   Memchoubi Phanjoubam, Supriya Keisham, Th. Meera Devi, Seram Elizabeth Devi, Soibam Neha

65. The Effects of Deep Breathing on Blood Pressure Reduction in Elderly Hypertensive Patients at a Retirement
   Home in Surabaya
   Moch. Chaerudin, Elida Ulfiana, Erna Dwi Wahyuni

66. Molecular Typing and Phylogenetic Analysis of Cutaneous Leishmania from Iraqi Patients
   Mohammed J.S. Al-Ghabban, Nagham Y. Al-Bayati, Qasim S. Al-Mayah

67. Role of Endoscopic Ultrasound Guided Fine Needle Aspirate for Evaluating Lesions in or Adjacent to
   Gastrointestinal Tract: A Single Tertiary Care Center Experience
   Mohanned H. Alwan, Alaa Hussein Alwan, Ihab Saeed Ahmed

68. Level of Knowledge and Awareness of Halitosis in the Dental Medicine Students
   Muhammad Arya Rizkianto, Novita, Cindy Shavia, Gempita Anargia, Farah Maulidiya Titani, Titian Fauzi
   Nurrrahman, Regina Purnama Dewi Iskandar

69. Awareness and Performance of Paramedics in Preventing toward Middle East Respiratory Syndrome Coronavirus
   Infection
   Myeong-Jeong Chae, Jong-Geun Yun, Boyoung Kim

70. Lemon Extract as an Alternative Etching Materials on Composite Resin Restoration Against Shear Strength
    Nadia Putri Syawalia, Endanus Harijanto, R. Moh. Yogiartono
71. Triangular Interaction of Decision Making for Breastfeeding a New Infant-Centered Care Model
Nikmatur Rohmah, Ah Yusuf, Rachmat Hargono, Saiful Walid, Purgaryantyas Subyantoro, Evi Triwahyuni, Rahayu Sri Wahyuni

72. Data Security and Privacy of Individuals in Data Mining: A Critical Analysis of Data Mining in India
Nilanjan Chakraborty, Yogesh Mishra, Prattyay Chakraborty, Debalina Sengupta, Aakash Bag, Ankita Mishra

73. Effectiveness of Exercise Regimen on Quality of Sleep in Patients with End Stage Renal Disease on Maintenance Haemodialysis
Nishtha Mehta, Meena Kumari, Rubal, Sakshee Sharma, Sudhir Kumar

74. The Effects of Service Payment Retardation from National Health Insurance Claim to the Employee’s Work Motivation According to Theory of Frederick Hezberg in the Hospital
Nita Indah Lestari, Sri Hernawati, Sebastiana Viphindrartin

75. Hyperpigmentation of Skin (Melasma) with Solitary Oral Pyogenic Granuloma Lesion: A Case Report
Nitin Tomar, Apekshaghai, Mayur Kaushik, Mevish Saleem, Mrinalini Agarwal

76. Profile of Medico Legal Autopsies at Tezpur Medical College & Hospital, Tezpur, Assam: A One Year Retrospective Study
Nitu Kr. Gogoi, Raihan Uddin Ahmed, Nabajit Barman, Diganta Thakuria, P.K. Thakuria

77. Viability Test of Water Hyacinth Leaf Extract (Eichornia Crassipes) on Human Gingival Fibroblast Cells
Noer Ulfah, Agung Krismariono, UllyNafisah Wardi, Ariska Dinaryanti

78. The Relation of Mixed Marketing with Patient Loyalty in Syekh Yusuf Gowa General Hospital
Nurfardiansyah Burhanuddin

79. Cardiac Ventricle Laceration in a Battered Child: A Case Report
Pawan Kumar Shukla, Swapan Debarma, Ashish Ramesh Bhute

80. Biomarkers in Orthodontics: An Overview
Poonam Agrawal, Dhirja Goel

81. Policy Study and Stunting Prevention in Surabaya
Queen Khoirun Nisa Mairo, Sherly Jeniawaty

82. Estimation of Skin Radiation Dose from Common Radiographic Examinations: A Preliminary Study to Establish Diagnostic Reference Levels (DRLs)
Raed Mohammed Kadhim M. Ali, Hussien Abid Ali Bakir Mraity, Ban Hassan Hadi, Sarah Hamed Dana

83. Sex Determination from Lower End of Humerus Using Morphological Traits in Indian Population
Rajan S., Surangama Chakraborty

84. A Revolution in Health Care Sector Through Data Sciences
Rajaram, Amit Kumar Pandey, Sanjay Saproo, Sanjeev Bansal

85. Differences of Gender in HIV- Risky Sexual Behavior among Adolescents and Parental Support in Luwuk City
Ramli, Fitrianity S. Lanyumba, Marselina Sattu, Winnie Tunggal Mutika, Erni Yusnita Lalusu, Ahmad Yani
86. Effect of Marital Status on Completeness of Antenatal Care Visits among Childbearing Age Women in Rural Indonesia

Ratna Dwi Wulandari, Agung Dwi Laksono, Zainul Khaqiqi Nantabah

87. Retrospective Analysis of Pattern of Injuries in Road Traffic Accidents: An Autopsy Based Study

Ravi Kumar Sharma, Himangshu Das, Anurupa Choudhury

88. The Correlation between Bacteria and Parasite Patterns on Flies with Prevalence of Fly Vector-Borne Disease at the Market and the Landfill in Jember District, Indonesia

Riza Indira Fadillah Zam Zam, Erma Sulistyawiningsih, Ancah Caesarina Novi Marchiant

89. Effect of Malaria Parasite on Haematological Parameters: An Institutional Experience

Roopak Aggarwal, Vineet Chaturvedi, Sanjeev Kumar Singh, Pinki Pandey, Savita Agarwal, Jaspinder Singh

90. Biofilm Bacteria and Cholesteatoma on Chronic Suppurative Otitis Media

Rosydiah Rahmawati, Nyilo Purnami, Artono

91. Impact of Health Care Sector on Indian Economic Growth and Challenges: A Socio-Legal Analysis

Rubi Talukdar, Prabir Kumar Pattnaik

92. Effect of Trunk Extensor Muscle Fatigue on Postural Stability in Women Undergone Lower Segment Cesarean Section

Rutuja Malavde, Amrutkuvar Rayjade

93. Influence of Dual Task Training in Indoor Versus Outdoor Environment on Physical Function and Social Activity among Elderly

S. Anandh, G. Varadharajulu, Mahendra M. Alate

94. Emotional Intelligence Factors Influencing on Interpersonal Problem of Adults

S. Antonysamy, J.M. Asgarali Patel, A. Velayudhan

95. The Difference of Dental Anxiety Level on Healthcare and Non-Healthcare Students

Sarah Amelia, Devi Listiani, Az Andini F., Natalia Monique J, Awalia Aprilizahrani P., Zakiya Rizki S., Retno Palupi

96. Social Impacts of Child Marriage in Grobogan Regency, Central Java Province, Indonesia

Saratri Wilonoyudho, Lutfi Agus Salim

97. Profile of Death Due to Thermal Burns: A Retrospective Study

Shailendra Patel, Jitendra Singh Tomar, Ankit Pandey Jain, Poornima Patel

98. Profile of Medicolegal Autopsies Conducted at Bundelkhand Medical College, Sagar (M.P.)

Shailendra Patel, Jitendra Singh Tomar, Ankit Pandey Jain, Poornima Patel

99. Assessment of the Knowledge and Attitude of Mothers Regarding Oral Hygiene of Under Five Children in Selected Rural Areas of Ambala, Haryana

Shalini, Vijyeta Bhasin, Soniya Thakur, Simran Bhatt, Techi Sonika, Twinkle

100. Load of Firearm Cases in Male at SMS Medical College, Jaipur

Shanti Lal Pargi, Lovekumar Bhagora, Deepali Pathak, R.K. Punia, Rohit Kumar Meena
101. Epitopes Prediction of PfEMP1-DBL2β Recombinant Protein from Indonesian Plasmodium Falciparum Isolate for Malaria Vaccine Development
Sheilla Rachmania, Erma Sulistyaningsih, Anak Agung Istri Ratnadewi, Rosita Dewi

102. Effectiveness of Video Assisted Teaching on Testicular Self Examination
Shenbagapraba N., Sathu Roslin, Thivya N., Yaga Jeyanthi M., L. Lakshmi

103. Knowledge, Awareness and Attitudes About Research Ethics among Faculty and Post Graduate Students of the Medical & Dental Professionals in Professional Institutions
Shivananda S., Vidya G. Doddawad, Ravi Vaswani

130. Clinical Comparative Study for Some Biochemical Changes in Sera of Pregnant with Iron Deficiency Anemia .... 710
   Ahmed Ghitheeth Mathwar, Raid M.H. Al-Salih

   Haitham Noaman Al-Koubaisy, Jalil Ibrahim Saleh, Mothana Ali Khalil, Najoh Kadhim, Hadeer Naeem, Nawar Sahib Khalil

132. Evaluation the Effect of** Blastocystis Hominis** to the Levels of Ghrelin, Growth Hormone and Lipoproteins in Sera of Patients with Gastrointestinal Manifestations in Baghdad ..........................................................................................721
   Wasnaa Abdulmaged Hasan, Aysir Saleh Mohammed Al-Samarrai

133. Histological and Physiological Effect of Turmeric (Curcuma Longa) on Liver, Pancreas and Kidney ..........726
   Muna Hussain Al-Aameli, Rajaa Ali Moheiseen Al-Taee, Kadhim S. Kadhim

134. Backache among Different Specialties in Dentistry (An Over World Survey) ........................................732
   Mohammad Munthir Abdulrazzaq

135. Stye, Bacterial Eye Infection among the Students of the Technical Medical Institute, AL-Mansour ..........739
   Mohammed Abed Jawad, Taghreed Khudhur Mohammed

136. Uterine Artery and Endometrial Vascularity Doppler Indices and Pregnancy Outcome in ICSI ..............744
   Asmaa Abd Al Razzak Hassan, Huda Ali Hussaini, Lubna Ammer Al-Anbari

137. Detection of Epstein–Barr Virus and JC Polyomavirus in Gastric Cancer Tissue by Quantitative Real Time PCR...
   751
   Asmaa B. Al-obaidi, Bashar A. Abdulhassan, Dalya B. Hanna, Noora M. Kareem, Haidar A. Shamran

138. Study of the Level Total Antioxidant Capacity in Urinary Stones Patient ..................................................757
   Marwa Amer Ali, Alaa Hasan Kadhim, Safa Amer Ali, Faten Abdul Ghani Hammoudi

139. Association of LPL Gene Variant and Serum LPL Level with Ischemic Stroke in Iraqi Population ..........761
   Jaafer Mukdad Mohmmed, Moaed E. Al-Gazally, Mushtak A. Wtwt

140. The Effect of Vaccinated and Unvaccinated Bridles Flocks on Identification of** Avian Metapneumovirus (aMPV)**
   and** Ornithobacterium rhinotracheale (ORT)** in the Middle Euphrates Region in Iraq ..................................767
   Al-Hasan Baraa A., Abdullah O. Alhatami, Hussam Muhsen

141. Comparative Analysis of Tumor Infiltrating T Cells and Serological Markers between MIBC and NMIBC Patients .................................................................770
   Ifad Kerim AlShibly Ammad Hasan Mahmood, Fouad Qasim Jubair Al-Zayadi

142. Prevalence of Foreign Bodies in the Ear, Nose and Throat in Alramadi City .............................................776
   Omar Malik Bargas, Qays Jaafar Khalaf, Omar Abdulqader Ajaj

143. Ultrasound Value in Diagnosis of Acute Appendicitis at Al-diwaniyah Teaching Hospital-Iraq ..............780
   Shaimaa A. Kadhum Al-Zubaidi

144. Association of Syndecan 4 and Osteocalcin with Application of BMP2 and BDNF in Bone Healing of Osteoporotic Rats .................................................................................................................784
   Lobna K Al-khafaji, Athraa Y Al-hijazi, Noor Natik Raheem
145. Urinary and Serum N-acetyl B-Glucosaminidase as Biomarkers of Albuminuria in Patients with Type 2 Diabetes 791
   Ahmed Mahdi Daham, Raid AL-Timimi

146. Impact of Dyslipidemia and Body Mass Index (BMI) in Development of Osteoarthritis (OA) in Iraqi Patients 796
   Mohammed I. Hamzah, Moazaz Rashad Saed, Muhammed Abdul-Gabar Hamoodi Aldabagh, Hadeel Sameer Abd Alwahab

   Ahmed Obaid Rashid, Yagoob Yousif Ibrahim, Ayad Khalf Marzoog
159. The Effect of the Comparative Marital Competition Method on Developing the Most Important Motor Abilities and Learning the Technical Performance of the Students’ Effective Shot Putting .........................................................879
Ebtighaa Mohammed Qasim, Rami Abdul Ameer Hassoon, Anjed Hashim Mohammed

160. Calcium Administration to Improve Parturition in Dairy Cows .................................................................885
Murtadha A. AL-Mudhafar, Majed Abed Talal Al-Fatlawy, Morteta H. AL-Medhiy, Nabeel Alsharifi, Ghadeer Sabah Bustani

161. Strong Evidence of Highly Pathogenic and Low Pathogenic Avian Influenza Viruses in Domestic Poultry in Iraq. 890
Karar Mohammed Abdul-Sada

162. Assessment of the Relationship between Obesity and Female Breast Carcinoma in Imamein Kadhum clinic Medical City ..................................................................................................................................................904
Anees K. Nile, Alnahrain, Mohammed A. Hamdawi, Alaa Maan Nassier

163. Impact of Age at Starting Cysteamine Therapy on Serum Chitotriosidase in Cystinotic Iraqi Children.........911
Zainab Ahmad, Shatha H.A., Hala Sameh

164. Asthma Knowledge and Behaviors among Parents of Asthmatic Children Attending Paediatric Hospitals in Mosul City .................................................................................................................................................917
Najlaa Ibrahim Al-Sammak, Safwan Hashim Jamel, Ahmed Talib Ibrahim

165. Detection of Parvovirus B19 in B-thalassemia Major Patients by Serological and Molecular Method ..........924
Rand Rasid Abdul Sadah, Huda Dhaher Al-marsome

166. Prevalence and Clinical Features of Ocular Adenoviral Infection among Patients Attended to Ibn-Alhaitham Teaching Eye Hospital in Baghdad, Iraq: A Molecular Study ........................................................931
Mohamed Abdallah Mohammed, MothanaAli Khalil, Rafea Allawi Fayyadh

167. Hepatitis B Virus Reactivation in Patients Receiving Chemotherapy and Immunosuppressive Therapy ........938
Israa Hameed Al-shareef, Ghanim Aboud Jaber Al-Mola, Dakhel Ghani Omran

168. Microphages Count and Activity, a Comparison Study between Radiotherapy Technicians and other Hospital Occupational ........................................................................................................................................941
Weam Saad Al-Hamadany

169. Alternative Preservatives of a “Nisin A” with Silver Nanoparticles for Bacteria Isolation from the Local Food Markets of Baghdad City ........................................................................................................................................945
Mais E. Ahmed, Alaa R. Kadhim

170. Immunological Study of Some Pathogenic Bacteria Isolated from Patients with Chronic Kidney Failure ........952
Areej Hamad Hassan, Muthana Badeea Farhan

171. Assessment of Some Inflammatory Biomarkers in Children with Febrile Seizure and Bacterial Meningitis .....957
Eman Saadi Saleh, Sarah Hashim Mhaibes, Mustafa Shihab Al-Anbaki, Sonia Imad Naser

172. Evaluation of the Genoprotective and Cytoprotective Activity of Vitamin K-7 Against Doxorubicin in Bone Marrow Cells and Spleen Cells of Rats ................................................................................................................................963
Ali Faris Hassan, Ruaa Fadhil Abbas, Nada Nafi Al-Shawi, Intesar Tarik Numan
173. Assessment of Serum Interleukin-4 and Filaggrin Protein in Patients with Atopic Dermatitis ........................................969
   Aseel Kasim Kareem, Alaa Jawad Hassan

174. Synthesis of New Drug Carriers of Metronidazole as Antifungal Agents ..........................................................974
   Naeemah J. Al-lami, Zaina Jassim, Yasmeen H. Muhamad, Mahdi Jaffer

175. Evaluating of Serum Electrolyte Changes in Chronic Renal Failure Pre and Post Dialysis .................................980
   Wafaa H. Ajam

176. Retinoic Acid Teratogenicity in Mouse Embryo .................................................................................................984
   Alghareeb Maha R., Alani Louay M., Alhadad Nedhal I.

