge, influenced by previous social and scientific experiences, individuals begin to form different types of beliefs that appear in the form of alternative perceptions of some real concepts.
Each cognitive activity is designed to explore, activate the perceptions stored in memory. Through a content that depicts the man in the menopause, the man looks at the mirror according to his social and cognitive perceptions, results of this study is consistent with study of Rodolpho, et al. (2016)7.

There is no relationship noticed between men’s perceptions and attitudes toward their wives experiencing menopause in Jordan and age, nationality, educational level, and marry year. Same results showed by Parish, et al.10 except for educational level which was positively correlated to men’s perception of menopause. On the other hand, the results showed that there is a positive relationship between men’s perceptions and attitudes and number of children. This result was consistent with other studies 21. This study result may due to increase males’ involvement in family matters and health concern when they have more children since they have to help the mothers in caring of children and decision making. In Arab culture the males are considered the gatekeeper for all important decisions related to family health and they have a direct effect on their wives and children health. Also the bond between husband and wife increase with the number of children so this will lead to increase male involvement.

The results showed that there are no statistically significant differences in the men’s perceptions and attitudes toward their wives experiencing menopause in Jordan according to the age, and nationality in Jordan. While, there are statistically significant differences in the men’s perceptions and attitudes toward their wives experiencing menopause in Jordan according to the marry year in favor of 1-10-year category. This result is logical because when two marrying couple spend more years to gather they will develop more acceptance and understanding to each other physiological and psychological wellbeing, also sense of support to each other will increased.

Limitations of the study: The findings of the current study should be generalized with caution due to the following limitations: the study focuses only on men’s perceptions and attitudes toward their wives, and geographical limitation.

Conclusion

This analysis described men’s perception and attitude of their wives menopause. Men are aware of changes experienced by their wives during their menopause. To create a more positive attitude towards menopause, men need positive information from health professionals. Advising men to engage in various activities with his wife during menopause can positively affect their attitudes, improve their body image. Further research needed about the role of women’s husband in easing the menopause transition period for their wives and how they can support them in this period.

Ethical Clearance: Ethical Approval was taken from the Ethical committee in the university where the researchers work in, and the administrative department in the private clinics where the participants were recruited.

Conflict of Interest: The authors declare no conflicts of interest.

Source of Funding: This research received no specific grant from any funding agency, commercial entity, or not-for-profit organization.

A Randomized Case-controlled Clinical Trial of the Effect of Preemptive Etoricoxib, Prednisolone and a Control Group on of Postoperative Sequelae after Surgical Removal of Impacted Mandibular Third Molars

Hasanin A. Mubarak¹, Sahar S. Al-Adily²

¹Master Student, Department of Oral and Maxillofacial Surgery, College of Dentistry-University of Baghdad, ²Assistant Professor, Department of Oral and Maxillofacial Surgery, College of Dentistry-University of Baghdad

Abstract

Background: The aim of this study was to compare the anti-inflammatory effects of prednisolone and etoricoxib after third molar extraction.

Method: A prospective, controlled study was conducted on 39 volunteers were allocated in three different groups, to receive either 120 mg etoricoxib or 10mg prednisolone 30 minutes prior to the procedure, and also a controlled group who didn’t receive any medication pre-operatively. Baseline measurements were obtained preoperatively, and subsequent assessments were made on immediate postoperative, at 48 hours and 7 days after surgery to measure postoperative facial swelling by use of linear measurements, interincisal mouth opening width and visual analog scale score for pain. The amount of analgesics consumed was recorded. Descriptive statistics were used to compare the two groups at \( P < 0.05 \).

Conclusion: Considering the results that were obtained upon the efficacy of different pre-emptive medication, Etoricoxib showed statistically significant values in terms of pain reduction and restriction in mouth opening, in the other hand prednisolone showed significance results in terms of edema reduction.

Keywords: Corticosteroids, COX-2 selective, third-molar surgery.

Introduction

Removal of impacted third molars is a common procedure in the field of oral and maxillofacial surgery (1). The most important step in removal of impacted mandibular third molars is achieving an appropriate mucoperiosteal flap that provides enough access to the tooth. An envelope flap with or without releasing is the common flap design (2).

Pain generated following third molar surgery has got short duration and moderate intensity that peaks in short time after the procedure and drives the patients into taking some analgesic medications(3).

Limitation of mouth opening is one of the problems which occurs following this surgery; this could be related to the inflammation of masticatory muscles. The medial pterygoid muscle is usually involved because of being inadvertently penetrated by the needle during inferior alveolar nerve block injection. This complication is not often severe and it will improve in 10–14 days(4).

Glucocorticoid agents and NSAIDs are generally used in managing some post-operation difficulties. Inhibiting the cyclooxygenase path is the mechanism of action of NSAIDS while glucocorticoids restrain production of acid arachidonic by inhibiting the phospholipase A2 enzyme(5). COX-2 is considered as the main isoenzyme in producing pro-inflammatory prostaglandins(3). Although some side effects such

as cardiovascular risks, GI bleeding and acute renal failure should be kept in mind (6), some recent studies showed that there is no relationship between celecoxib consumption and mentioned risks (7, 8). The aim of this study was to compare the efficacy of prednisolone with celecoxib on maximum mouth opening (MMO) and pain relief following impacted mandibular third molar surgery.

Materials and Method

Subject: Patients requiring surgical removal of impacted 3rd molar.

Materials: Etoricoxib 120 mg preoperatively on group 1.

Prednisolone 10 mg preoperatively on group 2.

No medication preoperatively on group 3.

All 3 groups were subjected to take the following tablets postoperatively: paracetamol 500 mg on need, Augmentin 1000 mg bid and Metronidazole 500 mg tid.

Sample Size: 39 patients aged between 18-40 years.

Procedure/Intervention: The medications were given 30 minutes before the procedure on each group. follow up was conducted on 48 hours, and 1 week to check for the criteria of interincisal mouth opening distance by using a digital caliper, pain by using visual analog scale, and 2 lines to record inflammation: the first line is the distance from corner of mouth to attachment of ear lobe and the second line is the distance from outer canthus of eye to angle of mandible.

Removal of the desired tooth according to Pell and Gregory classification was recorded. And all the procedures will be conducted by same surgeon. Patients were distributed into 3 groups of 13 patients each and received either etoricoxib, prednisolone or no medication group.

Time was calculated on all procedures assist difficulty.

All surgical flaps were conventional ones with a releasing flap in the mesial side of second molar and then sutured by silk 3-0.

Timetable: One year started from February 2020 until the end of July 2020.

Results

Note: patients were allocated on 3 groups Etoricoxib group (group A), Prednisolone group (group B) and placebo control group (group C).

Age and Gender:

![Figure 1: Distribution of study patients by age](image-url)
Figure 2: Distribution of study patients by gender

In comparison between study groups by age and gender, we found that there were no significant differences in age (P= 0.495) and gender (P= 0.899) between the groups.

**Follow Up: Mouth Opening**

**Percentage of change between the groups:** Percentage of change in mouth opening was compared between study group in the 1st and 2nd postoperative follow up, as shown in table (5). In the 1st postoperative follow up, means of degree of mouth opening were significantly different between the three groups (-12.9% in group A, -14.5% in group B, and -24.5% in group C, P= 0.001).

No statistical significant difference between study groups (P= 0.42) in the 2nd follow up.

Discussion

There have been many surveys investigating the influence of administration of NSAIDs or glucocorticoid drugs on post-operative inflammation, but as a result of differences in inflammation assessment, prescriptive drugs, patterns of administration and provided dose, the comparison between the results is rather difficult. (9)

Age, sex between the three groups: Patients in the age range between (20-30) represent the highest percentage in this study which is in keeping with Breik and Grubor (10), in 2008, Hashemipour et al. (11), in 2013 who found that most patients in their study were in the third decade of life.

This may be related to the fact that problem associated with impacted third molar started at the time of eruption that indicate their removal, as the prevalence of third molar impaction decreased with increasing age due to extraction of impacted teeth (12).

The majority of patients in this study were between (20-30) and it corresponds with the studies mentioned earlier, and 56.4% was in age range (≤25) and 43.6% (>25) years.

The data of this study revealed that the percentage of female patient was (59%) and the percentage of male patients was (41%) and there was no significant difference in distribution of males and females in study and control groups.

The higher occurrence in female may be the result of growth difference between male and female. Female growth usually stops with time of eruption of third molar, while in male jaws growth persists during third molar eruption, providing more space for eruption (13).

Angulation, classification, favorability and no. of roots and side of impacted lower third molars.

In the present study, mesioangular impaction was the most common (51.3%) followed by vertical (20.5%), horizontal (17.9%), and distoangular (10.3%).

Mesioangular impactions may be the most common type and this probably due to their late development and maturation, path of eruption and lack of space in mandible at later age. This finding was reported by many other studies (14,15).
However, this result disagreed with the different studies(16, 17, 18) who reported the vertical angulation is the commonest one. This could be due to the fact that a different method of classifying angulation was used in these studies.

The findings of the present study were in agreement with a large number of reports that show most impacted third molars were at Class II position, Almendros-Marques et al., in 2006(17) reported Class IIB as the most common position of mandibular third molar.

Duration of operation: There was no significant difference between study and placebo control groups regarding time of operation as p-value equal to 0.907. This may be due to the type of impacted teeth where the teeth selected in same position, position B, and all the surgical operations were performed by the same operator. So the time of operation had no effect on the results of this study. As previously suggested that there may be a close association between time of operation and postoperative morbidities(18).

Pain and trismus: Numeric rating scale was utilized in this study to rate the intensity of pain that felt after surgical removal of the wisdom teeth, as it is easy to be understood by patient and does not need language translation. The data that have been gained by VAS are interpreted and documented in simple manner and parametric tests can be used for analyzing its result(19).

The results of this study showed that the highest level of pain for all three groups was seen in the 2nd day of operation, after that the pain score tended to decline with time till the seventh day and a significant difference between the days within each group confirming that the maximum pain intensity occur within first 24 hrs after operation. Since pain starts with the termination of local anesthesia with peak level in (6-12) hrs after surgical operation(20), and it persists for about two to three days, then its intensity gradually decreases till the 7th postoperative day(21), so in this study the pain was measured from the first day of operation throughout 7 days.

The results of this study also revealed the most significant decrease in pain scores in the Etoricoxib group followed by predisolone group then with placebo control group, that reached a significant level on the 2nd and 3rd day which was in favor of the etoricoxib followed by prednisolone then the placebo control group, while it was non-significant in the 4th, 5th, 6th and 7th days between the placebo control and study groups, this may be due to analgesic effects of prednisolone and etoricoxib.

Limitation in mouth opening reaches its maximum intensity in the second postoperative day then the symptoms gradually improved and get better at theseventh postoperative day(22), so in this study the trismus is measured at the 2nd and 7th postoperative days.

In this study: It was noticed that the significant reduction of the mouth opening (p value 0.001) was seen in placebo control group (-24.5%) in the 1st follow up appointment. The least reduction of the mouth opening was seen in Etoricoxib (-12.9%) followed by prednisolone group (-14.5%).

There is was insignificant value between study and control groups in the 2nd follow up (p value 0.42).

The finding of this study is inconsistent with Carrieches et al (23) who compared the efficacy of methylprednisolone (glucocorticoid) versus diclofenac (NSAID) upon inflammation and trismus after removal of impacted mandibular teeth. They did not find any significant difference between groups.

This study was comparatively consistent with Claseman et al(24) assessed the analgesic efficacy of preemptive ketorolac and dexamethasone for third molar surgery. According to their results, the pain and the amount of having extra analgesics reported by patients receiving 8 mg IV dexamethasone did not have significant difference with patients receiving 30 mg IV Ketorolac. In this study, celecoxib had better effects on pain relief in 24 h after surgery; this difference may be related to different routes of drug administration.

Moore et al(25) evaluated the effects of rofecoxib and dexamethasone on pain and trismus after third molar surgery. In their study, MMO of patients receiving dexamethasone had a reduction of 24.1 % from the base limit while the rofecoxib group had 43.3 %. Reported pain did not show any significant differences and both groups had moderate pain perception. These differences may be contributed to the type of rescue dose given to patients which was 400 mg ibuprofen. Ibuprofen is a NSAID type of drug and can add on anti-inflammatory response and effects of rofecoxib or dexamethasone.

Whereas Baxendale et al.(26) observed the
elimination of analgesic intake by administering preoperative dexamethasone while trismus was not affected.

This effect can be related to the role of prostaglandins in local pain and their inhibition by NSAIDs will result in pain relief. Glucocorticoids are effective in each step of inflammation process and subsequent decrease in capillary dilation, circulating lymphocytes, fibroblast proliferation and prostaglandin and leukotriene inhibition. Most single dose glucocorticoid drugs used in oral surgeries are not effective for more than 24 h, so for maintaining their anti-inflammatory effects they should be taken for a minimum of 3 and maximum of 5 days for gaining the maximum efficiency and minimum risk of delayed healing and suppression of HPA axis (27).

**Swelling:** Facial measurement was performed by measuring the distance distance from corner of mouth to attachment of ear lobe (line A) the second line is the distance from outer canthus of eye to angle of mandible (line B) Preoperative measurement was used as baseline record as of Amin and Laskin methodology (28).

In this study the effect of study drugs showed significant difference in A and B lines of inflammation in comparison with placebo control group in the 1st follow up (p value 0.002). However there was insignificant difference in the 2nd follow up between study and control groups.

The significance was in favor of prednisolone 10 mg as in compare with placebo control group. However, there was slight difference between the study groups but it was insignificant.

Costa et al. (29) analyzed the preemptive effect of etoricoxib (120 mg) and placebo on inflammatory events after the removal of third molars and found no significant difference in facial measurements between groups at any evaluation time.

Sotto-Maior et al. (30) compared the anti-inflammatory effects of etoricoxib (120 mg) and dexamethasone (4 mg) administered orally one hour prior to the procedure and found no significant differences in postoperative swelling.

Mojsa et al. (31) evaluated the submucosal injection of dexamethasone and found that peak swelling in patients who received placebo occurred on the third day and these patients had significantly larger facial measurements.

Antunes et al. (32) compared the administration of dexamethasone intramuscularly (masseter muscle), orally and a placebo and found that the control group had the greatest swelling.

**Conclusions**

1. Etoricoxib 120mg showed a significant effect on reduction of pain following surgical removal of impacted 3rd molar.
2. Etoricoxib 120mg showed a significant effect on reduction of trismus following surgical removal of impacted 3rd molar.
3. Prednisolone 10mg showed a significant effect on reduction of facial swelling following removal of impacted 3rd molar as in compare with other two groups, however the result showed no significant difference as in compare with Etoricoxib 120 mg.
4. The effect of etoricoxib was significant in the short-term effect (48hrs) and was insignificant in one week follow ups in comparison with placebo control group.

**Acknowledgment:** The study was self-funded.

**Conflicts of interest:** None of the authors have any competing interests in the manuscript.

**Ethical Clearance:** This research has exemption as it a routine treatment (no new materials were used).

The Relationship of Some Immediate Chemo-Chemical Variables after the Aerobic Physical Increasing Effort for Football Players

Hatou Abdulkareem Mohammed1, Firas Abdulhameed Khalid2

1The General Directorate of Education in Anbar Province/The Open Educational College/Department of Physical Education and Sports Sciences, 2The General Directorate of Education in Anbar Province/The Open Educational College/Department of Physical Education and Sports Sciences

Abstract

In order to study some biochemical variables on the increasing aerobic physical stress-test, the researchers selected a sample of individuals represented by the Anbar University football team of 16 players who underwent this study. The researchers used the descriptive approach in their research. The research experiment included taking blood samples before and after the escalating physical exertion on the Treadmill device in order to know the effect of this effort on some biochemical variables (cholesterol, white blood cells, lactic acid). They conducted aerobic increasing physical effort stress-test on a Treadmill device which has an impact on the targeted Chemo-chemical variables and the existence of correlative relationships between those variables. The researchers concluded that there are significant changes in these variables in favor of the post-test measurements, as well as obtaining significant correlation coefficients between these three biochemical variables. Then the researchers recommended the necessity of conducting studies in the same regard to the rest of the other difference games and the need to study other variables and recognize the correlations between those variables. To design curricula Modern training according to scientific foundations to enhance the positive correlation between the variables that were discussed and reduce the relative difference between the variables whose relations have gone in the negative direction and that negatively affects the physical achievement.

Keywords: Chemo-Chemical Variables, Aerobic Physical.

Introduction

In recent years, the world has seen considerable progress in various fields. Physical education has had a significant share of that progress, as demonstrated by the results, achievements, and record subjects of various sports and events, both individual and team. It is through continuous research and proper recruitment, and the aim of that research for the service of achievement and its upgrading. The training process is a difficult and complex process that needs a lot of data and information from the game to give the trainer a clear picture of that player, which in turn will make it easier for the trainer to develop appropriate training curricula that are compatible with the capabilities and capabilities of each player. The blood variables from the internal variables that are to be studied deeply reflect a clear picture of the inner environment of the player’s body during and after the performance because “blood forms the inner perimeter of the body”[1]. The concentration or level of these variables is directly related to performance, as the rise of some of them supports performance and increases its quality, while the reduction of some of them negatively affects performance. As a result, there are many changes in their work, such as the respiratory system, the heart, and the circulatory system, the nervous system, the neuro system, the hormonal, enzymological system and other devices Internal to the training load on the player and in a way that serves performance and achievement.
This is why a football player is exposed to the fatigue that can occur because of these chemical changes in the internal environment of the body, which may affect negatively on his physical, professional, plan, and psychological performance, which has led us to research of some of his body Biochemical changes caused by increased physical activity and the study of the quality of relational relationships between these variables.

It is important to study the current changes in some blood variables due to an increasing aerobic physical effort and therefore to know the relationships between these variables, which in turn gives us a clear picture of the nature of these changes and how they affect the level of performance of the player, whether negative or positive, especially given that knowledge The nature of relational relationships between these variables will allow the trainer to reinforce the positive and minimize the negative results.

The research problem was the effectiveness of football match that requires a major physical effort that lasts for (90min), The problem of research is the need to know and study these changes and to know the nature and level of these changes by the coach and even by players and their effects on performance, especially given that knowledge. The nature of relational relationships between these variables will allow the trainer to reinforce the positive and minimize the negative results.

The method and procedures

The researchers used the Descriptive study, which studies of some blood variables and their impact on an increased physical effort and the relational relationships between those variables. The aims of the research were:

1. Recognize the impact of increased physical effort on some blood chemical variables (white blood cells, lactic acid, and cholesterol).
2. Identify the level of the relational relationship between the Chemo-chemical variables under study.

The sample of the research was 16 players of Al Anbar University participate in the reconnaissance experiment. The Experiment location was the main stadium of Al Anbar University and the Faculty of Science laboratories in the university. And the temporal domain was (5/9/2018 to 26/9/2018). The Research means and tools were used the TREDEME 4 of the same type and origin and special blood-preservation tubes containing anticoagrotic, medical injection, and gauze. Survey experience Research procedure the researcher uses to organize and arrange his field research work, identify obstacles and problems that may arise for the researcher when initiating his main experience, distribute tasks and roles for the assistant staff, identify their capabilities and capabilities to carry out their assigned tasks and ensure the safety of the equipment and tools used in the research.

The assistant staff performed the pre-test measurements of the Chemo-chemical variables on the sample members for research, as these variables were measured by the changes of white blood cells, lactic acid, and cholesterol at 4:00 p.m. on Thursday, 09/13/2018 in Al Anbar University, where blood samples are taken from the sample individuals, and by a quantity of (5 ccs). The test is a very good way to get the test to be used, and the test is a good way to get the test done another influential is the physical practice or any physical effort.

The assistant staff conducted the Tread-Mill physical Stress-Test upon completion of the blood sample sampling of the research samples and represented the test with the physical Stress-Test. The procedure for this test is as follows:

The player sample warmed up for (10 minutes) on the device by walking on the Tread-Mill with speed (3.5 hours/miles) and with inclination angel (0%) and after the warm-up, the testing begins on the Tread-Mill, as the player runs on the device with speed (7 hours/miles) (2 minutes), inclination (0%), and after two minutes, theinclination increases to (2.5%) after every (2 minutes) until the end of the test, and it is known that the test time is (12 minutes) continuous and continuous without any interruption[2].

The assistant staff performed the following measurements of the research sample blood-blood variants by venous blood draw from the sample, and by the fact that two blood clouds were immediately upon the sample descent from the device and by (5 cc) to measure the changes of white blood pellets and cholesterol and the second five minutes after they have completed an upward physical effort as post-test (5 cc) also, to measure lactic acid variant after withdrawal, blood samples were placed in special blood-preservation tubes prepared for this implantation, transferred to the laboratory and analyzed to see all changes due to the increased physical effort.

Because of this research method, the researchers developed the following research questions:
1. Is an increasing physical effort having clear and significant effects on blood Chemo-chemical Variables?

2. Are there any relationships between the blood Chemo-chemical variables after increased physical effort?

Results

The following measurement of the biochemical variables in blood was handled between the pre and post results with used the SPSS Statistical Package. It was presented by researchers in the following tables (1 and 2), and they were provided with analyzes and attached, strengthened by scientific sources and references.

Discussions

We find out from Table(1), which includes the statistical parameters, that there are differences between the post and pretest results of the variables, and for the benefit of the post-tests. The researchers attribute these differences to the increased physical effort of the sample research, which has had a direct impact on the target Chemo-chemical variables, and it is known that a physical effort with an inclination would increase the alert status of the body’s internal environment and all its organs and clearest, making it work faster, stronger, and more to confront the requirements of that work.

The increase in the rate of blood pressure in the arteries and the roses that pass through them affects blood components in general and blood cells, the white blood is especially so as indicate that there are a large number of white blood cells that are adjacent to the walls of blood vessels that the blood passes through during the rest time, and these pellets are pushed with blood when performing a physical effort, as these cells are left on the walls of blood vessels to get into the bloodstream[3]. The higher the level of physical effort increases the number of white cells. The longer and more physical effort, the more white blood cells, and this view are reached after a series of research, concluding that these white cells have increased their number by a certain percentage after a runaway race (200) meters this percentage of white cells increased further after the race at two (800) meter runners and the increase was significantly higher, but this increase was more apparent after the previous (1500) meters[3]. Which indicates that exercise and athletic performance of physical efforts increase blood components in general as both red and white blood cells and hemoglobin increase in size due to the exigencies of performing physical work[4].

The researchers attributed the differences in lactic acid variant between the pre and post-tests that were in favor of the post-test to the fact that the increased physical effort means the difficulty and severity of the sample during the performance was the increasing degree of the device’s inclination after every two minutes, which makes it difficult. The intensity gradually increases as the performance progresses and this increasing continuously elevate heart pulses, making more effort on the player gradually increase, and it is known that increasing performance leads to more metabolic processes and energy release to match that intensity and work requirements, causing the formation of metabolic residues, including acid The lactic action is one of the most important causes of fatigue. A physical effort of maximum or lesser intensity increases the amount of lactic acid that causes muscle fatigue and this acid gradually increases the performance intensity, i.e. the higher the performance the acid build-up. Studies
have suggested that lactic acid not only increased muscle to non-oxygenated exercises or efforts but also even in oxygen training and efforts, it appears because of adrenaline hormone but less.[5]

We explain the results of the differences between the pre and post-tests of the cholesterol variant that was in favor of the post-test, to the direct effect of the increased physical effort on the sample, as this step-by-step effort by increasing the device’s inclination degree after every two minutes increased the frequency of metabolic operations. The increased need for energy production is the result of the muscular work produced during this effort, resulting in the accumulation of many unfinished substances in the blood after the severe physical effort, which is part of the substances. The period immediately following “intense work performance” is the blood on non-combustion substances such as lactate acid, pesticides, and ketones. All of these materials are burned when oxygen is taken in the break-in period following intense work.”[6]

The exercise of physical activity would provoke the body’s hormone system, which would make it responsive and work to create a state of internal balance. This makes it increase during the performance period and it is known that increasing the proportion of this hormone in the blood directly affects the percentage of fatty acids, which makes them increase further and which can be used as a source of energy[11]. The growth hormone is more susceptible to increase as physical activity increases, its importance appears to be in its ability to metabolize and consume fat as a source of energy, and it also plays an active role in metabolizing fatty acids and converting them from fatty tissue to the energy, and it also plays an active role in metabolizing fatty acids and converting them from fatty tissue to the energy, and it also plays an active role in metabolizing fatty acids and converting them from fatty tissue to the energy, and it also plays an active role in metabolizing fatty acids and converting them from fatty tissue to

Discussions

The table above shows the statistical multiple correlation values that show the relationship between the research variables, white blood cells, lactic acid, and cholesterol. The multiple correlation values between the 3 Variables (0.601) is significant, and there relative confidence 95%. The researchers attribute that the physical effort of subjects has caused a state of alert in the internal environment of the body, which is, of course, a result of the degree of performance or work due to the increased of the device inclination, which has made it more difficult to work requirements and has led to a cardiac arousing and blood pumping circuit for the common muscles in the work to continue. In energy liberalization, this has made the circulatory system heartbeats increase its frequency. Which directly affected the number of white cells and made them go out in more numbers than their natural numbers and go into the brain stream. The topic of the effects of training on white blood cells and the quality of training related to the type of cells that increase the number of short-range anaerobic training increases the number of lymph white blood cells (Lymphocyte), long-term aerobic training affects the equivalent white blood cells (nitro Ville), which make up a large proportion of the total number of white blood cells, reaching approximately 60%-70% of the total number of cells and appears and their added value in being the first line of defense[8]. The increased exposure of the research sample to the increased intensity of the search also increased the of lactic acid concentration that caused a rise in an acidic grade of the center or the internal environment (blood) due to the hydrogen ions that are free from lactic acid and which in turn reduced the pH value. The longer the exercise lasts, the more the time the production of lactic acid[9], increases and the increase in the central acid caused by the decrease in phages, confirmed by[10]. The increase in lactic acid in the blood is seen as contributing to the reduction of pH[11].
From the above, it becomes clear to us that the relationship between the increased physical effort and white blood cells is a significant correlation, so with the increase in the physical effort, the level of these blood cells rises, as well as the relationship between the physical effort and lactic acid as well as a positive relationship, its increases the level of lactic acid and this increase is caused by the increase in the frequency of oxidation processes as a result of the physical load to which the research sample was exposed, so by increasing the level of oxidation processes (the oxidative) that accompanies the implementation of the physical load, the level of each level of both lactic acid and white blood cells rises, and this is confirmed by James, Bosch, and Aldred. As this research team found through a field study conducted at the College of Medical Sciences and Dentistry at the University of Birmingham in Britain that the practice of strong physical exercises would increase the oxidative stress in the internal tissues and blood, which leads to a high level of white cells and that this rise is caused by the high level of the adrenaline hormone, which increases with the progress of the effort, which in turn reduces the adhesion of white cells on the one hand and increases their release from the lining the blood vessels in which the blood passes, and some of its stores in the spleen and lungs, on the other hand.