177. Dipeptidyl Peptidase 4 in Women with Polycystic Ovarian Syndrome ..............................................................991
   Sura Salah Hadi, Shyamaa Z. Nada, Mousa Mohsin Allaq

178. CT Scan Parameters as Predictor of Ureteric Stone Impaction and Ureteric Injury Post Laser Lithotripsy ..........999
   Laith Amer Al-Anbary, Firas S. Alquraishi

179. Risk of Incident Rheumatoid Arthritis Related to Anemia and Associated with CRP ........................................1004
   Maryam Kadhim Al-Shemery

180. The Prevalence of Metabolic Syndrome and its Complication in Patients with the Blood Disorder ....................1010
   Rusul Ali AL-Masaaodi, Jasim M. Saleh

181. Effectiveness of Health Education Intervention Regarding Family Planning Among Iraqi Women Attending
   Primary Health Centers in Baghdad During 2019 .................................................................................................1016
   Lujain Anwar Alkhazrajy, Sarah Waleed Mizher, Alak Mohammed Alabayachi

182. The Correlation of Epicardial Fat Thickness with Ischemic Heart Disease among Patients Consulting Merjan
   Medical City in Babil .........................................................................................................................................1022
   Hassan Salim Aljumaily, Abdulhamza Rajooj Hmood

183. Comparative Evaluation of Efficacy of Three Port Versus Standard Four Port Laparoscopic Cholecystectomy .....1029
   Nitin Nangare, Aniket Survase, A.Y. Kshirsagar

184. Assessment of Psychiatric Illness in Burnt Patients ............................................................................................1032
   Sharad Vasant Kshirsagar, Ajay Deshmukh

185. Evaluation of Prevalence of Depression and Anxiety among Breast Cancer Patients .........................................1035
   Sharad Vasant Kshirsagar, Ajay Deshmukh

186. Evaluation of Incidence of Adverse Events Associated with C Section ............................................................1039
   Sanjaykumar Patil, Shivaji Raje, Hiren Kathiria, Puja Priya

187. Occurrence and Dissemination of Antimicrobial-Resistant Salmonella Isolated from Diarrheic Stool Samples of
   Human .........................................................................................................................................................1042
   Abeer Mohammed Ali Al-garawyi

188. Impact of Serum level of L-Carnitine on Chitotriosidase in Women with Gestational Diabetes Compared to T2DM
   Pregnant & Non Pregnant Iraqi Women .........................................................................................................1045
189. Socio-Epidemiological Study of Infectious Skin Diseases among School Children in Heet District, Iraq........1057
   Thamir Abdulmajeed Alkubaisy, Jalil Ibrahim Saleh Al-Mashhadani, Naeem Naser Abed Alhayani, Jafar Sadiq Obeid Al-Kubaisy

190. Comparative Study between Recurrent Tonsillitis and Tonsillar Hypertrophy Based: Histopathological Grading and Hematological Parameters in Children.................................................................1063
   Halah Amer, Sahar A.H. Al-Sharqi, Firas H. Bairawi

   Israa Abdul Ameer Al-Kraety, Sddiq Ghani Al-Muhanna, Aaya Hamid Al-Hakeem

192. Ultrastructure Study of Hydatid Cyst Isolated from Sheep Exposure to Tendazol and Bendaziole...........1075
   Fatimah H. Al-Ataby, Jalal Y. Mustafa, Suzan A. Al-Azizz

193. Association between ki67 and PR Expression in Grades of Meningioma and its Prognosis.....................1080
   Sarah Ali Abed, Roaa Salih Mahdi, Ali Adnan Jabbar, Ali Mohammed Khaleel, Suha Suhiel Hussein

194. Distinguishing Exudative from Transudative Effusion by Using Pleural Fluid Cholesterol and Bilirubin in Comparative Study to Light’s Criteria .................................................................................1087
   Hanaa Jabbar Ismail, Haider Abdulhameed Alqaraghuli, Hashim Mahdi Hashim

195. Determine the Effect of Polymorphisms of and IL23R Genes on in Psoriasis in Babylon Province........1093
   Dheyaa B. Mohammad, Thana M. Alswedi, Wisam AliAwadh

196. Intratellar Electromechanical Conduction Delay by ECG P-Wave and Echocardiographic Tissue Doppler Imaging for Diabetics Attending Merjan Teaching Hospital, A Comparison Study.........................................................1099
   Jabbar Sirhan Hassan, Safaa J. Kadhim, Oday J. Al-Salihi

197. Religious Character and Service Innovation toward the Improvement of Sustainable Quality of Primary Health Services in South Sulawesi..................................................................................................................1106
   Muhammad Tahir, Ridwan Amiruddin, Sukri Palutturi, Fridawaty Rivai, Lalu Muhammad Saleh

198. Correlation of Glycated Haemoglobin with Netrin-1 and High Sensitive C-Reactive Proteinin Type 2 Diabetes Mellitus Patients .......................................................................................................................1113
   Erika Rosaria, Nurahmi, Liong Boy Kurniawan

199. Awareness Mental Health During Pregnancy in Practice Midwife of Bogor, Jawa Barat........................1118
   Nurul Husnul Lail, Rizanda Machmud, Yusrawati, Adnil Edwin

200. Decentralization Implementation of HIV/AIDS Programs in the Province of South Sulawesi..................1126
   Darmawansyah, Muhammad Alwy Arifin, Muh. Yusri Abadi, Muhammad Al Fajrin, Anwar Mallongi

201. Nalysis of the Use of Bags and Bottle Plastic Containers and Drug Compliance Based on Drug Swallowing Supervisor (DSS) in Reducing the Risk of Pulmonary Tuberculosis Transmission .................................1131
   Sorimuda Sarumpaet, Evawany Aritonang, Lina Tarigan, Syarifah, Anwar Mallongi

202. The Analysis Quality of Inpatient Room Service to Patient Satisfaction (Case Study of Saparua General Hospital) .............................................................................................................................................1138
   Marinus Hanry Siahainenia, Amran Razak, Indar, Muhammad Alwy Arifin, Arifin Seweng, Muh Asdar, Anwar Mallongi
203. Ultravioletlight Application Model in Lowering Germs on Food Snacks Atelementary School in Makassar ...1142
   Zaenah, Rafidah

204. Evaluation of Drug Planning and Procurement at the Pharmacy Installation of Regional General Hospital Dr. M. Haulussy Ambon ............................................................1150
   Marchine Arsia Misi, Muhammad Alwy Ariefin, Sukri Palutturi, Indar, Ridwan Mochtar Thaha, Furqaan Naiem,
   Muh. Yusri Abadi

205. Analysis of the Effect of Access Dimensions and Waiting Times on Satisfaction of Hospital Inpatients Prof. Dr.
   J.A. Latumen Ambon Level III Hospital.................................................................1157
   Stefanus G. Manuhuwa, Sukri Palutturi, Amran Razak, Darmawansyah, Saifuddin Sirajuddin, Ridwan Mochtar
   Thaha, Anwar Mallongi

206. Evaluation of the Ability Family Planning Center Officers in the Youth Counseling Information Center Program in
   South Buru Regency..................................................................................1163
   Samna Detek, Sukri Palutturi, Muhammad Alwy Ariefin, Amran Razak, Arsunan Arsin, Nurhayani, Anwar Mallongi

207. Analysis Risk Factors of Stunting Incidence on Toddlers in the Working Area of Porto Haria Public Health
   Center........................................................................................................1169
   Zacarias Latupeirissa, Indar, Amran Razak, Muhammad Alwy Ariefin, Andi Zulkifli, Muh. Yusri Abadi, Anwar
   Mallongi

208. Study of Covid 19 Occurrence in Relation to Masks and Hand Sanitizers Use........................................1175
   Anwar Mallongi, Agus Bintara Birawida, Noer Bahri Noor, M. Fais Satrianegara, Wa Ode Fifin Annur, Fatmawati

   in Ambon City of Maluku Province ..............................................................1181
   Vonny Bathseba Leatemia, Darmawansyah, Amran Razak, Sukri Palutturi, Anwar Mallongi, Masni, Dian Saputra
   Marzuki

210. Effects of Different Antihypertensive Drugs on Systolic and Diastolic Blood Pressure, Heart Rate and Lipid
   Profile........................................................................................................1187
   Khalid Abdalstar Hussein, Wisam Abd Abbas Abd Majeed, Zahra Salih Andulnabi, BintAlhuda, Ahmed Habeeb
   Jalil

211. Effect of Lifestyle, Dietary Pattern, School Based Weight Control Program on Overnutrition among Schoolchildren
   in the Northeast of Thailand .................................................................1193
   Pannee Banchonhattakit, Surachai Phimha, Petchurut Sirisuwan

212. Neonatal and Birth Complications in Adolescent Pregnancy of Tikrit City ........................................1199
   Marwa Thair Abass, Massriyah Rashad Hussein

213. Dental Faculty’s Knowledge and Attitude Regarding Covid 19 Disease in Qassim University, Saudi Arabia 1202
   Asma Munir Khan, Shazia Nawabi, Muhammad Qasim Javed

214. The Effects of Model IVS 2 MAP Progesterone, eCG, GnRH, and PGf2α on Pregnancy of Tail Fat Ewes Strain
   Sapudi Islands Subjected to A Short-term Synchronization of Estrus ......................................................1211
   H.A. Hermadi, M. Hariadi, H. Ratnani

215. Sociodemographic Profile of Thyroid Masses: A Cross-Sectional Study........................................1216
   Basumatari Bharati, Borah Pollov, Mahanta Putul, Hazarika Devid
16. Ultrasonographic Evaluation of Thyroid Masses with Pathologic Correlation
   Basumatari Bharati, Hazarika Devid, Mahanta Putul, Borah Pollo

17. Effect of Alcohol Consumption Severity on Oral Health Status in Relation to Salivary Parameters, Smoking and Tooth Wear in Baghdad, Iraq
   Ali Hadi Fahad, Rafeef Ahmed Mohamed, Noor Mohammed Hadi Layedh

18. Effects of Stress, Depression, Self-efficacy, and Social Support on Quality of Life of Community Dwelling Elderly with Chronic Diseases
   Hee Kyung Kim

19. Detection of Class 1 Integron-intI1 Associated with Neomycin and Ciprofloxacin Resistant Bacteriain Different Spots of Bay Receiving Sewage water
   Saad Hameed Abood, Saif Talib Jasim, Zaynab Khorsheed Rasheed, Shadman Tariq Sadiq

20. The Effectiveness Meaning of Life and Antiretroviral Therapy (Metart) Modul to Improve Antire to Viral Therapy Adherence among Newly Diagnosed HIV/AIDS: Pre Intervention Survey
   Yafi Sabila Rosyad, Firmina Theresia Kora, Rika Monika, Salis Miftahul Khoeryah, I. Putu Jurni Andika

21. Triple Drug Therapy with Proton Pump Inhibitor a Better Option for Helicobacter Pylori Eradication
   Lamture Y.R., Thavendra Jaglal Dihare, Varsha Gajbiyi, Gode Dilip

22. Correlation of Helicobacter Pylori Infection with Acid Peptic Disorders
   Thavendra Jaglal Dihare, Lamture Yashwant R., Varsha Gajbiyi, Gode Dilip

23. Increased Paediatric Screen Time During Pandemic: A Cause of Concern to Child Health
   Yogita Shrivas, Sujata Shamkuwar, Radha Andhare, Ashish Varma

24. Indirect Impact of Covid-19 Lockdown on Society and Environment
   Radha Andhare, Yogita Shrivas, Shubhada Guru, Abhishek Joshi

25. Participation in Community-Based Road Safety Program Associated with Motorcycle Helmet Use in Udon Thani Province, Thailand
   Surachai Phimha, Attapong Rittitit, Nakarin Prasit, Nathakon Nilnate, Prachak Bouphan

26. Dermatological Manifestations in Patients of Chronic Kidney Disease (CKD)
   Bansal Charu, Varshney Anshul

27. The Predictive Power of Moral Intelligence on Professional Commitment of Nurses
   Madineh Jasemi, Hossein Habibzadeh, Rasool Gharaaghaji, Parivash Karimi

28. The Development of Early Detection Tool for Stunting Prediction
   La Banudi, Bedjo Santosso, Purnomo Leksono, Matius Rantesalu, Sukri Palunturi

29. Factors Affecting Subjective Well-Being of the Middle-Aged Class
   Hae Kyung Chang

30. E-Learning Innovation in Indonesia: Journal Sharing of Critical Care (JSCC) for Nursing Students in the Pandemic Covid-19
   Heru Suwardianto, Vitaria W.A.
231. Regional Exposure to Air Pollution and Health Behaviors as a Risk Factor for Suicide Attempt: The Seventh Korean National Health and Nutrition Examination Survey (KNHANES), 2016-2017, Korea Centers for Disease Control and Prevention ............................................................ 1305
   Jung Nam Sohn

232. Tuberculosis in Baghdad, Iraq 2012-2016: Retrospective Study .................................................. 1311
   Ali Kareem Durib, Ekterina Valerievna Blinova

233. Immediate Induction of Labour Versus Expectant Management (Waiting for 24 Hours Before Induction) Forprelabour Rupture of Membranes at Term .............................................................. 1315
   Muna Kasim Mahmood, Batool Abdzaid Alsultany

234. Effects of E. Coli Infection on Kidney Function Tests in Experimentally Inoculated Rats .............. 1319
   Mundher Jabbar Irsan AL_Okhedi, Thaar Mohammed Najim, Bahjat Fakhri Mahmood Al-shammari, Mustafa Salah Hasan, Marwa Raad Jead

235. The Effectiveness of Audio-Visual Education on Lactation Management and Choking in Mother with Baby in Pandemic Time Covid-19 ................................................................. 1323
   Heru Suwardianto, Rimawati

236. Analysis of Worring among Lecturers of Indonesian Bethel Theology on Covid-19 ....................... 1330
   Gernaida K.R. Pakpahan

237. Evaluation of Health Services System Process Based on Island Clusters (Case Study in Tanimbar Island District) 1338
   Juliana Chatarina Ratanak, Muhammad Alwy Arifin, Darmawansyah, Amran Razak, Muhammad Syafar, Muh. Yusri Abadi, Anwar Mallongi

238. Analysis of Serum Vitamin D and Major Histocompatibility Complex Class I-Related Chain a (Mica) Levels in Patients With Breast Carcinoma ................................................................. 1343
   Asvin Nurulita, Budi Mulyono, UmiSolekhah Intansari, Mansyur Arif

239. Critical Overview of Adolescent Suicides in India; A Public Health Concern ................................. 1351
   Ashwin Mathew, Suja M.K., V. Priya

240. How are Government’s Liability in Indonesia and Netherland?: Juridical-Normative Study with a Comparative Approach .............................................................. 1359
   Firzhal Arzhi Jiwantara, Karmal Maksudi

241. Mediating Effect of Self-Leadership in the Relation between Job Commitment and Job Competence among Care Workers in Korea ................................................................. 1364
   Hee Kyung Kim

242. Periodic Acid Schiff (PAS) Staining: A Useful Technique for Demonstration of Carbohydrates ......... 1370
   Swapna Shedge A., Priya Roy, Ajay Shedge, Megha A. Doshi

   Tirna Purkait, Sangeeta Pandey

244. Analysis of Injury Pattern & Forensic Medicine Management in a Case of Bomb Blast Injury ............. 1381
   Toshal Wankhade, Deepak Bhagwat, Ambedkar Ranjan, B.H. Tirpude, P.N. Murkey, I.L. Khandekar
245. An Autopsy Study of Brought Dead Cases at a Tertiary Care Hospital in Port Blair, Andaman and Nicobar Islands..................................................................................................................................................................1386
   Udayashankar Yadiyapur, A.K. Malle, Deepak H.D’Souza

246. Deleted.................................................................................................................................................................................1392

247. Efficacy of Neural Mobilization and Cervical Stabilization in Cervicobrachial Pain: A Randomized Controlled Trial .....................................................................................................................................................................1398
   V. Rajalaxmi, R. Lavanya, K. Kirupa, S.M. Divya Mary, M. Yuvarany

248. A Study to Compare the Effectiveness of Sensorimotor Training and Balance Exercise in Subjects with Neck Pain ......................................................................................................................................................................1404
   V. Rajalaxmi, K. Varalakshmi, S. Meena, I. Deepa, C. Ishwarya, S. Latha

   Vaibhav Anjankar, Ashish Anjankar, Anil J. Anjankar

250. Age Estimation by Different Techniques of Dentin Translucency: A Literature Overview .................................................1416
   Vidhya A., Nagabhushana Doggalli, Sushma Rudraswamy

251. Study of Fingerprint Pattern: A Cross Sectional Study ........................................................................................................................................................................1421
   Vijay Kumar Ag, Suresh J.

252. A Study to Re-Design the Lay Out for Tertiary Level Health Care Mortuary ........................................................................1424
   Vishva Deepak Bijawat, Ankit Kumawat, Vipin Gupta

253. Determinant Analysis of Factors Influencing Tuak Consumption Culture on Guardian Earth Through the Leininger Model Sunrise Approach Theory ........................................................................................................................1429
   Wahyu Tri Ningsih, Titik Sumiatin

254. Personal Hygiene Relationship with Typhoid Fever Occurrence in Gowa Regency, Indonesia ........................................1434
   Wahyuni Sahani, Syamsuddin S., Inayah, Muspida, M. Askar

255. The Analysis on Input and Process to K4 Achievement in Bondowoso District ................................................................1440
   Widya Choirun Nisak, Ancah Caesarena Novi Marchianti, Ristyana Widi Endah Yani

256. Demineralisation Resistance by Bonding Agent Containing Calcium Oxide-Nanoparticles ...............................................1446
   Suhad Jabbar Hamed Al-Nasrawi, Wijdan Abdulameer Kadhim, Bushra Habeeb Al-Maula, Abtesam Imhemed Aljdaimi

257. Environmental and Personality Influences on Nurse Discipline Public Health Center .................................................................1451
   Suprapto, Trimaya Cahya Mulat, Nur Syamsi Norma Lalla

258. Inhibition Activity of Lemongrass Extract (Cymbopogoncitratus) to the Growth of Supragingiva Plaque Bacteria Colony ........................................................................................................................................................1455
   Wimardian, S.M., Bargowo L., Savitri I.J.

   Abirami P., Suseelal T., Jelin Elizabeth G., Dr. C. Kanniammal
260. Salivary Levels of Interleukin-6, Interleukin-8 and Tumor Necrosis Factor-alpha in Smokers Aged 35-46 Years with Dental Caries Disease

Bayan Jebur Hussein, Hawraa Noori Atallah, Najlaa Abdulameer Ali AL-Dahhan

261. Pandemic Corona Virus and Policy of Forest Resources Conservation

Aries Isnandar, Absori, Harun, Natangsa Surbakti

262. Redefining Dental Practice During and Post-COVID-19 era: A Review

Bharath Rao K., Saurabh Kumar, Madhumitha Natarajan, Arul Amalan, Runki Saran, Pradeep S.

263. Prevalence of Hearing and Vision abnormalities in School Children in Udupi District Karnataka

Vasanthalaxmi K., Manjula S.D., Benita, Sindhu, Suchetha P.K.

264. Perception of Dental Students about Tooth Carving in Dental Education at a Tertiary Level Health Care Facility

Diksha Singh, Pragya Pandey, S. Kudva, Manish Kumar Singh, Shaleen Chandra

265. Case Report on Oligohydramnios

Lalhriatpuii, Manjusha Mahakalkar, Manoj Patil

266. Case Report on Full Term Normal Delivery

Pradnya Gavhale, Shalini Moon, Manoj Patil

267. Case Report on Obsessive-Compulsive Disorder

Samuel Vanlalpeka, Jaya Gawai, Manoj Patil

268. Yash Scoring System in the Diagnosis of Acute Appendicitis

Yeshwant Lamture, Rahul Y. Netragaonkar, Varsha Gajbhiye, Ranjeet Ambad

269. Tzanakis Scoring System in Acute Appendicitis Concern to Indian Population

Yeshwant Lamture, Rahul Y. Netragaonkar, Varsha Gajbhiye, Ranjeet Ambad

270. Comparison Between the Tzanakis Scoring System and Yash Scoring System in the Diagnosis of Acute Appendicitis

Aditya Mundada, Yeshwant Lamture, Varsha Gajbhiye, Ranjeet Ambad

271. Euthanasia: Ethical or Non-Ethical

Aakansha Saraf, Ishaan Gupta, Pooja Chaudhuri, Nitesh Malhotra, Aksh Chahal

Effects on Quadriceps Muscle Strength Using EMG in Supervised vs Unsupervised Post-Operative Anterior Crucial Ligament Reconstruction

Sumit Saxena¹, Aparna Sarkar², A.K. Naik³

¹PhD Scholar, Amity Institute of Physiotherapy, Amity University Uttar Pradesh, India, ²Professor Physiology, Amity Institute of Physiotherapy, Amity University Uttar Pradesh, India, ³Professor, Department of Orthopedic, Dr. RML Hospital, Delhi, India

Abstract
Anterior crucial ligament (ACL) injury is one of the most common ligament injuries in the knee. The ACL injury is the anterior ligament tear or sprain (ACL). The objective of this paper is to compare the effectiveness, recovery rate and the variance in the affected and non-affected limbs muscle strength/activation potential readings of both knees in supervised v/s unsupervised groups of patients after undergone ACL reconstruction surgery at RML Hospital Delhi. The participants were divided into two groups (A-Supervised, and B-Unsupervised) through random sampling. The supervised exercise in group a performed according to the WILK protocol at RML hospital, and un-supervised group B performed the same WILK protocol at home. The method adopted for this study is to compare both Pre-operative and Post-Operative quadriceps(vastus medialis and vastus latralis) EMG readings of the respondents has been recorded using NEURON SPECTRUM 5 using NEUROSOFT Neuro-MEP.NET software at RML Hospital Delhi. The study findings indicated the significant difference in recovery rate as well as the difference in between supervised v/s unsupervised groups i.e. The average pre-operative-VM values of EMG- affected for supervised was 97.1µV, and for unsupervised was 94.2µV and the average post-operative-VM values of EMG for supervised was 130.1µV (36% variance), and for unsupervised was 95.2 µV (1% variance). The average pre-operative-VM values of EMG- normal for supervised was 135.8 µV, and for unsupervised was 139 µV and the average post-operative-VM values of EMG for supervised was 135.1 µV (-7% variance), and for unsupervised was 135.7 µV (-6% variance).

Keywords: Quadriceps; Muscle girth; ACL; EMG; Recovery.

Introduction
The anterior cruciate ligament (ACL) is one of the cruciate pairs in the human knee (the other being the posterior cruciate ligament). The two ligaments are also known as crossed ligaments, as they are arranged in a crossed formation. This name is appropriate as the ACL crosses the rear ligament to form an “X.” This consists of a heavy fibrous fibre which helps to regulate repetitive movement. This is done by restricting the joint’s mobility. The anterior cruciate ligament is one of the four main ligaments of the knee, providing the anterior tibial displacement of 85% of the force of the restraint at 30 degrees and the knee flexion of 90 degrees ¹–⁵. The quadriceps is critical for lowering/reducing limb control during dynamic activity and quadriceps weakness can change movement strategies, which can lead to injury. To prepare patients optimally to return to full activity it is necessary to restore full quadriceps function. Before the severity of quadriceps deficits can be effectively counteracted, however, there must be a deep understanding as to why the weakness of the quadriceps persists throughout recovery. Quadriceps disuse atrophic...
arises after the immobilization of the knee joint and may lead to the weakness of the quadriceps after ACL injury and after reconstruction. Deficits of 3% are 12–18 months post-operative, in volume 6 and cross-sectional area (CSA). Similar amounts of quadriceps atrophy were documented, although no link between atrophy and force was found. The authors concluded that the weakness of quadriceps alone did not lead to incomplete volitional muscle activation.

Atherogenic inhibition of muscles results from an activation of several different joint receptors that function upon the synapses of the inhibitory interneurons on the joint muscle motor neuron pool. Cryotherapy has more “disinhibition” or activation of the VM than the transcutaneous neuromuscular electrical stimulation community of longer-life effects. Disinhibition is defined as “a return of some measure of recruitment to baseline or preinjury levels.”

### Materials and Method

80 patients were selected for participants who volunteered to participate in recent knee surgery. Those who have undergone surgery post-operation after 3 weeks of data collection can take part.; one was omitted following secondary screening and the inclusion criteria alone were not fulfilled. Another person reported for MRI but did not report the CAR test. 80 patients were subjected to semitendinosus graft with the inside out technique of ACL reconstruction of CAL (62 males, 18 females). Medical clarification for the restoration of full activity before reconstruction was given to patients, reported pre-operation screening and assessment ACL reconstruction. Exclusion criteria as following.

1. Any lower extremity injury except recent ACL;
2. Partial or full meniscectomy;
3. Cumulative ligament damage to other ligaments ACL injury; or
4. Common heart conditions. Even pregnant women were excluded.

The volunteer respondents enrolled focused on physical therapy to facilitate postoperative knee rehabilitation through pre-established rehabilitation protocols (WILK). The subjects were seated on a padded table with both knees firmly supported against a wall. At the beginning of the session, the knee girth measurements were carried out at the upper margin of the patella. According to a 10-point visual analogue scale, the pain levels were reported explicitly to measure subjective symptoms during knee operations. At the beginning of each data collection session, a review period was conducted for all subjects. This time the subjects were familiarized with the research procedure and practised the full 3,12,15,16. Joint effusion was measured by lying supine on couch from superior pole of the patella in patients. A tag placed 1 cm near the top pole, and a tape scale was used to measure the circumference of the knee. An average of three MVIC knee extension periods with a minimum of 2 minutes rest between repeating until no torque change was detected by the investigator. and the QAF evaluation was used as a benchmark 4,17,18. The eligible patients underwent anterior reconstruction in cross-ligaments (ACL R) using inside out technique;

### Procedure:

Enrolled volunteers have registered for the study has to undergo measurement of MVIC 2 weeks Pre Operation then 12 to 14 weeks post-operation. Knee rehabilitation with pre-established recovery guidelines for outpatient physical therapy was started. The subjects were seated on a padded table with their backs against a wall completely extended on both legs. At the beginning of each data collection session, a review period was conduct. Maximum voluntary isometric contraction (MVIC) was calculated with the help of the EMG machine for all subjects. This time, the participants were familiarised with the study procedure and the overall MVIC (three to five experimental studies) performed on both the limbs normal and surgical. During three QS trials, EMG measurements of the VM, and VL from the surgical leg were obtained (Figure 1). The subjects were given verbal commands to press the back of their surgical knees as hard as possible into the padded table below their knees before they were ordered to stop. QS Test lasted 5 seconds with a rest of 30 seconds between each test. The subjects were advised to relax as the data was processed. The participants were asked to assess their pain after the three QS tests with a 10 point visual analogue scale using the verbal commands “up,” “push” and “stop,” and were instructed to stretch their knees with full effort for 5 s, with 30 s remaining between two trials. Knee extensor MVIC EMG activity was obtained with the participant lying supine on an examination bed with a foam roller (diameter15cm) placed below the knee to ensure a slight knee flexion. The pelvis was fixated to the examination bed by a non-elastic strap. The hand was placed on top of the lower leg in a distance corresponding to the width of two fingers above the medial malleolus. This procedure has been recorded with
excellent intra-class correlation coefficient (0.929, 95 percent confidence interval [CI] = 0.857–0.966). 36 All MVIC’s lasted 4 secs to allow optimum muscle activity and good verbal encouragement. Three MVIC tests with a 30-second rest between each test were conducted to avoid fatigue build-up for each muscle.

Assessment: Detail assessment was performed according to the assessment Performa measuring the mid-thigh circumference and special tests and strength of the muscle Pre-operation, and post-operation 12 to 14 weeks. WILK protocol was adopted for the strengthening exercise for both the groups for 3 months post-operative.

Quadriceps EMG recording and data analysis: NEURON SPECTRUM 5 using NEUROSOFT Neuro-MEP.NET software surface measurements are carried out. Single differential bar-electrode Ag-AgCl (DE-2.1; Delsys Inc.) were fastened to the medial malleolus of the non-chirurgical body using an electrolyte gel and an adhesive skin interface over a set inter-electrode length of 1 cm 27. EMG data are obtained for the following muscles of the surgical leg: VM (two finger-widths near the superomedial border of the patella along the expected fibre line), and vast lateralis (VL, four finger-widths next to the superolateral border of the patella). Bandpass filters (20–500 Hz) and notch filters (60 Hz) were used. During the maximum voluntary isometric contraction (MVIC) the EMG signal was obtained for 5 s for the monitoring of quadriceps and the knee was extended (isometric effects of the monitored muscles). For each of the muscles, 5-s MVIC root-mean-square (RMS) was tested for three tests in the middle of three seconds. The highest value was then evaluated in the three consecutive trials.

Statistical tests: The SPSS 24 (Statistics System for Social Science) was used for statistical analysis. The paired t-test and was performed, which was having a significance p-value (less than 0.05) 19–21.

Results

Figure 1 and figure 2 showed the data for supervised and Un-supervised groups. The following information was tabulated in the Excel spreadsheets: sex, age, Pre-Operative EMG VL, Pre-Operative EMG VM, Post-Operative EMG VL, and Post-Operative EMG VM for both supervised and unsupervised groups. For affected and Normal leg readings pre and post-operation for both supervised and unsupervised groups. A total of (80) participants were divided into two groups. The findings of the data analysed is mentioned group wise below:

- The average pre-operative-VL values of EMG-affected for supervised was 95.2 µV and for unsupervised was 94.6 µV and the average post-operative-VL values of EMG for supervised was 126.9 µV (32% variance), and for unsupervised was 135.7 µV (43% variance).
- The average pre-operative-VL values of EMG-normal for supervised was 144.5 µV, and for unsupervised was 145 µV and the average post-operative-VL values of EMG for supervised was 133.8 µV (-7% variance), and for unsupervised was 121.4 µV (-16% variance).
- Similarly, the average pre-operative-VM values of EMG-affected for supervised was 97.1 µV, and for unsupervised was 94.2 µV and the average post-operative-VM values of EMG for supervised was 130.1 µV (36% variance), and for unsupervised was 95.2 µV (1% variance).
- The average pre-operative-VM values of EMG-normal for supervised was 135.8 µV, and for unsupervised was 139 µV and the average post-operative-VM values of EMG for supervised was 135.1 µV (-7% variance), and for unsupervised was 135.7 µV (-6% variance) figure 1 and figure 2.
Discussion

Our hypothesis that supervised exercise have a better impact on strengthening and post-operative recovery in comparison with the unsupervised exercises knee surgery leads to an improvement in EMG quadriceps muscles amplitude. We also noted the VM was the muscle in which EMG after surgery that could vary because of atherogenic inhibition of the muscle. Although traditional views and clinical observation suggest that VM is more inhibited after joint injury than other Quadriceps heads, recent findings suggest uniform weakness, atrophy and quadriceps deactivation following joint injury.

The study also showed that due to the unequal strength of both limbs, weight-bearing asymmetry in both limbs would also cause difficulties in dynamic operation. This research also gave us a quantitative meaning in relation to the difference in strength recovered in both groups,
which are also beneficial in the future for the individual to tailor the rehab protocol. The intensity of exercise, as determined in a given percentage of maximum muscle contraction strength, is a fundamental element in muscle strength progression. Surface electromyography (EMG) is also used for indicating exercise intensity as a positive linear association between isometric muscle strength and amplitude was previously reported. In addition, during dynamic muscle contraction, there are positive proportionate relationships between muscle strength and EMG amplitude, although this relationship can be slightly curvilinear in some muscles. Normalizing the EMG amplitude for the average EMG amplitude obtained under isometric conditions improves measurement reliability. Therefore, the standardized EMG (nEMG) amplitude measured as percent of the mean EMG amplitude provides an indicator of exercise strength and is widely used in exercise evaluation studies. Nonetheless, traditional strength training method are still not used in clinical practice and for home-based recovery. One of the key areas of focus in recovery following ACL reconstruction is to implement safe exercises which target quadriceps muscles gradually at appropriate levels of activity. However, reduced lower limb muscle strength is documented, often far beyond post-operative rehabilitation, not only in the quadriceps but also in the hamstring muscles after ACL injury/reconstruction. During strong dynamic movements, hamstrings co-activation is critical for dynamic knee joint stabilisation and excessive prevention.

**Conclusion**

With the above study, the authors concluded that supervised exercises in post-operative ACL reconstruction plays a very significant role in the recovery and also reduces the chances of post-operative complications remarkably.

**Ethical Clearance:** This research was approved by the Ethical committee of Amity University Noida and Dr RML Hospital Delhi. Before participation, all subjects signed informed consent documents and the interests of all subjects are secured.

Abstract

The aim of this article is to provide an overall view of the literature available about “Poisons” and changes in oral cavity due to poisons. “Oral Cavity” is the first source to identify or analyze the poisonous features and different manifestations observed in postmortem. “Forensic Odontologists” here plays a major role to provide the oral manifestations and diagnosis. The oral cavity can be considered as a region with tremendous potential especially in regard to coming to a final forensic diagnosis. This article revolves around this concept and reviews the different manifestations in the oral cavity observed in post mortem.

Keywords: Poisons, Oral Cavity and Oral Manifestation, Forensic Odontologist.

Introduction

In the field of Forensic the most challenging one is the poison cases. Oral cavity is the major insight for poison consumed cases because it is easy to analyze which type of poison by using the color changes. So, here we are trying to explain the poisons and oral manifestations (ie) clinical or autopsy changes in oral cavity. Law has not tried to define death. The death, in Black’s law dictionary means “cessation of life” or “ceasing to exist.” Medico-legally, death is defined as permanent and irreversible cessation of functions of the three interlinked vital.[1] Oral cavity can be described as a window to changes occurring in the human body; almost all systemic variations show manifestations orally.[2]

Various Sources of Poisons in India:

1. Domestic or household sources: Detergents, disinfectants, antiseptics, insecticides, rodenticides, etc.
2. Agricultural and horticultural sources: Different pesticides, fungicides, and weed killers.
3. Industrial sources: In factories, where poisons are manufactured or poisons are produced as by products.
5. From uses as drugs and medicines: Due to wrong medication, overmedication, and abuse of drugs.
6. Food and drink: Contamination in a way of use of preservatives of food grains or other food material, additives such as coloring and odor agents or other accidental contamination of food and drink.
7. Miscellaneous sources: Snakes bite poisoning, city smoke, sewer gas poisoning, etc.[3]

Classification of Poisons: Poison may be classified in several method, following are 2 sorts during which poison may be classified:

I. Chemical

   Inorganic
   (a) Corrosives
   (b) Metallic and non-metallic salts
Organic
(a) Volatile
(b) Non-volatile, non-alkaloidal
(c) Alkaloidal

II) Physiological/pharmacological

Corrosive
(a) Strong mineral/organic acids
(b) Strong alkalis

Irritant
(a) Metallic
(b) Vegetable
(c) Gas

Commonly Used Poisons in India: Suicidal (KCN, HCL, opium, barbiturates, Organophosphorus), homicidal (arsenic, aconite, thallium, oleander, madar, carbamates). Pesticides are commonly used for self-poisoning. Pesticides are highly toxic and poisoning may be a significant problem in India. In parts of Northern India, aluminum phosphide (AlP) causes most deaths.

Organophosphorus Compound and its Oral Manifestations: Organophosphorus compounds are the overall name for any compound containing phosphorus. OP compounds are widely used for a couple of decades in agriculture for crop protection, pest control & additionally, in veterinary, medical uses and “nerve gases” in chemical operations.

Classification of organophosphorus compounds:

According to their toxicity and clinical use OP compounds are classified as:

1. **Highly toxic OPs**: Agricultural insecticides.
2. **Intermediately toxic OPs**: Animal insecticides.
3. **Low toxicity**: Household application and also in field applications.

Most OPs are highly lipid-soluble agents and are well absorbed from the skin, oral mucous membranes, conjunctiva.

Clinical Manifestation: The onset and severity of symptoms of organophosphate depend upon the precise compound, amount, route of exposure, and rate of metabolic degradation. A person’s can are available contact with OP by various means like ingestion, eating or drinking, inhalation or dermal contact.

Oral Manifestation of OP Poisoning: Most OPs are highly lipid soluble compounds and well absorbed from intact skin, oral mucous membranes, conjunctiva. Most characteristic garlic smell from the mouth.

AlP (Phostoxin, Fumitoxin) And Its Oral Manifestation: AlP is an compound, which is usually used as a fumigant since 1940. It’s utilized for control of pests in buildings (structural fumigation) and also used during processing of products to be imported or exported to stop transfer of exotic organisms. AlP when ingested, liberates of Phosphine gas within the stomach, which features a very pungent smell.

Symptoms of more severe toxicity includes: Individuals after death consuming AlP on external examination during autopsy, face when observed appears to be livid or distinct bluish discoloration. Garlicky pungent odor are often noted in many cases. Froth are often noted round the mouth and/or nose.