Aqeel believes that the increase in the level of physical load would increase the level of concentration of growth hormone and that increasing this hormone increases the concentration of fatty acids in the blood, and that this increase in the level of fatty acids contributes directly to the increase in the level of cholesterol, which is the main carrier of these acids as indicated previously, which he refers to Fadel, in that he has an important role during the exercise of physical exertion and exercise. He pointed out that all fats, with all their varieties and types, which exist in different proportions in the human body, including cholesterol, play an important and major role in supplying the body with the energy needed when needed, especially for the practice of continuous and relatively long physical load and this is what it makes us conclude that the correlation between each of the physical exacerbations and the intensity of cholesterol is a direct relationship, so with increasing load intensity or performance, the concentration of cholesterol increases. If we address the level of the relationship between physical exacerbation and intensity of lactic acid, we find that the increased demand for the body’s need for more energy to continue working as a result of the exacerbated physical exertion led to an increase in the speed of metabolic processes that produce lactic acid.

The increase in the intensity of performance contributes to the increase in metabolic activity, which in turn leads to the accumulation of lactic acid as a by-product of this activity.[13]

We conclude that a positive relationship between physical stress and increasing intensity and cholesterol is a direct relationship. The increase in the level of physical effort with increasing intensity is offset by an increase in the concentration of cholesterol, as it becomes clear to us that the correlation between the physical increased effort and lactic acid is also a positive relationship, that is, the increase in physical load work. It is accompanied by an increase in the concentration of lactic acid and this leads us to say that the correlation between both cholesterol and lactic acid is a positive relationship and this is confirmed by[14], as they see that the physical effort contributes to increasing the outputs of the metabolic processes that are represented by the production of fatty acids as a result of lipolysis as well. The production of lactic acid that releases hydrogen ions that cause the pH value to drop[14].

**Conclusion**

Based on the discussions discussed in Tables 1 and 2 on the results of Chemo-chemical tests before and after the increasing effort stress-test of the football players sample, we came to summarize the conclusions as follows:

- We conclude that the aerobic increased Physical stress-test on the treadmill device significantly affects the Chemo-chemical variables of blood, such as white blood cells (leukocytes), cholesterol, and lactic acid. Thus, the assumption of the first research question was answered.

- We conclude that the three Chemo-chemical research variables have significant internal multiple correlations, which are white blood cells (leukocytes), cholesterol, and lactic acid. With this result, we were able to answer the second research question.

**Recommendations:**

- An increasing physical effort having clear and significant effects on blood Chemo-chemical Variables such as white blood cells (leukocytes),
cholesterol, and lactic acid, therefore, these results should be taken into account well in training programs for various sports and endurance activities in particular.

- The relationships between the blood Chemo-chemical variables after aerobic increased physical effort stress-test, those results should be paid attention to studying other variables of the circulatory system and blood because of its importance in the general health of athletes in general and the effects of training units in particular.

Role of Retinol-binding Protein 4 as an Early Biomarker for Diabetic Nephropathy in Type 2 Diabetic Patients

Hayder Huwais Jarullah¹, Inaam Ahmed Ameen²

¹Lecturer, College of Pharmacy, Baghdad University, Baghdad, Iraq, ²Ass Proof, College of Pharmacy, Baghdad University, Baghdad, Iraq

Abstract

Assess the relationship and diagnostic performance of retinol-binding protein 4 (RBP-4) as a biomarker of diabetic nephropathy (DN) at different levels of albuminuria (normo-, micro- and macro-albuminuria). A case-control study that involved 185 participants, 47 were healthy control, and 138 diabetic patients (46 were normoalbuminuric patients [NA], 48 patients were microalbuminuria [MiA], and 44 patients were macroalbuminuria [MaA]). All diabetic patients were treated with antidiabetic medication (metformin and/or oral sulfonylureas), all the participants were interviewed by the researcher, and full medical (history of liver, kidney, lung, and other diseases), and sociodemographic data taken from them and recorded in the questionnaire. In the present study, RBP-4 was 14.08±1.82 ng/ml in the control group, 15.98±3.74 ng/ml in the normoalbuminuria (NA) group, 30.38±6.02 ng/ml in the micro-albuminuria (MiA), and 41.01±5.78 ng/ml for macro-albuminuria (MaA), there was a significant difference between all their groups compared to control (p-value <0.001), and between each other (p-value <0.001) except that no significant difference found between control and normoalbuminuria. In conclusion, RBP4 is an excellent predictor of both microalbuminuria and microalbuminuria, there was an inverse relationship between RBP4 with GFR, which indicate it is a good predictor for the progression of diabetic kidney impairment.

Keywords: Albuminuria, renal impairment, RBP4, microalbuminuria, macroalbuminuria, diabetic nephropathy.

Introduction

The term diabetes mellitus describes diseases of abnormal carbohydrate metabolism that are characterized by hyperglycemia. It is associated with a relative or absolute impairment in insulin secretion, along with varying degrees of peripheral resistance to the action of insulin. Type 2 diabetes accounts for over 90 percent of cases of diabetes in the United States, Canada, and Europe; type 1 diabetes accounts for another 5 to 10 percent, with the remainder due to other causes¹.

The term “diabetic nephropathy” was historically defined by the presence of albuminuria accompanied by retinopathy in patients with type 1 diabetes². The presence of albuminuria was considered to be an early sign of classical diabetic glomerulopathy, which is characterized by glomerular basement membrane thickening, endothelial damage, mesangial expansion and nodules, and podocytes loss. Diabetic nephropathy was further subdivided into “overt nephropathy” by “macroalbuminuria” and “incipient nephropathy” by “microalbuminuria.” These albuminuria distinctions were proposed to reflect a disease spectrum from mild to severe ². Retinol binding protein 4 (RBP4) It is a specific transporter for vitamin A in the blood, and it is produced from either the liver or adipocytes, which was later proven to be associated with insulin resistance in type II DM. It was shown that increased of RBP-4 will cause reduction in insulin-dependent glucose uptake in muscular tissues³.

The current work aimed to assess the relationship between the studied biomarker and the different levels of albuminuria (normo, micro and macroalbuminuria), and

the relationship between the serum levels of the RBP-4 with glomerular filtration rate (calculated GFR).

**Method**

**Study Design:** A case control study (a diagnostic accuracy study [67]), that involved 185 participants, 47 were healthy control, and 138 diabetic patients (46 were normoalbuminic patients [NA], 48 patients were microalbuminuria [MiA], and 44 patients were macroalbuminuria [MaA]).

**Study Settings:** The study carried out in private laboratory in Al-Nasiriyah, Iraq, the participants were recruited from the Diabetes Mellitus at Diabetic and Endocrine Center in Al-. Nasiriyah City. The recruitment started in October 2019 and ended in February 2020.

**Participants:** All diabetic patients were treated with antidiabetic medication (metformin and/or oral sulfonylureas), all the participants were interviewed by the researcher and full medical (history of liver, kidney, lung, and other diseases), and sociodemographic data taken from them and recorded in the questionnaire.

Inclusion criteria: Type II diabetic patients diagnosed by physician based on the 2010 American Diabetes Association guidelines (which is briefly as fasting blood sugar [FBS] above 126 mg/dL, or random blood sugar above 200 mg/dL) \(^4\), or HbA1c above 6.5% \(^5\).

Exclusion criteria: pregnant women., Patients on insulin therapy, Patients with other metabolic disorders, Patients with cardiovascular disease, Patients providing incomplete information during completion of the questionnaire also will be excluded from the study, End stage kidney and liver disease, and eGFR below 60 ml/min (stage III or higher).

**Statistical Analysis:** Chi square test used for assessing the statistical significance between categorical variables, while independent t-test used for assessing the degree of significance between two continuous variables, in case of assessing the difference between four continuous variables one way ANOVA was used.

Linear regression analysis was used to assess the relationship between eGFR and various markers, negative sign indicate inverse relationship while positive sign indicate direct relationship. Receiver operator curve (ROC) used to assess the diagnostic performance of various biomarkers for predicting nephropathies. All analysis carried out using SPSS 24.1 (Chicago, IL), MedCalc Statistical Software version 14.9.2 software package, p-value is significant if less than 0.05.

Discussion

It is an adipokine marker that was initially examined as a marker for vitamin A (since its bind to vitamin A)\(^3\), the primary production site is the liver and adipocyte\(^6\). Many studies had correlated RBP-4 to some of the aspects of diabetic including obesity and insulin resistance\(^7\).

In the present study RBP-4 was 14.08±1.82 ng/ml in the control group, 15.98±3.74 ng/ml in the normo-albuminuria (NA) group, 30.38±6.02 ng/ml in the microalbuminuria (MiA), and 41.01±5.78 ng/ml for macroalbuminuria (MaA), there was significant difference between all these groups compared to control (p-value <0.001), and between each other (p-value <0.001) except that no significant difference found between control and normo-albuminuria.

Our findings was in agreement with previous studies; in a Saudi study Mahfouz et al 2016 examined RBP-4 in the same setting like our study (200 participants divided into four groups each with 50 patients), they found that like us serum RBP-4 was significantly higher MaA
compared to MiA, NA and healthy control (39.4 ± 7.7, 28.9 ± 8.26, 17.5 ± 4.2, and 14.4 ± 1.95 ng/mL) 8.

In Raila et al study 2007, was in agreement with our work in which RBP-4 was significantly higher in the MiA compared to both NA and control (2.22, 1.75, and 1.59 μmmol/l, p-value <0.05) 9.

In Chang et al 2008 study similar findings to our study was observed in which was significantly higher in MaA, MiA compared to both NA diabetic and healthy control (64.7 ± 27.6, 57.3 ± 24.2, 43.4 ± 14.9, and 32.6 ± 10.0 respectively), while there was significant difference between MiA and MaA 10. All these studies showed an important observation as the diabetic nephropathy progress it is directly associated with increase in RBP-4 levels, since there was inverse relationship between RBP-4 with eGFR (r = - 0.694, p-value <0.001).

The kidneys play central role in the control of normal homeostasis of the body 11, since GFR give us an estimation about the functionality of the kidneys so any deterioration will be associated with decline in GFR, and inability to perfume the reabsorption process of many materials including RBP-4 in the PCT 11.

Our observation of the inverse relationship was also noted in other studies like Mahfouz et al 2016, (r = -0.306, p-value = 0.002) 8, thus increase the accumulation of RBP-4 in the body.

Several other factor can also increase RBP-4 which included increase excretion of transthyretin (the protein that bound and transport RBP-4 in the blood) thus increase the accumulation of RBP-4 12. In addition elevation in RBP-4 is associated with increased risk of hypertensive, abnormal lipid profile, and deterioration in GFR 13.

In the present study RBP-4 showed excellent ability to predict MiA from NA diabetic patient since the area under the curve (AUC) = 0.993, in addition the positive likelihood ratio was 58.0 which indicate it had 45% increased posterior probability to confirm the MiA when used as conformation test, while its negative likelihood was 0.001 which indicate it increase the exclusion of disease by 45%. In term of diagnostic performance RBP-4 value above 22 ng/ml has 99.0% specificity and 99.0% sensitivity and 99% accuracy. This indicate the overall value of this marker is to both confirm and exclude the disease MaA to similar degree.

Our findings were in agreement with Mahfouz et al 2016 in which RBP-4 showed excellent ability (AUC = 0.912) to predict nephropathy from those diabetic patients without nephropathy in which they found that the optimal cut – off was >24.5 ng/ml with 84% sensitivity, 90% specificity and 86% accuracy which comparable but somewhat lower than our findings, this could be attributed to differences in studied population since Mahfouz et al involved Saudi subjects while in ours involved Iraq patients 8.

The kidney play central role for RBP-4 homeostasis, since its metabolic degradation is dysregulated in chronic renal impairment (CRI) patients. A possible explanation that diabetic patients are exposed to increased risk of oxidative stress which in turn lead to endothelial damage. In addition RBP-4 enhance oxidative stress, so its accumulation will lead to further enhancement of kidney impairment in diabetic patients 14. RBP-4 elevation thus is most likely to be related to kidney dysfunction rather than diabetic itself 15, which will lead to MiA and MaA. Which indicate its usefulness for predicting diabetic nephropathy rather than diabetic.

These observations is interesting since it suggest we could use RBP-4 as target for treatment by reducing its circulatory level will be proven to reduce the risk of kidney impairment progression, especially those related PCT damage 8. In adipose-Glut4-knockout mice, therapy with anti-diabetic (rosiglitazone) will invert insulin resistance and stop RBP-4 elevation 16. While treating obese mice with fenretinide will enhanced RBP4 renal elimination thus return RBP-4 to its normal values 16.

**Conclusion**

Retinol binding protein – 4 is an excellent predictor of both microalbuminuria and microalbuminuria, and there was inverse relationship between Retinol binding
protein – 4 with GFR, which indicate it is good predictor for the progression of diabetic kidney impairment.

Molecular Study of MDR Bacteria Contaminated Hospital Environment

Hazim Aziz Naji Alhadrawi¹, Raad A. AL-Harmoosh², Salam Razzaq Miftah Alzurfi³

¹Ph.D. Professor. Academic (Microbiology) in Dep. of Ecology, Faculty of Science, University of Kufa, Najaf, Iraq, ²Ph.D. Assist. Professor. Academic (Microbiology) In AL-Toosi University College, Medical Laboratory Techniques Najaf, Iraq, ³M.Sc. in Dep. of Ecology, Faculty of Science, University of Kufa, Najaf, Iraq

Abstract

Some isolates of bacteria were taken from various places inside the hospital, including operating theaters, corridors, ventilation areas, floors, and other samples were taken from patients suffering from antibiotic resistance.

The study aims to discover the multiple resistant bacteria present in the hospital environment, to discover the extent of their resistance, and to detect the gene NDM-1, NDM-2, which when they are present, the bacteria are highly resistant.

When a patient is infected with multiple resistant bacteria, he suffers from all antibiotic resistance and may lead to death, which is the biggest problem in the world today.

Keywords: MDR, NDM-1, NDM-2, Nosocomial Infection.

Introduction

Multi Drug Resistance (MDR) is resistance to more than one antimicrobial. "To date, no standard definition has been agreed upon in the medical community. Multiple definitions are used to describe patterns of multiple drug resistance in Gram-positive and Gram-negative organisms" ¹,². The lack of specific definitions of MDR in clinical study protocols creates data that are difficult to compare. The authors and relevant authorities are used to characterize organisms as MDR. And that depends on their sensitivity to the antibiotics applied to the organisms in the laboratory. "Resistant to multiple agents, classes, or subclasses of antimicrobial agents" ³. The most commonly used definition of Gram-positive and Gram-negative bacteria is “it means that any bacteria that are resistant to 3 or more antagonists are An overview of the diversity of these definitions is provided in a comprehensive review of MDR resistance in P. aeruginosa and A. baumannii by ⁴. The authors note that a large number of studies do not suggest any specific definitions of MDRs, but most define MDR as “resistance to three or more classes Another method used to characterize bacteria as MDR is when they are “resistant to a major antimicrobial agent” ⁵. These bacterial isolates may have general health significance due to their resistance to only one major antimicrobial agent, but they often exhibit common or shared resistance to multiple classes of antimicrobials, making them Creating an acronym for a bacterium based on its resistance to a major antimicrobial agent (such as methicillin resistance in S. aureus, i.e. MRSA) immediately highlights its epidemiological importance ². The advantage of using this approach for monitoring purposes is that it can be applied easily ⁶.

The aim of the study: The present study aimed to determine the prevalence of multi drug resistant bacteria among clinical and environmental samples collected from hospitals in the Najaf province.

Method

Extraction of DNA from Gram-positive, Gram-negative bacteria The DNA extraction method presented
in this paper is an improved method of the standard phenol/chloroform method.

We eliminated the lysis step that uses SDS/lysozyme or proteinase K, and lysed cells directly by phenol. To extract the DNA from Gram negative or Gram-positive bacteria, 1 ml cell suspension was centrifuged at 8000g for 2 min, except for K. pneumoniae where 13 000g for 10 min was used to pellet cells. After removing the supernatant, the cells were washed with 400 ll STE Buffer (100 mM NaCl, 10 mM Tris/HCl, 1 mM EDTA, pH 8.0) twice. Then the cells were centrifuged at 8000g for 2 min, except for K. pneumoniae (13 000g for 10 min). The pellets were resuspended in 200 ll TE buffer (10 mM Tris/HCl, 1 mM EDTA, pH 8.0). For yeasts, 50 mg of 425–600 lm size-fractionated glass beads (Sigma) were added to the cell suspension. Then 100 ll Tris-saturated phenol (pH 8.0) was added to these tubes, followed by a vortex-mixing step of 60 s for bacteria, 120–200 s for yeasts, to lyse cells. The samples were subsequently centrifuged at 13 000g for 5 min at 4 C to separate the aqueous phase from the organic phase. 160 ll upper aqueous phase was transferred to a clean 1.5 ml tube. 40 ll TE buffer was added to make 200 ll and mixed with 100 ll chloroform and centrifuged for 5 min at 13 000g at 4 C. Lysate was purified by chloroform extraction until a white interface was no longer present; this procedure might have to be repeated two to three times. 160 ll upper aqueous phase was transferred to a clean 1.5 ml tube. 40 ll TE and 5 ll RNAse (at 10 mg/ml) were added and incubated at 37 C for 10 min to digest RNA. Then 100 ll chloroform was added to the tube, mixed well and centrifuged for 5 min at 13 000g at 4 C. 150 ll upper aqueous phase was transferred to a clean 1.5 ml tube. The aqueous phase contained purified DNA and was directly used for the subsequent experiments or stored at -20 C. The purity and yield of the DNA were assessed spectrophotometrically by calculating the A260/A280 ratios and the A260 values to determine protein impurities and DNA concentrations. PCR Condition no stage

### Result

**NDM-1:** Successful PCR amplification was confirmed by agarose gel electrophoresis. Agarose gel was prepared by dissolving 1.6 gm of agarose powder in 80ml of TBE buffer (pH:8) in concentration 0.02 in boiling microwave, allowed to cool to 50oC and ethidium bromide at the concentration of 0.5mg/ml was added. The comb was fixed at one end of the tray for making wells used for loading DNA sample. The agarose was poured gently into the tray, and allowed to solidify at room temperature for 30 min. The comb was then removed gently from the tray. The tray was fixed in an electrophoresis chamber filled with TBE buffer that covered the surface of the gel, 5µl of DNA sample was transferred into the wells in agarose gel, and in one well we put the 5µl DNA ladder mixed with 1µl of loading buffer. This result in agreement with

Effect of Child-to-Child Approach on Practices of Primary School Children Regarding Epileptic Seizures First Aids

Heba Al-kotb Mohamed¹,², Mohammed Saad Abo Elsoud³

¹Assistant Professor of College of Applied Medical Sciences, Bisha University, Saudi Arabia, ²Family and Community Health Nursing, Faculty of Nursing, Suez Canal University, Egypt, ³Lecturer of Community and family health Nursing, Faculty of Nursing, Suez Canal University

Abstract

Background: Many studies showed that epileptic seizures occur more commonly in childhood stage. Most children epileptic seizures occur, during the school day. During this seizure, the child requires immediate first aid for an epileptic seizure. **Aim:** The study aimed to evaluate the effect of Child-to-Child Approach of Primary School Children Regarding Epileptic Seizures First Aids. **Design:** A quasi – experimental design (one group pre and posttest) was used in this study. **Setting:** This study was conducted at six governmental primary schools at Ismailia city. **Sample:** A multi-stage random sample was used in this study, the total number of children was 180 (both male & female) divided into two groups. Trained children group (12 child) and intervention group (168 child). **Tools:** Two tools were used. **First tool:** Interviewing questionnaire was developed by the researcher and included three parts: Socio demographic data, knowledge about epileptic seizure and its first aid measures, Students’ attitudes toward epileptic seizures. **Second tool:** Practical Checklist: it was used to assess the practice of student’s in relation of first aids of epileptic seizures based on the Camfield et al., (2019).

**The Results:** Showed that there were statistically significant increases in mean scores of knowledge of studying sample about epileptic seizure. And showed that there were highly statistically significant increases in mean scores of practices. The results showed that there were statistically significant increases in mean scores of positive attitudes as well as the total score.

**Conclusion:** The knowledge, practice, and attitude of primary school children about first aid of epileptic seizure were improved post implementation of the program compared to pre implementation of the program.

**Recommendation:** Continuous Child-to-Child Approach for Primary School Children about first aid of epileptic seizure.

**Keywords:** Epilepsy, First aid, primary school children, Child to Child (CtC) approach.

Introduction

Children during their primary education are initial stage of learning process will take up all the new things in the way of fast track¹. So, if they express any purposeful messages, the people especially their parents and relatives never neglect them instead, accept them and of their full aspirations of speech.²

Children at this stage are provided with new knowledge, skills and information in order to make the growing buds to spread health-related messages to the community in preventing many health problems³. There are different effectiveness types of educational programs was implemented to engaged children during this stage to improve knowledge of toward some health problems such as child to child approach⁴.

Child to Child (CtC) is an approach in which

Assistant Professor in Community Health Nursing,
Bisha University, Saudi Arabia
e-mail: hebamohamed@ub.edu.sa
children rely on their knowledge of health problems and motivate them to participate in the community through training them in various activities to prevent diseases and instill healthy habits, which leads to the promotion of health and community development led by children.

Even though we take more actions to maintain health in schools, some health problems are still prominent, such as infectious and nutritional diseases, accidents, poisoning, etc. In addition, many children experience seizures during the school day because of developing epilepsy.

Epilepsy is a neurological condition that affects the brain and nervous system, in which a person develops seizures that start from the brain that contains millions of neurons that use electrical signals to control various body functions, but when these functions are impaired, they cause an epileptic seizure.

Most children epileptic seizures occur, during the school day. The child in epileptic seizure suddenly falls with unconsciousness, his body hardens, and vibrations cause him to lose control of himself. During this seizure, the child requires immediate first aid for an epileptic seizure.

The school authorities lacked knowledge how to deal with child during epileptic seizures. During picnic and educational tour, children are exposed to life threatening emergencies from epileptic seizure. Immediate first aid measures to be given to prevent complications and save the life of the children and adult, children also must have enough knowledge about emergency measures to be taken in emergency.

Health education to primary school children is the most effective way to improve knowledge about epilepsy and low level of epilepsy-related social isolation and educational performance. Children in primary education stage are more accepted changes in ideas related to health problems, because the child in this wishes to be successful in order to obtain information to communicate to his family and his friends, which leads to the subsequent promotion of children to health and prevention of diseases.

Numerous studies have proven that schools are the most appropriate places for proper education in first aid.

Significance of the problem: Globally, 50 million of people in different age stages suffering from epilepsy and most of them in developing countries as about 4.7 million epilepsy cases are in the Eastern Mediterranean Region. The prevalence of epilepsy in Kingdom of Saudi Arabia was about 7 cases out of 1000 children while the prevalence of epilepsy in Egypt was 6.98/1,000.

Children aged 7-12 are an ideal target group for an epilepsy educational program through child to child approach. At this age they are learning to think logically about happenings around them and they are becoming aware of other people’s perspectives. Based on this and results from afore mention studies.

Aim of the study: The study aimed to evaluate the effect of Child-to-Child Approach of Primary School Children Regarding Epileptic Seizures First Aids through:

1. Assessing knowledge, practice, and attitude of primary school children about epileptic seizure and its first aid.
2. Implementation and evaluating child to child approach for primary school children about epileptic seizure first aid.

Hypotheses:

To fulfill the aim of the study, the following hypotheses were formulated:

H1: Child to child approach will improve knowledge and practice regarding epileptic seizure first aids management among primary school children

H2: Child to child approach will reduce negative attitudes toward epileptic seizure first aids management among primary school children

II. Subjects and Method:

1. Technical design:

Study Design: A Quasi–experimental design (one group pre and posttest) was utilized to conduct the current study.

Study Setting: This study was conducted at six governmental primary schools at Ismailia city (North Ismailia administration); that named as following: (Atef Barakat, Omar Ibn El-Khatab, Garden City, and Al-Nahda, Al-sheikh Zayed, and Al Salaam)

Sampling: A multi-stage random sample was used in this study, according to the following stages:
**First Stage:** The total number of governmental primary schools in North Ismailia educational administration at Ismailia city is sixty eight, six schools were chosen randomly for the conduction of the study, Atef Barakat, Omar Ben El-Khatab, Al-Nahda and Garden City, Al-sheikh Zayed and Al Salaam.

**Second Stage:** One class from sixth grade was selected randomly from each school.

**Third Stage:** All school children in the selected classrooms were taken; total classes included in the study were six classes. Each class was contained 30 to 40 children. The total number of children were 180 (both male & female) divided into two groups:

**Group I:** Peer review group (trained children) for training by researchers to apply child to child approach with the following inclusion criteria: Both genders, their aged ranged between 11-13 years, high score in pretest assessment and the verbal consent were taken from children and their parents to participate in the study.

**Group II:** Intervention group will be provided intervention by peer review group and post evaluation to determine the effect of child to child approach on knowledge and practices regarding epileptic seizure first aid.

**Tools for data collection:**

**Tool (I): interviewing Questionnaire:** An interview questionnaire was designed by the researchers to collect the required data after reviewing related literature. It was written in simple Arabic language and it consisted of three parts.

**Part I: (Socio-demographic data):** Covered the studied children’s socio-demographic characteristics, such as: Age, gender, parent’s education, parent’s occupation, and school grade.

**Part (II):** Entails questions about children’s knowledge about epileptic seizure and its first aid measures it included meaning, symptoms, onset age of epilepsy, and prevention, and aim epileptic seizure first aids based on Minicucci et al[14].

**Part (III):** Students’ attitudes toward epileptic seizures to assess students’ attitudes about first aids epileptic seizures. It included the best action to take when see some students in the class when your colleague at the school is suffering from an epileptic fits.

**Scoring system for knowledge:** Knowledge obtained from the children was checked with a model key answer. A correct answer was scored one, and an incorrect answer was scored zero. For each area of knowledge, the scored elements were summed up. The total score of knowledge was (15) points. The student’s score less than 50% was considered poor. <50% was considered poor, 50-< 75% was considered fair and -75% was considered good.

**Scoring system for attitude:** The total scores of all questions categorized into two levels as follow: Agree for positive direction answer was scored one, and disagree for negative direction answer was scored zero. Total positive direction seven statements and negative direction five statement.