Lead Poisoning: Lead (Pb) may be a soft, ductile, bluishgray metal that’s extracted chiefly from galena. Additionally on mouth, it causes astringency & metallic taste. Chronic plumbism results when small amounts of lead are taken in over a extended period.

Oral Manifestation of Lead Poisoning: A “lead hue” of skin with pallor is another feature. A blue line along the gum, with bluish black edging to the teeth is another indication of chronic plumbism. Fig: 1 & 2

---

Fig: 1 Shows gingival enlargement
Arsenic Poisoning and Its Oral Manifestation:
Arsenic may be an element that happens in many minerals, mainly combined with sulfur and metals, also it’s commonly used as a semiconductor.[19]

Oral Manifestation of Arsenic Poisoning:
Groundwater contamination by arsenic is a major public health concern worldwide. Chronic exposure to arsenic cause various types of skin lesions including raindrop pigmentation, hyper-pigmentation, hyperkeratosis, squamous cell carcinoma, basal cell carcinoma, and Bowen’s disease.

Signs and symptoms are also found on other tissues of the body including the tongue, gingival, and buccal mucosa.[15] Toxic metals have profound effects on oral health. Melanocytes present in the basal cell layer of the oral mucosa are similar to those found in the skin.[20] The changes are shown (fig 3).

Boric Acid Poisoning and its Oral Manifestation:
Boric acid (BA) is an odorless compound (H3BO3; 5.5% Boron) which can be used as pesticide, water softener and personal care products such as toothpastes & disinfectant. It is also used in high concentrations as pesticide (99% boric acid).[21&22]
External Oral And General Manifestation of Boric Acid Poisoning:

1. At first glance, intense cyanosis of lips and nail beds were evident.
2. Inflammatory changes in oral cavity and brownish stains along with right angle of mouth and right nostril.[23]

Sulphuric Acid Poisoning and its Oral Manifestations: Sulfuric acid is one of the most widely used industrial chemicals. Sulfuric acid is widely used in electrical industry, chemical laboratories, jewelery, and agriculture. The commonest means of intoxication usually takes place through ingestion, acidic vapors are strong irritants to the respiratory mucosa and may cause pulmonary edema in the more severe cases.[24]

Oral Manifestation of sulphuric poisoning:

Insensitive yellowish spongy tongue, gums, buccal mucosa, and palate.[24]

Case Report of Poisoning and Oral Manifestations:

Case 1- Organophosphorous Poisoning:

The first subject was a moderately built, male with approximate age ranging from 30-32 years. Presence of white froth observed in corners of mouth & nose. The eyes characteristic hazy presentation also referred to as glassy appearance. Examination of oral cavity revealed thickening of the oral mucous membranes with mild whitish discoloration, and moderate to intense white discoloration with the attached gingival. The tongue also displayed white patches. (fig 4). [2]

After the Chemical analysis it revealed the cause of death is to be ingestion of organophosphorus compound.[25]

This has three types of effects: (1) muscarinic, (2) nicotinic, and (3) central effects.[26]

Case 2: Sulphuric Acid Poisoning:

A 36-year-old jeweler was admitted to our emergency department 30 minutes after he accidentally ingested highly concentrated solution of sulfuric acid. He suffered immediate cutaneous burns of varying extent and depth on his face, neck, thorax, and abdomen. He had a severe trismus with insensitive yellowish spongy tongue, gums, buccal mucosa, and palate (Fig. 5).[24]

Fig 5: The necrosis of the lips, tongue, and gums is evident.

Case 3: Sulphuric Acid Poisoning:

The second subject was a moderately built female, approximately 17-20 years of age. Various patches exhibiting yellowish discoloration were also present all over the body. Darkening of the skin was observed from the facial region extending till the neck. Swelling of lips was presented along with signs of cyanosis.

Examination of the oral cavity revealed a faint generalized yellowish tinge with the oral mucosa; the teeth exhibited unusually white shade and were brittle in consistency (fig 6). There was moderate to intense yellowish discoloration of the tongue seen. The chemical analysis in this case showed the cause of death to be sulphuric acid poisoning.[2]
The injuries in mouth, throat, esophagus, reversible or irreversible. The damaged mucous membrane, the sub-mucus regenerate only with great difficulty because of the surrounding inflammation and secondary complications.[27] Naik SM et al (2012) reported a case of acute accidental formic acid poisoning and examination of oral cavity revealed intense corrosion of tongue and the oral mucosa.[28] Vijanath V et al (2010) presented a suicide case, consumption of sulphuric acid and the autopsy revealed extensive demarcated cutaneous burns on the inner aspect of the lips.[29]

In a study performed by MalcolD (1961) on the effect of sulphuric acid on the teeth of battery workers observed the initial lesion to be etching of the labial surface of the enamel, giving a dull ground glass appearance barely visible naked eye. The exposed surface of teeth were highly polished or etched & also said that both material alba and calculus dissolved completely from the exposed surfaces in vivo, which shows false presentation of good oral hygiene.[30]

Snakes Poisons and its Oral Manifestations:
Deaths due to bite/sting of a venomous animal accounted for 10.7% of all deaths due to unintentional injuries, with an adjusted mortality rate of 6.2 (95% CI 6.0±6.3) per 100,000 population. By seeing the oral manifestations we can judge and conclude the snake bite.

Oral Manifestations: Spontaneous systemic haemorrhage is most often detected in the gingival sulci. Later the face, palate, jaws, tongue, vocal cords, neck muscles become paralysed, Locally froth formation and Bluish or Blackish discoloration of oral cavity and face.[34]

Case Report of Snake Bite:

Case report 5: 14 years/girl, Respondent: Brother

Brother of the deceased told that his sister had slept at night after dinner. After sometime, someone went to check on her but she was found dead. Her whole body had turned pale and froth was coming from her mouth. Because of the froth, they came to know that a snake had bitten her.

Summary: A general review of this literature showed us many cases with documented post-mortem oral manifestations. The oral cavity can be considered as a region with tremendous untapped potential especially in regard to coming to a final forensic diagnosis, but this aspect of forensic medicine is relatively undiscovered and overlooked. The above cases shed light on the prospects offered by observation of the manifestations of the oral cavity post mortem and their significance in the field of forensic science.[2]

Organophosphorus insecticides appear to be the most commonly ingested pesticides in rural Asia, accounting for around two thirds of cases.[32] Organophosphorus poisoning; after hanging (49%) is known to be the second most common method of suicide in India (40.3%).[33]

Findings from arsenic poisoning suggest that a higher level of urinary arsenic concentration is associated with higher risk of arsenical lesions of gums & tongue. In the present review, we provide further direct evidence that arsenichas stronger association with arsenicosis symptoms of gums & tongue. These findings imply that contamination of drinking water with arsenic might also be a risk factor for arsenicosis of the gums and tongue.[20]
A dead body with erythematous rash, redness of skin, bluish green color of vomitus and fecal matter, corrosive changes in oral & nasal cavity & multiple organ damages can be highly suggestive of Boric Acid poisoning.[23] Sulfuric acid is widely used in electrical industry, chemical laboratories, & agriculture.[24]

**Conclusion**

The main aim of forensic toxicology is that the technology and therefore the techniques that are utilized in obtaining and interpreting the results. The explanation for death could also be achieved after considering all the forensic investigations. The aim of this paper was to report the likelihood of poisoning and the way to interpret the oral manifestation (ie) (Oral Cavity Changes) in perfumes and other household products which will contain this substance.

Knowledge of Nurses Concerning Ventilator-Associated Pneumonia (VAP) Prevention in Mosul Teaching Hospitals

Ahmed Ali Hussein

Lecturer, University of Mosul, College of Nursing, Mosul, Iraq

Abstract

Background: Ventilator-Associated Pneumonia (VAP) is one of the popular Intensive Care Units (ICUs) nosocomial infections with a prevalence rate of ten to seventy percent. The frequency of VAP is about twenty percent. Lack of awareness of VAP standards and the low quality of nursing practice can become a barrier to preventing VAP.

Objective: The purpose of this study is to assess the knowledge of nurses concerning VAP prevention in Mosul teaching Hospitals.

Material and Method: A descriptive design study was used to assess knowledge and sources of knowledge among nurses about VAP prevention. From Mosul Teaching Hospitals picked 200 respondents working in different intensive care areas (ICU, CCU, NICU, and PICU) as a sample for the current study using the accidental sampling approach. A questionnaire developed for nurses have been updated and revised for the purpose of the study. The questionnaire was tested for validity and reliability and passed for use in the present study. Using Microsoft Excel, data coding, entry, cleaning, and analysis were done, and results were presented using standard frequency distribution tables.

Results: In relation to Sociodemographic data of the studied sample is shown in Table 1. The average age of nurses was founded (26.13 ± 4.25) years, and (62.7 %) had a diploma in nursing (secondary schools). Also, the mean experience period was (7.31 ± 3.81) years. The study found that (67%) of Nurses had poor knowledge about pneumonia and VAP. The highest (86%) of nurse’s little knowledge was gained through their practice of nursing in Mosul hospital.

Conclusion: Multieducational and training courses and programs need for nurses to improve their knowledge about prevention of VAP and may decrease Pneumonia associated with Ventilator among patients were concluded in current study.

Keywords: Knowledge, Ventilator, Pneumonia, (VAP).

Introduction

“Ventilator Associated Pneumonia” (VAP) is a nosocomial lung parenchyma infection that occurs more than 48–72 hours after the intubation of a patient and the initiation of mechanical ventilation(1). It is a subtype of Hospital Acquired Pneumonia that occurs in people on mechanical ventilation via an endotracheal or tracheostomy tube for at least 48 hours with 6-20 times higher incidence recorded in these patients(2). Especially in intensive care units (ICUs), where the reality of the diseases, the circumstances of the patient and the type of micro-organisms involved make infections a severe problem(3). Invasive procedures have been the focus of health-associated infection (HAI) epidemiology studies and are known to be common risk factors, such as central venous catheters for bloodstream infections and mechanical ventilation for pneumonia(4-6). Because patients in the Intensive Care Unit (ICU) focus exclusively on the caregivers, the awareness, perceptions, and behaviors implemented by the nurses have a direct impact on patient recovery. Miserably, oral health issues in chronically ill patients are typically overshadowed by other severe needs. There are major effects of chronic illnesses and disorders, leading to
disabilities and a decreased quality of life. Individuals with the most prevalent oral conditions tend to have the highest oral disease rates, associating poor oral health with adverse health effects such as aspiration pneumonia and cardiovascular disease (7-10).

**Aim:** The purpose of this study is to identify knowledge of ventilator-associated pneumonia among critical care nurses.

**Method**

A descriptive design study was used to assess knowledge and sources of knowledge among nurses about VAP prevention. From Mosul Teaching Hospitals picked 200 respondents working in different intensive care areas (ICU, CCU, NICU, and PICU) as a sample for the study using the accidental sampling approach. The questionnaires developed for nurses have been updated and revised by professors of Community Health Nursing and was tested for validity and reliability and passed for use in the present study. The information about sociodemographic profiles of health care professionals in the ICU like age, number of years of experience and past attendance of training courses on infection control were gathered directly from them. Questions to assess the nurse’s knowledge about VAP (what is meaning, risk factors, causes, sources, route of transmission, and mission of infection control as well as Knowledge about recommendations suggested by APIC for reducing associated pneumonia in the ventilator) are arranged and addressed to the participants. The correct answer is marked with (1) and the wrong answer is marked (0). Using Microsoft Excel, data coding, entry, cleaning, and analysis were done, and results were presented using standard frequency distribution tables. Simple proportions have been used to define the numerical and categorical details.

**Results**

The average age of nurses was reported (26.13 ± 4.25) years, and (62.7 percent) had a nursing certificate (secondary schools). The mean period of experience was also (7.31 ± 3.81) years. The study showed that Nurses (67 percent) had no knowledge of pneumonia and VAP. The highest (86 percent) of the little awareness of nurses was gained by their nursing practice at Mosul hospital. The study found that (67%) of Nurses had poor knowledge about pneumonia and VAP. The highest (86%) of nurse’s knowledge was gained through their practice of nursing in Mosul hospital. One of the top barriers to VAP management, having multiple physician groups managing VAP, can lead to poor patient outcomes, particularly due to the increased likelihood of communication errors in multiple providers. (Table 3).

Discussion

Ventilator-related pneumonia (VAP) is one of the hospital-acquired infections most often found in intensive care units and is related to severe morbidity and high care costs. VAP’s pathophysiology, epidemiology, diagnosis, and prevention have been researched widely for decades, but no specific preventive strategy has yet emerged.

It revealed, according to the result, that bad knowledge respondents are higher than those who had good knowledge. This result comes in agreements with another study. (11) Performed at New Zealand that fond Just 48% of critical care nurses working in New Zealand have some information about pneumonia prevention associated with ventilator nosocomial. Similar to the literature (12-20), The level of information on VAP among nurses was found to be deficient in the present research. Healthcare teams and academics have put in place and tested various approaches aimed at increasing patient health and reducing inhospitable performance.

Health care-associated infections are the most frequent adverse events that threaten patient safety worldwide. About 5% to 15% of patients admitted to intensive care hospitals in developed countries acquire a healthcare-related infection at any time. The risk of developing infection in developing countries is 2 to 20 times higher. Health-associated infections (HAI) pose a danger to the health of patients. CDC offers regional leadership in monitoring, disease investigations, clinical testing and health-associated infection prevention. CDC uses the information gained from these activities to identify infections and establish new approaches to avoid infections associated with the healthcare. CDC and other healthcare agencies’ public health intervention has contributed to changes in clinical practice, medical protocols and the continued development of evidence-based infection control guidelines and advances in prevention. (21-24)

However, given the reported findings, there are variations in knowledge of the evidence and the incorporation of evidence-based recommendations into routine nursing. Often, when implementing patient safety or risk management interventions to address healthcare problems, a simple principle must be considered: matching strategies to the source of the problem. (25,26) Focusing on all mechanisms known to...
cause VAP allows health care providers to carry out successful risk management measures for patients (27,28).

About the definition of ventilator-related pneumonia, the study found that (%) of the nurse defined pneumonia and VAP correctly. This result ties well with previous studies wherein the analysis showed that 90 percent of the research sample responded correctly about ventilator definition, and 66.7 percent responded correctly concerning ventilator-related pneumonia (29). Regarding the signs and risk factors of ventilator-associated pneumonia, the study results of the current study were broadly in line with another study that showed the average knowledge of the respondents about signs of ventilator-associated pneumonia was (33.3%), while the average knowledge of the respondents about risk factors of ventilator-associated pneumonia was (34.6%) (30).

Additionally, this is similar to what was reported in Boston by a study where average knowledge score was (43.28) percent for signs and symptoms of ventilator-associated pneumonia (31). Regarding prevention strategies the results of the current study comes in a similar pattern of results was obtained in another study that showed only 31.9 percent of the research sample replied with correct responses about ventilator-associated pneumonia prevention strategies, while 58.7 percent replied correctly concerning the diagnosis of ventilator-associated pneumonia (32). Regarding understanding the concept of VAP (50 percent) had strong knowledge, regarding risk factor more than one third (36.7 percent), Regarding knowledge of signs and symptoms of VAP (30 percent) had poor knowledge Concerning knowledge of airway type humidifier (55 percent) had poor knowledge, two-thirds (65 percent) of nurses changed humidity. And the majority of nurses (85%) used open suction, had equal knowledge of endotracheal tube forms (81%) (33).

“The recommended oral route is based on the evidence-based guidelines (EBG’s) for the prevention of ventilator-associated pneumonia (VAP). of all the participants, 58(6 9.88%) responded correctly, and 25 (30.12%) responded incorrectly, indicating that nurses know that the oral route is preferred for endotracheal intubation” (34).

The current study indicates the following obstacles to the implementation of VAP-based evidence guidelines: deficiency of resources, no VAP procedure in the unit, and dissatisfaction with the proposed strategy associated with a lack of awareness of the VAP guideline among nurses in Iraq (35).

**Conclusion**

Our study indicates that the awareness of nurses about the guidelines for nosocomial pneumonia is not sufficient and highlight the necessity for thorough training and education.

Social Gain or Social Pain: Subjective Socio-economic Status, Income and Attitudes towards Social Relations

Abstract

Social pain is usually defined as the experience of pain because of interpersonal rejection or loss. The aim of this study was to find out the peculiarities of attitudes towards social relations in different groups of income and perceived socio-economic status in a representative sample of Lithuanian population (n=1001). We have found that mean ranks in the lowest-income quintile, agreeing that “my relationships are supportive and rewarding”, were almost twice lower than in the highest-income quintile. A similar tendency was observed with the statements “I actively contribute to the happiness and well-being of others” and “People respect me”. Mean ranks in the subjectively poorest group regarding perceived respect from people were almost three times lower than in the subjectively rich group. It appears that having low income and low subjective socio-economic status may harm psychological well-being. Our study raises concern regarding societal well-being: we suggest that in order to achieve the prosperity of society, it is necessary to reduce socio-economic inequalities and through various programs and projects strengthen people’s ability to establish and maintain supportive, compassionate social contacts.

Keywords: Subjective perceptions, public administration, social relationships, social connections.

Introduction

Interest in the influence of social relationships on psychological well-being has a long history, starting with works of E. Durkheim (1897/1951), J. Bowlby (1969) and many others. Recently, researchers worldwide have investigated positive as well as challenging aspects of social relationships, including social power,¹ social class,² or aggression.³ Some researchers have suggested central role of morality in social connections and revealed that supportive social relations reduce the adverse consequences of a wide variety of stressful life events, contributes to psychological well-being irrespective of the level of life stress, and may enhance overall subjective well-being.⁴ Some researchers investigated whether low (vs. high) subjective socioeconomic status increase both prosociality and aggression,⁵ and some have found that we choose our social ties because of their capacity to provide rewards relative to costs, and our choices lead to construct social networks composed predominantly of rewarding social ties. Person perception studies show that negative information about others has higher impact than positive information, and unpleasant encounters with bureaucracies are far more predictive of clients’ overall evaluation of services provided than are pleasant encounters.