**Second tool practical check list:** Entails questions about children’s practices about epileptic seizure, filled in by the researchers, it was used to assess children practices regarding epileptic seizure to assess students’ assess the practice of student’s in relation of first aids of epileptic seizures based on the Camfield et al[15] and included the following nine steps. 1) Stay calm - remain with the person during the seizure. 2) Protect from injury - remove any hard objects from the area. 3) Protect head place something soft under their head and 4) loosen any tight clothing. 5) Gently roll the person on their side as soon as it is possible to do so and firmly push the angle of the jaw forward to assist with breathing. A person cannot ‘swallow their tongue’ but the tongue can move back to cause a serious block to breathing. 6) Stay with the person until the seizure ends naturally and 7) calmly talk to the person until the regain consciousness, usually within a few minutes. 8) Reassure the person that they are safe and will stay with them while they recover. 9) Requesting ambulance if the seizure lasts more than five minutes.

**Scoring system for practice:** Scoring system: done step was scored one and not done step was scored zero. The total scored of first aids epileptic seizure was (16) point. The student’s score 50% or more was considered satisfied and less than 50% unsatisfied poor.

**Operational Design:**

**A. Preparatory Phase:** It included reviewing of literature, different studies and theoretical knowledge related to epileptic seizure and its first aid using books, articles, internet, periodicals and magazines.
**B. Content Validity:** The study tools were presented to five experts specialized in the field of community health nursing, to ensure the suitability of the tools chosen to carry out the study and achieving its goal.

**C. Reliability:** All tools used in the present study showed good to very good reliability as follows: was done by applying the questionnaire to ten students using test-retest and Pearson Coefficient Factor was 90.8%. The scale was applied on them and retested after 2 weeks. The degree of Spearman’s rank Correlation coefficient test was (0.82).

**D. Pilot Study:** The pilot study was applied on twenty-one children excluded from study sample to test the clarity and arrangement of the items and time needed for each sheet. The final form was achieved through rearrangement, and modification of the tools’ item based on the findings of the pilot study. Some questions and items were omitted, added, or rephrased, and then the final form was developed.

**F. Field Work:**

- The study was conducted over a period of 6 months started from 15th of October 2018 to 15th of April 2019, where the researchers were available in the study setting three times/week from 9.00 a.m. to 12.00 mid-day. The researchers started by introducing themselves to the studied children and a verbal consent was obtained from each child studied and their parents.

- The studied children were fully informed about the aim of the study prior to the completion of questionnaire in convenient time, which was not interfering with their class schedule.

**Application of child to child approach through four steps:**

**Assessment Phase:**

- During first month from study distributed pretest for children understudy from selected schools. The researchers interviewed with children separately, and the answers were marked by the researchers, about 20 minutes was needed to complete the questionnaire.

- Analysis pretest results and select two children with satisfactory scores in pretest from selected schools. Demonstrate names of selected children on their teachers to take opinions and approval

**Planning Phase:**

- Determine the topics, which were organized according to priority of selected children needs among the study participants. The content included meaning of epileptic seizure, why do children get epilepsy, and its first aid measures.

- Design teaching material and booklet with Arabic simple sentences and colorful pictures regarding first aid for epileptic seizures. This booklet containing systematically organized information about epileptic seizure and its first aid measures to cover the child’s deficit in knowledge and practices.

- Establishing a schedule for training the selected children in each school and giving training sessions two times per week during the school activity hour, and the session period is 45 minutes. Total numbers of sessions for each child eight sessions.

**Implementation Phase:**

- Researchers provided training sessions to trained children on first aid procedures for epileptic seizures using PowerPoint lectures, animated videos, and role-plays. Researchers use the feedback method to make sure trained children understand.

- The trained children’s knowledge and practices were assessed by making them to do rehearsal to the researchers and the same questionnaire was given to determine their adequate level of knowledge and practices on the next day. If the knowledge was average or poor and the practice score inadequate, then the trained children were encouraged to do the rehearsal again, under the supervision of the researchers, until the knowledge and practice scores were good and adequate.

- Trained children start to be training another group of children (163) were divided into 6 groups and each group consisted of 15 - 20 children under supervision the researchers.

- Trained children distribute booklet to each child in first session and used power point lecture and role play as teaching method under supervision the researchers. The researchers take feedback from children after every session.

- Posttest was done next day after finished training sessions by same questionnaire.

**Evaluation Phase:** It involved a post-test done, using the same formats of the pre-test to determine change
in knowledge level and practice regarding epileptic seizures

3. Administrative Design: The current study was conducted after obtaining the approval of the educational administration after clarifying the purpose of the study. The principals of the selected schools are notified of the approval of the educational department to collect data, goal and expected results of the study are clearly explained.

Ethical Consideration: Approval of the Educational Administration in North Ismailia to apply the study in their primary schools. Children and their parents consent to participate in the study orally. Participants confirmed the information from them will be treated confidentially. It is used for research purpose only. Participants’ Anonymity, confidentiality, privacy, safety, and protection are secured. The intervention had no adverse effect on the participants. The studied children were informed about their rights to refuse or withdraw at any time without giving reasons and without consequences.

4. Statistical Design: Data were fed to the computer and analyzed using IBM SPSS software package version 20.0. (Armonk, NY: IBM Corp) Qualitative data were described using number and percent. Quantitative data were described using range (minimum and maximum), mean, and standard deviation. The significance of the obtained results was judged at the 5% level. The used tests were 1 ANOVA with repeated measures: For normally distributed quantitative variables, to compare between more than two periods or stages 2 Friedman test: For abnormally distributed quantitative variables, to compare between more than two periods or stages.

Results

Socio Demographic characteristics: The current study was 45.8% boys and 54.2% girls. Mean age was 12.93±0.83. Only 7.4% of children resident in rural area. As regards father’s education level 60% had secondary education, and 51.21% were workers. Regarding mother’s education level, 57.56% had secondary education and 63.90% were working, while 20.2% were housewives’ mothers. The study showed also only 20.20% of studied children taken first aids training.

Knowledge and practices regarding epileptic seizure first aids among peer children: from the present it is observed that, improvement in the total knowledge and practices of studied children regarding epileptic seizure first aid after application of CtC approach compared to before implementation.

Figure (1) Distribution of knowledge regarding epileptic seizure among peer children.
Knowledge of the studied children regarding epileptic seizure: From present study observed that there was statistically significant different (p≤0.01) improvement in the mean score of knowledge regarding epileptic seizure among studied children after application of child to child approach.

Table (1): Statistical Difference between knowledge scores before and after application of child to child approach (n=168).

Attitude of the studied children regarding epileptic seizure: the present study reveals the results of change between attitude scores before and after application of the child to child approach.

Discussion

The epileptic seizure appears in the age group from 8 to 12 years, and since the primary education stage represents one fifth of the population in most of the world. An epileptic seizure exposes the child to risks during the seizure, along with the stigma and shame of other children due to lack Knowledge and delay in first aid during a seizure. Child to child approach has the potential effect to bring visible improvement in health and education among the children and it helps in enhancing children participation. Therefore, the aim of the current study was to measure the effect of child-to-
child educational method approach regarding epileptic seizures first aid measures among primary school children.

The study results revealed that slightly more than half of the children were in the age group of 12-13 years. This result agreed with Elewa & Saad [10] who in apply child to child approach regarding first aids in Egyptian primary schools’ children, said that most of the students under study were 11-12 years of age.

Regarding to gender, the present study result shows that more than half of studied children were girls and most of them had never previous first aids training. These results are in the same direction with those of Dasgupta et al [18] who stated that most of study sample were females and most of students had never been exposed to any first aid training before the study was undertaken. These results were in disagreement with those of Abd el Ghany et al [17] who carrying out a study in Suez Canal, Governorate, Egypt; they reported that more than three quarter of the studied students had information and training about first aid.

The current study in which peer children were selected based on their level of knowledge of the pre-test and their level of knowledge and practices was less than one-tenth with regard to knowledge about the meaning, purpose, and first aid of an epileptic seizure. After the peer children received training educational sessions by researchers, the level of knowledge of the peer children improved to a satisfactory degree. This result was in the same line with that of Farrokhmanesh et al [18] when studied application child to child in Iran who reported that selected peer children according to knowledge level in pretest. This is It may be attributed that most children think so first help can only be provided by doctors, health workers and not a commoner. Additionally, there was no educational program or any intervention about first aid in school or included in the school curriculum.

The current study, after application child to child approach, showed an improvement in more than three quarters of the children under the study sample in their knowledge about epileptic seizures. In addition, there were statistically significant improvements in children’s knowledge before and after child to child application in total knowledge. Farrokhmanesh et al., (2018) when studied in Iran who indicated improvement in knowledge level about nutrition among middle school students after applying the child-to-child method. The current study result was also supported by Elewa and Saad [18] who applied child to child approach in elementary schools at Egypt, who found that there was a significant improvement in knowledge about various first aids during implementation phase. This may be related to the effect of child to child approach as a dynamic method that encourages learning by using activity and entertainment between children. In addition, the children are equipped with new knowledge, and skills that increase health and prevent many health problems.

Regarding to the practice of studied children about epileptic seizure first aids, there were statistically significant improvements in the totalscores of practices related to epileptic seizure first aids after application of child to child approach educational method. This result was consistent with Teklehaimanot et al [19] who carried out a study in Ethiopia and found that improvement in students practices who received educational material about epileptic seizure first aid. In addition, Mohammed 2018 in Ahmedabad city in Iran when applied training program regarding first aids among secondary schools’ students reported that there was a highly statistically significant improvement in the mean score of total practice throughout his study. In addition, Abd El-Hay et al [20] in Tanta City (East & West), Elgharbia Governorate, reported that there was a highly statistically significant improvement in the mean score of total practice throughout his study. This may be attributed to an increase in knowledge among the studied children after training which led to improve their practices. Primary school students are more likely to accept epileptic seizure first aid. Training than older students, and they are motivated to learn and do so quickly and easily. Also, children during early stages of development and initial stage of learning process will take up all the new things in the way of fast track.

Hence the research hypothesis (H1) which stated that child to child approach will improve knowledge and practice regarding epileptic seizure first aids management among primary school children.

The present study revealed that there were reduce negative attitude regarding epileptic seizure after applied child to child approached. This result was consistent with that Bozkaya et al [21] who carried out a study in Ankara and found that increase positive attitude toward epileptic seizure among primary school children after application of health education program. In addition, Brabcova et al [22]
when studied effect of educational video on reduce stigma of epileptic seizure in several primary school in Czech Republic reported that reduce stigma regarding epileptic seizure after implementation educational video. Moreover, children may be much more familiar with TV media, drama and may therefore find it a more acceptable approach.

**Conclusion**

In the light of the study findings, it can be concluded that utilization of child to child approach succeeded in achieving significant improvements in the primary school children’s knowledge and practices regarding epileptic seizure first aid measures. Also, there were reducing negative attitude regarding epileptic seizure first aids.

Mutans Streptococci Count and Salivary Histatin 5 Level in Relation to Early Childhood Caries

Heba k. Salman¹, Zainab A. Aldhaher²

¹Master Student, Department of Basic science, College of Dentistry, University of Baghdad, Iraq
²Professor, Department of Basic Science, College of Dentistry, University of Baghdad, Iraq

Abstract

Background: ECC is one of the most common chronic infectious diseases of preschool-aged children (3). Mutans Streptococci (MS) is the chief microorganism that causes ECC. Saliva is a significant factor in the development of teeth decay. Saliva have many innate defense molecules that take part in the protection of oral tissues by either direct antimicrobial effect or interference with microbial colonization. These molecules include antimicrobial peptides AMPs among the main natural antimicrobial proteins of saliva. Salivary histatine-5 (HST-5) is one of the protective factors in saliva that possess anti-bacterial properties against several types of oral bacter. This study aimed to measure the viable count of mutans streptococci and salivary histatin 5 level in relation to early childhood caries.

Materials and Method: Sixty three children with ages of 4-5 years old were enrolled in this study. They were divided into two groups; 33 children with severe type of ECC) ategory as the study group and 30 caries free child) as the control group. Unstimulated saliva sample were collected for ms count on mitis bacitracin agar and for evaluation of salivary Histatin 5 level.

Results: Statistical analysis revealed that M.S. count was higher significantly in study group compared to than control group and salivary histatin 5 was significantly higher than the control group.

Keywords: Early childhood caries, Mutans streptococci, histatin 5.

Introduction

Early childhood caries (ECC) is one of the most common chronic infectious diseases of preschool-aged children, characterized by the destruction of tooth tissues by synergistic complex effects among acids generated from the fermentation of dietary carbohydrates by bacteria and susceptible host factors, such as teeth and saliva(1). Tooth decay of primary teeth in children 71 months of age or younger was regarded to early childhood caries (ECC). In accordance to American Academy of Pediatric Dentistry, ECC is “the finding of one or more decayed (non cavitated or cavitated lesions), missing (due to caries), or filled tooth surfaces in any deciduous tooth in a child below the age of six (2). ECC is a multicausal disease that happened due to host, environment, and microorganism as the causative factors (3). Mutans Streptococci (MS) is the chief microorganism that causes ECC. In the past decade, numeral researches conducted in the relationship between the occurrence of caries and the founding of salivary MS (4). Saliva may transport the bacteria and have a role as a reservoir for the colonization of the bacteria. If the cariogenic bacteria presedant in saliva and plaque, it will raise the acids, which are made by them through the fermentation process of carbohydrate. Then will rise up the colony of the bacteria and begin creating biofilm on tooth surface(5).

One of the fundemantal factors of MS virulence is the potency to give glucan made up by glusyltransferase, which mediated microorganism attachment to the tooth surface along with other protein (6).

Numerous of studies previously have based a positive correlation between MS and ECC (7). A positive correlation was also found between severity of ECC as measured by the dmft index and high levels of MS counts, indicating that as the number of colonies increased, the number of teeth and surfaces affected by
decay also increased. Colonization with MS is thus a key event in the pathogenesis of ECC that can be targeted for caries prevention in clinical practice (8).

Increasingly more and more attention is being paid to the potential of saliva as a potent anticaries agent (9). Saliva protects the tooth against missing of calcium and phosphate ions from the enamel by creating a dental pellicle. The salivary pellicle acts as a protective barrier and helps in preventing demineralization, promoting remineralization, keeping the oral cavity pH neutral and cleaning tooth surfaces by washing away remaining food (1). The development of caries is affected by the physiochemical careteria of saliva, such as pH, salivary flow rate, buffering capacity, varying protein concentrations and other contenant of saliva. Saliva has many innate defense molecules that take part in the protection of oral tissues by either direct antimicrobial effect or interference with microbial colonization. These molecules include antimicrobial peptides AMPs (cathelicidin peptide LL-37, alpha-defensins, beta-defensins, histatins and statherin), major salivary glycoproteins (mucins, proline-rich proteins (PRPs) and immunoglobulins) and minor salivary glycoproteins (agglutinin, LF, cystatins and lysozyme). These proteins play specific functional roles in the first line of defense of the oral cavity (10).

Histatins are small cationic peptides made up of at least 12 histidine-rich basic peptides. Histatins (HST)-produced in parotid and sublingual salivary glands-are among the main natural antimicrobial proteins of saliva. The HSTgroup includes HST-1, −2, −3, −4, −5 and −6. Salivary histatine-5 (HST-5) is one of the protective factors in saliva; it is a salivary peptide that consists of 24 amino acids produced in parotid and sublingual salivary glands., salivary HST-5 was demonstrated to possess fungicidal and fungistatic properties against Candida albicans and antiviral activity against the human immunodeficiency virus (HIV), in addition to antibacterial properties against several types of oral bacteria (11, 12).

Materials and Method

Sixty three children with ages of 4-5 years old during the period from December 2019 to march 2020 were enrolled in this study. They were divided into two groups; 33 children with severe type of ECC according to Wyne (13) category as the study group and 30 caries free child according to WHO (14) as the control group. They will be selected from pediatric and preventive departments clinics/college of dentistry/Baghdad university Baghdad city.

3-5ml of unstimulated saliva was collected by drooling method (15). 1 ml from each sample for microbiological investigation and bacterial culturing then the remaining of each salivary sample was centrifuged for 10 minutes at 1000×g at 2.8°C. The supernatant which is about 1-2 ml was transported to eppendorffs tube with the same number of the child for freezing. The sample was stored at -20°C for further biomarkers detection procedure.

Microbiological Analysis: The collected salivary samples were homogenized for 1 minute using vortex mixer and then ten-fold serial dilutions were performed From dilution 10-3 of salivary samples 0.1 ml was spread microbiological on MSB agar plates. The plates were incubated anaerobically by using a gas pack supplied in an anaerobic jar at 37◦C for 48hrs, followed by aerobic incubation for 24hrs, at 37◦C.

Identification was done according to colony morphology, Gram stain reaction, Biochemical test, catalase test. Carbohydrate fermentation test for M.S and bacterial colony count was also done (16)

Biomarker Detection: The level of salivary histatin 5 was estimated by using commercially available sandwich enzyme-linked immunosorbent assay (ELISA) kit and performed as recommended in leaflet with kit (MyBiosource; USA).

Statically analysis will be carried out using statistical package for social sciences (SPSS) version 21. Descriptive statistics using: frequencies, mean and standard error in addition to the following statically test: Independent sample T test, correlation coefficient (r), chi–square.

*Highly significant at P≤0.001

Table 1 illustrate the viable count of M.S among E.C.C study group and healthy control group.

The results demonstrated that the viable count of M.S was higher in study group than control group with highly significant differences.

The results of this study were in agreement with other researchers who also found that MS.. is associated with E.C.C (E.C.C children had more colonies) (17)

Other researchers were also in agreement with the present study (18)(19)

Is well-known that M.S. IS the causative microorganism in the development of dental caries because they drop the plaque pH and produce acids from carbohydrates and survive in the acidic environment.(20)

M.S. constitutes about 60%of cultivable flora of dental plaque obtained from preschool children with ECC(21). Horizontal and vertical transmission of microbes can be seen. Horizontal transmission occurs between siblings and care givers (22, 23).Vertical transmission is also known as mother to child transmission (24). Poor maternal oral hygiene and sugar exposure increases chances of vertical transmission(25).

In appropriate feeding practice can prolong the exposure of teeth to fermentable carbohydrates which in turn may aggravate the chances of ECC (26). Also Bottle feeding during bedtime or sleeping (27) is the most important cause of ECC and hence also known as nursing bottle caries, baby bottle caries. Frequent exposure to sugar, frequent snacking, taking sweetened drinks to bed, sharing foods with adults, as well as maternal caries status, oral hygiene and dietary habits predispose to early S. mutans colonization and establishment of its high counts (26).

*Highly significant at P≤0.001

Table 2 illustrates salivary levels of histatin 5 in E.C.C. group and healthy control group, the results showed that the levels of histatin5 was higher in E.C.C. group compared with healthy control group and there were highly statistical differences between the two groups.
These results are in agreement with the results of other researchers\(^{(28),(29)}\). Increased activity of HST-5 was observed in wide pH range. However, in low pH (with presence of caries dental changes) protonation of histidine residues occurs, additionally increasing the antimicrobial force \(^{(30)}\).

Histatins are a group of small, cationic, histidine-rich peptides secreted by human salivary glands.

The increased level of histatin 5 may be explained by the fact that high-intensity caries is associated with increased levels of some salivary components (histatin-5) that possess strong bactericidal or bacteriostatic effects resulting in agglomeration of oral bacteria and their clearance from the oral cavity, \(^{(29)}\).

**Conclusion**

Salivary histatin 5 level in saliva of children can be used as diagnostic tool or marker for the prediction of caries risk.

The Prevalence of *Pseudomonas aeruginosa* among Baghdad Hospitalised Patients

Heba K. Tawfeeq¹, Muthanna Hamid², Harith Jabbar Fahad Al-Mathkhury³

¹Assistant Lecturer, Department of Biology, College of Science, University of Anbar, Anbar, Iraq, Department of Biology, College of Science, University of Baghdad, Baghdad, Iraq, ²Assistant Professor, Assistant Lecturer, Department of Biology, College of Science, University of Anbar, Anbar, Iraq, ³Professor, Department of Biology, College of Science, University of Baghdad, Baghdad, Iraq

Abstract

In order to determine the prevalence of *Pseudomonas aeruginosa* among hospitalised patients, 156 specimens were collected from hospitalized patients referring Baghdad, Iraq hospitals. Bacterial isolates were identified using conventional biochemical tests and then identification was confirmed by the locating of 16SrRNA. *Pseudomonas aeruginosa* constitutes 30.05%. In conclusion, the attention should be paid toward the infections of this opportunistic pathogen.

**Keywords:** *Pseudomonas aeruginosa*, hospital, 16SrRNA, PCR.

Introduction

*Pseudomonas aeruginosa* is a Gram-negative bacterium that is ubiquitous in different ecosystems and involves in numerous forms of relations with eukaryotic host. It is an opportunistic pathogen extensively spread in humans and animals (¹), leading to a wide range of infections in community and hospitals (², ³). Due to the extended spread of *P. aeruginosa* habitat, the control of the organism in a hospital setting is very difficult, and makes it practically impossible to prevent contamination (⁴). The major threat is the infection of immunocompromised patients or those in burns, neonatal and cancer wards (⁵). Infection of *P. aeruginosa* is still one of the main causes of death among the critically ill and patients with impaired immune systems in spite of the development of newer and stronger antibiotics (⁶).

Due to the extended spread of *P. aeruginosa* habitat, the control of the organism in a hospital setting is very difficult, and makes it practically impossible to prevent contamination. The major threat is the infection of patients who are immunocompromised or those in burns, neonatal, cancer wards, it is the main cause of morbidity and mortality in cystic fibrosis patients and one of the leading nosocomial pathogens affecting hospitalized patients (⁷).

Due to the innate capacity of resistance to antimicrobial agents, this bacterium is greatly difficult to treat. What’s more, such resistance is being progressively a problematic issue because of increasingly development of resistance to agents regarded as powerful therapeutic options (⁸).

In this study we have used a genus specific bacterial 16S PCR to investigate the prevalence and diversity of *P. aeruginosa* among Iraqi hospitalised patients.

Materials and Method

**Ethical Statement:** All participants agreed to provide the investigator with the specimens. Informed consent according to the Declaration of Helsinki was obtained from all participants.

**Pseudomonas aeruginosa isolation and identification:** One hundred and fifty-six specimens included mid-stream urine, burn swabs, wound swabs, and blood were collected from hospitalized patients referring Al-Yarmouk teaching Hospital and Baghdad Medical City in Baghdad, Iraq. All specimens were cultured on enrichment media such as blood agar and transferred onto MacConkey agar. Pale colonies on MacConkey agar (lactose non-fermenter) were assayed for the conventional morphological and biochemical characterization comprising Gram stainability was conducted alongside the activities of oxidase and
catalase. Thereafter the primarily identified P. aeruginosa isolates were submitted to molecular identification by polymerase chain reaction (PCR) technique.

**Detection of 16SrRNA**

**Extraction of Bacterial DNA:** Genomic DNA was extracted using Presto™ Mini gDNA Bacteria (Geneaid, Thailand). Upon the procedure itemized by the manufacturing company, DNA was extracted from overnight cultures of the carefully chosen staphylococcal isolates. Purified DNA concentration was measured using Biodrop (Biodrop, Canada).

**PCR:** To confirm the identification of P. aeruginosa isolates, conventional PCR technique was carried out in accordance to Spilker et al. (9) to amplify a fragment of 16SrRNA (956 bp). Two microliters of each primer PA-SS-F (5’-GGGGGATCTTCGGACCTCA-3’) and PA-SS-R (5’-TCCTTAGGTGCCCACCCG-3’), different concentrations of DNA (depending on DNA yield) extracted from each P. aeruginosa isolate and deionized D.W. were added to PCR premix tubes (Bioneer, Korea) in order to reach 20 µl as a final volume. The thermocycling conditions (Bio-Rad T100, USA) set at 94°C for 2 min, followed by 25 cycles of 94°C for 20s, 58°C for 20s, and 72°C for 40s. A final extension of 1 min at 72°C was applied. PCR products were visualized using 2% agarose gel stained with diamond nucleic acid dye (Promega, USA).

**Results**

**Isolation and identification:** A total of 52 (33.33%) isolates developed a growth on cetrimide agar, pale colonies on MacConkey agar, and succeeded to grow on nutrient agar at 42°C. Moreover, they were oxidase and catalase positive. Hence, these isolates were primarily identified as P. aeruginosa.

**DNA extraction and preparation:** After DNA extraction by Presto™ Mini gDNA Bacteria Kit, DNA concentration was between 24 and 78 ng/ml; whereas, purity was about 1.82-1.99. A ratio of 1.8 -2.0 is generally accepted as “pure” for DNA (10). Gel electrophoresis was done to confirm the integrity of extracted DNA.

**Molecular Detection:** The current results revealed that 16SrRNA was located in 50 (96.1%) out of 52 biochemically P. aeruginosa isolates. Correspondingly, two isolates were identified using traditional method as P. aeruginosa, they did not have this gene.

**Discussion**

Pseudomonas aeruginosa is an opportunistic pathogen capable of causing a wide array of life threatening acute and chronic infections particularly in patients with compromised immune defense (11). Earlier reports have shown that the antibiotic resistance of bacteria due to biofilm formation contributes to the persistence of bacterial cells and causes problems in the complete eradication of infection (12, 13).

The present work is in agreement with (14) as they found that the results of 16S rRNA showed that all P. aeruginosa isolates were resistance to gentamicin harbored this gene. Al-Derzi (15) stated that out of 8038 and 1878 clinical specimens submitted for culture in Mosul and Duhok, respectively, 180 and 21 clinically significant isolates of P. aeruginosa were isolated, resulting in a prevalence of 5.2% and 1.6%, respectively. Moreover, cultural and biochemical identification revealed that 63 P. aeruginosa isolates were recovered from 158 samples in Karbala, Iraq (16). Also Hasan et al. (17) reported that 21.6% P. aeruginosa isolates were collected form 185 swab samples in Kirkuk City, Iraq.

The variability in P. aeruginosa isolation percentage may be attributed to geographic, climatic, and hygienic factors among different areas. As well as, the high prevalence of P. aeruginosa in our community may be related to the rise of burn and wound patients than other samples in our population; which may be the result of different increased kitchen accidents, terrorist incidents, and electrical fire (18).

**Conclusion**

Pseudomonas aeruginosa was isolated in relatively considerable number; consequently, much work is needed to overcome and control this opportunistic pathogen.

**Conflict of Interest:** None

**Funding:** Self

**Ethical Clearance:** Not required

Effect of Training Program Regarding Occupational Health Hazards on Nurse Interns’ Knowledge and Practice

Heba Nasser Rayan¹, Samia Mohamed Adam², Hanaa Mohamed Abdrabou³

¹Assistant Lecturer, ²Professor, ³Assistance Professor, Nursing Administration Department, Faculty of Nursing-Ain Shams University, Cairo-Egypt

Abstract

Background: Nurse Interns face a wide range of hazards in hospitals including needle stick injuries, back injuries, latex allergy, violence, and stress.

The goal of this study: Identify the impact of training program regarding occupational health hazards on nurse interns’ knowledge, practice and attitude through: assessing nurse interns’ knowledge regarding occupational health hazards before and after the program, assessing nurse interns’ practice regarding of occupational health hazards before and after the program, assessing nurse interns’ attitude regarding of occupational health hazards before and after the program, designing and implementing the training program and measuring the effect of training program regarding occupational health hazards on nurse interns’ knowledge and practice.

Design: Quasi- experimental research design.

Subject: The study was conducted at four hospitals affiliated to Ain Shams University. The subjects of this investigation included 91 nurse interns.

Tools of data collection: Data were collected by using four tools namely: Needs assessment sheet, Self-administered Questionnaire, Observation Checklist, and attitude scale.

Results: Highly significant differences of total occupational health hazards knowledge among nurse interns throughout program phases was observed. Nurse interns’ total practice regarding occupational health hazards was markedly increased throughout program phases. Highly significant difference in total attitude towards protection from hazards throughout the program phases was noticed.

Conclusion: Implementation of the training program led to significant improvements in nurse interns’ knowledge, practice, and attitude regarding occupational health hazards.

Recommendations: providing training program for nurse interns about occupational hazards and especially on protective measures, development and dissemination of policies and guidelines of safety practices, evaluation sheet of the nurse interns should include items related to occupational health hazards and compliance ways of protection, and further investigation might include factors affect reporting of occupational hazards.

Keywords: Nurse interns, Occupational health hazards, Training program.

Introduction

Nursing is one of the hazardous occupations, in which the risks are four times higher than those in other professions¹. Health care workers are continually exposed to occupational health hazards². Nurses are
exposed to many occupational hazards that may threaten their health and safety.\(^3\)

Occupational safety at the workplace improves the employees’ health and increases their productivity. In the medical profession, Nurses constitute the largest group of healthcare workers, and experience a higher rate of working environment dangers exposure than other health services laborers.\(^4\)

Nurses and nurse interns are the most significant individuals from the medical care group, who give direct consideration to the patient are presented to various occupational dangers, for example, drugs, chemicals, infectious agents, absence of materials and ergonomic conditions, extreme working, and unreasonable outstanding burden, and furthermore they have physical (needle stick, musculoskeletal disorders and pain, and varicose veins), chemical (skin problems, latex sensitivities), biological (infectious sicknesses), and psychological (stress, burnout, psychological health problems, sleep trouble) problems.\(^5\)

Health care organization likes other high danger work environment is described by exposure to an elevated level of occupational hazards that significantly imperils the health status and life of health care workers, and occupational hazards may be the leading cause of death and mortality.\(^6\) The World Health Organization (WHO) confirms that hospitals are the primary priority in preventing workplace hazards.\(^7\)

Nursing assistants are baccalaureate understudy nurses caretakers who start the job change from senior understudy to proficient nurse though internship preparing program.\(^8\) The internship program is required for a Bachelor of Science in nursing achieving the satisfaction of year of a baccalaureate. The internship year is viewed as a period of change from undergrad nursing understudies to starting level enlisted nurses. During this year, nurture understudies ought to procure the qualities, mentalities, and essential objectives to the nursing profession. The preparation internship program advances techniques for new graduate recruitment and retention, give a chance to unite clinical nursing information in new areas of practice.\(^9\)

Nurse interns like other health care workers in the profession that have the highest risk because exposure to high rate of occupational hazards. Nurses represent the largest group of health care workers and they have directly and indirectly contact with the patients the nurses and nursing intern exposure to a higher degree of workplace hazards than other professional does in the medical field. Therefore, this occupational hazard can be reduced by implementing number of programs such as; training, and education of the nurses and nursing interns.\(^4\)

Significance of the study: Occupational health hazards are very common in developing countries where work place risks are more extreme. There are upwards of 250 million occupational injuries every year, bringing about 330000 fatalities. Every year, an expected 160 million new cases of work related ailment happen around the world, hazards in workplace affect not only the workers but also the agency itself by its effect on wage loss, medical payment workplace disruption, effect on productivity, and high absenteeism rate, low employee morale and job loss.

Nurse interns face a wide scope of perils in hospitals including needle stick wounds, back injuries, latex hypersensitivity, violence, and stress. In spite of the fact that it is conceivable to prevent or lessen nurse intern’s exposures to these hazards, nurse interns actually are experiencing large numbers of occupational hazards and illness. Rates of occupational injury to health care team have increased over the past decade.

**Aim of the study:** This study aims at identifying the effect of training program concerning occupational health hazards on nurse interns’ knowledge, practice and attitude through:

1. Assessing nurse interns’ knowledge related occupational health hazards before and after the program.
2. Assessing nurse interns’ practice regarding of occupational health hazards before and after the program.
3. Assessing nurse interns’ attitude regarding of occupational health hazards before and after the program.
4. Designing and implementing the training program.
5. Measuring the effect of training program regarding occupational health hazards on nurse interns’ knowledge and practice.

**Research Hypothesis:** Nurse Interns’ knowledge, practice and attitude regarding occupational health hazards will be improved after implementing the program.
Subjects and Method

**Research Design:** A quasi-experimental design was utilized in conducting this study.

**Setting:** This investigation was carried out at four hospitals affiliated to Ain Shams University where the nurse interns having their training, namely: Ain Shams University Hospital including (6 units) which was Cardiac Care Unit (CCU), Neurological ICU, Stroke ICU, Endemic ICU, and Kidney Dialysis Units, and Neonatal ICU, Medical ICU, Surgical Also, Academic Institution of Cardiac Surgery including (3 units) which was Adult ICU, CCU, Post Catheter Care Unit.

Setting: Cardiac Catheter OR. El-demerdash Hospital including (3 units) which was Operating room (21 rooms) and Intensive care unit and Emergency operating rooms (5 rooms). Pediatric Hospital including (4 units) which was Minor OR (1 room) ICU.

**Study Subjects:** All nurse interns having their training in the previously mentioned settings during the data collection period (academic year 2018-2019). The study sample was (91) nurse interns, 57 females and 34 males, distributed as follows: Ain Shams University Hospital (30) nurse interns, El-Demerdash Hospital (31) nurse interns, Pediatric Hospital (15) nurse interns, The Academic Institution of Cardiac Surgery (15) nurse interns.

**Data collection tools:** The data were gathered utilizing four tools namely: Needs evaluation sheet, Self-administered Questionnaire, Observation Checklist, and attitude scale.

1. **Needs assessment sheet:** developed by the researcher guided by¹⁰, to assess nurse interns’ needs regarding training program of occupational health hazards. It was used before beginning the training program. The sheet contained two parts.

   The first part: aimed to collect socio-demographic data of the study subjects like: age, department, gender, marital status, and attendance of training courses about occupational hazards.

   The second part: aimed to assess nurse interns’ needs regarding training program of occupational health hazards. It contains (10) items related to training program regarding occupational health hazards content. These items contain various topics such as: occupational health hazards, back pain and body mechanics, work related injuries, infection and nosocomial infection, disinfection and sterilization, safe handling and disposal of sharps, hand washing, personal protective equipment (PPE) in health care setting, cleaning of surgical instruments, psychological job hazards.

2. **Self-administered questionnaire:** This tool was aimed to assess knowledge of nurse interns regarding hazards facing them during internship training and the different method of protection from these hazards. This tool adopted from¹¹. The questionnaire sheet consisted of the following three parts:

   Part I: Aimed to collect socio-demographic data of study subjects like: age, gender, department, marital status, and attendance of training courses about occupational hazards.

   Part II: Aimed to collect medical and work-related data related to work hazard exposure to assess nurse interns’ actual exposures to various types of hazards during internship training, including (physical, chemical, biological, psychological, and social hazards). Through thirty-four items. These items were grouped under five questions and nurse interns select the answer (Yes or No).

   Part III: This part developed by¹¹. This part was aimed to assess nurse interns’ knowledge regarding occupational hazards. This part consisted of 25 multiple choice questions. These questions classified into ten categories.

   **Scoring system:** Knowledge items were scored (1) for the right answer and (zero) for the incorrect answer. The scores of the items were summarized and the total divided by the number of the items giving mean score of the part. These scores were changed over into a percent score. The mean and standard deviation for third part were calculated then converted into a mean percent. The maximum possible total score was (twenty-
five). Knowledge levels was considered high level of knowledge if the percent score was more than 75%, moderate if the percent score was 60-75%, low level if the percent score was less than 60%.

3. Observation Checklist: This tool aimed to assess the actual nurse interns’ practice related to safety standards, precautions, this tool adopted from. This tool was consisted of the 64 items. These items were grouped under nine categories: hand washing 15 items, gloving 10 items, eye protection 1 item, masking 2 items, personal hygiene 7 items, cleaning instruments 6 items, sharp box use 8 items, proper lifting 9 items, Safe waste disposal 6 items.

Scoring system: The scoring system ranged from done ‘(1)’ or not done ‘(0)’ or ‘not applicable ‘(not account)’. For each part, the score of the items were summed up and the total divided by the numbers of the items, then mean and standard deviation were calculated. These scores were converted into a mean percent. The practice was considered satisfactory if the percent score was 60 % or more and unsatisfactory if less than 60 %.

4. Attitude scale: This tool aimed to assess nurse interns’ attitude towards protection from hazards facing them during internship training. This tool developed by. The tool consisted of 12 positive and negative statements covering various types of hazards, in addition to the universal precautions, for example (I try to avoid infectious patients to avoid infection).

Scoring system: The scoring system was using three points likert scale Agree (2) and uncertain (1) and disagree(0). The scores of the items of each subscale were summed-up, converted into percent score, for the purpose of each presentation of each item. The nurse interns’ attitude score were considered satisfactory if the percent score is 60% or more, unsatisfactory if less than 60%.

II. Operational design: Operational design for this research included three phase’s namely pilot study, preparatory phase, and the fieldwork.

a. Preparatory phase: This phase started from January 2018 until April 2018 It contain review of the current and past literature, public and global related literature, journals concerning the different aspects of the study, using textbooks, thesis, and articles dependent on this review.

Tools validity & reliability: Tools validity: aimed at testing the validity of the evaluation tools and its components. Two kinds of validity tests were utilized: face and content validity. Face validity aimed at checking that the tool gives the appearance of measuring the concepts of occupational health hazards. Content validity was led to decide the suitability of every item to be included in the tools. The tools validity developed by.

Tools reliability: The reliability test was done to assure the consistency, determine how strongly the attributes were related to each other and to the composite score. The reliability test was used in this stage for three tools for data collection using Cronbach’s’ Alpha test. Cronbach’s alphas were (r= 0.896 0.917and 0.705) for Occupational hazards knowledge questionnaire, Occupational health hazards practice observation checklist, and Attitude scale respectively.

Pilot study: The pilot study was done on 10% of the study sample (9 nurse interns).These nine nurse interns were included in the main study sample. Data obtained from the pilot study was analyzed, and no modifications were done. The time consumed for fulfilling the study tools was 35 minutes.

Field work: The field work of the study lasted for seven months from beginning of February to the end of September 2019. The field work was done through the following phases.

Phase 1 (Assessment phase): This phase involved pre-testing of the study nurse interns’ knowledge, practice and attitude regarding occupational health hazards using the relevant data collection tools. The researcher visited each of the four hospital included in the study to explain the purpose and nature of the study to the administration and obtain their permission to carry out the study. Then, researcher met with the nurse interns, oriented them about the study aim and procedures, and invited them to participate. The needs assessment sheet was distributed to study subjects to assess their needs regarding the program. Then the researcher distributed the self –administered questionnaire form to study subjects to assess their knowledge and attitude scale regarding occupational health hazards, along with filling instructions.

The nurse interns were then observed individually by the researcher using the observation checklist to assess the actual nurse interns’ practice related to safety
standards, precautions. Each nurse intern was observed three times. The period between successive observations was two days.

**Phase II (Training program planning):** The content of the training program was developed based on review the regarding literature and based on the assessment of the knowledge questionnaire. Different instructional strategies were selected to suit the participant’s needs, and achieve the objectives and contents of the training program. It was aimed at providing trainers with much experience as possible. Within the available resources, a training program was developed by the researcher.

**Phase III (program implementation):** The training program was implemented to nurse interns working in the study setting. Nurse interns were divided into five groups. Training program consisted of 12 sessions. The training program sessions carry out four days/week (4 hours/day). It was carried out from 12:00 am to 2:00 pm, while in afternoon shift program was implementing from 3:00 pm to 5:00 pm for nurse interns in the different departments.

Time allowed for achieving the program objectives was 22 hour: 14 hour theoretical and 8 hour practical hours. Each session contain theory or practice content and including time for discussion. This phase take from beginning of April to middle of May 2019.

**Phase IV (post program evaluation):** Investigator evaluated impact of training program regarding occupational health hazards on nurse interns’ knowledge, practice and attitude. A post-test was done immediately after program implementation during May 2019. This was finished utilizing the same data collection tools and checklist as in assessment stage.

**Phase V (follow-up):** follow up test was repeated three months after post-assessment evaluation by using the same data collection tools to estimate the impact of training program related occupational health hazards on nurse interns’ knowledge, practice and attitude. This phase took four months.

**III. Administrative Design:** An official permission to conduct the study was obtained from hospital directors through letters. The letter included the aim of study and photocopy from data collection tools in order to get the permission and help for collecting data. Then the researcher met each director of the four hospitals, and demonstrates purpose of the study to obtain their cooperation and help during the study.

**Ethical Consideration:** The research approval was obtained from a scientific research ethics committee. The aim and purpose of the research were explained to each director of the four hospitals, as well as the nurse interns who were included in the study, and oral assent was gotten from every participant before the study conduction. Also, it guaranteed keeping up anonymity and confidentiality of the subject data. Nurse interns were informed that they were permitted to decide to participate or not in the study and that they had the right to pull back from the study whenever.

**Statistical Design:** Data entry was done utilizing SPSS V20 PC software package. Data were presented utilizing descriptive statistics in the form of frequencies and percentages for qualitative variables, and means ± standard deviations for quantitative variables. Qualitative variables were compared utilizing chi-square test. Moreover, paired t-test was utilized to compare two means in the same studied group pre and post intervention and between two means post intervention and during follow up stage. Pearson correlation co-efficient (r) was utilized for assessment of the inter-relationship between quantitative variables. The confidence level chosen for the study was 95%. Statistical significance was considered at p value <0.05.

**Results**

Table (1) demonstrates the socio demographic characteristics of study subject. As regard to age, 80.2% of nurse intern’s age ranged (22-23y), with mean age of 22.67±0.83. Moreover, more than half (62.6%) of them were female,(35.2%) of them had an internship training in OR in different hospitals. Also, more than half (66.7%) of them who had attend the courses was its duration was one day, and majority of nurse interns (83.4%) attend courses at time ranged (1-5 months). Also, shows the majority (80.2%) of nurse interns was not attending any of training courses. Also, clarifies that, physical hazards were at a first rank level of hazards which more than two fifth (44.0%) of nurse interns were exposed to physical hazards as perceived by them, followed by psychosocial hazards which slightly more than one quarter (29.7%) of them, while chemical hazards was at the last rank level of hazards which lowest percentage (9.9%) of nurse interns were exposed to.
Table (2) demonstrates that, at pre program phase only (4.4%) of nurse interns had high total knowledge level. As observed at post program and follow up phases the total knowledge level was improved markedly (91.2%, 80.2% respectively). Also, shows that, more than half of nurse interns (53.8%) had satisfactory practice in preprogram phase regarding gloving, while in post program phase the nurse interns’ satisfactory practice reached to (98.9%), and slightly decline (96.7%) in follow up phase. Also, minority (33.0%) of nurse interns had satisfactory practice level regarding occupational health hazards at preprogram phase. Moreover, there were highly improvement in total nurse interns’ practice during post program phases (94.5%), and slightly decline (85.7%) in follow up phase however the levels remained significantly high compared with preprogram phase. The present study finding showed that, majority of nurse interns (92.3%) had satisfactory attitude in post program and in follow up phase there was slightly decline (78.0%), while minority (8.8%) of nurse interns had satisfactory attitude in preprogram phase, with highly statistically significant difference in total attitude towards protection from hazards throughout the program phases.

Table (3) demonstrates there was a positive significance correlation among total knowledge score and total practice score related occupational health hazards among nurse interns throughout program phases. Also, shows that, there was a highly significance correlation among total attitude score and total knowledge score regarding occupational health hazards among nurse interns through post and follow up program phases. However, there was significant correlations among total attitude score and total knowledge score regarding occupational health hazards among nurse interns in preprogram phases.

**Discussion**

Nursing interns are more prone to occupational health hazards, and injuries in the course of their clinical training activities, and their day to day activities in the health care settings. Subsequently, WHO emphasizes on the primary prevention of work environment dangers, particularly because of the highest incidence of occupational injuries happens in hospitals and health care settings, in comparison with to the manufacturing industries.

Current study revealed that, physical hazards were at a first rank level of hazards which more than two fifth of nurse interns were exposed to physical hazards as perceived by them, followed by psychosocial hazards which slightly more than one quarter of them, while chemical hazards was at the last rank level of hazards which lowest percentage of nurse interns were exposed to. The study result is in congruence with a study conducted in Egypt by who decided that, attendants rank physical dangers followed by mental and social risks.

The present study finding revealed that, minority only of nurse interns’ had high level of occupational health hazards knowledge before implementing the program. It may be due to more than three fourth of nurse interns didn’t attend any training program or courses about occupational health hazards.

The findings of the present study is in congruence with that found, low knowledge and awareness level in their study among healthcare workers regarding occupational hazards in their health care settings in Malaysia. In contrary with the present study findings who reported that, respondents had an above average overall knowledge of workplace hazards and safety practices.

As observed the total high level of occupational health hazards knowledge was improved markedly throughout program phases. This finding may be due to the program was effective in improving the occupational health hazards knowledge among nurse interns. The same trend was observed by.

Moreover, slightly decline of total occupational health hazards knowledge level at follow up phase among nurse interns. This result may be due to normal phenomena of retention and forgetfulness due to the high work load. In agreements with the present study who reported that, a significant number of nurses have knowledge about occupational health hazards, although few numbers have insufficient knowledge.

Also, the result showed that, there were highly significant differences of total occupational health hazards knowledge between nurse interns all through program stages. This reflects positive influence of the health education program in enhancing occupational health hazards knowledge among nurse interns. This finding is consistent with who decided that, there were highly significant differences throughout program phases in improving nurses’ knowledge regarding total occupational health hazards knowledge.

In addition, as observed, the nurse interns gloving practice technique was improved markedly throughout program phases, with highly statistically significant differences between total practice regarding gloving throughout pre and post program phases. This finding may be due to the training program encourage the nurse interns to follow correct gloving practices and set a trend in their practical life. In the same line found that, in their study, wearing hand gloves for routine clinical system was rehearsed by almost all participants.
Moreover, as observed at post training program phases the total personal protective equipment practice (PPE) in health care setting among nurse interns was statistically significant improved markedly throughout pre and post program phases. This result may be due to educational programs for nurse intern help them in improving their knowledge and practice personal protective equipment. The same trend was observed by mentioned that, regarding application of the universal precaution revealed a significant increase in applying hand-washing, wearing gloves, and wearing face mask after the program compared with the application of the universal precautions before the program.

Moreover, there was slightly declined occur in total practice regarding personal protective equipment practice (PPE) in health care setting among nurse interns at follow up phase. This finding may be due to lack of closed supervision related to personal protective equipment practice. It may also be attributed to nursing staff shortage, work overload, and the time constrains of having to deal with a large number of patients within a limited time. Similarly, who found that, guideline recommendations for routine preventive care are not always followed, such as hand washing, wearing mask, goggles, sterile gown, and gloves 6 months after implementation.

Moreover, as observed at post program phase the total personal hygiene satisfactory practice level among nurse interns was statistically significant improved. This result may be due to instructive meetings for the staff to affect emphatically on the consistence to personal hygiene. Also, may be due to an effective infection control depends on nurse interns’ ability to advise and encourage them to keep a satisfactory practice to hygiene practice. In the same line with the study mentioned that, people that know about infection transmission are more spurred to follow cleanliness schedules and to keep up aseptic conditions than individuals that haven’t.

While, there was slightly declined of total personal hygiene satisfactory practice level in follow up phase. This result may be due to lack of supervision affects compliance to personal hygiene negatively. In the same context mentioned that, when there are gifted and committed nurses in cleanliness practice this influences the consistence to cleanliness schedules among the other staff at the ward in a positive manner.

Moreover, nurse interns’ total practice regarding instruments/equipment processing (Cleaning) increased at post program stage. Also, there were a highly significant difference in whole items of instruments/equipment processing (Cleaning) and total practice regarding cleaning in pre and post program phases. This is emphasized the necessity of updated in-service education and training about infection control measures and principles to improve the level of nurse interns’ knowledge and practices. A similar trend was observed who indicated that, large percentage of nurses had good level of practice regarding appropriate decontamination of equipment.

While, nurse interns’ total practice regarding instruments/equipment processing (Cleaning) was slightly declined at follow up phase. This finding may be due to lack of equipment and resources, lack of time, and work load were the factors impeded the nurse interns from proper instruments/equipment processing (Cleaning). This study finding is congruent with indicated that, lack of equipment and resources and lack of time were the factors impeded the nurses from proper infection control practice.

As observed, nurse interns’ practice regarding use sharp container was statistically significant improved at post program phase. This finding could be due to trainings was be useful on nurses interns’ practice and update their knowledge regarding use sharp container. Similarly, was reported in his study that, behaviors of the nurses working in the clinics changed positively as far as taking measures against sharp and needle stick wounds after the training, which is an expected.

While, nurse interns’ total practice regarding use sharp container was slightly declined at follow up phase. This finding may be due to understaffing, nurse interns’ attention deficit, and desire to finish all the work quickly. concluded that, understaffing, working conditions, absence of preparing and experience, consideration shortage, and want to complete all the work rapidly are accounted for as the elements to not used sharp container probably, and increasing the incidence of sharp and needle stick injuries.

As observed, nurse interns’ practice regarding body mechanics (when lifting) was significant improved at post program phase. This might be identified with the participation of the interventional preparing program and the accentuation on psychomotor abilities application
both during and after the program practice was effective and helpful, confirmed to the previous result\textsuperscript{30}.

While, nurse interns’ total practice regarding body mechanics (when lifting) was slightly declined at follow up phase. This finding may be due to nonattendance of nonstop supervision and direction, increment in number of patients, lack of the nurses and increment work tasks, which adversely sway their performance practice regarding body mechanics and their quality of work life. In contrary,\textsuperscript{31} concluded that, nurses’ body mechanics and ergonomics practices had highly significant satisfactory level at both following and following 3 months from program execution.

As observed, nurse interns’ practice regarding safe waste disposal was statistically significant improvement at post program phase. This finding may be due to active participation in training programs positively affected nurse interns’ practice regarding safe waste disposal. The same trend was observed by\textsuperscript{32,14}.

While, nurse interns’ total practice regarding safe waste disposal was slightly declined at follow up phase. This finding may be because of lack of clear rules and written policies, lack of personal protection tools regarding safe waste disposal. In agreements\textsuperscript{33} found that absence of all mentioned previous factors, in addition inappropriate training programs are the most factors that affecting hospital waste management system.

In addition, the present study found that, minority of nurse interns had satisfactory practice level regarding occupational health hazards at preprogram phase. This finding may be due to absence of effective execution framework, absence of data and precise records of occupational diseases and accidents, and absence basic professional training in occupational health and safety. The present study result is congruence with a study conducted at Nigeria by\textsuperscript{34} they revealed that, almost half of nurses had bad practices regarding safety practices about occupational health hazards.

The present study result showed that, nurse interns’ total practice regarding occupational health hazards throughout program phases was markedly increased. Also, there were highly statistical improvement in overall nurse interns’ practice during post program phases and slightly decline in follow up phase as compared with preprogram phase. This finding may be because of nurse interns’ participating in the education program made a significant difference on the level of knowledge and changing the practice regarding occupational health hazards.

This is congruent with the finding by\textsuperscript{22} who found a significant difference pre/post implementing nursing guidelines about hazards prevention and nurse’s practice about safety. Also,\textsuperscript{35} reported that, significant improvement in nurses self-reported compliance with the standard precautions, as well as the observed compliance scores with standard precautions after the educational intervention.

The present study result revealed that, score of nurse interns’ attitude towards protection from hazards was generally low at preprogram, while nurse interns satisfactory attitude at post program improved markedly and there was slightly declined at follow up phase, but it reminded higher than preprogram. Also, highly significant difference in total attitude towards protection from hazards throughout the program phases was observed.

This could be due to the training program advance nurse interns’ knowledge and practice skills and as a result enhance nurse interns satisfactory attitude level, also may be due to dread of occupational infections and ailments which could be terminal and life dangerous in certain instances. In agreements\textsuperscript{4} showed that, majority of nurses had positive attitude regarding safety precaution and prevention of occupational hazards. Similarly,\textsuperscript{6} mentioned that, nurses had positive attitude regarding occupational health hazards.

Moreover, current study finding reported that there was a positive highly significance correlations among total knowledge score and total practice score related to occupational health hazards among nurse interns throughout program phases. This study finding may be due to implementation of educational and awareness program to ensure occupational safety for nurse interns established safe practices to create a safe environment, identified, and minimize potential hazards. The same trend was observed by\textsuperscript{36}. Additionally the consequences of the current study demonstrated that there is positive significant correlation among change of knowledge and change of training, as knowledge improved, practice improved.

In the current investigation, there was positive impact of knowledge regarding occupational health hazards in improving nurse interns total practice score. This finding supported the hypotheses of the study,
which was there is a change in nurse interns’ knowledge and practice regarding occupational health hazards after implementing the program. These results are considered satisfactory and demonstrated the achievement of the expected results in the study. In addition proving that, practical interventions were viable, without high costs and applicable to the reality of institutions can be effective.

This finding is supported by\textsuperscript{37} found a strong positive correlation between the implementation of educational intervention and improvement of knowledge and change in preventive practices about the occupational risks by nursing professionals in the experimental group. Also,\textsuperscript{22} the study demonstrated the effect of educational intervention in improving nurses’ knowledge and practice, as it was reported that, significant difference among knowledge and practice pre/post implementing nursing guidelines about hazards prevention was observed.

Also there was highly statistically significance correlations between total attitude score and total knowledge score regarding occupational health hazards among nurse interns through post and follow up program phases. This finding may be due to implement of training programs regarding occupational hazards, promote high knowledge, and this translated to positive attitude and subsequently good behavior. In this regard,\textsuperscript{23} compared the distribution of respondents by performance on composite knowledge, attitude and practice, participant had positive attitude.