Research on societal quality of life has established social relationships as extremely important factor in the psychological well-being of society. Researchers argue that we are “social animals” who, through relationships with others, can experience the joy of life, discover the meaning of life, as other people are the most important objects in our world.⁶ If one succeeds in establishing and managing social relationships in a qualitative manner, it may determine the ability to experience the fullness of life.⁷ ⁸ In addition, relationships with other people are reflected in best life experiences.⁹

Research shows that social relationships are better predictors of our own well-being than higher income: “people are firmly anchored in social networks, and
person’s health and well-being affects the health and well-being of another human because happiness is not the happiness of isolated individuals. Social relationships also link to mental and physical health: individuals living alone or having no close friends are twice as likely to suffer from cardiovascular disease; they are more likely to have infectious or respiratory diseases. Quality of social connections determines the speed of wound healing: if a person has very poor quality social relationships, wounds heal twice slower than in a group of people having supporting and satisfactory social relationships. Deprived social connections relates to social exclusion: exclusion means that a person is geographically present in a society but cannot participate actively as other citizens. Research has shown that in some countries poor people, especially children or youth, may suffer social exclusion or stigma and related bullying. Due to a lack of material resources, some people may not be able to get proper education and achieve their goals in the labour market.

For decades, researchers have been interested in how exclusion affects person’s social relationships, or whether being the poorest member of society results in social stigma and consequent social pain. This research is extremely important as it demonstrates that social pain could also arise from social comparisons, perceptions regarding personal income or socio-economic status, and not only because of interpersonal rejection or loss. Research has also demonstrated positive value of personal initiative to be an active member of society. Some researchers revealed that not only qualitative social relationships, but also any contribution to society can increase quality of life: altruistic social behaviour, community engagement and group assistance aimed at helping others positively links to longevity, help overcome stress and negative emotions.

By magnetic resonance, neurobiologists have found that some parts of the brain activate at the time we receive money so that we experience pleasure. However, when we give money to other people for charitable purposes, our brain activates in a way that gives us even more pleasure. Thus, social relationships are crucial to the quality of life. According to research, many people in the world suffer from low self-esteem and lack of willingness to live, which can lead to their diminished economic value. In order to make effective public administration or social policy decisions, it is important to clarify factors possibly related to people’s economic value and societal wellbeing. This study aimed at analysing Lithuanian population attitudes towards social relationships in different income and perceived socio-economic status groups. We hypothesised that income or perceived socio-economic status relates to different attitudes towards social relations.

**Materials and Method**

The study of Lithuanian population was carried out by multilevel probability sampling. The overall number of respondents was 1001. To measure attitudes towards social relationships, we used Psychological Flourishing scale created by Ed Diener. The Flourishing Scale is a brief 8-item summary measure of the respondent’s self-perceived success in important areas such as relationships, self-esteem, purpose, and optimism. The scale provides a single psychological well-being score. However, we have selected 3 items for this survey: “People respect me”; “My social relationships are supportive and rewarding”; “I actively contribute to the happiness and well-being of others”.

Objective and subjective indicators relate to socio-economic status. Objective indicators include, for example, personal income, and subjective indicators include, for example, perceived socio-economic stratification. We evaluated the objective socio-economic status according to the person’s income. We subdivided the study sample into income quintiles. In the lowest income group, quintile Q1, there were 17.2 percent of the respondents. In Q2, the second quintile, there were 19.9 percent, in Q3, the third quintile, there were 24.9 percent, in Q4, the fourth quintile, there were 19.4 percent, and in Q5, the fifth quintile, the highest income group, there were 18.7 percent of respondents.

Because the data were distributed asymmetrically across the groups, non-parametric statistics were used to analyse the data, and Kruskal-Wallis independent sample intergroup comparisons were performed. The limitations of this part of the analysis are, of course, the specifics that other assets or debts of the individual were not taken into account, because the income received monthly does not necessarily reflect the actual economic situation of the individual.

In this study we aimed to evaluate the role of subjective socio-economic stratification, therefore we have also analysed subjective socio-economic status assessment. We applied the modified Subjective Social Class Measure, which measures a person’s subjective socio-economic status, and based on the results, we divided the respondents into 5 groups:
– affiliating themselves with the wealthy, who live a rich and privileged life, who have a lot of money and feel themselves as VIP;
– assigning themselves to the middle class who have enough money to live a normal life;
– assigning themselves to the middle class, who sometimes have limited amounts of money;
– affiliating themselves with the poor, who have no money for a normal life;
– assigning themselves to the poorest of the poor who do not have the money for basic everyday needs.

According to the subjective assessment of the socio-economic situation, only one person attributed himself to the rich, so we did not investigate this further. As the remaining four groups were distributed asymmetrically, non-parametric statistics were used to analyze the data, and Kruskal-Wallis independent sample intergroup comparisons were performed.

### Results and Discussion

To determine whether groups of different income quintiles differ in their attitudes towards social relationships, we performed Kruskal-Wallis cross-group comparisons of independent samples. The results of the study showed statistically significant differences in attitudes towards social relationships between different groups of income quintiles (Table 1). Mean ranks in the lowest-income quintile Q1, agreeing that “my relationships are supportive and rewarding”, were almost twice lower than in the highest-income quintile Q5 (H (2) = 127.585, p = 0.000). A similar tendency is observed for the statement “I actively contribute to the happiness and well-being of others”, with mean ranks in the lowest income quintile Q1 being almost twice lower than in the highest income quintile Q5 (H (2) = 110.829, p = 0.000).

To find out whether subjective stratification, self-attribution to different socio-economic status groups is associated with different evaluations of the quality of social relationships, we performed Kruskal-Wallis cross-group comparisons of independent samples. As shown in Table 2, the results of the study indicated statistically significant differences between the different groups of subjective socio-economic stratification. The mean ranks in the subjectively poorest group, agreeing that “my relationships are supportive and rewarding”, were almost three times lower than in the subjectively rich group (H (2) = 130.374, p = 0.000). A similar tendency is observed for the statement “I actively contribute to the happiness and well-being of other people” – the average ranks in the subjectively poorest group were almost twice lower than in the subjectively rich group (H (2) = 111.070, p = 0.000).

To find out whether groups of different income quintiles differ in perceived respect from people, we
performed Kruskal-Wallis cross-group comparisons of independent samples. As we can see in Table 3, the results of the study showed statistically significant differences in perceived respect from people among different income quintile groups. Mean ranks in the lowest-income quintile Q1, agreeing that “people respect me”, were almost twice lower than in the highest-income quintile Q5 (H (2) = 69.904, p = 0.000).

To find out whether subjective stratification, self-attribution to different socio-economic status groups is associated with different evaluations of perceived respect from people, we performed Kruskal-Wallis cross-group comparisons of independent samples. As we can see in Table 4, the results of the study showed statistically significant differences in perceived respect for people among the different groups of subjective socio-economic stratification (H (2) = 78.111, p = 0.000), with mean ranks in the subjectively poorest group almost twice lower than in the subjectively rich group.

</table>
To sum up, the Lithuanian population’s survey revealed statistically significant differences in attitudes towards social relationships between different income quintile groups. In the Lithuanian population, the mean ranks in the lowest income quintile, agreeing that “my relationships are supportive and rewarding”, are almost twice lower than in the highest income quintile. A similar tendency is observed with the statements “I actively contribute to the happiness and well-being of others” and “People respect me”. It appears that having low subjective socio-economic status may harm psychological wellbeing. Our study raises concern regarding societal wellbeing, especially, having in mind some of the studies reporting that lower class participants respond with greater hostile reactions to threat than do upper class participants or that low subjective socio-economic status is related to increased aggression.

**Conclusions**

The results of the study revealed statistically significant differences in attitudes towards social relationships between different income quintile groups. Mean ranks in the lowest-income quintile Q1, agreeing that “my relationships are supportive and rewarding”, were almost twice lower than in the highest-income quintile Q5. A similar tendency observed with the statement “I actively contribute to the happiness and well-being of others”. The results of the study showed statistically significant differences between different groups of subjective socio-economic stratification. Mean ranks in the subjectively poorest group were almost three times lower than in the subjectively rich group. A similar tendency observed with the statement “I actively contribute to the happiness and well-being of others”.

The results of the study showed statistically significant differences in perceived respect from people among different groups of subjective socio-economic stratification, where the average ranks in the subjectively poorest group were almost twice lower than in the subjectively rich group. It appears that having low income and low subjective socio-economic status may harm psychological wellbeing. Our study raises concern regarding societal wellbeing. In order to achieve the prosperity of society, it is necessary to reduce socio-economic inequalities and through various programs and projects strengthen people’s ability to establish and maintain supportive, compassionate social contacts.

Drowsiness Detection Using Eye Blink and Facial Features Image Analysis

Ajay S.¹, Azariah John K.¹ R. Subhashini², Joshua Thomas³

¹Student, ²Professor, Department of Information Technology, Sathyabama Institute of Science and Technology, Chennai, India, ³Senior Lecturer, Department of Computing, UOW Malaysia KDU Penang University College, Malaysia

Abstract

Drowsiness detection and alert system is developed using OpenCV library and deep learning algorithms and implemented with a night vision camera and a computer to detect if a person is drowsy. The system uses a camera to capture the person’s face and eyes to detect fatigue. In such a case where fatigue is detected, a warning signal is issued to alert the person and an SMS to a person related to the victim.

Keywords: EAR (Eye Aspect Ratio), Fatigue, Drowsiness, Blink Detection, SMS alert.

Introduction

Drowsiness is the state of feeling tired or sleepy. It mostly occurs when a person has lack of sleep or is tired. Drowsiness can lead to many other consequences if it is not taken care properly[7,8]. Health wise it might lead to forgetfulness or falling asleep at inappropriate times. Some researchers say Driving drowsy is considered more dangerous than driving on alcohol[2,3]. Drowsiness of a person not only affects the person drowsy; it might also affect the people around them. In a workplace when an employee is drowsy and sleeps, it affects the organization and the person. If the person feels drowsy and sleeps during work, it can lead to any accident, which might interrupt the orderly progress of the work. Drowsiness also may lead to breach of security in many places if the security personnel at work gets drowsy.

Our objective is to provide an alert system to this problem. In this manner the person and the person concerned to the victim can be alerted before it’s late. To accomplish this, we will need a system, which will track the face and eyes of a person to check if drowsy, and sound an alarm to the victim and send an SMS to the person concerned to the victim.

The purpose of this study is to provide a real time monitoring using face and eye detection techniques. The video will capture with camera after all the analysis the victim who is drowsy and the person concerned with the victim will be warned separately.

Proposed Method: Existing drowsiness detection systems are only focused on driver drowsiness but the proposed system can be used for general drowsiness detection and can also send SMS unlike other drowsiness detection system[4,5]. Generally, drowsiness detection systems use different method to analyze drowsiness. Some method use the position of the head to analyze drowsiness, some use yawns to detect drowsiness, and some method use visual information of the eyes to analyze drowsiness [6]. Commonly most algorithms use face and eye movements to detect drowsiness. We propose a system which is cost efficient and has additional features for alerting the person and the person concerned with the victim. Our system finds the face and eye movements from the web camera to determine the state of the person’s eyes and if drowsy. The alert system in this advanced than others since it not only warns the person, it also sends a SMS to the concerned person of the victim.

System Overview: Detection of drowsiness is done using computer vision and deep learning algorithms and Twilio api is used for SMS alert. The architecture is described as shown in Fig 1. The program flow of this projected system is:
A. Algorithms: The proposed system uses a combination of dlib’s library, Eye aspect ratio algorithm[1] and Twilio SMS api.

**Step 1:** Getting input video stream from the webcam.

**Step 2:** Detecting face using dlib’s pre trained hog face detector.

**Step 3:** Apply dlib’s facial landmark predictor on the face and extract eye region.

**Step 4:** Calculating Ear value using the 6 points.

**Step 5:** If Ear threshold value is satisfied go to step 7.

**Step 6:** Go to step 2.

**Step 7:** Alert the person with warning sound and send SMS to the concerned person.

B. Working of the System: The system starts with the initialization process and acquires the face and eyes from the video stream. Then the system performs detection to extract the face and eye regions. For each frame we identify face and get the facial points and the coordinates of the points of eyes from dlib’s facial landmark predictor. After localizing the eyes and finding the points, we compute a value called eye aspect ratio (EAR) [1] to find if the person blinks or not, and check with the threshold if the person has closed the eyes for sufficiently long time to know if drowsy or not? If the value goes below the threshold, we sound an alarm and send a SMS to the concerned person.

C. Eye Aspect Ratio: It is a mathematical formula which gives an elegant solution to find the blinks of a person. After finding the landmarks of the eyes, the 6 (x, y) points are used to compute the aspect ratio between the height and width of the eye. The value of the ‘EAR’[1] value becomes less than 0.1 when the eyes are closed. Equation 1 is used to calculate the ‘EAR’ value using the 6 points (p1, p2, p3, p4, p5, p6) which is depicted in figure 2.

\[
    EAR = \frac{|p2 - p6| + |p3 - p5|}{2|p1 - p4|} \quad ...(1)
\]

This equation (1) finds the vertical and horizontal distance between the eye. The numerator calculates the vertical distance between the eye and denominator computes the horizontal distance between the eye.

---

**Fig. 1. Architecture of System Flow**
Fig. 2. Points of eye landmarks

Fig. 2 shows the 6 eye landmark points of the 68 dlib’s facial landmark points detector.

Fig. 3. Visualization of the eye aspect Ratio

Fig. 3 depicts the visualization of the eye aspect ratio when the eyes are open and close. As show in the figure the eye aspect ratio is constant when the eyes are open and is close to zero when the eyes are closed.

Fig. 4. SMS alert sent when user drowsy.

Fig. 4 shows the SMS sent by the system to the concerned person alerting that the user is drowsy.
Results and Observation

The existing Drowsiness detection systems are made and focused on only driver drowsiness and doesn’t provide any additional features to be used in other applications. Drowsiness detection can be used in other applications such as employee monitoring. The proposed system can be implemented in both driver drowsiness system and in employee monitoring with an additional feature which doesn’t just alert the victim (the person being drowsy) but also the concerned person by sending an SMS.

Conclusion

Drowsiness is a very serious issue in many situations. The present systems mainly concentrate on driver drowsiness and only alerts the driver or the person drowsy. Our proposed system is a general-purpose drowsiness detection system which can not only be used for driver drowsiness detection but can also be used to check employee’s activity and it can also be used to send SMS to the concerned person and alert the person who is drowsy. Our system is fairly straightforward. A camera is setup to find faces. After finding face we send the bounding box of face to find the eye region using facial landmark algorithm. The eye aspect ratio is computed and if the video segments average ear value exceeds the threshold value, we infer as the person is drowsy and send SMS to the concerned person and alert the person who is drowsy. This system can be further expanded with features like mobile use identification to find if the user is using phone and it can be improved to identify drowsiness in different cases such as, When the person is wearing shades.

Serum α–Amylase Level in Sudanese Patients with Long Standing Diabetes Mellitus Type 2 in Khartoum State, Central Sudan

Akram H. Awadalla¹, Ahmed M. Ahmed², Saifeldein Babiker Abdalla³, Ahmad M. Saleh⁴, Ahmad Khaleel AlOmari⁵

¹Associate Professor, Division of Clinical Chemistry, Faculty of Medical Laboratory Sciences, University of Kordofan, Elobied, Sudan, ²Associate Professor, Department of Clinical Laboratory Sciences, Faculty of Applied Medical Sciences, Taibah University, Medina, Saudi Arabia, ³Assistant Professor, Division of Clinical Chemistry, Faculty of Medical Laboratories, College of Applied Medical Sciences, Jazan University, Saudi Arabia, ⁴Assistant Professor, Department of Nursing, College of Applied Medical Sciences, Prince Sattam Bin Abdulaziz University, Alkharj, Riyadh, Saudi Arabia, ⁵Assistant Professor, Department of Biomedical Technology, College of Applied Medical Sciences, Prince Sattam Bin Abdulaziz University, Alkharj, Riyadh, Saudi Arabia

Abstract

Objectives: To evaluate and correlate the serum activity of α-amylase in Sudanese patients with type 2 long standing diabetes mellitus.

Methodology: This is a descriptive, cross- sectional, hospital based, case- control study was done in fifty patients (twenty male & thirty female) above forty years with long period diabetes mellitus type 2 referred to Jabber Abu Eliz Diabetes Center and Bahri Diabetes Center in Khartoum state in central Sudan within six months. Thirty healthy volunteers with matching age and sex and socioeconomic status were included. Data was collected through, clinical evaluation form, questionnaire, and laboratory investigations. Serum concentrations of α- amylase were measured by spectrophotometer and t test and correlation were used in statistical analysis for the comparison between test and control group for example: control group.

Results: The result showed a significant difference between the mean of serum α- amylase of the control group compared with that of the test group (Mean ±SD): (39.83±9.0) versus (32.22±13.5) U/L respectively, (P<0.05). Also, there wasa significant positive correlation between the levels of α- amylase and the duration of diabetes mellitus. Correlation coefficient (r) = (r = 0.27, P= 0.000) for example: 0.0000.

Conclusion: From this study it was concluded that; the diminution of the serum levels of α- amylase could be part of the exocrine pancreatic insufficiency since α- amylase activity decline correlated well with the duration of long-standing type 2 Diabetes Mellitus.

Keywords: α-amylase, Diabetes Mellitus, Pancreas exocrine Insufficiency.