**Conclusion**

According to the study findings, it can be concluded that, there were highly significant differences of total occupational health hazards knowledge among nurse interns throughout program phases. Nurse interns’ total practice regarding occupational health hazards throughout program phases was markedly increased. There was a highly significant difference in total attitude towards protection from hazards throughout the program phases. The training program implementation led to significant improvements in nurse interns’ knowledge, practice, and attitude regarding occupational health hazards.

**Recommendations:** According to the main study findings, we can recommend.

**Education:** Providing training program for nurse interns regarding occupational hazards and especially on protective measures. Dissemination and development of policies and rules of safety practices among nurse interns, and psychological counseling and therapy should be easily accessible and available for troubled nurse interns.

**Practice:** Encourage and supervise the use of personal protective equipment by the nurse interns, perform regularly routine check-up of nurse interns to ensure occupational health, provide regular vaccination for all nurse interns to minimize liability for acquiring work related infection (to prevent biological hazards), supervise nurse interns’ safety practices and it’s need to be ameliorated through training as well as close supervision of their application, and observe and supervise nurse interns’ practices to ensure their compliance with safety regulations.

**Research:** Further studies are also recommended to investigate the relationship among nurses’ safety practices and occupational hazards training program analyze the after effect of work related injuries and illnesses on the nurse, evaluate the effect of work related injuries on the organization.

**Conflict of Interest:** Nil

**Source of Funding:** Self

**Ethical Clearance:** Obtained from a scientific research ethics committee.

Abstract

Introduction: Euthanasia which is done by doctors to their patients is considered as a part of the act of human rights violations, this matter would raise a dilemma for those who are pursuing a medical profession. Therefore, it is necessary to conduct research concerning legal liability related to euthanasia from the perspective of a medical code of ethics in Indonesia.

Purpose: This research aims to acknowledge and analyze the legal liability related to euthanasia from the perspective of a medical code of ethics in Indonesia.

Research Methodology: This research uses qualitative method with a normative juridical approach. The data collection technique is done through literature study.

Conclusion: Doctors must not neglect the obligation to always protect human life, as regulated in the medical code of ethics in Indonesia so that the act of euthanasia is contrary to professional and legal ethics and if it continues to be carried out, it can create criminal liability as regulated in the Criminal Code.

Keywords: Law; Euthanasia; Medical Code of Ethics.

Introduction

In Indonesia, the tools of regulating human rights have been regulated through the constitution and various laws and regulations under it as an implementing regulation. The 1945 Constitution of the Republic of Indonesia, both before and after the amendment, explicitly states that every citizen has freedom, not only freedom of association in expressing opinions in public, but also the freedom to live and embrace a religion, which is not only aimed to individualist protection but also collective. Likewise, access to freedom in the political and legal fields has been limitedly regulated through the provisions of Article 27 and Article 28 of the 1945 Constitution of the Republic of Indonesia.¹

Regarding the freedom to determine self-fortune related to euthanasia, in various international regulations, it is emphasized through various international conventions which essentially do not respond to the implementation of medical actions to end one’s life based on their request or their family request through the medical actions performed by a doctor.² In the Universal Declaration of Human Rights in the provisions of Article 3, it is stated that “Everyone has the right to life, liberty and the security of person”. This provision indicates that the right to instruct ending someone’s life is part of a violation of human rights.³

Legal liability concerning the implementation of the profession in medical procedures, including medical euthanasia, according to Anny Isfandyarie, is distinguished between the responsibility for professional provisions or medical code of ethics and the responsibility for legal provisions contained in the law.⁴

Based on the provisions of Article 344 of the Criminal Code, euthanasia is categorized as a crime.
against life. Euthanasia is legally a murder at the request of the victim, that is, the patient’s request to the doctor. Articles that can be applied to euthanasia are articles regarding murder, namely Articles 338, 340, 344, and 345 of the Criminal Code.

The experts of religion, morals, medicine, and law have not met the same agreement in facing euthanasia, especially at the person’s request of death to end their suffering. This situation raises a dilemma for the doctors, whether they have the legal rights to end a patient’s life based on their request or their family’s request, with a reason to end the patient’s long-term suffering, without the doctor faces legal consequences, which in this case, is a criminal threat as regulated in the Criminal Code. Of course, in this case, the doctor faced a conflict in their mind. Therefore, it is important to research legal liability related to euthanasia in the medical code of ethics in Indonesia.

From the previous background, the purpose of this study is to acknowledge and analyze legal liability related to euthanasia from the perspective of a medical code of ethics in Indonesia.

**Research Methodology**

This study uses a qualitative research method with a normative juridical approach. The normative juridical research method is research on the principles of positive law written in statutory regulations and aims to conceptualize law as a written method. SoerjonoSoekanto argues that only legal research carried out by examining library materials or secondary data alone can be called normative legal research. Data collection is carried out by a literature study to collect legal materials, such as laws, law books, and legal research journals related to the topic of this research.

**Discussion**

Euthanasia Study Group from Koninklijke Nederlandsche Maatschappij tot bevordering der Geneeskunst/KNMG (Dutch Medical Association) gives limitation for euthanasia, as follows: “Euthanasia deliberately does not do anything to prolong a patient’s life or deliberately does something to shorten or end a patient’s life, and all is done specifically for the patient’s benefit.” ImronHalimy defines euthanasia as an act of stopping someone’s life who is suffering from their illness, whether done sooner or later by a doctor or health team who treats them either at the request of the patient or the patient’s family to reduce the burden of suffering. According to forensic medicine, euthanasia is a form of murder, where a person is killed to end someone’s suffering, which is often found in cases of incurable cancer and the patient’s closest people decide.

Based on some of the definitions above, what is meant by euthanasia, in general, is taking action intending to shorten one’s life or end one’s life due to long-term suffering from an illness that cannot be cured by a doctor at the request concerned in these matters.

In general, euthanasia can be divided into two, which are as follows:

1. **Active Euthanasia (mercy killing):** Namely where a doctor or other medical personnel deliberately takes an action to shorten the patient’s life or end the patient’s life. It is considered as active euthanasia because the doctor took an action. Active euthanasia can occur because of request or not upon request, the meaning is as follows:

   a. **Upon request (voluntary euthanasia):** Active euthanasia on request is also called voluntary euthanasia because a patient voluntarily asks to end their life.

   b. **Without a request (involuntary euthanasia):** Active euthanasia without request is also called forced euthanasia because the action is not done at the request of the patient.

2. **Passive Euthanasia:** Namely where doctors or other medical personnel deliberately stop providing medical assistance to patients that can support their life. So, it is not by taking any action that will directly result in the end of the patient’s life.

From all the analyzes above, juridically, Euthanasia, especially active euthanasia is indeed a criminal act, but not everyone who commits a criminal act should be punished. Barder Johan Nasution stated that the existence of a medical code of ethics aims to prioritize the interests and safety of patients, ensuring that the medical profession is always carried out with noble intentions and in the right way.

Thus, society does not need to worry too much that euthanasia will very easily be carried out by a doctor, although of course doctors are also human beings who cannot possibly be free from mistakes and wrong considerations. Control is needed in addition to the right legal in terms of euthanasia.
Apart from the Indonesian Medical Code of Ethics and Article 344 of the Criminal Code, Indonesia has a legal instrument that regulates euthanasia. This regulation only formulates actions seen from the point of view of protecting the patient without threatening a clear criminal rule. This regulation is Law Number 36 of 2009 concerning Health.

The formulation of articles that regulate euthanasia is contained in Article 56 of Law Number 36 of 2009 which regulates patient protection. The article states: Every person has the right to accept or reject part or all of the aid action that will be given to him or her after receiving and understanding the complete information regarding the action. The right to accept or reject as referred to in paragraph (1) does not apply to patients of a disease whose disease can quickly spread to the wider community; the condition of an unconscious person; or severe mental disorders. Provisions regarding the right to accept or reject as referred to in paragraph (1) shall be regulated following the provisions of statutory regulations.

From the formulation of Article 56 it can be understood that although the criminal act of passive euthanasia has not been regulated in Indonesian written law, the Health Law has explained that the right to receive or refuse treatment is invalid when the patient is unconscious. So that the act of passive euthanasia cannot be justified and can be threatened with a criminal penalty because the decision to accept or refuse treatment is entirely in the hands of the patient’s family. Unlike the omission or pseudo euthanasia which cannot be punished if the patient is conscious and asks the doctor to stop all treatment for them.

The weakness from the formula in Article 344 of the Criminal Code is in the process of gaining the evidences, someone’s request made intentionally and sincerely will be very difficult to be proved because the person who requested his life to be taken is already dead and cannot be asked for their testimony or witness.

Therefore, the sincere statement should not only be done orally, but also should be done in written form and signed by several witnesses, because, in the verification, the element of the sincere statement should be able to be proved by the witnesses or other evidences, as stated in Article 184 of the Code of Criminal Procedure, that is the testimony of a witness, the testimony of an expert, a document, an indication, and the testimony of the accused. However, the existence of proof of request cannot make the action acceptable. The action can still be reached by Article 344 of the Criminal Code.

Another weakness from the formulation of Euthanasia action in Indonesia is there is no explanation that the perpetrator of the criminal action is a doctor and the victim is the patient because the element from Article 344 of the Criminal Code is only stated by “Whoever”. Therefore, the interpretation of the Article will be wider because the element is not stated clearly.

Generally, there are two kinds of ethics: general ethics and professional ethics. For the general ethics, someone who wants their family member to be quickly dead is considered unacceptable, but if the patient is having a very serious illness, for instance, having a severe illness for a long time where the condition of the body is emaciated, only bones wrapped in skin and the cancer wounds continue to expand and emit a very strong odor over a considerable distance, the people around will feel sorry for the patient and will not blame the patient’s family too much if the family “would prefer it if the patient died soon”.

The other kind of ethics is professional ethics. In this case, a doctor’s professional ethics, or a medical worker’s are pledged to the oath stated when they are initiated to be a doctor. The current doctor’s oath pronunciation is following the Decree of the Minister of Health No. 434/MENKES(SK/X/1983 dated October 28, 1983, which essentially contains a code of ethics for the medical profession and this serves as a guideline for doctor’s behavior in carrying out their profession.

The Indonesian Medical Code of Ethics regarding the obligations of doctors to sufferers in Article 11 states that every doctor must always remember his obligation to protect human life. From this ethical point of view, Euthanasia is against Indonesian medical ethics. This statement is true it is not only contradicting the medical ethics in Indonesia but also to the Hippocratic Oath which is the basis of the oath of doctors around the world. In medical ethics that is rooted in the Hippocratic Oath, it is stated that doctors will respect every human life from conception. This means that after a meeting between the egg or ovum and the sperm, the presence of the fertilized egg must be respected.

Regarding life, the doctor’s oath states that a doctor will respect life from the moment of conception. Thus, as long as there is life, that life must be respected. Even
if life is not of a healthy quality, which in this case is very painful and makes people around them feel pity for them, it still has to be respected. However, the way to respect it depends on the views held by the people around or the doctor. Some read the Yaasin, some asked what holds them so that it should be removed immediately, some gave incantations or medicines, and of course, some suggested or by the patient asked for Euthanasia. One of the most common and most confusing moral dilemmas in health care arises when moral principles concerning whether health care workers should improve the patient’s condition or respect the patient’s autonomy clashes. Doctors and other healthcare professionals are obliged to do what is beneficial to the patients and not only preventing harm to them.

The reason Euthanasia until now is considered terrible, inhuman, violating the right to life, and so on, is because it is seen from an ethical perspective, both general ethics and professional ethics. Understanding medical ethics is a demand that is seen as increasingly necessary, serious handling of medical ethics issues is quite urgent. Medical ethics discusses doctors’ ethics in carrying out their profession. Medical ethics is very noteworthy in this profession. Starting from when they were students, prospective doctors have been given bioethics course material, even not only ethics towards fellow humans or patients, but also ethics in dealing with or manipulating experimental animals and corpses used for lessons. Ethics towards fellow humans is not only ethics towards patients but also teaches how to behave towards peers, teachers, and others.

Many people easily give moral judgments on others based on that person’s outward behavior. To judge so is self-guilty. We never know how the intent and conviction of the person when they are doing something the good and the bad depends on whether he acts accordingly or not according to his consciences. The same thing also applies to a doctor’s actions, even though they have been bound by the doctor’s oath and their behavior can be seen, what they perceive cannot be seen from the outside.

Guwandi in his book called it a trilogy of medical secrets, which consists of informed consent, medical records, and medical secrecy. The regulation of medical secret matters is stated in the context of Medical Ethics and Law. Ethics and medical secrets are stated in the Hippocratic Oath which is always spoken by doctors who just graduated from their education. The original Hippocratic Oath was composed by a small group of Pythagorean medical from the island of Coss in the late fourth century BC.

The Hippocratic Oath provides instructions regarding medical ethics, namely: that it fulfills the need for an instruction and coordinated registration from a doctor. The public should be protected wherever possible from con artists who are not doctors. The doctor takes action for the benefit of the patients. Doctors must do everything in their power to provide treatment. They must not do something that they know will harm their patients. Euthanasia and abortion are prohibited. Lithotomy guidelines may also forbid performing mutilating operations such as castration. There is also a limitation that only those skilled in the art are allowed to do so. An outline of the nature of the doctor-patient relationship is provided. For example, to take advantage of this relationship is not justified. Finally, the Hippocratic Oath confirms the doctrine of Medical Secrets.

Hippocrates of Greece, Galenus, and Rome are some of the pioneers of ancient medicine who had laid the foundation for the establishment of a noble medical tradition. Together with all medical figures and organizations in international forums, they then intend to base these traditions and medical disciplines on a professional ethic. This ethic, all the time prioritizes patients who seek treatment and for the safety and interests of the sufferers. This ethic itself contains principles, namely: beneficence, non-maleficence, autonomy, and justice.

With this principle, the doctor who treats his patient must consider that his action must be useful for his patient or the principle of beneficence, if it is not useful, at least it must not harm the patient or the principle of non-maleficence which has the right of autonomy over his own body. The last, a doctor must be fair or aligned with the principle of justice.

The code of ethics stated by Mustika, as quoted by SuryaniSoepardan, is the norm that must be paid attention to by every profession in carrying out their professional duties and their lives in society. These norms contain instructions for members of the profession on how they should carry out their profession and their prohibitions, namely provisions regarding what members of the profession can and cannot do, not only in carrying out their professional duties but also regarding general behavior in daily interactions.
According to SigitLesmonojati, today’s demands call for medical practice to prioritize ethical principles. The modern ethical principles are such that is taken from Catherine Tay Swee Kian: the principle of Autonomy, the principle of Generosity, the principle of Not Hurting, the principle of Justice, the principle of Loyalty, and the principle of Honesty.18

The Indonesian Medical Code of Ethics states that a doctor has general obligations, such as19:

1. Every doctor must uphold, live, and practice the doctor’s oath.
2. Must always strive to carry out his profession according to the highest professional standards.
3. Must not be influenced by something that results in the loss of freedom and professional independence.
4. Avoid having vanity.
5. Any action or advice that may be psychologically or physically debilitating is only given for the benefit and benefit of the patient, after obtaining consent.
7. Only provide certificates and opinions that have been self-checked for the truth.
8. Provide competent medical care, technical and moral freedom, with compassion and respect for human dignity.
9. Honest in dealing with patients and colleagues, remind colleagues if there are deficiencies, fraud, and embezzlement in handling patients.
10. Respect the rights of patients, the rights of colleagues, the rights of other health workers, and must keep the patient’s trust.
11. Always remember the obligation to protect human life.
12. Paying attention to the interests of the public and paying attention to all aspects of comprehensive health services, whether physical, psychosocial and trying to be true educators and community servants.
13. In cooperation with health officials and others must respect each other.

Obligations to Patients:
1. Have a sincere attitude, use all knowledge and skills for the benefit of the patient. If unable, with the patient’s consent, refer to others who are capable.
2. Allow the patient to connect with his family and counselors in terms of religious acts and/or other problems.
3. Must keep everything they know about a patient to themselves, even after the patient has died.
4. Obliged to carry out emergency aid as a humanitarian task, unless there is someone else who is certainly willing and able.

Obligations to peers:
1. Treat peers as they would like to be treated.
2. Must not take over the patient from a peer, except with consent or based on ethical procedures.

Towards oneself:
1. Must keep being healthy, so that one can work properly.
2. Keep informed of the developments in medical/health science and technology.

Therefore, it is clear that the Indonesian Medical Code of Ethics prohibits active and passive euthanasia. In other words, doctors cannot act as a God (don’t play God). Medical ethics must be pro-life, not pro-death. A doctor is a person who saves or enhances life, not a person who determines life itself (lifesavers, not life judgers). There is no need for further explanation on how the matter of Euthanasia for the parties involved is problematic that cannot simply be solved and overcome. The implementation of Euthanasia action to terminal patients is simply an act that flows from a deep source of humanity and out of respect for the wants of others. The doctor’s emotional involvement is the only reason why he is willing to offer real help to a patient who is dying.

Thus ethically, it is not allowed for doctors to kill a dying patient. If a doctor is proven to practice Euthanasia of the patient because of pity for seeing his pain, then he has violated the Decree of the Indonesian Medical Council number 17/KKI/KEP/VIII/2006 concerning Guidelines for the Enforcement of Medical Discipline, which states that ‘every doctor is not allowed to commit an act that is aimed at ending human life, because it is not only contradicting to the Medical Oath and/or medical ethics and or the objectives of the medical profession but also it is against the rules of criminal law.’

Because ethical norms do not cover strict penalties for doctors who continue to engage in Euthanasia to their patients, they must be returned to what is regulated
by the Criminal Code regarding this matter. Article 344 of the Criminal Code states that “Whoever takes the life of another person at the request of his person, which he calls real and sincere, is sentenced to a maximum imprisonment of 12 years”. Meanwhile, Article 345 of the Criminal Code states that ‘Whoever induces another person to commit suicide, helps him in that act, or provides the means for him to do so is punishable by a maximum imprisonment of 4 years if that person commits suicide’.

Conclusion

The legal liability for euthanasia actions in the perspective of the medical code of ethics in Indonesia is that doctors must respect every human life from the moment of conception. In this case, it means that no matter how serious a patient’s illness is, every doctor must still protect and defend the patient’s life. In such circumstances, this patient may have been dying for months. However, in this relationship, the doctor must not escape from the obligation to always protect human life, as stated in his oath. Therefore, Euthanasia has no medical indication to achieve a concrete goal, except only to stop suffering from pain. Thus Euthanasia is contrary to professional and legal ethics and if it continues to be carried out, it can create criminal liability as regulated in the Criminal Code.

Abstract

Biosynthesis (green synthesis) of metal nanoparticles such as Silver Nanoparticles (AgNPs) has been one of the safest, most cost-effective and environmentally sustainable method in recent years. In this research, AgNPs were synthesized using Withania Somnifera (Ashwagandha roots). For the characterization of synthesized AgNPs different techniques were used, such as X-ray diffraction (XRD), Ultraviolet Visible (UV-VIS) spectroscopy, Fourier transform Infra-Red (FTIR) spectroscopy, scanning electron microscopy (SEM), Energy Dispersive X-ray (EDX) analysis, and atomic force microscope (AFM). X-ray diffraction analysis showed that the particles were crystalline, while in nature. UV-Visible absorption spectra of the reaction medium containing silver nanoparticles showed maximum in the visible region at 430 nm. FTIR analysis confirmed the reduction of Ag⁺ ions to Ag⁰ ions in synthesized silver nanoparticles. The SEM analysis the size 5 nm shape and spherical in structure. The antibacterial activity of silver nanoparticles was performed on the growth of both gram-positive and gram-negative bacteria. A bactericidal was observed through the highest zone of inhibition against the bacterial strains, with higher activity for Meropenem. The root extract of Ashwagandha quickly reduces Ag⁺ to Ag⁰ and enhances the synthesis of silver nanoparticles with highly significant antibacterial activity.

Keywords: Green Synthesis, Silver Nanoparticles, Withania Somnifera, Characterisation, Antibacterial activity.

Introduction

Nanotechnology was considered one of the most emerging fields of science and it deals with the synthesis of nanoparticles and nanomaterials, which have dimensions of 1 to 100 nanometers (¹). The most important and distinct property of nanoparticles is that they have a larger surface to volume ratio (²). The properties of nanoparticles, such as high diffusion, durability and versatile chemical and biological activities have gained importance in technological applications (³). A metal nanoparticle synthesis study has increased in number due to possible applications in nanotechnology (⁴). The nanoparticles can be synthesized by physical-chemical and biological method, but the green synthesis of silver nanoparticles has several advantages over physical and chemical method as it is cheaper, can be achieved with a single process and eco-friendly (⁵-¹⁰). Silver Nanoparticles (AgNPs) have attracted growing interest due to their unusual physical, chemical and biological properties, including high electrical and thermal conductivity, Surface-Enhanced Raman Scattering, chemical stability, catalytic activity, and nonlinear optical behavior. AgNPs have wide applications in pharmaceuticals, cosmetics, medical devices, footwear, and textile industries. It has been also AgNPs were helpful in the purification of drinking water/effluent water by efficient removal of the water-born pathogen (¹¹). The synthesis of AgNPs is speedy, cost-saving, eco-friendly and single step synthesis procedure (¹²).
The roots of *Withania Somnifera* (L.) Dunal (Family-Solanaceae)-a vital Rasayana herb is traditionally known as ‘Ashwagandha’ or winter cherry. In Ayurveda, it is called ‘Indian ginseng’. Ashwagandha is widely used in most Indian herbal drugs and nutraceuticals for the treatment of various diseases including nervous, infectious diseases, diabetes, cancer, ulcer, immunological disorders, stress, arthritis, etc[13].

*Withania Somnifera* (Ashwagandha) as Medicinal plants has therapeutic potential due to the presence of natural antioxidants functioning as reducing agents, free radical scavengers and quenchers of singlet oxygen. Majority of different medicinal plant and their antioxidant activity are due to bioactive compounds viz. flavones, isoflavones, flavonoids, anthocyanins, coumarins, lignans, catechins and isocatechins[14].

The aim of this work, Ashwagandha root extract was used for the production of AgNPs by green method. The different properties of biosynthesized AgNPs have been investigated by XRD, SEM, UV-visible, and FTIR to evaluate their shape, distribution of particle size distribution, and functional groups. The biosynthesized formulation of AgNPs was obtained to investigate the antibacterial against Gram-positive and Gram-negative bacterial strains in the inhibition zone compared to the standard antibacterial drug Meropenem.

**Materials and Method**

The plant extract used in the study was obtained from Ashwagandha root extract. In the synthesis method, Silver Nitrate (AgNO₃, purity 99.8%) was used.

**Preparations of plant extract:** The extract was prepared by the freshly Ashwagandha root extract. The root powder was weighed about (5g) and mixing with distilled water (100 ml) on a magnetic stirrer with a hot plate then the solution was boiling at 50°C for 15 minutes. The plant extract was filtered through filter paper after cooling, and the filtered extract was stored for further experiments at a temperature of 4 °C.

**Green synthesis of silver nanoparticles:** The Silver nitrate solution was freshly prepared about (0.09 g) with distilled water (100 ml) under dark conditions. Prepared root extracts were used to reduce Ag⁺ to Ag⁰ by combining it with silver nitrate solution (AgNO₃) at a ratio of 1 to 1 mol. These plant extracts and AgNO₃ mixtures have been kept under 27 °C with continuous stirring. Reduction of silver ions in solution was monitored by a visible change in the color. This indicates the initial confirmation that Ashwagandha was formed as silver nanoparticles (As-Ag Nanoparticles). Figure 1 shows the steps to prepare silver nanoparticles using Ashwagandha root extract.
The Antibacterial activity for AgNPs by well diffusion method: Antibacterial of green synthesis for AgNPs was evaluated using a well-diffusion method against bacterial strains of gram-negative (Escherichia coli) and gram-positive (Staphylococcus aureus). Microorganisms were grown at 37°C in the medium of Uti chromagar (UCA) and Mannitol salt agar (MSA). Holes of 6 mm in diameter were filled with 60 μl impregnated with equal concentrations of Ashwagandha plant extract, AgNO₃ solution, synthesized AgNPs and Meropenem, and kept at 37°C. The diameter of the growth inhibition zones was measured in millimeters (mm) after the 24-hour incubation time.

Characterization of Silver Nanoparticles: The crystal structures of AgNPs were analyzed using SHIMADZU LabX X-ray diffractometer with CuKα1 radiation at λ =1.5406 Å. While the absorbance spectra of the samples were recorded in the wavelength (190-1100 nm) using a UV-VIS (SHIMADZU1800) spectrophotometer. FTIR analysis was performed in the 400 cm⁻¹ - 4000cm⁻¹ range with (SHIMADZU 8400S) spectrophotometer device to determine which functional groups were involved in the reduction of plant extracts. Scanning electron microscopy (SEM) and Energy-dispersive X-ray analysis (EDX) was used to verify the presence of AgNPs in the elemental composition. Atomic force microscopy (AFM) used to study the surface morphology of the samples was the AFM model AA 3000 scanning probe microscope from Angstrom Advanced Inc., USA).

Results and Discussion

X-ray diffraction analysis (XRD): The XRD technique was used to confirm the crystalline nature and particle size of silver nanoparticles. The XRD pattern of green synthesized silver nanoparticles (AgNPs) that extracted from mixing AgNO₃ with Ashwagandha was analyzed as in figure (2). The sharp diffraction peaks indicate the good crystallinity of the prepared AgNPs. The intense and narrow peaks (111), (200), (220), (311), (222), (400), (331), (420) and (422) were assigned at 2θ = 38.11°, 44.27°, 64.42°, 77.47°, 81.53°, 97.88°, 110.49°, 114.92° and 134.88°, respectively. The sample indicated a face-centered cubic structure (FCC) of silver structure with the lattice constants (a = b = c = 4.086 Å). Figure (2) shows that silver nanoparticles (111) diffraction peak is the strongest ones which indicates that formed silver particles have a preferential crystallographic (111) orientation. This is due to the organic compounds which are present in the extract and responsible for silver ions reduction and stabilization of resultant nanoparticles. This observation confirms the silver nanoparticles synthesized from Ashwagandha roots were crystalline in nature. The average crystallite size (D) for synthesized silver particles was calculated according to the Debye Scherrer equation(15) and was equal to 21 nm.