Introduction

Diabetes mellitus is a common metabolic disease that is characterized by mis regulation of blood glucose levels leading to hyperglycemia¹². The disease affects millions of people worldwide and the number of people affected by diabetes is increasing³. The prevalence of diabetes is high among Middle Eastern and North African countries with frequencies between 4% and 10%⁴. Diabetes is associated with several complications that include renal deteriorations, retinopathy leading to vision disturbance, nerve damage and predisposition to cardiovascular diseases. Globally, the statistics are

e-mail: am.saleh@psau.edu.sa
staggering. Diabetes is the third leading cause of death in the United States after heart disease and cancer[5].

Type 2 diabetes was previously called non–insulin dependent diabetes mellitus or adult-onset diabetes because the peak age of onset is usually later than type 1 diabetes. In adults, type 2 diabetes accounts for about 90% to 95% of all diagnosed cases of diabetes. Type 2 diabetes usually begins with insulin resistance, a disorder in which the cells primarily within the muscles, liver, and fat tissue do not use insulin properly[6].

Since the tight control of enzyme activity is essential for homeostasis, any malfunction (mutation, overproduction, underproduction or deletion) of a single critical enzyme can lead to a genetic disease. The importance of enzymes is shown by the fact that a lethal illness can be caused by the malfunction of just one enzyme out of the thousands of enzymes present in our bodies[7].

α- amylase is marked increase (five to 10 times the upper reference limit) in acute pancreatitis; severe glomerular impairment; severe diabetic ketoacidosis and moderate increase (up to five times the upper reference limit) in acute abdominal disorders as perforated peptic ulcer and salivary gland disorders, Mumps, salivary calculi and myocardial infarction (occasionally), renal failure — due to reduced excretion[7].

There is a significant reduction in pancreatic outputs of amylase, trypsin, chemotropism, and to a lesser degree, bicarbonate in patients with long standing type 2 diabetes mellitus. Clinical evidence of disease of the exocrine pancreas was missing. There was no discernible relationship between the abnormality of external pancreatic function and the duration of diabetes mellitus[6]. In Type 2 diabetes mellitus, there are defects in secretion and signaling of insulin. These defects may also affect the exocrine pancreatic activity[7].

**Materials and Method**

**Setting and participants:** This study was carried out in Khartoum state in central Sudan. The subjects were selected in Khartoum city randomly. The data obtained from different sites in Khartoum city: Khartoum and Khartoum north (Bahri). The study was conducted for three months.

Fifty patients (Twenty male &Thirty female) above forty years with long standing diabetes mellitus (more than ten years), were selected after taking their consent. Each volunteer in this study was asked to come to Jabber Abu Eliz Diabetes Center in Khartoum and Bahri Diabetes Center for medical assessment and sample collection. Thirty healthy subjects (Twelve males, eighteen females) were selected as a control group who were age, sex and socioeconomic status matched to the diabetic group (test group) Clinical data was obtained from the patient’s history and recorded on a questionnaire sheet. Clinical assessment of the study group was done by a medical doctor and they were not suffering from acute pancreatitis or salivary gland disorders which led to increase α- amylase level.

**Data collection Procedure:** After informed consent, venous blood sample (5 ml) was collected from the study subjects. After blood clotting, the samples were centrifuged within 20 minutes after collection at 3000 rpm for 5 minutes and the sera were stored -20°C until analysis. The serum was allowed to reach the room temperature and α- amylase specific activity was measured spectrophotometrically in the direction of 2-chloro-4-nitrophenol formation at 405 nm wavelength using α- amylase kits from Biosystem Company Costa Brava, 30, Barcelona (Spain).

**Quality control:** Control serum of known α-amylase value was used to verify the performance of the measurement procedure.

**Statistical analysis:** The data collected in this study were analyzed by using SPSS computer program package. The mean and standard deviations of α-amylase were used to compare between the test group and the control group. The P values were obtained using the (t) test. Correlation between the serum levels of α-amylase and the duration of the disease were tested using Pearson correlation. Pvalues<0.05 were considered to be statistically significant Pvalues<0.01 were considered highly significant.

**Observation and Results**

**Serum α- amylase:** The following table shows a significant difference between the mean of serum α-amylase of the control group compared with that of the test group (Mean ±SD): (39.83 ±9.0) versus (32.22 ±13.5) U/L, (P<0.05).

Independent sample t-test was used for comparison.

The table shows the mean ± SD, range in brackets () and probability (P).

![Figure 1. A scatter plot shows correlation between the serum α-amylase levels and duration of the disease (r = 0.27, P= 0.000).](image)

**Discussion**

In Sudan, there were a great number of published study regarding diabetes mellitus but infrequent related published data regarding the serum levels of α- amylase enzyme in Sudanese with long standing type 2 diabetes mellitus, so this study have a tendency to compare the results with that obtained in other previous studies in none Sudanese people.

This study showed a significant difference between the mean of the serum levels of α- amylase of the test group when compared with that of the control group, the mean of the test group is significantly reduced as shown in table 1(P<0.05). This may be due to the effect of long-standing type 2 diabetes mellitus on pancreatic exocrine function. The above results agree with a study done by Matteo Piciucchi et al.[8] who were found a significant reduction in pancreatic outputs of amylase, trypsin, chemotropism, and to a lesser degree, bicarbonate in patients with long standing type 2 diabetes mellitus. Clinical evidence of disease of the exocrine pancreas was missing.

Also, there was a significant positive correlation between the serum levels of α- amylase and the duration of the disease (in years). (Figure 1) and this may be by reason of enzyme utilization in carbohydrates digestion
and to the pancreatic exocrine insufficiency. In a study done by Vishwanath, et al. [9] on patients with long standing diabetes mellitus, they found that the reduction in serum amylase in type 2 diabetes was more in patients with longer duration of illness (59%) and in patients with low serum insulin values (79%). An association between reduced level of serum amylase and reduced levels of lipase was found in type 2 DM was due to decrease of exocrine acinar cells.

**Conclusion**

This study concluded that the serum activity of α- amylose is reduced in patients with long standing diabetes mellitus type 2 with a considerable constructive correlation with the duration of the Diabetes Mellitus. The repercussion that; analysis of serum pancreatic enzymes could be supplementary informative parameter for the reflection of chronic and progression of the disease.

Serum Calcium and Serum Alkaline Phosphatase Levels and their Correlations with Disease Activity in Patients with Rheumatoid Arthritis

Albedri Khudair Z.¹, Elias Afnan A.², Al Derwibee Fadya A.²

¹Prof., ²FIBMS (Rheumatology And Medical Rehabilitation), University of Baghdad, Collage of Medicine, Medical City, Baghdad Teaching Hospital.

Abstract

Rheumatoid Arthritis is a systemic autoimmune disease, characterized by chronic synovial inflammation leading to joint destruction and bone erosion. Metabolic changes have been studied in rheumatoid arthritis, with several studies reported decrease in serum calcium, and increase in serum alkaline phosphatase in rheumatoid arthritis patients in comparison to healthy individuals. This study has been undertaken to evaluate serum calcium and serum alkaline phosphatase levels in patients with rheumatoid arthritis, and their correlation with disease activity. A total of 100 patients with rheumatoid arthritis were enrolled in the study and compared with 50 healthy controls (46 female: 4 male) matched for age and sex. No significant differences have been noticed in mean values of serum calcium, corrected calcium, and serum alkaline phosphatase in patients with rheumatoid arthritis and healthy controls. The mean values of serum calcium, corrected calcium and serum alkaline phosphatase levels were slightly higher with moderate and high disease activity in comparison to low disease activity in patients with rheumatoid arthritis, but the differences did not reach the statistical significance.

Keywords: Rheumatoid Arthritis, Serum Calcium. Alkaline Phosphatase.

Introduction

Rheumatoid Arthritis (RA) is a chronic systemic inflammatory disease, affecting all ethnic groups throughout the world, characterized by chronic synovial inflammation, leading to joint destruction and bone erosions¹². The prevalence of RA is from 0.5% to 1% of the general population worldwide, with female: male ratio of 3:1³⁴. The diagnosis of RA is chiefly based on the clinical features, radiological findings and laboratory results⁵. The classification of RA is based on 2010 ACR/EULAR Classification Criteria for RA⁶. Clinical Disease Activity Index (CDAI) is a new simple tool for measurement of disease activity in RA⁷. Disease Activity Score of 28 joints (DAS28) is another common tool used to assess disease activity in RA⁸. Calcium is an essential element for various biological processes from fertilization to death. The serum calcium is divided into three fractions: 50% of calcium ions in the active form, 40% bound to serum proteins, principally albumin, and 10% bound to anions such as bicarbonate and citrate⁹. Calcium has numerous functions, including: controlling ions transport across cell membranes, acting as an intracellular second messenger, activation of blood coagulation factors, coupling neuromuscular excitation and providing the strength of bones and teeth¹⁰¹¹. Alteration of protein levels, can cause changes in total calcium without affecting ionized calcium physiologically or clinically, thus, the total calcium adjustment to albumin is very important when trying to determine the value of normal calcium⁹. Alkaline Phosphatase (ALP) presents in the plasma membrane of Osteoblasts and in the cells of the liver, kidney, intestine, spleen and placenta¹². Alkaline phosphatase is involved in mineralization, possibly by catalyzing the formation of phosphate from pyrophosphate. In the gut, there is an evidence of having a role in lipid transport¹³. Several studies reported that serum calcium level is decreased and ALP is markedly elevated in RA. The elevation in ALP might be explained by a compensatory bone regeneration mechanism and osteoblastic proliferation in an effort to restore the eroded bones in the joints⁵.
Low level of serum calcium in RA patients might be explained by the intermediate metabolism of vitamin D which may be abnormal in RA, although reports on cases with RA and osteomalacia have drawn attention to the coexistence of these two diseases\(^{14}\). Another study reported the increased level of ALP in RA indicates that the disease is more active, and ALP is a biochemical marker of bone turnover which provides a clinically useful evidence of the pathologic process that reflects bone cell activity on the skeleton\(^{11}\).

**Subjects and Method**

This study is a case-control study conducted at Baghdad Teaching Hospital in Medical City, Baghdad, Iraq, with a total of 100 patients of RA (96 females: 4 males) according to the 2010 American College of Rheumatology/European League Against Rheumatism classification criteria for Rheumatoid arthritis was included and compared with 50 healthy controls (46 female: 4 male) matched for age and sex.

**Exclusion criteria:**

- Overlap connective tissue diseases.
- Patients with vitamin D deficiency, thyroid and parathyroid diseases, malignant diseases, renal and hepato-biliary diseases, bone fractures and diabetes mellitus.
- Patient who wastaking (calcium and vitamin D supplements, bisphosphonates, diuretics and alcohol).
- Pregnant women or those in postpartum period.

The exclusion had been done by a full history, examination and investigations (serum vitamin D, Thyroid function test, Parathyroid hormone, liver function tests and renal function tests). Blood samples were taken from individuals in both groups under aseptic venepuncture and 5ml of blood were collected without tourniquet to test for Serum Calcium (S.Ca), with normal value \((8.4-10.4)\) mg/dl. Serum Alkaline Phosphatase (S.ALP), with normal value \((46-116)\) IU/L by Dimension EXL, immunoaassay analyser which was made in Germany. Serum albumin \((3.4-5)\) g/dl, Blood urea \((15-38)\) mg/dl, Serum creatinine \((0.5-1.3)\) mg/dl, Serum aspartate transaminase (AST) \((15-37)\) IU/L, Serum alanine transaminase (ALT) \((14-63)\) IU/L, erythrocyte sedimentation rate (ESR) \((0-20)\) mm/H, C-Reactive Protein (CRP), Rheumatoid Factor (RF). Disease activity was measured using Clinical Disease Activity Index (CDAI), and Disease Activity Score 28 (DAS 28).

**Statistical Analysis:** Data analysis carried out using SPSS version 23. Numbers and percentages had been used to represent the categorical data, while the mean and standard deviation were used to express the numerical data. Anova, independent student test, Pearson correlation and Chi-square tests (fisher exact test when not applicable) were used to confirm significance. Statistical significant considered whenever the P-value was less than \((0.05)\).

**Results**

The demographic characteristics of both groups are shown in **Table 1**. No statistically significant differences have been found between both groups in all variables. The laboratory and clinical characteristics of RA patients group are shown in **Table 2**. The rheumatoid factor was positive in \((87\%)\) of RA patients, CRP was positive in \((45\%)\) and negative in \((26\%)\), not measured in \((29\%)\) of patients group. Mean ±SD duration of disease was \((9(2.3)\) years. The activity of disease according to DAS28 showed that \(9\%, 46\%\) and \(45\%\) of patients presented with mild, moderate and high disease activity respectively while according to CDAI, the results showed that \(10\%, 56\%\) and \(34\%\) of patients had mild, moderate and high disease activity respectively. The treatment of RA patients was: Biologics \(64\%\), cDMARD \(89\%\), NSAID \(17\%\) and steroid \(47\%\). No statistically significant difference \((p\geq0.05)\) in mean values of serum calcium, corrected calcium, serum alkaline phosphatase and serum albumin levels has been found between RA patients and controls groups, as shown in **Table 3**. No statistically significant correlation between RA disease activity according to (CDAI and DAS28) with S.Ca, corrected Calcium or S.ALP level. The mean values of serum calcium, corrected calcium and serum alkaline phosphatase levels were slightly higher with moderate and high disease activity in comparison to low disease activity in RA patients group, but the difference did not reach the significant level \((p\geq0.05\) for all) **Table 4**. There is a weak non-significant indirect correlation between the CDAI value and serum alkaline phosphatase level \((R=0.01, P\geq0.9)\), in **Figure 1**. There is a weak non-significant direct correlation between the DAS-28 value and serum alkaline phosphatase level \((R=0.02, P\geq0.8)\) as illustrated in **Figure 2**.
Discussion

Few data were published about the assessment of serum calcium and serum alkaline phosphatase levels in RA and their correlation with disease activity. No statistically significant differences (p≥0.05) have been found between RA patients and healthy controls regarding mean values of (S.Ca, Corrected Ca, S.ALP) levels. This result differs from several studies, which revealed that (S.Ca) level decreases and (S.ALP) level elevates in RA patients as compared to healthy controls. This elevation in ALP was explained by a compensatory bone regeneration mechanism as an effort to restore the eroded bones in the joints. Circulating pro-inflammatory molecules & hormones that alter calcium metabolism contribute to the diminished calcium status(5). Other studies showed that the (S.ALP) level in RA patients significantly increased when compared to controls, in which bone formation increases with cytokines mediated increased resorption of bones, which correlates with increased ALP in RA patient serum(15).

The possible explanations for these differences from the current study might be related to: first; the difference in sample sizes, Second; alteration of protein levels can cause changes in the total calcium, without affecting the ionized calcium physiologically and clinically, thus, the total calcium adjustment to albumin is very important when trying to determine the value of normal calcium(9). Third; the decrease in (S.Ca) level and elevation in (S.ALP) level in RA patients might be related to vitamin D deficiency, most of these studies did not exclude patients with vitamin D deficiency in their samples. In the current study, patients with vitamin D deficiency in RA patients and controls group (about 25 RA patients and 3 healthy control have been excluded from study due to their vitamin D deficiency in those who reported with low S.Ca or high S.ALP levels or both). Serum vitamin D was positively correlated with serum calcium level that reported by Kiran et al(16). Raised serum alkaline phosphatase (ALP) is a sensitive marker which could be used as a screening test to detect vitamin D deficiency(17). No statistically significant correlation has been found between the disease activity(according to CDAI and DAS 28) and serum calcium, corrected calcium and alkaline phosphatase levels. Although the mean values of serum calcium, corrected calcium, and alkaline phosphatase were slightly higher in moderate and high disease activity indices( P ≥0.05). The current study demonstrated that there was no significant difference (P≥0.05) in mean values of (S.Ca, Corrected Ca and S.ALP) levels when compared according to the biomarkers disease activity (ESR level, CRP and RF positivity) in RA patients group.

Conclusion

No significant differences between rheumatoid arthritis patients and healthy controls in serum calcium and serum alkaline phosphatase levels have been found, as well as no significant correlation with disease activity indices.

Effectiveness of Nursing Management Educational Program upon Head Nurses Knowledge Regarding Staff Management

Ali Hussein Ali Al-Jazaeri¹, Muna A. Khaleel²

¹PhD Student, University of Babylon-College of Nursing-Family and Community Health Nursing,
²Prof. Dr. Al-Bayan university-College of Nursing-Family and Community Health Nursing

Abstract

Background: Globally, the role of the unit nurse manager has evolved exponentially over the past several decades from that of clinical ward sister, overseeing mainly patient care on a single unit, to that of nurse manager with a much wider scope of practice. Unit operations including budget, recruitment and retention, staff development, quality and evidence-based practice for patient outcomes. Prior to that era, “ward charge nurses” were responsible for only clinical patient care on their single unit, and were expected to perform patient care (Bailey, 2014).

Objectives: Implement the nursing management education program for the study group.

Methodology: A quasi-experimental design is carried out throughout the present study with the application of test-retest approach for the study and control groups from March 24th 2019 to Feb 19th 2020.

Settings of the Study: This study was conducted at the nursing units of Al-Najaf AL-Ashraf City Hospitals which include (Al-Sadr Medical City, Al-Hakeem General Hospital and Al-Zahra Teaching Hospital, they represented AL-Najaf AL-Ashraf city).

Result: Showed that the study group participants had benefits from the implementation of nursing management education program.

Conclusions: The program considered an effective mean for the improvement of the head nurse’s knowledge.

Recommendations: Head nurses should have the required knowledge about wards management regarding staff management. And nursing management education program is an important tool for the development of head nurses’ skills. Accordingly, head nurses need to be encouraged to participate in nursing management education program focused on staff management. Finally, the study proved that there is an essential need for collaboration between the Ministry of Higher Education and Scientific Research with Ministry of Health and Environment to improve the nursing management courses as a part of curriculum in nursing institutes and universities.

Keyword: Effectiveness, Nursing, Management Educational Program, Head Nurses, knowledge, Staff Management.

Introduction

Management is ability of leading, planning, staffing, organizing, and controlling actions to reach objectives. Planning includes determine of objectives and finding method to achieve them. Staffing and organizing is the process of confirming that the important physical and human resources are obtainable to attain the objectives of planning. Organizing also includes identify job to the correct individual or team and identifying who has the manager to achieve responsibilities. Managing is effecting others staff to reach the organizations objectives and includes directing, energizing and persuading others staff to reach those objectives. Controlling is comparing real role to a standard and rereading the original strategy as required reaching the objectives.¹
Methodology

Design of the Study: A quasi-experimental design is carried out throughout the present study with the application of test-retest approach for the study and control groups from March 24th 2019 to Feb 19th 2020.

Settings of the Study: This study was conducted at the nursing units of Al-Najaf AL-Ashraf City Hospitals which include (Al-Sadr Medical City, Al-Hakeem General Hospital and Al-Zahra Teaching Hospital, they represented AL-Najaf AL-Ashraf city).

</tbody>
</table>

As it shown in (Table 1), the comparisons of mean knowledge score of the head nurses in both groups at pretest, posttest 1 and posttest 2 revealed that the overall mean knowledge score in the study group changed from 2.43 before training to reach 2.85 after training (posttest 1) and maintained at 2.81 at posttest 2. The differences in pairwise multiple comparison were statistically significant, when compare Post 1-Pre (P<0.001), Post 2 vs. Pre (P<0.001) and post 2 vs. post 1 (P=0.001). Indicated that the overall mean knowledge score for this study at posttest 1 was significantly higher than that at pre training and at posttest 2, and that at posttest 2 was significantly higher than that at pre training. No such changes had been reported in control group and the differences in mean knowledge score were not significant at pre, post1 and post 2. From other point of view, the comparison between both groups at posttest 1 and posttest 2 revealed significantly higher change in study group than controls with a large effect size of 1.29 and 1.19, respectively, indicated that much of the change in the knowledge scores attributed to the training program. Larger effect size also reported when the mean difference are compared between the study and control groups. Moreover, the trends of changes in mean knowledge score in both groups are graphically compared in (Figure 1).

Discussion of the Results

Staff management is the method of receiving work done by head nurse through staff nurses. Nursing staff management is the process working through nursing personnel to provide care, cure, and comfort to groups of patient (Council & Nurses, 2018). There are potentials for head nurse supervision in wards to participate in the development of skilled workforce and nursing staff which can positively contribute to hospitals objectives.²

Table (1), indicates that the overall mean knowledge score for this study at posttest (1) was significantly higher than that at pre training and at posttest (2) and that of posttest (2) was significantly higher than that at pre training. No such changes had been reported in control group and the differences in mean knowledge score. The differences were not significant at pre, post (1) and post (2). On the other hand when both groups compared the effect size of training program was large.
(1.62), in the change of mean knowledge score for this domain at posttest (1), large (1.28) at post-test (2), and cumulatively much large effect size of (3.42) and (3.0) when the mean differences posttest (1) pretest and posttest (2) pretest taken into account, but small effect size of (0.33) reported at posttest (1) posttest (2) but it still significant in study group than controls. This means that head nurses acquired high improvement in nursing staff management knowledge by education program compared to their knowledge at pretest.

Misiukonis, (2011) reported that head nurse and staff nursing are motivated when training is used as a management philosophy to develop nursing staff performance. Similarly.\textsuperscript{3}

Saleh, (2015) mentioned that there was highly improvement for level of head nurses’ knowledge in all topics of clinical supervision after implementation of educational program compared with pretest.\textsuperscript{4}

This result consistent with Wiley (2016), in that he showed that after nursing management education program, head nurses gained better coping mechanisms and increased confidence resilience in improving staff nursing management and cohesion.\textsuperscript{5}

Conclusions:

Much improvement in the knowledge of study group was detected after implementation of teaching program (post-test1) regarding staff management; therefore, highly significant differences were reported between study group and controls in the proportions of correct responses towards the items of domain with a large effect size.

Recommendations:

1. Head nurses should have the required knowledge about wards management regarding staff management.

2. Nursing management education program is an important tool for the development of head nurses’ skills. Accordingly head nurses need to be encouraged to participate in nursing management education program focused on wards management.

3. The study recommends focusing on scientifically qualified nurses with minimum of BSc degree to work in the nursing wards.

4. The study proved that there is an essential need for collaboration between the Ministry of Higher Education and Scientific Research with Ministry of Health and Environment to improve the nursing management courses as a part of curriculum in nursing institutes and universities.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the College of Nursing, University of Babylon, Iraq and all experiments were carried out in accordance with approved guidelines.

Association of Explosive Power and Agility among Cricketers of State Level

Anagha Ghosalkar1, Shishir Nigam2, Preeti Saini3

1Masters Student, 2Assistant Professor, 3Assistant Professor, Department of Physiotherapy, Faculty of Applied Science, Manav Rachna International Institute of Research & Studies, Faridabad, Haryana, India–121001

Abstract

Often cricket is stated as an aerobic sport however when broken down the game is played by the players performing at various speeds and intensities—jumping, sprinting, catching, diving, majority of the play is in intervals and the activity does not lasts for long periods of time (e.g.; batting, bowling, fielding, wicket keeping, making a run). Purpose of the study is to determine association between explosive power agility in state level cricket players. Previous studies have investigated physical performances with respect to injury incidence and prevention. In this study physical aspects such as power, agility and anaerobic fitness shall be considered. Also due to paucity of evidences and studies on this literature it is important to find an association between the explosive power, agility among cricket players of state level. Total 100 male state level cricketers from different cricket academies were included in the study. Subjects with age group of 16-23 were taken in the study. Screening and assessment protocol were followed to select participants. Performance tests were measured. Explosive power with vertical jump test, agility with run a 3 test. Result of study showed:

1. Correlation between explosive power and agility was -.305** and it was significant at .002.

Present study concluded that explosive power is negatively correlated with agility.

Keywords: Fast twitch muscle type, anaerobic capacity, fitness testing, professional cricket, performance.

Introduction

Cricket is a sport that is played by millions from all the corners of the globe. All over the world three formats are practised at the elite level: Test, One day, and Twenty-20.21 Cricket involves large physiological demands of the human body, muscular strength and endurance, CVS endurance, speed, agility, power, flexibility etc. Often cricket is stated as an aerobic sport however when broken down the game is competed by the athletes playing at a range of speeds and intensities—jumping, sprinting, catching, diving, greater part of the sport is in pauses and the movements does not lasts for long periods of time (e.g.; batting, bowling, fielding, wicket keeping, making a run).

Cricket involves sudden movements which are often slow and fast. A professional player is expected to perform a large number of sprints, jumps, lunges and rapid directional changes. As well as another characteristic of cricket is execution of sporadic or fast movements of moderate to high intensity relate to repetitive actions of short duration but greater intensity as it occurs in other sports with similar characteristics like (squash etc). The shorter game formats tend to be more physically intensive when related to match duration, incorporating more maximal sprints when fielding, bowling, and batting. As a result of these demands, running speed, agility and power or strength has become an essential athletic quality for cricketers and therefore must be assessed correctly. Appropriate speed & agility assessments can provide an indicator of an athlete’s level of ability, and be used to monitor physical development.

Leg strength and speed (power) are vital for cricketers. These two elements to influence the speed and agility necessarily meant for fielding, wicket keeping and
running between wickets. It is even essential for bowlers because it helps them monitor and practice their ability to absorb the forces experienced by the legs during a delivery.\textsuperscript{4} Strength of the muscles of lower extremity upper extremity and trunk is of utmost importance for the execution of strokes of the ground.\textsuperscript{32}

Cricket is termed as an interval sport with equally anaerobic and aerobic components.\textsuperscript{26} At advanced ability intensities, technical performance may be reduced by physical attributes, physical fitness and performance qualities.\textsuperscript{31} Also, cardiorespiratory fitness in terms of max O2 uptake (VO\textsubscript{2max}) reflects physical fitness of a person hence; VO\textsubscript{2} max is the single preeminent measure of cardiorespiratory capacity and is considered as a bench mark to quantity CVS functional capacity and aerobic fitness.

There are various study conducted to assess agility and explosive strength but there are lack of literature studying association between explosive power agility in cricket player

**Methodology**

Subjects were taken after signing informed consent including 100 male state level cricket players with age group of 16-23 with normal BMI (<25), who fulfilled the inclusion criteria playing for at least 1 year at state level. Players were asked to perform general warmup for 20 mins2 performance tests were measured. Explosive power using vertical jump test. Agility using run a 3 test. Data will be collected from academy in Faridabad and Delhi. Assessment form was filled (details pertaining to sport, dominance, level of playing position etc.)

The demographic details are recorded and information about subject is collected in assessment formheight (cms) and weight (kg) and BMI was calculated. After completing the assessment form the testing for vertical jump, run a 3 test was done after a general warmup. Height was measured using a wall mounted stadiometer with a horizontal head board. Players stood barefoot, feet together and stand tall. Height and weight was recorded to a precision of 0.1 cms and 0.1kg respectively.

Sargent chalk jump test: Subjects stood with one side against a wall, heels together and held a one inch piece of chalk in the hand nearest to the wall. With the heels together the subject was asked to make mark as high as possible on the wall. Then were required to jump as high as possible to make another mark on the wall, the score was calculated at the distance in centimetres between the reach mark and the highest jump mark attained by the subject.

Run a three test: To assess agility, “Run a three” protocol of Bourdon et al was chosen. The subjects were asked to warm up prior to the test and allowed at least two trials at sub maximal pace. The test was performed on a cricket wicket or crease of 17.68m or 22 yards respectively. Subjects were instructed to presume the starting position, with one foot behind the popping crease line and cricket bat in hand and with knee pads, physically and mentally ready to take run. No cue was given to begin the test. The timing began when the subject’s rare foot left the ground and finished as the bat crossed the popping crease line at the end of the third run. Subjects had to perform three trials with the fastest average time was recorded as the best score. A rest interval of ≥5 minutes was given between trials. The average time from the two stopwatches was recorded to the nearest 0.1 second.

The statistical tests were applied which includes mean, standard deviation, Karl Pearson correlation for assessing the correlation between agility and explosive strength, SPSS 21 version was used as a statistical tool. Relationship between the test variables were determined by using bivariate correlation.

In this study the level of significance was set as p ≤ 0.05.

**Conclusion and Discussion**

Study was to assess the explosive power of the cricket players. According to the result of the present study mean scores of explosive power (cms) were 53.10. Similar studies Gabbet et al stated there was limited research pertaining to the enhancement of athletic performance although he stated that a study on professional rugby players had a better or significant impact of lower body explosive power and speed on their physical playing performance. On the contrary longitudinal studies on rugby players found no differences in explosive strength as a marker of physical performance.\(^\text{23}\) A study by Carr et al on elite cricketers measuring their explosive power over a range of season showed improvements in lower body power scores overall the seasons.\(^\text{5}\) Studies by Johnstone on explosive power differences in batsman and bowlers showed negligible differences among them. Jakovljev through his studies concluded “explosive power is an essential pre requisite for sports that demand explosiveness and fast maximal energy production and finds need to be incorporated for planning and training, performance prediction and talent identification in various sports”.\(^\text{19}\) Castagna has also further layed emphasis on the varying role of explosive power in various sports like cricket and basketball which is
essential for improving their performance. Secondly study was focused to assess agility of cricket players. According to results of the present study the mean scores of agility (secs) were 10.6. A study stated role and efficacy of agility in cricket is increased with implementation of a 6 week specific exercise programme. Similar study done by Shrivastava (2015) confirmed specialized exercises help in increase of cricket specific agility in male cricket players. Agility is the most crucial factor influencing movement also as important to influence motor action. Boora (2016) also emphasised agility has a distinctive role in cricket to execute competent footwork and rapid changes in body position. Various studies done to evaluate variable of physical fitness i.e. agility in batsmen and bowlers reviewed batsmen had better agility that had an influence on physical performance. According to a study on effect of different types cricket batting pads on running and turning speed showed no significant differences in running or turning speed due to the influence of different cricketing pads.

Third objective of study was to determine the association between explosive power and agility of cricket players. Results of the present study stated explosive power showed moderate negative correlation \((r=-.305^{**})\) and was highly significant at \((p=.002)\) with agility and the result states that with improved vertical jump height scores there is an eventual decrease in time required to complete 3 consecutive runs. A study done to assess role of explosive power of male footballers showed explosive power was the most dominating variable for improving agility. Numerous studies by other researchers have same results which supported this study. Conducted similar study measuring these variables on basketball players. Study stated that leg strength and power were most significant factors required by cricketers especially fielders such that it contributed to further increase in agility and speed required for fielding. Studies have supported that with specific 6-8 week exercise programme including plyometric, resistance and interval training has shown to improve the explosive power and impact the influence of agility desirable for athletic performance. Exercises have an effect on anaerobic pathway ATP-PCr system and neuromuscular adaptions that cause improved balance and body position that favours on improving explosive power and agility. Also due to explosive nature of the sport there is definite need to develop power for increasing run up speed and agility.

## Conclusion

While computing the correlation coefficient between Explosive power, Agility the present study concluded that explosive power is negatively correlated with agility i.e. with peak score of jump height there is decrease in time taken to complete 3 runs by the players which stated that good anaerobic power contributes in improving the agility performance necessary for the cricket players. Findings of the study can be used by physiotherapist, coaches as well as trainers or the sports professionals to train the team in relation to certain particular aspects that needed to be improved for the team to achieve better performance.

Classification of Cancer Model for Clinically Actionable Genetic Mutations Using Machine Learning

Anandh B.¹, Akash U.¹, Subhashini R.², Sethuraman R.², Saravanan M.²

¹Student, Department of Information Technology, Sathyabama Institute of Science and Technology, Chennai-600119, India, ²Faculty, School of Computing, Sathyabama Institute of Science and Technology, Chennai-600119, India

Abstract

Classification of Cancer Model Clinically Actionable Genetic Mutations Using Machine Learning Algorithms. Its task is to classify genes based on text evidence from clinical issues with good results. If a normal person has symptoms of cancer we can find it easily, but we have nine types of viruses in cancer in that which type of viruses has been attacked to the person cannot be easily predict by the doctors. So in hospitals there will be a clinical pathologist. Clinical pathologist has the data’s of cancer attacked before and he will collect the gene sample and the person blood sample and predict which type of virus of cancer will attack to the person.

Keywords: Genetic Mutations, Clinical Evidences, Clinical Pathologist, Natural Language Process.

Introduction

Cancer is one of the most dangerous diseases. If cancer attacked to a person and not treated properly, it may lead to death. Health wise cancer may lead to blood vomit, loss of hair falls, body weakness etc. Researchers who are researching about the cancer has said that if a cancer is attacked a person would be dangerous for his life, which may lead to death. If the cancer not only it will affect him but also affect his future generation through his genes attacks a person, a person attacked by cancer also led to interrupt the normal routine work.

Our objective is to solve to these types of problem, so in this way person and person concerned to the victim can be alerted before it’s late. To accomplish this, we need the data’s which clinical pathologist will have victim’s gene sample and blood samples to check which type of class(virus) of cancer will attack the person¹⁻².

This project is a real time project based on “TF-IDF, TF-IDF/BOW, XGB, Meta Bagging, Text Reduction, and SVD” techniques. It will predict which types of class (virus) of cancer will attack the person so that doctors and the person concerned can help him to recover from the cancer³⁻⁵.

Review of Literature: The machine-learning task is to addressing the crucial clinical method. In the previous research of cancer some other researchers have done for breast cancer and lung cancer by using some the machine learning algorithms like 5-fold cross validation and logistic regression etc. In our project what we have done is cancer classification with genetic mutations by using machine learning algorithms are Logical-Regression, K means ++, Naïve Bayesian, K-fold cross validation, X-boost, LDA Cosine Similarity, K Nearest Neighborhood⁶⁻¹². Naïve Bayesian is a supervised learning, in supervised learning input data’s should be well labeled it collects the data and predict the before results and make it better accuracy¹⁰. The theory applied here is to compare the genetic mutations with the collection data samples from the patients and predict the possibility of getting cancer².

The importance of using more algorithms than the previous research is to find better accuracy than the existing one. When we use algorithms one by one it will take much more time to complete the process so we use the method called hyper tuning which will take less amount of time to complete the process¹³⁻¹⁵.
**System Overview:** Classification of Cancer Model for Clinically Actionable Genetic Mutations is done for the theranostics. The architecture is described as shown in Fig 1. The program of this projected system are:

1. Included Sample Data (ISD)
2. Experimental Data Analytics (EDA)
3. Data Pre-processing:
   - Text Reduction
   - Dimension Compression
   - Component Extractions
4. Component Extraction against classified data
5. Genetic mutation classes 1-9 for classification of cancer
6. Result

![Fig. 1. Architecture of Described Technique](image)

After analyzing the data, the clinical evidences must be extracted for the components\[^1\]. The Neuro Linguistic Programming method are used here. The text data is represented using VSM. The features is being represented via formula given below:

\[ t_i = w_a, w_b, \ldots, w_n \]  
\[ W_j = tf_j \times idf_j \]  
\[ Idf_j = \log \]  
\[ \frac{X}{H} = P(X)/P(H) \]

Let \( n \) consist of total amount of unique contents in the text variant data, and \( w_j \) is the weight of the \( -n^{th} \) term in \( w_j \). The recurrence of the term is given by \( tf_j \), and the transposed document recurrence is given by \( idf_j \). The \( N \) is the total amount of documents in the training variant data set, and \( r_j \) is the amount of documents that contains the term \( j \) (text_variant). These extracted components are used for future operations.

The components are extracted using one hot encoding technique from genes and variation\[^2\]. For test train the sample input data we are using the naïve Bayesian classification. The above naïve Bayesian formula consist the predictor and hypothesis\[^9\].

The logical regression technique is used to validate the accurateness and logarithmic loss.