![Figure (2): XRD pattern of synthesized AgNPs from Ashwagandha roots.](image-url)
**UV-Visible Spectrophotometer Analysis:** The formation of silver nanoparticles was easily monitored with color change and it is due to excitation of surface plasmon vibration of metal nanoparticles. When colorless AgNO$_3$ solution mixed with Ashwagandha roots at 0 hour time watery pale yellow color was shown. The mixed solution color at time 4 hours, 24 hours, 28 hours, 48 hours, and 72 hours, was gradually from light yellow to dark reddish-brown. The color change indicates the synthesis of AgNPs by UV–Visible spectrum analysis as shown in (Figure 3). In our result, maximum absorption was observed at 430 nm (Figure 3), the optical properties of silver nanoparticles change which depends upon the collective oscillation of free electron when particles aggregate and the conduction electrons near each particle surface become delocalized and are shared amongst neighboring particles. The resulted observe the spectrum shifts the surface plasmon resonance (SPR) to lower energies. i.e. The absorption peaks move to red shift of plasmon resonance (increases the wavelength at which plasmon resonance occurs) with wide and lower intensity spectrum towards blue shift because of the accumulation effect. The increase of color intensity and (SPR) band sharpness clearly indicates the reduction of Ag$^+$ into Ag$^0$.

![Figure (3): UV-visible spectra of Silver Nanoparticales with Ashwagandha at different time.](image)

**Fourier Transform Infrared Spectroscopy (FTIR):** FTIR measurement was used to identify the possible biomolecules responsible for capping and reducing agents for the stabilization of Silver nanoparticles synthesized from Ashwagandha root extract. The FTIR spectrum of the silver nanoparticle is shown in Figure (4). The observed main peak at 495 cm$^{-1}$ corresponds to metal confirms the formation of (Ag). The peak value at 3413 cm$^{-1}$ may arise due to the O-H stretching vibrations, indicating the presence of hydroxyl groups on the root extract surface of the maize shifted due to the interaction between the Ashwagandha root extract and the silver metal. The medium peaks of 2968 cm$^{-1}$ and 2889 cm$^{-1}$ indicate the C–H and C≡H of alkanes and alkynes, respectively. The peak at 1635 cm$^{-1}$ is a signal of N–H bond vibrations from amide groups of the proteins.
Field Emission Scanning Electron Microscope (FESEM): AgNPs was analyzed by FESEM shows in the high density AgNPs image. It was shown that AgNPs synthesized by a green method using Ashwagandha root extract. The FESEM image of AgNPs indicates the interactions between the various phytochemical molecules bound to the AgNPs. Images of biosynthesized nanoparticles in SEM show surface morphology of AgNPs were clearly indicated that AgNPs were roughly spherical in shape and uniformly distributed and agglomeration was found in AgNPs at different magnification ranges at 500 nm - 1 μm as shown in Figure (5).

Antibacterial activity of Silver Nanoparticles (AgNPs): When the inhibition zone of silver nanoparticles against both bacterial groups was greater than 6 mm is considered active. Bacterial inhibition zone measurement by well diffusion method. However, the antibacterial activity of green synthesized AgNPs...
has shown positive results against both gram-negative. Initially, the antibacterial activities of AgNPs were examined along with plant extract of Ashwagandha, AgNO$_3$ solution, AgNPs and Meropenem against bacterial cultures through well diffusion method. The results showed that AgNPs were highly effective than all other solutions for gram-negative (E.coli) bacteria while for gram-positive (S.aureus) it was more effective than Ashwagandha, AgNO$_3$, and Meropenem (Figure 6). In S. aureus bacterial cultures, AgNPs a greater maximum inhibition zone of 8 mm. In gram-negative bacteria, AgNPs highest maximum inhibition zone (17 mm for E. coli). Thus obtained results clearly indicate that prepared AgNPs were more beneficial against gram-negative bacterial growth than the gram-negative (E.coli) and gram-positive (S.aureus) bacterial pathogenic strains.

Conclusion

The bio-reduction of Ag$^+$ ions by the root extracts of Ashwagandha has been demonstrated. Probably the biomolecules present in the extract of the roots is responsible for the reduction and stabilization of silver nanoparticles. The synthesized silver nanoparticles were characterized using XRD and confirmed the FCC phase. The obtained silver nanoparticles showed significant antibacterial. We found that the green synthesis of silver nanoparticles from Ashwagandha root extract might be

![Figure (6): Antibacterial activity of AgNPs against pathogenic bacteria By well diffusion method (Ashwagandha, AgNO$_3$ solution, AgNPs, Meropenem).](image-url)
used as antibiotics in the future due to non-toxic, eco-friendly, cost-effective, and highly effective against the bacteria.

Abstract

Introduction: Diabetic foot syndrome (DFS), a complex disorder, affects diabetics. It is the unique anatomy of the foot that leads to potentially serious infection. Three cardinal aetiological factors that predispose to diabetic foot ulcers are ischaemia, neuropathy and infection. DFUs are challenging to cure as often the diagnosis is delayed; there is presence of ischaemia, infection with multidrug-resistant organism and extension of infection to the bones. This study was conducted with the aim to determine the clinical and microbiological profile of diabetic foot patients and to assess their outcome.

Methodology: Sixty five male and female patients of 18 and above age that presented with diabetic foot ulcers were enrolled over a period of 18 months.

Results: Of the 65 patients enrolled, 70.77% (n=46) were males while 29.23% (n=19) were females. Male to female ratio was 2.4:1. Diabetic foot ulcers are common in elderly population. Most commonly seen in the age group of 51 to 60 years. When we evaluated the Wagner grade of the ulcers, it was observed that majority of the patients had Wagner grade III ulcer (44.62%) followed by grade II ulcer in 24.62% of the patients. None of the patients enrolled in the present study had wagner grade I ulcer. When the risk factors presence was evaluated in the patients, 63.08% patient had suffered trauma, this was followed by peripheral neuropathy which was present in 60.00% patients. Among the patient enrolled, 36.92% were smokers. 63.08% patients had diabetes for more than 10years while 20% had diabetes of 5-10 years duration and only 16.92% patients had diabetes of less than 5 years. We observed that USG showed presence peripheral vascular disease in 41.54% patients, which is considerably high. In the present study X-ray showed presence of Charcot’s joint, osteomyelitis, fracture and osteoporosis in 10.77%, 24.62%, 3.08% and 4.62% patients respectively. We observed that in our study, anemia was present in large proportion of patients, 67.69%, in the present study. In the present study, ulcer was managed conservatively in 38.46% of the patients. I & D was performed in 35.38% of the patients. While amputation was performed in 12.31% of the patients. In the present study, the following organisms were isolated: Staphylococcus aureus, Pseudomonas Aeruginosa, Klebsiella pneumonia, Streptococcus pyogenes and Proteus Mirabilis were present in 36.92%, 9.23%, 13.85%, 18.46% and 10.77% patients, respectively. Thus the most common isolate was Staphylococcus aureus followed by Klebsiella pneumonia. We observed that 50% staphylococcus aureus isolates were resistant to methicillin, that is methicillin resistant staphylococcus aureus. However, the isolated staphylococcus did not demonstrate resistance to vancomycin or linezolid. Gram negative organisms showed no resistance to Piperacillin+tazobactum,
Imipenem and Meropenem in the present study. Amputation was performed in all the patients with Wagner grade IV and V ulcers, while it occurred in 48.15% patients with vasculopathy and 33.33% patients with neuropathy. It was also observed that in those patients with proteus infection, amputation had to be performed in 100% patients.

**Conclusion:** Diabetic foot ulcers pose a significant burden on the patients and on the health care system. The cost of disability, loss of work and lower extremity amputation extends beyond the economic impact, with regards to patient quality of life.

Proper management of diabetic infections requires appropriate antibiotic selection based on culture and antimicrobial susceptibility results; however, initial management comprises empirical antimicrobial therapy, which is often based on susceptibility data extrapolated from studies performed on general clinical isolates.

**Keywords:** Diabetic foot, diabetes, microorganisms.

---

**Introduction**

**Diabetes:** Among one of the oldest known diseases is diabetes.[1] Diabetes mellitus is a metabolic disorder that is characterised by impaired carbohydrate metabolism and affects a large number of people of all social conditions throughout the world and cause of large numbers of complications; thus posing a significant threat to health resources globally. It results in complications, such as diabetic nephropathy, retinopathy and neuropathy.[2,3] Diabetes are unique group in the way they are more prone to develop infections than others.

**Epidemiology:** Around 422 million patients of diabetes exists globally.[4] By 2030 this number may double.[2] As per the International Diabetes Federation, 7.1% of the adults are affected with diabetes.[5] In the USA, around 8.3% population is diabetic.[2] It is also common in India where 8.7% diabetic population exists.[6] As of today, Aug 2019, around 72.94 million people in India have diabetes and this would worsen with time.[7] The problem is diabetes are at 10 fold higher chance of hospitalization due to various infections.[8]

**Diabetic foot ulcer:** Within increased prevalence of diabetes globally, there is increase in its complications too.[9] Diabetic foot syndrome (DFS), a complex disorder, affects diabetes.[10,11] The common estulcers site is dorsalisplantar regions followed by heel and plantar metatarsals.[12] Ulcers classification is as in the table 1 below:

It is the unique anatomy of the foot that leads to potentially serious infection. Diabetic foot ulcers (DFUs) arise due to its two major complications:

(i) **Neuropathy**

(ii) **Vasculopathy (microas well as macro)**

Neuropathy makes the foot insensitive to chronic or acute injuries. Diabetic suffer from repeated traumas that go non-recognized. This results in development of causes callosities, cracks, fissures, and ulcer formation.
The diabetic foot ulcers are complex from other ulcers away because micro-vascular circulation is impaired due to atherosclerosis that limits the blood causing ischemia and decrease access of phagocytic cells and antibiotic to infected area.[14]

DFUs are infection prone as high blood sugar levels provide ideal media for the organisms growth. As the immune system is compromised in diabetics there is rapid and relentless growth of organism resulting in local sepsis and sometimes lifethreatening septicemia. The infection causes further ischemia by microthrombi formation that result in necrosis and gangrene. Sometimes the infection is so severe that it calls for limb amputation.[15]

DFUs are chronic in nature, requiring repeated hospitalization. The patient is sometimes exposed to several antibiotics thereby increasing risk of multidrug resistant infection development.

**Epidemiology of DFU:** India has 3.6% prevalence of diabetic foot ulcers.[6] Between 12%–25% of diabetics are at its risk.[16-18] Around 40%–80% DFUs are associated with morbidity and mortality.

**Problem Statement:** DFUs have become a source of morbidity and are a leading cause of hospitalization in diabetics to the extent that 20% of hospital admissions in diabetics are due to DFU. These can also lead to infection, gangrene, amputation and sometimes even death in the absence of necessary care.[2]

Chronic DFU is one that fails to heal within 30 days and is a precipitant of amputation.[19] Amputation of even one limb significantly increases the cardiac risk of the patients. Thus, it is utmost necessary to save limb, not only from the view point of mobility and morbidity but also the view point of cardiac safety.

To decrease the burden of DFUs and increase the awareness among the masses, a novel project ‘Step-by-Step Improving diabetes Foot care in the developing world’ has been initiated in India, it also trains people on treatment of trivial foot lesions.[20]

Three cardinal aetiological factors that predispose to diabetic foot ulcers are ischaemia, neuropathy and infection. DFUs are challenging to cure as often the diagnosis is delayed; there is presence of ischaemia, infection with multidrug-resistant organism and extension of infection to the bones. Fetid foot is combined infection involving bone and soft tissue.[21]

Proper management of diabetic foot infection is a difficult and debatable. It is necessary to isolate and identify the causative microbial flora and initiate appropriate antibiotic therapy. A multidisciplinary approach is required to manage the DFU and its infections.[21]

The infections are usually caused by polymicrobials thus requiring proper management with appropriate antibiotic selection.[15] Identification of the causative organism is must for the optimal management. Certain factors like microbes in lower limb, metabolic factors, earlier use of antibiotics and hygiene of feet play an important role in this.[12] Under some specific conditions even fungal infection of diabetic foot can occur.

Infection by multi-drug resistant organisms (MDROs) is common in diabetics and this makes them recalcitrant to healing.[22]

Pathogens such as methicillin resistant *S aureus* (MRSA) or vancomycin-resistant *Enterococci*, are commonly isolated and are usually resistant to most antimicrobial agents. [2] Presence of MDRO infection is influenced by previous use of antibiotic and the duration for which they were administered, hospitalization frequency and duration, presence of osteomyelitis and proliferative retinopathy. [2]

Predominantly the aerobes that are commonly seen in patients with infected DFUs are *Staphylococcus aureus*, coagulasenegative *staphylococci*, *Streptococcus* species, *Enterococcus* species, *Corynebacterium* species, *Enterobacteriaceae* and *Pseudomonas aeruginosa*. However, many infections are polymicrobial and sometimes even fungi may be present. [2] Fungi are common in chronic foot ulcers in elderly diabetics having high Wagener grade and poor glycemic control.

This study was conducted with the aim to determine the clinical and microbiological profile of diabetic foot patients and to assess their outcome.

**Materials and Method**

This prospective, interventional study was carried out in the General Surgery Department of Dhiraj Hospital, for one year and half year from April 2018 to September 2019. Those patients that had diabetic foot ulcers were enrolled in the study which was conducted as per Ethical guidelines and local regulatory guidelines.
Inclusion Criteria:

1. Patients of both the sexes that had an age of 18 years or older.
2. All patients who reported to surgery department with diabetic foot ulcers.
3. Patient who gave written informed consent.

Exclusion Criteria:

1. Patients who did not agree to give consent for participation in the study.

Results and Discussion

In the present study 65 patients that had diabetic foot ulcer and had presented to the general surgery department were enrolled.

1. Gender Distribution: Of the 65 patients enrolled, 70.77% (n=46) were males while 29.23% (n=19) were females. (Table 1, graph 1) Male to female ration was 2.4:1. Relatively, males spend more time outdoors exposing them to risk of trauma and subsequent ulcer, this could be one of the reasons for male preponderance. Another reason could be that our hospital receives patients from rural background who have a habit of walking barefoot, thus exposing themselves to injuries and contamination of wound.

2. Age Distribution:
Mean population age = 50.88± 16.42 years.

Patients age range = 21-80 years.

Majority of the patients were found to be of 51 to 60 years.

Diabetic foot ulcers are common in elderly population. The reasons for the same may be that skin softens with age and can easily break even with trivial trauma. The ability of the cells to proliferate decreases as age progresses, response to stress and also immune response is diminished. Also the complications of diabetes that is neuropathy, vasculopathy worsen as the duration of uncontrolled diabetes increases.

3. Wagner Grading: Majority of the patients had Wagner grade III ulcer (44.62%) followed by grade II ulcer in 24.62% of the patients. None of the patients enrolled in the present study had Wagner grade I ulcer.

4. Risk Factors: When the risk factors presence was evaluated in the patients, 63.08% patient had suffered trauma, this was followed by peripheral neuropathy which was present in 60.00% patients. Among the patient enrolled, 36.92% were smokers. Considering the risk involved, 63.08% patient had suffered trauma, this was followed by peripheral neuropathy which was present in 60.00% patients. Among the patient enrolled, 36.92% were smokers. Neuropathy is a known precursor of trauma as it makes patient unaware of the trivial traumas that occur on daily basis and thus result in ulceration.

5. Duration of Diabetes: We classified the population on the basis of duration of diabetes diagnosis it was observed that 63.08% patients had diabetes for more than 10 years. It can be seen that as the duration of diseases increases so is the incidence of the ulceration, the reason for the same could be as follows, as the duration of disease increases so is the degree/severity of neuropathy and vasculopathy and thus predisposing the patients to ulceration that are resistant to heal. Patients are exposed to repeated traumas that cause ulcers to increase in size.

Human Cytomegalovirus Infection as a Risk Factor for Type 2 Diabetes Mellitus Development in a Sample of Iraqi Patients

Huda Mohammed Hasan¹, Dunya Fareed Salloom¹

¹Scholar Researchers, Biology Department College of Science, University of Baghdad, Iraq

Abstract

Type 2 diabetes mellitus which abbreviate as T2DM is a complex endocrine and metabolic disorder arising from genetic and environmental factors interaction which in turn induce various degrees of insulin functional alteration on peripheral tissues. Globally, T2DM has develop into a public health problem. Therefore, The study included (75) patients(37 female and 38 males) suffering from T2DM who visit al-kadhimiya teaching hospital with age range 20-80 years and (70) as healthy controls with age range 20-70 years. All studied groups were evaluated CMV IgG by ELISA,B. urea, S. Creatinine, cholesterol and triglyceride the results showed that B.urea, S.creatinine and serum cholesterol showed a non-significant differences between studied group, While there was significant differences in concentration of triglyceride between both studied group. The seropositivity of CMV IgG was 62(82.87%) in T2DM patients with significant differences in compare to control.

Keyword: Type 2 Diabetes mellites, viral infection and Cytomegalovirus infection.

Introduction

The term T2DM derives from lack of the body ability to effectively use of insulin (¹). The risk factors for T2DM are genetic, obesity, family history for disease, sedentary lifestyle,ethnicity and other (²). On the other hand, Environmental influences may also contribute in T2DM development and progression(¹,²). Moreover, T2DM consider as a low grade chronic inflammatory disorder with differences in function of immune cells(³–⁵). The duration of diabetes is one of the strongest determinants of complication risk so, there was a positive correlation between FBS and duration of diabetes(⁶,⁷). There is some proofs refer that chronic viral infections such as hepatitis B and HIV can increase susceptibility to chronic inflammation and immuno-metabolic responses and this result in T2DM development. The association between viral infection and diabetes may reflect an increased risk of pathogenic mechanism for some chronic viruses such as HBV and HIV, resulting in insulin resistance linked to chronic inflammation (⁸). Some research also indicates that T2DM patients are more susceptible to incidence of viral infection since diabetes affects healing. Moreover, hyperglycemia frequently impairs coagulation, fibrin action, body fat and endothelium function (⁹). Cytomegalovirus like EBV since both of them belong to Herpes family can trigger autoimmunity and chronic inflammation (¹⁰). The outstanding feature of latency for CMV caused unusual expansion of the CMV-specific resting effector population of memoryCD8 + T cell and thus leads to developed chronic inflammation and disturbed the host immune mechanisms(¹¹–¹³).

Materials and Method

Samples Investigated: A total sample of (145) Iraqi volunteers (75 T2DM patients: 38 males and 37 females compared to 70 healthy control individuals: 35 females and 35 males) were enrolled in a case-control investigation during the period from November 2019 to February 2020 after obtaining the approval of Ethical Committee at the University of Baghdad, College of Sciences, Biology Department and the Iraqi Ministry of Health. The written informed consent was possessed by all volunteers. The study was accomplished in accordance with the Ethics Code of the World Medical...
Detection of CMV IgG Antibody by ELISA:
The detection of CMV IgG class of Ab in serum of human is relied on the technique of ELISA according to manufacture company human Germany.

Statistical Analysis: The data of CMV IgG serum level, age, gender, blood urea, S.creatinine, cholesterol and s. TG was analyzed for linearity, homogeneity and normal distribution using IBM SPSS statistical package version 26.0 (IBM Corp. Released 2019). The mean, standard error and the probability were calculated to determine the statistically significant differences.

Results and Discussion
One hundred forty five volunteers were incorporated in this study included seventy five T2DM patients and seventy healthy individuals considered as control group. Diabetic patients group included 38 males and 37 females’ patients who were already diagnosed by laboratory test (FBS). In contrast, control group included 35 males and 35 females’ participant. The present results showed a non-significant difference between T2DM group age mean and controls (Table 1). Also, the current study included T2DM patients with age range 20 – 80 years, the highest age group was at the 41 – 50 years age group (34.55%), followed by 51 – 60 years age group (29.1%). While the lowest age group was at 20 – 30 years (3.6%).

These findings were in agreement with another previous study that reported that T2DM can be detected at all age groups, So T2DM, diagnosed previously in adults, now impacts children and teenagers \(^{(14,15)}\). In contrast, some studies found an inverse relationship between age of onset of T2DM with complication risk and mortality\(^{(16,17)}\).

The reasons for age participation in Diabetes have been reported in many studies as by Maedler et al. stated that aging of human pancreatic islets is correlated with decreased proliferation and increased susceptibility to hyperglycemia-induced apoptosis, this represent one explanation for age involvement in diabetes elicition\(^{(18)}\). In respect to the gender the current study suggest that there is non-significant (P > 0.05) differences found between the two groups concerning samples distribution according the gender as shown in the table (1). The number and percentage of the female were 37, 49.1% in the patients compared with that in control 35, 50%; while of the male were 38,50.6% in the patients compared with that was in control 35, 50%. The result of this study that infer non-significant differences in gender distribution was in agreement with some studies in this domain that refer to” male and female have similar diabetes prevalence biologically”\(^{(19)}\). One of explanation for this similarity in overall prevalence in both sex that in T2DM, the deficiency of insulin sensitivity and insulin secretion is significant and identical in both gender\(^{(20)}\).

With respect for investigating kidney function in diabetic patients through determining of B. urea and S. creatinin shown in table (2) and according results of this present study there is a non-significant increase was found in levels of B.urea between two studied groups (T2 DM patients 32.10 ± 1.60control 28.52 ± 0.84). On the other hand, there is a significant differences in level of S. Creatinine between both groups (patients 0.85 ± 0.04 and control 0.71 ± 0.02), although both groups within the normal range of creatinine.

The present study results which concern with the levels of urea was agreed and disagreed with some previous studies. Disagreed studies state that HbA1c and urea were elevated notably in T2DM patients compared to the control (21–23). Another study reported that there was a strong correlation between F.B.S, postprandial blood sugar level and HbA1c in diabetic patients and urea level(21). The covariance results of our study may be explained by Pathan et al finding who indicates that the period of initiation of T2DM and its severity is strongly associated with an imbalance in serum urea levels, but this state is not similar in case of serum creatinine(24).

With respect to serum creatinine although the control group had a higher values than patients but both group result might be with normal range (below 1.2 mg/ dl). A weaker correlation between hyperglycemia and serum creatinine levels was shown according to(22).

</tr>
</tbody>
</table>

In recent decades, the mean triglyceride was risen in line with the growing epidemic of diabetes mellitus and obesity, but the mean levels of cholesterol in America was reduced(27,28).

Previous studies have indicated that serum triglyceride are positively correlated with diabetes(29,30) since abdominal obesity releases unhealthy free F.A. which are transported to the liver and pancreas contribute to insulin signaling response inhibition or insulin resistance(31).

Less data is available on the relationship between total cholesterol and diabetes. Some studies found that people with abdominal obesity, who respond abnormally to 2 h PG, associated with high total cholesterol since total cholesterol will increase the dimerization of the endothelial nitric oxide -synthase enzyme, which decreases the activity of glucokinase and thus decreases the glucose intra-cytoplasmic metabolism(32).

In addition to what was mentioned previously, CMV IgG serum level around 82.67 % of T2DM patients are positive for anti-CMV IgG antibody, while only 31.43% of control are recorded seropositivity for this viral infection, so this difference was high significant \( p < 0.01 \), as shown in figure (1).

The findings of this study suggest that anti-CMV IgG antibody may be involved in aetiopathogenesis of T2DM and these results are consistent with other studies in this field. One of these studies that reported by Schmidt et al. who indicates that among those who were cytomegalovirus-seropositive, T2DM crude odds were 47 percent higher than cytomegalovirus-seronegative, after adjusting of age and other factors, the correlation...
was greatly reduced and no longer significant, so the correlation between CMV and T2DM is clarified by age and other diabetes risk factors (33).

More frequently, nucleic acids of CMV have been found in diabetic people arterial walls relative to those without diabetes(34). In the pancreata of individuals with T2DM, CMV-RNA has also been identified by(35); However, it is unknown if the pancreatic CMV virus directly affects beta cells and impairs the release of insulin, causing diabetes, or if T2DM patients are a great extent susceptible to CMV infection(35,36).

![Figure (1): Anti-CMV antibody (IgG) in T2DM group compared to healthy control group](image)

Another potential mechanism that support finding of current study in relation to T2DM elicitation by CMV assumes that the molecules used in the structure of the envelope, such as viperin, which is necessary for extracellular budding and complete CMV virion shedding, could modify the pathways of lipid and glucose metabolism (37).

But our study has some limitation like smallest sample size, difficulty for determining if the CMV infection proceed diabetes onest or the diabetic patients are more susceptible for CMV infection because IgG does not show at what time the infection occurred (before or after the emergence of T2DM), but rather demonstrates that an infection occurred at a certain stage in the lifetime of a person(33).

**Conclusion**

The viral infection especially CMV infection may have a risk role in etiopathogenesis of T2DM.

Relationship between Socio-Economic Aspects and Education Level of Group Ages 18-25 towards Teeth-Brushing Habit

Indriasari Putri Rahmadhany, Aulia Ramadhani, Abigail Reyhan Kesuma, Riska Nur Arifianti P.N., Nada Fajrina, Nadhia S. Latuamury

1Undergraduate Student, Faculty of Dental Medicine, Universitas Airlangga, 2Graduate Student of Health Administration and Policy, Faculty of Public Health, Universitas Airlangga, 3Department of Dental Public Health, Faculty of Dental Medicine, Universitas Airlangga

Abstract

Background: Dental and oral health problems in the community can arise due to behavioral factors or attitudes ignoring oral and dental hygiene. The level of education and the factors that affect children’s own dental health have been presented in various studies.

Objective: To analyze the relationship between socio-economic aspects and the level of education of people aged 18-25 years towards the habit of brushing teeth in the city of Surabaya.

Method: This type of research is an observational analytic study with a design using a cross sectional study approach. In this study, related data were collected regarding the relationship between education and socioeconomic levels of the age range of 18-25 years on the habit of brushing properly taken at the same time.

Results: There was no significant relationship between education and socio-economic level with the habit of brushing teeth.

Conclusion: It was concluded that there was no significant relationship between education level with the habit of brushing teeth and the relationship of socioeconomic level with the habit of brushing teeth.

Keywords: Education, Socio-economy, teeth-brushing habit.

Introduction

Oral health is important for general health and quality of life. A healthy mouth condition is free from throat cancer, mouth infections and wounds, gum disease, tooth decay, tooth loss, and other illnesses, which can cause limiting disorders in biting, chewing, smiling, talking, and psychosocial well-being. Dental health is part of oral health, which is important. Dental caries is one of the dental health disorders. Dental caries are formed due to the presence of food scraps attached to the teeth, which then causes a decrease in tooth mineral. As a result, teeth become porous, hollow, even broken. Dental caries causes a decrease in the chewing power and disruption of digestion, which indirectly results in a child’s growth is less than optimal.

Behavior Maintaining health Oral cavity, one of which is done by regularly brushing teeth and choosing the right toothbrush. Brushing teeth is the most important thing to maintain oral health. Brushing teeth must be accustomed since childhood. The recommended method for brushing teeth is the bass method, which is by tilting the toothbrush 45 degrees brushed from the
direction the tooth root touches the edge of the gum. The toothbrush is moved back and forth within 15 seconds. In the posterior teeth, the tooth surface is brushed in the vertical direction. In addition to paying attention to how to brush your teeth, the selection of toothbrushes and toothpaste must also be considered. The shape of the toothbrush must have a surface of the bristles having a length of 2.5-3 mm and a width of 8-9.5 mm and the brush bristles evenly cut. After each use, the toothbrush must be washed with water so that no food remains are left behind. Toothbrushes must also be replaced 2-3 months.

Oral hygiene has been applied since ancient times, but brushing teeth is only done in modern times. Nowadays, various oral care products have been introduced to the public. This shows how important it is to maintain oral health. Brushing teeth has the effect of removing dental plaque in varying degrees according to the characteristics of the duration of toothbrushes and brushing. Brushing teeth can also alleviate certain oral diseases, such as periodontitis and caries, which are considered to be a public health problem.

Knowledge, attitudes, and actions of the mother will determine the dental and oral health status of children later. Parents must know how to care for their children’s teeth and must be able to teach their children how to maintain good dental health. Many parents still assume that baby teeth are only temporary and will be replaced by permanent teeth. So parents often assume that damage to baby teeth caused by poor oral hygiene is not a problem.

Based on data from the Indonesia Basic Health Survey 2018, it states that the proportion of dental and mouth problems is 57.6% and only 10.2% receive services from dental medical personnel. The percentage of people who have the right brushing behavior is only 2.8%. Dental health problems that commonly occur in Indonesia is dental caries. The treatment needed to solve these dental health problems requires high costs. Therefore, it is necessary to prevent prophylaxis against diseases of the teeth, one of which is to brush teeth properly regularly. Dental and oral health problems in the community can arise due to behavioral factors or attitudes ignoring dental and oral hygiene. There is a relationship between the level of educational background with one’s knowledge of how to brush teeth properly. The level of education and the factors that affect children’s dental health have been presented in various studies. On the other hand, similar studies have not been done in adults. With this phenomenon, the researcher aims to conduct research to determine the relationship between social economic aspects and the level of public education on knowledge about how to brush teeth properly. And to predict the relationship, researchers used sample data from Surabaya residents.

**Method**

This study was a cross-sectional observational analytic study with a research instrument in the form of a questionnaire. The sample used was 118 related to good tooth brushing habits. Analysis of the data used in this study is Bivariant Correlation with the Spearman Correlation test.

**Results**

</tbody>
</table>
Based on the characteristics of “Educational background” shown in table 2, it can be seen that the respondents with the last elementary and junior high school education are 0 people with a percentage of 0%. Respondents with the most recent high school education were 91 people with a percentage of 77.1%, and respondents with the most recent Bachelor/diploma education were 27 people with a percentage of 22.9%.

Based on socio-economic characteristics based on the average salary received by respondents in table 2, it appears that respondents with low socio-economic status are 93 people with a percentage of 78.8%, respondents with Medium socio-economic status are 15 people with a percentage of 12.7%, and respondents with high socio-economic status as many as 10 people with a percentage of 8.5%.

Based on the table above, it can be concluded that there is no significant relationship between the level of education and the habit of brushing because Sig. 0.296, where the value is more than 0.05. Similarly, the relationship between the socio-economic level and the habit of brushing teeth has a Sig value of 0.769.

Discussion
This research was carried out around the area of Universitas Airlangga, Surabaya, East Java. This research was conducted by the method of distributing online questionnaires through social media platforms. The results of the questionnaire as many as 118 respondents were dominated by adolescents with educational background at the high school level.

The results of this study indicate that there is no significant relationship between the level of education and socio-economics with the habit of brushing teeth in people aged 18–25 years in Surabaya. These results were obtained from the analysis of the data we did using a questionnaire distributed to random samples in the Surabaya area. The results showed that 88.1% of adolescents aged 18–25 years in the Surabaya area answered the questionnaire well. The insignificant result was due to the possibility that most of the samples were taken from adolescents living in urban areas especially in the East Java area of Surabaya, with most of their socioeconomic status and high level of education and anything easily accessible.

This study shows that the high socioeconomic figures in urban areas are far higher when compared to remote areas. The higher the socioeconomic level of the community, the higher the level of education of the community, conversely if the socioeconomic level of the community is low, the lower the level of education taken14. Therefore, it can also be concluded that the level of education in urban areas has begun to be evenly distributed so that an increase in the level of socio-economics and with the presence of such education the level of knowledge is also increasing15. Public awareness will also maintain oral hygiene by brushing teeth properly and has been implemented well.

Conclusion
Based on research conducted with 118 samples ranging in age from 18-25 years in the area around Campus A, B, and C of Universitas Airlangga, Surabaya, it was concluded that there was no significant relationship between education level with toothbrushing habits as well as the relationship between socioeconomic levels and habits brushing teeth.

Abstract

Introduction: Due to COVID-19 pandemic outbreak, a lot of countries are under lockdown for more than 30 days. The study is about the physical activity and emotional status of college students and the working sector for 1 month lockdown.

Aim: To check the physical and emotional status of college students and in the working sector, while the response is either positive or negative towards the health concern.

Method: A web survey was used which is based on IPAQ and PERS scales by 150 candidates.

Result: IPAQ show the physical activity perform by the 150 candidates where the maximum candidate was of low activity and PERS shows the positive and negative reactivity of the candidates where the negative reactivity was high than positive reactivity.

Conclusion: The low physical activity stimulates the negative reactivity.

Keywords: COVID-19, IPAQ AND PERS, Physical and Emotional Status.

Introduction:

As the COVID-19 has a globally pandemic effect on whole globalization. Due to which the people have to be quarantined from more than 30 days for the welfare of each person who can be treated from COVID-19. This lockdown will help to locate the people who are being symptomatic with COVID-19 and are not yet located or reported. Therefore the lockdown has an effect on one’s human body in many ways and the two factors which are more affected are physical and emotional factors. Human existence is possible if there is correlation between the neurobiological and integration of movement for the proper function of the human body and to balance this equation movement and mental health plays an important role. Due to restrictions for COVID-19 there is a great impact on the physical activity which is not properly followed by college students and the workplace. BECAUSE these two sectors are the most active groups of the society which perform vigorous to moderate types activity. The sudden lockdown may associate with sudden physical inactivity which further associate with insulin resistance in muscle tissue and even there is an decreased glucose utilization in muscle which further cause the muscle atrophy. Therefore the sudden cessation of physical inactivity can also cause the decrease in the rate of blood flow back to the heart and reduced the coronary blood pressure.

The World Health Organization (WHO) has provided some information to follow over the physical activity during this lockdown which is essential as well
as beneficial for each of us for the proper functioning of the body and even for the balance of adequate health.

The guidelines are such that an individual should engage at least

(a) 150 min/week on moderate intensity physical activity
(b) 75 min/week on vigorous/high intensity physical activity
(c) or, the combination of both moderate-vigorous/high physical activity².

DUE to prolonged time of lockdown the physical inactivity also affects the bone and joint health due to inadequate stimulation in muscles⁷. The doctors say that with such a long time period of lockdown will not only affect the physical activity but also overall and general health in mainly patients like diabetes and hypertension will also have an affect on mental status⁸. Physical inactivity also affects the mental health which can be examined by unpleasant emotions such as anger, fear, sadness, happiness, frustration, irritation etc. Psychological disorders like post traumatic stress, post traumatic depression and post traumatic confusion among people was followed by the author’s like Brooks³. The impact on emotional inactivity is much depress by the anxiety among people in days of lockdown⁶. Reports of China, about the psychological health of people over there cause fear-anxiety, increased domestic violence and babies being abandoned⁸. The effect of lockdown on mental stability is they have fear of spreading virus, about the family welfare, phobias and anxiety are prioritizing the current situation⁸. The lockdown is not providing the platform to meet loved ones with each other which is also the major cause of depression⁷. The news that are occurring can cause more anxiety and stress on people during

lockdown⁷. The alcohol consumption in this lockdown is increased due to stress and certain emotions that emerging within individuals⁷. The lockdown period is such an emotional phase for each one due to which there is an intense fear among the people which causes them panic attacks on future delaying, the health status of one wellbeing [7]. As the habit of working either physically or mentally during not lockdown or simple routine lifestyle caught into the trap of COVID-19 in bad terms. The impact of covid-19 for one month lockdown creates an impact on physical health, mental health as well as life satisfaction which is supported by Dr. ZHANG⁹. Work helps people in their wellbeing, in their state of mind through the daily routine, through some hopes and purpose in life⁹. Reports claim that during this lockdown if the sedentary lifestyle of youth is increased more than demand will be a major cause of depression and anxiety¹⁰. The impact of covid-19 is directly affecting the financial income of employees⁸. The sector are allowed to work through telecommunication². To work on these two sector with two factors. the scales are used for further reports. The scale which is used is IPAQ scale international physical activity questionnaire. the scale is used to measure the activity related that is perform within population¹¹. The scale consist of two types of activity

(a) Vigorous type activity
(b) Moderate type activity
(c) No activity

That a person does in their routine for the last 7 days. The other scale which is used to measure the emotional events during this lockdown is by PERS scale (Perth Emotional Reactivity Scale). The scale has several measurements which depend on one’s response that are based on activation, intensity, and duration questionnaire that are proposed in two ways positive and negative. The purpose of the topic is to find out the physical activity and emotional status on the college student as well as on the working sector during this one month lockdown⁶.

Method

Description: During this pandemic outbreak of covid-19. The college and all the working

The sector is locked down under the government orders. The proverb is “Prevention is better than cure” during this locked down how the physical and emotional inactivity is analyzed between these two sectors where the data is collected on the basis of web surveys.

Study Population: The population which is taken in this web survey was the population of college students and the working sector. The survey is based on physical inactivity and emotional inactivity on the population during a one month lockdown. There are 150 individuals which based their answers through the questionnaire survey.

Survey Instrument: The web survey was based on the multiple choice questions, it took approximately 10 minutes to complete the survey. The two different scales
are used for two different factors, questions explored the following:-

(a) The knowledge or concern of physical inactivity among individuals
(b) The stability of emotional status among the two sectors
(c) The impact of lockdown is positive or negative in context of physical and emotional health.

The impact of physical inactivity is checked by the IPAQ scale ‘International physical activity questionnaire’ where the questionnaire is based on 2 types of activity, vigorous activity and moderate activity in the last 7 days which is done between the age of 15-69\(^\text{12}\). The impact of emotional inactivity is checked by the PERS scale ‘Perth emotional reactivity scale’ is the questionnaire to measure the reactions of emotions at emotional events. The scale has several measurements which depend on one’s response that are based on activation, intensity, and duration questionnaire that are proposed in two ways positive and negative\(^\text{13}\).

**Statistical Analysis:** The collection of data is based on a web survey questionnaire which is formed in Google forms.

The survey consists of questionnaires which are of physical activity and emotional status.

**Physical Activity:** The physical activity data is based on the components that is determined by the IPAQ scale. The components are:

(a) No activity.
(b) Mild/low activity.
(c) Moderate activity.
(d) Vigorous/high activity.

The components give the detailed general analysis of hours and minutes that is collected by 150 respondents according to activity they performed during 1 month lockdown.

(a) **No activity:** the no activity includes (sitting for long hours). The data shows 44.2% responders sits for within 6 hours while 2.4% sits above 18 hours.
(b) **Mild activity:** The mild activity includes the activity of walking, the data and analysis represents the days, hours and minutes by the sectors(working sector and college students).

(c) **Moderate Activity:** Moderate activities refer to activities that where the oxygen uptake is moderate higher than the normal. The examples of moderate activities are carrying little loads, bicycling at a pace, or play doubles tennis which does not include walking. Therefore the data that is collected is based on the days/week, hours an minutes/day.

(d) **Vigorous/High activity:** Vigorous physical activities refer to activities that where the oxygen uptake is vigorously higher than the normal and heart cardiac output is obtained. The activities include heavy weight lifting, aerobics exercises or regime, bicycling at high pace. Therefore, the data that is collected is based on the days/week hours and minutes/day.

</tbody>
</table>

The low activity is slightly increased as compared to moderate activity .Therefore, the high/intense activity is decreased compared to both activity (moderate and low).

Mean & Standard deviation of low, moderate & high activity was 1547.24 & standard deviation was 1728.37

**Emotional Status:** The emotional status is measured by the PERS questionnaire; the questionnaire is based on the scale that has several measurements which depend on one’s response that are based on activation, intensity, and duration questionnaire that are proposed in two ways positive and negative.

The data is based on the negative (activation, intensity, duration) as well as on the positive (activation, intensity, duration).

- **Negative activation:** The negative activation is noted or determined when there are terms which are used like (upset, disappointed, frustrated, and negative.)
- **Negative Intensity:** The negative intensity is noted or determined when there are terms which are used like, upset, frustration, unhappy...
• Negative duration: the negative duration is noted or determined when there are terms which are used like, upset, anger, frustration, negative mood, and annoyed.

**Distribution of negative reactivity:** The mean value of negative reactivity was 2247 & standard deviation for the negative reactivity was 113.859 (overall composite score) 150 n numbers who had participated in the study
• Positive activation: The positive activation is noted or determined when there are terms which are used like, happy, positive, enthusiastic, good news
• Positive intensity: The positive intensity is noted or determined when there are terms which are used like, happiness, joyful, positive moods
• Positive duration: the positive duration is noted or determined when there are terms which are used like, happy, feeling positive, enthusiastic, pleasant news, paying compliments.

**Distribution of positive reactivity:** The mean value of positive reactivity was 2187.33 and standard deviation of positive reactivity was 7.50. N=150 who had participated in the study

**Count on for negativity vrs. positive reactivity:** It shows that count on for negative verses positive reactivity shows that overall negative reactivity is higher than the positive reactivity.

**Result**
1. The low activity is slightly increased as compared to moderate activity.
2. The negative reactivity is higher than positive reactivity from the data that is collected.
3. The intense or moderate activity performed is less than the low activity or no activity

**Discussion**

The lockdown in COVID-19 is the pandemic effect of the 21st century.

The effect of this pandemic outbreak is currently a point of discussion or a burning issue within the whole

Globalization, the scales which are used for determining the analysis for 'physical activity and emotional status’ that proposes the certain answers. The vigorous physical activity which is proposed by WHO is quite 75min/week². Therefore the data which is collected in this project determines that less than 30% of respondents have worked vigorously. The moderate physical activity which is proposed by WHO is quite

150min/week². The respondents that worked moderately physical activity are 42.8%. As the physical inactivity can cause 17% lower risk to heart, 95% confidence interval. Cardiovascular mortality can risk upto 23% and type2 diabetes can be risked upto 26% according to WHO. There should be allowance of physical outdoor activities like running, walking or any other sports where there is an adequate amount of social distance is maintained where the pandemic covid-19 lockdown causes the consequences of cardiovascular diseases².

“With about five million dead, lack of exercise is the fourth most frequent cause of death globally in 2017”¹. To check such data the ‘no activity’ analysis is a perfect response which determines that 80.3% of respondents have done no activity from the last 7 days except sitting where the data intensifies 8 hours sitting.

The sector (college student and working sector) is the age of active stage, hence, the fact is that 78% of young men and 84% of young girls are affected by the lack of exercise¹. As physical activity increases the immune system and reduces stress so the impact of physical activity is positive on each individual¹⁴. The consequences of homestay is no activity towards the healthy body are obesity, behavioral addictions disorders, exposure to sun is less (Vitamin D) and isolation from society¹⁰. The reductions in physical activity results in the emotional status which may be experienced such as negative or positive response according to events². Extended duration of indoor stay which cannot be avoided accompanied the binging time spent on watching television, playing games online through mobile and the break from socialization, that has worsen the behavioral (i.e. internet, screen, or television) addiction, disorders¹⁰. Longer the duration of lockdown increase in the PTSD symptoms¹⁴. The comparison of data with negative emotion with positive emotion. The scoring of negative emotions is well more than Positive emotions thought, physical activity affects the emotional reaction of an individual.

**Conclusion**

The resolving part is to check the physical activity
and emotional status of college students and working sector people in a 1 month lockdown. The results that we found are negative with relation to physical activity and also negative with emotional status. As the article suggests the lack of activity difference one’s mental or emotional ability. Though the data stand on this sentence. I would recommend that lack of physical activity not only affect the emotional status but also affect the cardiovascular activity, musculoskeletal activity, metabolic activity, hormonal activity. The research can further perform on old age and their physiology and psychology status. Within 1 month of span time of total lockdown in India. The data find out that there is a lot of variation in physical inactivity but not so much elevation disturbances in emotional status.

**Ethical Clearance:** It is the web survey study that is done in the institution (galgotias university) under the Department of Physiotherapy. This proposed project was placed before the Ethical Committee and has been approved as there is no objection to hold this project work.

**Conflict of Interest:** There is no conflict of interest of the author.

**Funding of the Research:** Self Funding.

Formulation Policy of Euthanasia Criminal Action in the Indonesian Criminal Law System

Jane Margaretha Handayani, Edy Lisdiyono, Bambang Joyo Supeno, Wahyu Satria Wana Putra Wijaya

Abstract

Introduction: Euthanasia is considered to be contradictory to the 1945 Constitution of the Republic of Indonesia, which is contained in Chapter XA, second amendment about human rights which are concerning about the right to live and the right to be protected. There are no specific laws and regulations which regulate Euthanasia in Indonesia; therefore, it is important to research the laws and regulations that have to possibility to regulate Euthanasia, especially in the Indonesian criminal law system at present time.

Purpose of Research: This research aims to acknowledge and analyze the Euthanasia criminal action formulation policy in the criminal law system at present time.

Research Methodology: This research is a normative juridical legal research with a statute approach.

Discussion: The practice of Euthanasia is prohibited by Article 344 of the Criminal Code; therefore, the regulations must be based on the court order, either the active Euthanasia which is stated real and sincere by the victim or the passive Euthanasia which is stated by other parties other than the victim.

Keywords: Formulation Policy; Criminal act; Euthanasia.

Introduction

Euthanasia is considered to be contradictory to the 1945 Constitution of the Republic of Indonesia, which is contained in Chapter XA, second amendment about human rights which give clarification and regulations that state every human being has the right to live and the right to be protected. Article 28A in the second amendment which states that “everyone has the right to live and the right to defend their life”, declares clearly that everyone has the right to live and to defend their life. In Article 281 paragraph (1) the second amendment emphasizes that “the right to life cannot be reduced into any form, and the right to live is also stated and regulated in Article 28J paragraph (1) in the second amendment which states that “everyone is obliged to respect the human rights of others in an orderly society, nation and state, including the right to life”.

Currently, the regulation concerning active euthanasia crime is regulated in Article 344 of the Criminal Code which is the act of taking the life of another person at their request which is expressed with sincerity. Article 11 Decree of the Executive Board of the Indonesian Doctors Association Number 11/ PB/A.4/02/2013 concerning the Application of the Indonesian Medical Code of Ethics, the Executive Board of the Indonesian Medical Association explained that every doctor is obliged to remember their obligation to protect other human beings’ lives because the doctor’s obligations are explained as the principle of “Aegrotisalus lex suprema”, which means patient’s safety is the highest or main law and the principle of “Sa science et sa conscience” also applies, which is science and conscience.

Law Number 36 of 2009 concerning Health does not explain Euthanasia, however it explains the definition

Corresponding Authors:
Jane Margaretha Handayani
University 17 Agustus 1945, Pemuda Street, Semarang City, Indonesia
e-mail: janemargarethahandayani@gmail.com
of death which is stated in Article 117 concerning the
definition of death, which states that a person is declared
dead when the function of the heart and respiratory
system has stopped or the brain stem dies.

Based on these facts, Indonesia has not had the
regulations concerning passive euthanasia crime.
However, Indonesia is only using articles in the
Criminal Code as a reference for the punishment of the
perpetrators of the crime of euthanasia.

Several countries in the world have legalized the
crime of euthanasia, such as the Netherlands, Belgium,
and Switzerland, based on the laws of these countries
humans have the right to terminate their life or the right
to die. However, in Indonesia, this act is prohibited due
to several considerations, namely that it is not under
the formulation of articles in the Criminal Code and the
declare of the Indonesian Medical Oath. Therefore, it
is important to research euthanasia crime formulation
policies in the Indonesian criminal law system.

Based on the previous background, therefore the
purpose of this research is to acknowledge and analyze
the Euthanasia criminal action formulation policy in the
criminal law system at present time.

**Research Methodology**

This research is a normative juridical legal research
with a statute approach because it is conducted to
examine all the laws and regulations relevant to the
legal issues being handled, which in this case is the
issue of Euthanasia based on the policy formulation of
criminal law in Indonesia at this time.

**Discussion**

Terminologically, the word Euthanasia comes from
the Greek language, which is from the word “eu” which
means good without suffering, and “Thanatos” which
means death. Etymologically, euthanasia can be defined
as “good death”, meanwhile “ethanatos” (adjective)
means dead with ease. Euthanasia is broadly defined as
the practice of accelerating one’s death who is in pain
and suffering that cannot be healed.

In medieval times, it was emphasized that
euthanasia was a painless death. At the beginning of
the 20th century, euthanasia was under the influence
of Nationalist-Socialist politics where euthanasia
could be used as a legalized act of killing people who
were considered unworthy of life. In its development,
currently, the definition of euthanasia is narrowed down,
where the euthanasia action can only be carried out by
a doctor on the willingness of the patient concerned.

There are currently no new and complete regulations
in Indonesia regarding this euthanasia. However, because
the issue of Euthanasia concerns the safety of human life,
it is necessary to look for a regulation or article which is
at least relevant to the elements contained in the practice
of Euthanasia.

The practice of euthanasia is prohibited by Article
344 of the Criminal Code; therefore, the regulations must
be based on the court order, either the active Euthanasia
which is stated real and sincere by the victim or the
passive Euthanasia which is stated by other parties other
than the victim. In Article 344 of the Criminal Code,
it only regulates active Euthanasia, which is the victim
declares in a real and sincere manner to accelerate the
death of the victim and without force from any party.
As it is formulated as follows: “whoever takes the life
of another person at his request, which is clearly stated
with sincerity, shall be punished with a maximum
imprisonment of 12 (twelve) years”.

And the elements are as follows: the first is whoever.
The formulation of offense in regulations usually begins
with the words “whoever is”, the word “whoever”
cannot be interpreted other than “a person”. The element
“whoever” is subjected to anyone who is the legal
subject to whom that person can be accountable for the
committed act. According to Sudikno Mertokusumo:
A legal subject (Subjectum Juris) is anything that can
obtain, have or bear rights and obligations from the
law, which consists of persons (Natuurlijkeperson):
Legal entity (Rechtsperson); People in the conditions
of punishment must be in the elements of a criminal act
(strafbaarfeit), namely being able to take responsibility
and the existence of mistakes (culpa); Article 344 of the
Criminal Code as stated above explains that “whoever”
is a person who commits a criminal act, however Article
344 of the Criminal Code does not explain that a doctor
or medical officer has committed the crime of euthanasia.

The second element is taking other people’s lives, is
an objective element, namely the act of a person is the
connect point and basis of giving punishment. These
actions include doing and not doing, the act of taking
someone else’s life must cause the death of a person, a
dead person is someone else and not themselves. The act
of taking someone else’s life must fulfill the subjective
element of strafbaarfeit, that is, the action must be done wrongly. Death does not always occur immediately, but it may occur later. According to Article 117 of Law Number 36 of 2009 concerning Health, a person is declared dead if the function of the circulatory heart system and respiratory system is proven to have stopped permanently, or if the death of the brain stem has been proven.

The third element is the person’s intentional sincere request. Their request element is a request made by someone without forces from other parties aimed to make the perpetrator convinced to quickly do the practice that can finish their life. Sincerity here means that the request is continuously made by the victim by showing their intentions to convince the perpetrator. To decide that Euthanasia is a convictable practice, it must be proved to have material unlawfulness, which means not only contradicting to the applicable legislation but also contradicting to the customs. The practice of Euthanasia is highly disapproved by moral teachings as well as religion because it is only God who can decide whether someone should be alive or dead, not another man, even a doctor. The real motive of Euthanasia is “the feeling of giving up”. It is a disgraceful practice and it is prohibited by religious teachings, moreover if the feeling of giving up is expressed in a form of an action that may harm someone’s security and life.

The existence of the person’s request that is showed sincerely (Active Euthanasia) element is also found in the form of voluntary Euthanasia, therefore this type of Euthanasia can also be reached by Article 344 of the Criminal Code. The subject matter of Euthanasia, especially the active form, can also be related to suicide which is related to Article 345 of the Criminal Code, that is: “Any person who with deliberate intent instigates another to commit suicide, aids him thereby or provides him with the means thereto, shall, if the suicide ensues, be punished by a maximum imprisonment of four years.”

Article 345 of the Criminal Code implies meaning that even though not practicing active Euthanasia which according to most people is murder, helping or providing with the means towards it is going to be criminalized. The word ‘aids’ or ‘provides … with the means’ can be related to the intention to get Euthanasia. A patient or their family must be clueless about the ways to get rid of their sufferings. Medical and other health care workers know more about it if it is related to Euthanasia. In a condition where a patient’s health condition is becoming worse, a doctor will advise the patient’s family. The family chooses to take Euthanasia to solve the problem. The doctor agrees to the patient’s family’s request. What is done by the health care workers can be considered as a practice that ‘aids’ or ‘provides … with the means’. This regulation should be recognized by medical and health care workers because even though there are many reasons to help a patient in suffering, they are still going to face criminalization because of it.

Article 338 of the Criminal Code stated that “The person who with deliberate intent takes the life of another person, shall, being guilty of manslaughter, be punished by a maximum imprisonment of fifteen years.” Also, Article 340 of the Criminal Code stated that “The person who with deliberate intent and with premeditation takes the life of another person, shall, being guilty of murder, be punished by capital punishment of life imprisonment or a maximum imprisonment of twenty years.”

The main purpose of Euthanasia is to help to get rid of or to stop the suffering which according to the perpetrator there is no other way besides death. Knowing the purpose behind an action is very important, remembering the articles in the Criminal Code related to violence regarding wealth and life, mainly about abuse should be looked by the purpose of them. Even though a person is hurting others, if the real purpose is not to abuse them but for a good purpose such as when a doctor is taking a surgery for the patient or a teacher hits their students to educate them, it is not considered to be unlawful. Euthanasia in hospitals is clearly planned and it must have been through thorough consideration, and perhaps the person considering Euthanasia has been through some discussions with their friends.

In indirect active Euthanasia, a doctor whose main purpose is to relieve the patient’s suffering by injecting analgesic at high doses must already know that the high dose will kill the patient. This kind of Euthanasia is not an error, but rather an intention, remembering there are three types of intention: intention with purpose, intention with certain awareness, and legal intent.

Elisabeth Kubler-Ross in her book Questions and Answers on Death and Dying stated that some patients tend to commit suicide when facing the reality of dying. For these patients, if the nurse or the doctor gives them advice or suggestions leading to Euthanasia, they will tend to agree. In this case, health care workers are considered to help them commit suicide. Therefore, this
case applies Article 304 of the Criminal Code, which stated that “The person who deliberately brings or leaves someone, to whose sustenance, nursing or care he is obliged by the law applicable to him or under an agreement, in a helpless state, shall be punished by a maximum imprisonment of two years and eight months or a maximum fine of four thousand and five hundred rupiahs.”

The practice of passive Euthanasia can also be linked to this article, even for the case of when a very ill patient is forced to go home, which then is allowed by the doctor or usually called pseudo Euthanasia13. In this circumstance, the health care workers will say that they are respecting the patient’s rights, when in fact the one who knows more about the effect of the patient being sent home is the doctor. This condition can be relieved by doing at-home treatment. If this happens, it will be considered as passive Euthanasia or pseudo-Euthanasia and it means the patient is being left alone without care until the patient dies. This case will be charged with Article 304 of the Criminal Code, meanwhile for the case regarding the violation of someone in need of help will be charged with Article 531 of the Criminal Code stating “Any person who, witnessing the immediate danger of life that befalls another, fails to extend or provide the assistance which he is capable to extend or provide to him without reasonable danger for himself or another, shall be punished by a maximum light imprisonment of three months or a maximum fine of Rp 4,500”. If the death of the destitute person follows, charged with the Criminal Code 45, 165, 187, 304s, 478, 525, 566.

According to Hermien Hadafi Koeswadji, in the conclusion of his writing about Hospital Ethics and Laws for Hospital, law source for health and/or medical law is taken from written regulations, unwritten customs, permanent court judgments, and science doctrines or teachings14. A legal practitioner will face difficulty in analyzing law sources from medical science; therefore it is better if the legal practitioner is accompanied by a doctor in facing the work. For Euthanasia or malpractice by a doctor in Indonesia, it is not enough to regulate it based only on the Criminal Code, but many legal considerations are taken from science doctrines or teachings, including medical science.

**Conclusion**

Formulation policy of Euthanasia criminal action in the current Indonesian criminal law system is that the practice of Euthanasia is prohibited by Article 344 of the Criminal Code; therefore, the regulations must be based on the court order, either the active Euthanasia which is stated real and sincere by the victim or the passive Euthanasia which is stated by other parties other than the victim. Article 345 of the Criminal Code implies meaning that even though not practicing active Euthanasia which according to most people is murder, helping or providing with the means towards it is going to be criminalized. Regarding health care workers that are considered helping the patient to commit suicide will be charged with Article 304 of the Criminal Code, meanwhile, the case regarding the violation of someone in need of help will be charged with Article 531 of the Criminal Code.

Efficacy of Tongue Stimulation in Neurorehabilitation–A Narrative Review

Jayaprakash Jayavelu¹, Jasobanta Sethi², Sahil Kohli³, Tariq Matin⁴

¹PhD Scholar, Amity Institute of Physiotherapy, Amity University and Chief Physiotherapist, Narayana Superspecialty Hospital, Gurugram, ²Director and Professor, Amity Institute of Physiotherapy, Amity University, ³Consultant Neurology, Narayana Superspecialty Hospital, Gurugram, ⁴Senior Consultant, Neurointervention, Narayana Superspecialty Hospital, Gurugram

Abstract

Introduction: The tongue is being represented bilaterally in the motor homunculus of the brain. Tongue has been used as an effective interface to send signals to central nervous system. The purpose of this article is to review all articles related to tongue stimulation in neurological rehabilitation.

Method: All studies including case studies, cohort studies, experimental studies and reviews, which dealt with tongue stimulation in neurological conditions during the period between 2010 and 2020, were included in the study.

Results: Tongue Stimulation has been used effectively in rehabilitation for improving balance in patients with vestibular disorders, multiple sclerosis patients, spinal cord injury patients and stroke patients. Tongue Stimulation has also been used to improve motor recovery in stroke patients.

Conclusion: Tongue stimulation becomes a novel mode of stimulation in inducing neuroplasticity and can be used in wide variety of neurological patients. Further researches needs to be done on the effect of tongue stimulation on upper extremity rehabilitation in stroke patients.

Keywords: Hand Gesture, Speech, Tongue Movements.

Introduction

Tongue has been represented in both hemisphere and recovery of tongue in brain damaged patients is faster compared to limb recovery. This unique representation of the tongue has been used in various types of rehabilitation.

The purpose of this review is to review all articles which has dealt with tongue stimulation on neurological patients.

Method

Literature search for case studies, cohort studies, experimental trials and reviews on the tongue stimulation, hypoglossal stimulation and periglossal stimulation on neurological patients were performed in the following online databases: PubMed, EMBASE, The Cochrane Library, and Scopus. Three of the authors independently screened all papers titles and abstracts for relevance and reviewed by one reviewer.

Results

After appropriate screening, 11 articles published during the period between 2010 and 2020 have been taken for this review.

Wildenberg et al (2010) did a study on balance dysfunction of twelve patients and found that cranial nerve non-invasive neuromodulation involving tongue stimulation improved the balance of the patients by
increasing activity within the dorsal pons. Similar results were reported on nine balance impaired patients who were given tongue stimulation for 10 days and their sensory organization testing scores improved. 

Fourteen weeks of balance training along with tongue stimulation were given to twenty chronic multiple sclerosis patients and their dynamic gait index improved significantly. (Mitchell E Tyler et al, 2014).

In a study done by Brittany M. Young et al, sixteen subjects received up to 15 two-hour sessions of interventional therapy using an EEG-guided brain-computer interface (BCI) device, which incorporated visual display, tongue stimulation, and functional electrical stimulation as feedback. These BCI therapy sessions were scheduled over the course of up to 6 weeks with no more than three sessions per week. Functional MRI, Action Research Arm Test (ARAT), 9-Hole Peg Test (9-HPT), and Stroke Impact Scale (SIS) domains of Hand Function (HF) and Activities of Daily Living (ADL) were assessed before and after the therapy. The correlations noted between changes in functional (FC) measures and changes in behavioral outcomes indicate that both adaptive and maladaptive changes in FC may develop with this therapy. Similar results were found in nineteen stroke patients with upper extremity impairment.

Fourteen Multiple Sclerosis patients (7 in active tongue stimulation and 7 in sham stimulation group) received intensive physical therapy and working memory training for 14 weeks. Active group showed improvement in sensory organization testing scores. Results showed that tongue stimulation can enhance motor performance and working memory while also driving neuroplasticity. (Gabriel Leonard et al, 2017)

Rosaleena Mohanty et al (2018) did a study on twenty chronic-stage stroke subjects exhibiting persistent upper-extremity motor deficits and they were given intervention using a closed-loop neurofeedback BCI device for 3 weeks. Functional MRI, Action Research Arm Test, Nine-Hole Peg Test, and Barthel Index as well as subjective measures including the Stroke Impact Scale were assessed. Higher number of strengthening functional changes in comparison to the ones weakening between pre- and post-therapy in functional MRI suggests a greater overall positive impact of BCI intervention on stroke recovery at a whole-brain level.

Discussion
Tongue stimulation has been used in various patient categories with primarily sensory-driven balance deficits: people with vestibular loss, peripheral neuropathy, mild traumatic brain injury, and older adults, as well as people with stroke, Parkinson’s disease, and ataxia

Loss of motor function is a common deficit following brain insult and often manifests as persistent upper extremity (UE) disability which can affect a survivor’s ability to participate in activities of daily living.

Brain computer interface therapy has been developed in addition to tongue stimulation for improving motor functions in cerebrovascular accident patients.

Conclusion
Tongue Stimulation has been safely used in wide category of neurological as well as other non neurological patients. Further research can be done to find out the effect of tongue movement and/or stimulation in improving various motor deficits in stroke patients, creating new pathway for recovery.

Retrospective Study of Blood Transfusion Transmitted Infections (HIV, HCV, HBV, Syphilis & Malaria) among the Blood Donors in Dhiraj Hospital

Jigna Patel1, Trupti Rajeshbhai Jansari2, Amit Chauhan3

1Assistant Professor, Department of Pathology, Smt BK Shah Medical Institute & Research Centre, Sumandeep Vidyapeeth an Institution Deemed to be University Piparia 391760 Vadodara Gujarat, 2Assistant Professor, Department of Pathology, Smt BK Shah Medical Institute & Research Centre, Sumandeep Vidyapeeth an Institution Deemed to be University Piparia 391760 Vadodara Gujarat, 3Associate Professor, Department of Anesthesia, Smt BK Shah Medical Institute & Research Centre, Sumandeep Vidyapeeth an Institution Deemed to be University Piparia 391760 Vadodara Gujarat.

Abstract

A blood transfusion is a way of adding blood to your body after an illness or injury. It’s a kind of life saving procedure. But this procedure also has life threatening hazards. Transfusion transmitted infections are one of the major side effects of blood transfusion. We can prevent them by proper screening of blood products and public awareness. To know about trend of transfusion transmitted infections (TTI) for the blood donors of Dhiraj hospital blood bank, the study was done.

Method:
Study was done including blood donors of age 18-65 years from 2011 to 2016 retrospectively. TTIs testing for HIV, HBV and HCV was done with 3rd generation ELISA but from the year 2016 onwards 4th generation ELISA was used for HIV testing. Syphilis and malaria screening was done with rapid card test.

Result:
Over a six year period total blood donation was 20,392. The overall prevalence of HIV, HbsAg, HCV, syphilis and malaria were 0.16%, 1.43%, 0.10%, 0.61% and 0.009% respectively.

Conclusion:
Nucleic acid amplification testing (NAT) must be applied that identify positive blood donor during the immunological window period before seroconversion. Information to TTIs reactive donor is a best method to prevent the chance of repeated reactive donation.

Keywords: Blood donor, ELISA, NAT, Seroprevalance, TTI.

Introduction

Blood is a special form of natural fluid that is made & synthesized within the body and again used by the body for different bodily function. Despite all the medical advances, there is no good manmade substitute for human blood, which is why blood transfusion is still clinically important for human being. Blood transfusion is a unique technology in which its collection, processing and use are scientifically based. But its availability depends on the extraordinary generosity of the people who donate it.[1]

Blood banks are essential part of each and every hospital with basic purpose of provision of blood transfusion services. Blood transfusion services are required in a number of clinical conditions like...
anemia, thalasemia, hemophilia or may be required in gynecological problems or when surgery of the patient is unavoidable. Transfusion of blood/blood product becomes unavoidable if there is extensive bleeding during surgery. \[2\]

Large number of people are exposed to life - threatening risks of TTIs such as Hepatitis B, Hepatitis C, Malaria, Autoimmune deficiency virus infection and Syphilis due to transfusion of unsafe blood which can be avoidable. There is a challenge for safe transfusion, requiring the application of science & technology to blood processing & testing. \[1\]

The present study gives the idea about the current situation of transfusion transmission related infections and that will help in the way to establish a good national strategy for the blood donation system.

**Materials and Method**

The present study was carried out using a retrospective blood donor related data from January 2011 to December 2016 in Dhiraj blood bank unit of Dhiraj hospital.

**Inclusion:** Every single blood donor who came to Dhiraj Hospital from January 2011 to December 2016 who satisfied the criteria for blood donation as per drugs and cosmetic act 1940 were included.

**Exclusion:** Blood donor not satisfying the criteria for blood donation as per drugs and cosmetic act 1940.

The donor questionnaire forms with details of donors like demographic data, age, weight, hemoglobin status and the results of serological test are recorded and maintained in blood bank of Dhiraj Hospital. We saw the data and there were approximate 20,392 donors who donated blood in last 6 years.

From all related data records, we collected data of blood donors without revealing their personal identity.

Here in Dhiraj Hospital blood bank, firstly Blood Donors comes to Blood bank and their counselling is done by social worker. The venous blood is collected from all eligible donors with their permission after the complete physical examination by Blood bank medical officer. For screening, venous blood is collected in plain vaccute, it is allowed to clot naturally and serum is separated after centrifugation. Serum sample is then subjected to serological tests for HBV, HCV, HIV, syphilis and malaria infection screening.

Two kits are used based on WHO recommendation for two different testing strategies involved in ELISA and simple or rapid essays for surveillance. In house positive and negative controls are performed for each serological test.

- *HIV screening is done using Erba Lisa 3rd generation and Erba Lisa HIV generation 4 from the year 2016 onwards. (ELISA)*
- *HBS screening is done using Erba Lisa HBV generation 3. (ELISA)*
- *HCV screening is done using Erba Lisa HCV generation 3. (ELISA)*
- *Malarial parasite screening is done using pan/pf malaria rapid card.*
- *Syphilis screening is done using VDRL rapid card.*

Patients suffering from any of infections are referred for the necessary treatment.

Collected data was compiled in Microsoft office Excel 2013 format. Data was presented in tabulated format. Descriptive method was used for the preparation of result.

**Result**

We evaluated a total of 20392 units of blood during 1st January 2011 to 31st December 2016. The result was interpreted and following details were drawn in a table.

**Table 1: Blood collection during study period**

</tbody>
</table>

During the study period, 17205 (84.37%) of the donors were replacement donors and remaining 3187 (15.62%) were voluntary. The highest voluntary donation trend of 854 (26.79%) donors was seen in 2012. In six year study overall voluntary blood donation has decreased and replacement blood donation has increased.

Table shows 19,846 (97.32%) were males blood donors and 551 (2.7%) were females blood donors giving male: female ratio of 36:1.

Seropositivity distribution in the study with an average prevalence of 2.32% showed higher prevalence in the years 2013 (2.91%), 2012 (2.56%), 2015 (2.47%) and 2011 (2.41%). Lower prevalence was seen in the years 2016 (1.99%) and 2014 (1.81%).

As shown in table during the study period five donors showed co-infections.

Discussion

Though the blood transfusion plays a vital role in management of many diseases, it always carries a risk of TTIs and many other adverse reactions. Blood transfusion is a highly avoidable treatment ever prescribed. It is essential to adopt strict criteria in selection of donors and to avoid unnecessary transfusion because there is no screening method which can make transfusion transmitted disease rate at zero level.[3]

During the study period, the rate of all five mandatory TTI markers were 2.32%. Amrutha Kumari B et al[4] (2.81%) also found similar to lower transfusion transmitted infections marker rates and for other studies comparison see table no. 6.

Among all TTI markers, highest prevalence was for HBV (1.43%) in present study, but its prevalence was low when we compare it with Karnataka(1.77%)[4] and Bengaluru (1.86%)[5] studies. Frequency of occurring hepatitis infection after blood transfusion is higher than any other infection. HBV was the most prevalent TTI in blood donors, suggesting that it might be linked with poor health practice of people, high cost of good health facilities and economic status. Ensuring good health facilities at low cost by Government may reduce the risk factor of these common infectious diseases and ensure better health conditions. Economic status also plays a very important role. Consultancy with health specialist during early diseases may reduce the prevalence of infectious diseases.[2,6]

HCV infection is about 1% according to the national center for disease control in India. In this study its about 0.10%. As shown in table -6, majority of the blood donors studied from different regions of India have higher prevalence rate as compare to this study.[7,8,9]

Syphilis is sexually transmitted disease so when someone diagnosed with it, it means individuals maybe exposed to other sexually transmitted disease also. So screening of donated blood for syphilis is important. Thus it serves primarily as a surrogate test to identify donors with potentially high risk behavior. Our study showed that the prevalence of syphilis was 0.61%. Prevalence of syphilis is higher among male that might be related to common bed sharing in working place and no proper cleanliness. [2,8,10]

The HIV/AIDS pandemic has focused particularly on the importance of preventing transfusion-transmitted infections. Up to 3% of HIV infections worldwide are transmitted through the transfusion of contaminated blood and blood products.[11] In present study, six years sero-reactivity rate was 0.16%.

The fifth and mandatory but neglected marker for TTI screening in India is Malaria. In our study malaria prevalence rate was 0.009%. Its low because of better pre donation screening and people knows well about the symptoms of malaria.

Most blood banks in India use ELISA kit which cannot detect HIV before 22 days, HBV before 59 days and HCV before 82 days of infection. Usually when we do the blood transfusion, volume which is given is very large so even lowest viral load cause transmission of infection. Prevalence of asymptomatic carriers in the society, and when the blood donations done in window period of infections which also posses a great threat to safe blood supply.

The most effective strategy must be started where we inform the TTI positive donors and advice them for no such donation in future. They should be sent for appropriate treatment. Pre-donation counseling and donor self-exclusion will be effective in decreasing the TTIs as well as practices of autologous blood transfusion should be encouraged.

**Conclusion**

The present study has limitations in the use of ELISA test for TTIs screening. The latest more sensitive method such as PCR (Polymerase chain Reaction) and NAT (Nucleic acid amplification Test) can uncover latent infections in the window period and may actually suggest underestimation of prevalence by currently used screening tests in the present study. This implies that screening for TTI needs to be upgraded across blood banks in India. HBV was the most prevalent TTI among all, so there is a need of initiating efforts for community level health program for HBV in addition to UIP (Universal Immunisation Programme) with HBV vaccine started in 2007 and the government should focus on present youth population which has not taken this vaccine in childhood life.

Effectiveness of Parent Focused Group Program on Obesity-Related Behavior & Anthropometric Measurements among 6-12-Year-old Obese Children-A Pilot Study

Jomi John¹, Sushama SBai², R. Vijayraghavan³

¹Professor, INE, School of Medical Education, CPAS, Pala, Kerala, ²Former HOD, Dept. of Pediatrics, Institute of Child Health, Kottayam Medical College, Kerala, ³Research Director, Saveetha University, Chennai, India

Abstract

**Background:** Obesity is caused due to the mismatch between energy intake and expenditure, with food intake more than the requirements leading to an increase in Body mass index (BMI) as a body measurement parameter. Parent focused group program is an intervention program where parents are involved in targeting the changes in obesity-related behavior of their obese children.

**Objectives:** To determine the effectiveness of parent-focused group programs on obesity-related behaviors of children aged 6-12 years.

**Method and Results:** The study was conducted in two phases. The first phase included a survey design to identify overweight and obese children from two randomly selected schools as control and experimental from the southern part of Kerala, India. The second phase included an intervention design with a parent-focused group program for the program’s experimental group, and effectiveness was analyzed from children’s obesity-related behaviors. The key findings indicated that the parent-focused group program was effective in the pre-test and post-test scores of anthropometric measures in the experimental group for both boys and girls. The study suggested that parent-focused programs effectively bring changes in children’s obesity-related behavior, thus reducing the chances of getting overweight/obese.

**Conclusion:** Parent-focused group interventions are effective as a preventive strategy in reducing obesity-related behavior among children.

**Keywords:** Parent focused group program, obesity-related behaviors, BMI.

Introduction

In an individual’s lifespan, there are critical periods of development of obesity and its complications mostly observed during gestation, early in infancy, in the period of adiposity rebound, which usually occurs in 5-7 years of age and adolescence period. Behavioral and developmental processes have described these critical periods. Hence in this critical period, focus on preventive efforts should be made. There is a limited number of studies conducted in India around intervention programs for children in reducing obesity. Cochrane reviews have elicited studies involving parents, teachers, and children in the intervention programs. Several systematic reviews have reported that obesity is a global problem in both developing and developed countries. Early age interventions can help in changing and building a healthy lifestyle among children. Interventions like healthy eating habits, healthy lifestyle modifications, physical exercise, screen time interventions can help in controlling obesity.

Furthermore, involving parents in the intervention programs can make a difference in bringing changes in obesity-related behavior among children. An expert...
committee of the Maternal and Child Health Department of Boston, United States of America, concluded that parental skills are the basic foundation for having a successful intervention for managing pediatric obesity by targeting an increase in physical activity and reducing high fat and calorie foods in children. The report says further that the families need initial support in the weight management period and will gradually learn as a new behavior.

A multi-component intervention based randomized controlled trial with 120 children aged 10-16 years from 11 schools in India suggested being effective in reducing BMI among obese children. Therefore, raising the necessity to conduct studies on identifying effective strategies to improve obesity-related behaviors among school-going children.

**Aims and Objectives:** The study aimed to determine the effectiveness of the parent-focused group program on changes in obesity-related behavior and anthropometric measurements among children identified with overweight and obesity and to modify dietary habits, emotions & attitudes towards eating, screen viewing & sleep, and physical activities.

**Materials and Method**

**Study type:** An interventional study was conducted in two phases. The first phase included a survey design to identify overweight and obese children from two randomly selected schools as control and experimental from an education district of the southern part of Kerala, India. The second phase included an intervention design with a parent-focused group program for the experimental group, and the effectiveness of the program was analyzed from children’s obesity-related behaviors.

**Study area:** The study was conducted among school children of randomly selected eight schools of Pathanamthitta Education District of South Kerala, India.

**Study duration:** The study was conducted between June 2017 to September 2017.

**Study population:** The participants included boys and girls in the age group of 6-12 years attending schools from class 1 to class 6.

**Inclusion and Exclusion criteria:** The study included children belonging to both sexes in the age group of 6-12 years studying in class 1-6. Parents and children who knew both English and Malayalam were included in the study. Children having medical disorders, hormonal problems, metabolic disorders were excluded from the study. Also, both parents & children who refused to participate in the study were excluded.

**Sampling technique & Sample size calculation:** The sample size was calculated based on the review of literature. The study was conducted in two phases in which a descriptive survey design was carried out in the first phase among 175 children studying in class 1-class 6 in the age group of 6-12 years. They were selected from two schools randomly. Initially a survey method was used to identify children as overweight and obesity.

In the first phase, the height, weight and body mass index were calculated for each child. Height of the child was measured to nearer 0.1 cm using a non-flexible inch tape measure and noted in meters. Age of the child was derived using school records. Weight was measured using a calibrated standard weighing machine. BMI: Body Mass Index is generally used for assessing the nutritional status. It is expressed as a ratio of weight in kilogram to height in meter square. The BMI was calculated using the formula: BMI = Weight (kg)/Height (m²). All the measurements were done after removing the shoes and with light clothing. Prevalence of obesity and overweight were categorized using the age and sex specific BMI cut offs for Indian children. The demographic Performa was filled in first phase of study which had details related to child age, height, weight. The study was carried out during June 2017-September 2017.

In the second phase that includes the evaluative phase where the before and after control group design was involved. The questionnaires on obesity related behavior, child eating behavior was assessed. Both child and parents were involved during the data collection. The eating habits of the children were assessed using questions asked to both parents and to the child. The sample who met the inclusion criteria from both the schools were identified. These two schools were taken as control and experiment. The control group (20/90) was taken from one school while the experimental group (26/85) was taken from other school to avoid any contamination. The experimental group was intervened with the parent focused program for a period of one month comprising of two teaching session. The post test measures were taken after a period of 3 months to evaluate the effectiveness of Parent group program.
Ethical Consideration: Ethical permission was obtained from the institutional ethical committee of Saveetha University (approval number 028/06/2017/IEC/SU dated 09 June 2017). The study was conducted after obtaining necessary permission from the Headmaster as well as the District Director of Education in the month of June 2017. As the study involved both the child as well as the parent, informed consent and assent were obtained from both.

Data Collection Strategy: Appropriate tool was developed with the help of literature to collect background information on the age of the child, gender, place of residence, type of family, the annual income of the family, and the educational level of the parent. A second tool with 35 questions was developed to frame a questionnaire on obesity-related factors such as children’s physical activity, dietary habits, television viewing patterns, and sleep patterns. Each item on the tool was given the highest score of 3 and the lowest score of 1. Both the parent and child in the control and experimental group were assessed through pre-test, and intervention was given only to the experimental group.

The parent-focused group program was planned and implemented as two sessions covering 120 minutes in each session in one month, in the presence of a pediatrician and dietitian only for the experimental group. Each parent was made aware of the focused group program and how they have to bring obesity-related behavior changes in the intervention phase. The sessions delivered knowledge on obesity-related factors and how as parents, they can manage obesity & its complications, teach healthy eating habits, understand eating behaviors, and regulate healthy lifestyle, screen viewing & sleep habits. After the intervention, the parents in the experimental group had telephonic conversations and feedback, and the post-baseline data were collected after ten months of the parent-focused group program. Hence, in the study, the parents were given regular feedback through telephonic sessions only in the experimental group, but no further feedback was provided for the control group.

Statistics: The data were expressed in mean±SE, Median, Wilcoxon Signed rank sum focused group program.

Results

Table 1 shows the prevalence of boys with overweight were 21.6% and the prevalence of obese boys were 8.2% giving an overall prevalence (OW & OB) of 29.8%. The corresponding figures among girls were 16.7%, 5.1% and 21.8% respectively. The prevalence among boys was higher compared to that among girls. However, the difference was not statistically significant. The prevalence of overall overweight & obesity in both boys and girls was found to be 46(26%) which showed an increasing rise.

Table 2 shows the pre test and post test scores of obesity related behavior of the identified children in both control and experimental group. For the 12 items in the dietary habits subscale the experimental group showed an increase in median score from 22 to 23 which is statistically significant at p<0.001 (Z=4.204, W=283 & p<0.001). For the five items in the emotions and attitude subscale there is a slight increase in the experimental group from median scores 10 to 11 which is statistically significant at p<0.001 (Z=3.76, W=78, p<0.001). Similarly for the five items in the subscale physical activity changes there is a change in the median scores of control group from 6 to 6.5 but is not statistically significant (Z=1.58, W=2 & p=.195). In the subscale physical activity changes there is a slight change in the median scores of control group from 11 to 13 at p<0.001, which is statistically significant (Z=4.218, W=276 & p<0.001).

Table 3 shows when comparing post-test scores of parameters height, weight and BMI of Control group and Experimental group. It shows that the Mean height ±SE of control group after intervention is 148±1.19 while in the Experimental group it is 134.5 ±1.19 (t=8.014 p<0.001***). Similarly the Mean Weight ±SE of control group post test is 46.6 ±1.62 while the post test Mean Weight ±SE of the experimental group is 34.9 ±1.25 at(t=5.81 p<0.001**). Further the Mean BMI±SE of Control group is 21.13 ±0.51 and Experimental group is 19.22 ±0.51 (t=2.575 p<0.013).

Table 4 shows that Mean ±SE of parameter Height in both Control group and experimental group is significant at p<0.001 taken at baseline and follow up. However the other two parameters weight & BMI show no statistical significance within the groups.

Table 5 shows Mann whitney test showing T values and P values of eight subscales of eating behavior among
children in both pre test and post test of con-exp group. The results however show statistically no significance. The sample

**Limitations of the study:** The pilot study was done with an intervention period of three months which was inadequate to observe changes in eating behavior.