**Included Sample Data:** The datasets has been taken from kaggle. There 9 different type of categories of classified for the genetic mutations. The datasets square measure provided via 3 totally different files - coaching and take a look at. One (training_variants) provides training process for the data, (test_variants) provides the sample data testing and (training_text) will train the text formatted clinical evidences.
Experimental Data Analytics (EDA): Experimental Data Analytics (EDA) approach is employed for knowledge analytics. It used to analyse the experimental data of the classification method.

Data Pre-processing: The data pre-processing is used to check the input analysis data and gives result. The options of clinical text are extracted using TF-IDF technique. The options of genes and their variations are extracted using one hot cryptography technique.

Component extraction against classified Data: It is constructed for extracting the numerous classification algorithms already mentioned above. The options are being validated in form of logarithmic loss and accurateness.

**Conclusion**

Here by we have done our project classification of cancer model for clinically actionable genetic mutations with prior seven machine learning algorithms (Logical Regression, K Means++, Naïve Bayesian, K-Fold Cross Validation, X-boost, LDA Cosine Similarity, K Nearest Neighbourhood). Here we are using the meta bagging method to separate the data sample and ID-TDF showing the better result analysis. The result shows 86% accuracy. Further experimentation can be applied to increase the accuracy.

COVID-19: The Invisible Massacre of the Elderly and the Possible Professional Liabilities

Andrea Cioffi

Doctor in Training-Department of Anatomical, Histological, Forensic and Orthopaedic Sciences, Sapienza University of Rome, Italy

Abstract

The elderlies are probably the most affected by the COVID-19 Pandemic. Despite this, the measures aimed at preventing the serious consequences that this health emergency may have on the elderly are still inadequate. This study analyses the effects of the current pandemic on elderlies and debilitated patients. In addition, the study focuses on the legal implications of the damages that the elderlies are suffering in this worldwide emergency.

Keywords: COVID-19; Sars-CoV-2; Health Policy; Elderly; Medical Liability; Ethics in Policy; Legal Medicine.

Introduction

COVID-19 Pandemic has created serious health, social and economic damage worldwide. Deaths due to COVID-19 continue to increase with serious repercussions. National Health Systems are implementing preventive and curative strategies aimed at containing infections and related deaths.

In this context of emergency is developing silently, especially in Europe, a serious emergency in the emergency: the massacre of the elderly in elderly homes. The numbers are worrying and there are still no appropriate strategies and solutions to contain the problem. The problem is so serious and urgent that the WHO regional director for Europe, Hans Kluge, called the Situation “deeply concerning”. This statement is based on dramatic data, in fact as of April 13, more than 55% of deaths in Ireland were linked to long-term care facilities. In France, as of April 15, more than 49% of deaths were linked to care facilities, while in Belgium more than 49% of the 4,857 deaths linked to Covid-19 as of April 16 were in care homes. Care England, Britain’s largest representative body for care homes, said that estimates based on some of the death rates since April 1 suggested up to 7,500 people in British care homes may have died of the virus, five times the official estimate. Moreover, Covid-19 related deaths in care homes in Portugal and Spain were 33% and 53% respectively.

Therefore, in many European Countries, half of the deaths for COVID-19 are elderly residents in the care homes.

Also, in Italy, where 35% of the population is over 65, there is a serious emergency related to COVID-19 related deaths in Elderly homes. The worrying number of deaths in health care facilities for the elderly has led the Italian Higher Institute of Health to carefully monitor the situation. From the careful analysis of the available data (however provisional) it has emerged that the number of deaths in Elderly homes is increasing exponentially in a worrying way, especially in 3 Italian regions (Lombardy, Piedmont and Emilia Romagna).

Legal Implications: The dramatic data of infections and deaths related to COVID-19 in care homes are even more worrying if analyzed in relation to the possible causes involved. In fact, there is growing concern around the world that these deaths were somehow predictable and preventable.
With regard to predictability, it is considered that long before the pandemic declaration it was already clear that the severe form of COVID-19 developed more easily in the elderly and that deaths were age-related. This has been confirmed by subsequent studies which have shown a higher mortality rate in older people. So, it was absolutely predictable that this pandemic would hit the elderly and debilitated more severely.

With regard to the avoidability of the numerous deaths in the elderly homes, it is important to stress that in recent weeks there have been numerous concerns in the health management of care homes. In fact, reports from health workers and relatives of victims are increasing exponentially. The criticism concerns the approach, considered ineffective and deontologically incorrect, in the field of prevention and monitoring of COVID-19 among the elderly. The problems concern the non-use of personal protective equipments (which often would not even have been provided to operators), the insufficient monitoring of body temperature and symptoms typical of COVID-19 (resulting in inadequate epidemiological and statistical classification of infections) and, even erroneous death certificates.

In this context, full of doubts still not clarified on the civil and criminal responsibilities of some elderly homes, in some states, as in Italy, we think about the possibility of creating a legal immunity for health professionals engaged in the battle against the COVID-19.

The purpose of a possible legal shield would be to protect doctors and all health professionals who could be targeted by legal proceedings for professional liability (related to the emergency COVID-19). In fact, the risk of a possible legal immunity is that the possible responsibilities of the health directorates of hospitals and homes are not properly investigated and eventually sanctioned. In fact, there are situations in which there have been questionable choices of elderly homes and care homes in the management of elderly and debilitated patients, as stated by the President of the National Medicine Board.

In this context, full of doubts still not clarified on the civil and criminal responsibilities of some elderly homes, in some states, as in Italy, we think about the possibility of creating a legal immunity for health professionals engaged in the battle against the COVID-19.

The purpose of a possible legal shield would be to protect doctors and all health professionals who could be targeted by legal proceedings for professional liability (related to the emergency COVID-19). In fact, the risk of a possible legal immunity is that the possible responsibilities of the health directorates of hospitals and homes are not properly investigated and eventually sanctioned. In fact, there are situations in which there have been questionable choices of elderly homes and care homes in the management of elderly and debilitated patients, as stated by the President of the National Medicine Board.

Conclusions

It can be said that the problem of the protection of the elderly in care homes has been greatly underestimated in many Countries. The consequences of the spread of COVID-19 among weak and elderly people were, at least in part, predictable and avoidable. The responsibility of society as a whole can be seen in the poor and superficial management of vulnerable people. Unfortunately, this pandemic has shown us that the care, energy and resources we devote to the elderly are inadequate and inappropriate. It will probably be necessary to reform the entire organization of the elderly homes, often understood exclusively as a place where “abandon” individuals no longer “useful” and difficult to manage. It is hoped that the current concept of elderly homes will evolve to co-housing (managed by health professionals). As for psychiatric patients, even for elderly people who are not self-sufficient it is necessary to overcome the logic of institutionalization to implement the logic of “social healthcare”. All this must be aimed at not abandoning the vulnerable, but at ensuring all the necessary protection.

It is precisely in situations such as this - in which appropriate health policies become necessary - that society can demonstrate humanity, efficiency and effectiveness, or incivility and anti-ethical utilitarianism.

Phytosanitary Examination: 
Ukraine Experience and International Standards

Andrii V. Dukhnevych1, Nataliia V. Karpinska2, Iryna V. Novosad3

1 Professor at the Department of Civil and Juridical Disciplines, 2 Associate Professor at the Department of Criminal Law and Procedure, 3 Senior Lecturer at the Department of Civil and Juridical Disciplines, Lesya Ukrainka Eastern European National University, 43025, 13 Volya Ave., Lutsk, Ukraine

Abstract

The article explores Ukraine’s experience in conducting phytosanitary expertise based on international standards. It was stated that Ukraine should develop a series of draft in national legislation in the field of quarantine and plant protection, which would be adapted to the legislation of the European Union and at the same time meet the requirements of the International Plant Protection Convention. It has been emphasised that Law of Ukraine No 2501-VIII “On Amendments to Certain Legislative Acts of Ukraine on Regulation of Some Phytosanitary Procedures” came into force on February 2, 2019. It has been concluded that Ukraine is currently actively applying international standards, participating in their development and registering official translations of international standards for phytosanitary measures. This creates a positive image of Ukraine as a reliable trading partner that does not violate the requirements of other countries and guarantees the conformity of product quality, phytosanitary procedures to internationally recognised standards. Therefore, for qualified phytosanitary examinations, the mechanism of guaranteeing compliance with national and international standards, amending legislation, introducing effective penalties for violation of the rules and procedure for conducting phytosanitary examinations should be a promising area.

Keywords: World Trade Organisation, phytosanitary control, international organisations, phytosanitary sector.

Introduction

Membership of Ukraine in international organisations, in particular in the World Trade Organisation (hereinafter – the WTO), the International Convention for the Protection of Plants (hereinafter – the IPPC), the Food and Agriculture Organisation of the United Nations (hereinafter – the FAO), provides for mandatory observance of the basic principles and requirements in the field of quarantine and plant protection at the international level. In view of this, the State Consumer Service of Ukraine is actively working on the harmonisation and adaptation of national phytosanitary legislation to international norms and standards. Accordingly, the requirements for the level of work of the National Organisation for Quarantine and Plant Protection are increasing. Ukraine needs to develop a series of draft national legislation in the field of quarantine and plant protection, which would be adapted to European Union legislation and at the same time meet the requirements of the International Plant Protection Convention.

It is worth noting that Ukraine has partially implemented some structural reforms in the phytosanitary sector, but these processes require constant state support and stimulation, international coordination, which will contribute to the development of agriculture in general. Such coordination can be undertaken primarily in the framework of international universal organisations within the UN system, in particular within the FAO. Thus, the revised International Standards on Phytosanitary Measures (ISPM) were adopted at the 13th session of the Commission on Phytosanitary Measures (2018): ISPM No 5 – Glossary of Phytosanitary Terms; ISPM No 6 – Supervision; ISPM No 15 – Wood Packaging Regulation in International Trade (Appendix 1 – Approved Wood Packaging Approaches (2018) and Appendix 2 – Sign (Marking) and its Use (2018)); ISPM No 42 – Requirements for the use of temperature treatments as
Ukraine has also participated in the discussion and adoption of these standards. These standards are actively used by both quarantine and plant protection professionals and manufacturers to ensure that their products comply with international phytosanitary legislation. In addition, on February 2, 2019, Law of Ukraine No 2501-VIII “On Amendments to Certain Legislative Acts of Ukraine Regulating the Implementation of Some Phytosanitary Procedures” came into force. Among the innovations are the granting of the right to carry out expert examination to private laboratories, new terms in the field of plant quarantine and the creation of the Register of Phytosanitary Certificates issued. According to the Law, private laboratory specialists were granted the right to carry out plant phytosanitary examination. However, only exporters can use these services. The owner of the cargo can choose in which laboratory to carry out an analysis—public or private.

In order to use the services of a private laboratory, the exporter must inform the regional representatives of the State Consumer Service of Ukraine about: transport, cargo, date and time of the beginning of the analysis by specialists of a private laboratory. The fact is that a private laboratory can carry out the analysis on its own, but the state representative must monitor the sampling and inspection of a cargo. Then the samples are packed in safe packages, the state phytosanitary inspector signs the act on the sampling, so the products are sent for examination. Phytosanitary examination report is valid for 14 days.

Many scientists and researchers study the methodology and technical features of expertise procedure, in particular, V.A. Makarov, V.P. Frolov, M.F. Shuklin, A.O. Kunakov, I.G. Seryogin, G.A. Talapov and others. Special attention should be paid to the scientific developments of V.I. Khomenko, V.I. Shablii, N.K. Oksamitny, G.N. Kruglyakov, who have improved the method and method of performing examinations. V.V. Vlasenko, R.Y. Kravtsov, V.I. Khomenko and others in their studies considered the procedure of documentation preparation and discussed the effectiveness of expertise procedures. I.V. Gushchuk, E.G. Slautenko study the issues of water and air pollution, which directly affects the efficiency of crops. At the same time, the issues of substantiation and modern peculiarities of exactly phytosanitary examinations procedure deserve due attention.

The aim of the article is to consider and analyse the necessity of designation and peculiarities of carrying out phytosanitary examinations in modern conditions in Ukraine on the basis of international experience and international standards.

Analysis of Organisations Dealing with Phytosanitary Expertise: Standardisation covers most areas of human activity. The WTO Agreement on the Application of Sanitary and Phytosanitary Measures (SPS Agreement) places particular emphasis on the role of international standards in establishing a multilateral system of rules and requirements governing the development, adoption and application of sanitary and phytosanitary measures to minimise their environmental impact. Thus, Article 3 of the SPS Agreement refers to international standards:

- In order to harmonise sanitary and phytosanitary measures on a broader basis, members should base their sanitary and phytosanitary measures on international standards, recommendations, if any, unless otherwise provided in this Agreement, and in particular in paragraph 3;
- Sanitary or phytosanitary measures that are consistent with international standards, recommendations, are necessary for the protection of life or health of humans, animals or plants and do not contravene the relevant provisions of this Agreement and GATT 1994.

Of particular importance is paragraph 2 of Art. 3 of SPS agreements. Taking into account the text of the preamble, the Agreement contains a direct reference to the standards developed by these organisations. The SPS Agreement establishes the rights of members to take the sanitary and phytosanitary measures necessary to protect the life or health of humans, animals or plants, which may be different from the standards set out in the Codex Alimentarius. However, such a presumption is established: measures based on international standards meet the requirements of the WTO provisions, which may serve as a basis for protection in the event of a dispute. This de facto speaks of the special status of the Codex Alimentarius Commission standards.

The Regional Plant Protection and Quarantine Organisation (RPPQO) is an intergovernmental organisation that acts as the Coordinating Body of national quarantine and plant protection organisations at the regional level. There are now ten RPPQOs, but...
the development of regional standards is carried out by the following organisations: the European and Mediterranean Organisation for Quarantine and Plant Protection, whose standards cover phytosanitary regulations and plant protection products against pests; The North American Quarantine and Plant Protection Organisation, standards designed to protect agricultural, forestry and other plant resources; The South Cone Regional Phytosanitary Committee (COSAVE), which regulates plant protection issues of particular interest to Member States.

Some issues of standardisation in the field of plant quarantine are also addressed by the International Organisation for Standardisation (ISO), created in 1946 by 25 national standardisation organisations. Its purpose is to promote the development of standardisation worldwide to facilitate international trade and mutual assistance, as well as to enhance cooperation in the fields of intellectual, scientific, technical and economic activities. Ukraine has been a full member of ISO since 1993. Member of the Committees: CASCO, STACO, INFCO. A national committee member of the DEVCO, REMCO, COPOLCO. 25 TCs of the State Standard of Ukraine cooperate with 96 TCs and ISO PCs. Ukraine is actively involved in the work of the joint TC ISO/IEC STK1 “Information Technology”, which was established in 1987.

Features of Phytosanitary Examination in Ukraine: Ukraine actively applies international standards, participates in their development and registers official translations of international standards on phytosanitary measures. In addition, in recent years, information systems (technologies) in many countries have become increasingly widespread in agriculture that help producers manage technological processes competently, with the least risk. They are used in all fields of agricultural production, including in the field of plant protection.

Phytosanitary, agroecological and economic diversity forces a large amount of information to be analysed when making decisions. In this case, it is no longer enough to only the monitor biological objects – their diagnosis and assessment of the intensity of development. In the conditions of multifactoriality of the analysed processes and multivariate decisions, not only phytosanitary diagnostics of diseased plants, but also their phytosanitary expertise is required. According to Art. 13 of the Law of Ukraine “On Plant Quarantine”, phytosanitary examination of regulated objects is carried out in order to find and/or identify regulated pests.

Phytosanitary examination is a system of phytosanitary, agroecological and agrometeorological observations and analysis, which allows to evaluate the current phytosanitary situation and to predict its development, including crop losses. Phytosanitary examination is provided by the central executive body, which implements the state policy in the field of plant quarantine, in accordance with international standards, instructions and recommendations. According to L. Baidakova, phytosanitary examination is an integral part of the state system of phytosanitary control in Ukraine. It is a set of measures aimed at protecting the territory and health of the population of Ukraine from the penetration from abroad of quarantine facilities, which can cause significant damage to the national economy of Ukraine.

The important principle of external plant quarantine is the prevention of the importation of quarantine pests to Ukraine. Many years of practice show that during phytosanitary control at border crossing points harmful organisms that are not present in the territory of our country are often found. Thus, during the period from 17.08.2019 to 12.09.2019, in the process of monitoring and inventory of old quarantine organisms, state phytosanitary inspectors found limited quarantine organisms in Ukraine, in particular:

- American white moth: in the Kirovograd region (in one area) on an area of 7 hectares; in the Odessa region (in six districts) on an area of 76.45 ha; in the Ternopil region (in one district) on an area of 0.2 ha; in the Kharkiv region (in four districts) on an area of 1.99 ha.
- Western corn rootworm: in the Volyn region (in six districts) on an area of 283.94 ha; in the Transcarpathian region (Beregovo and Chop) on an area of 15 hectares; in the Ivano-Frankivsk region (in one district) on an area of 215.25 ha; in the Odessa region (in four districts) on an area of 329 hectares.
- Potato scab: in the Ivano-Frankivsk region (in two districts) on an area of 21.945 ha; in the Lviv region (in one district) on an area of 16.64 ha.
- Cuscuta campestris: in the Kirovograd region (in three districts) on an area of 0.211 ha; in the Odessa region (in one district) on the area of 3.54 ha; in the Kharkiv region (in nine districts) on an area of 5.541 hectares.
hectares; in the Kherson region (in one district) on an area of 46 hectares.

• Russian knapweed: in the Kherson region (in one area) on an area of 2.5 ha.

• Cenchrus: in the Kherson region (in one area) on an area of 2 ha.\(^6\)

The results of the examination of each sample, carried out depending on the complexity of the analysis by laboratory specialists or inspectors, determine the phytosanitary status of the entire consignment and recommend certain phytosanitary measures.\(^7\) Phytosanitary examination is carried out directly by phytosanitary laboratories, which are located in every region of Ukraine. Functional flowchart of phytosanitary examination covers four main stages: I – diagnostics of dangerous harmful objects; II – phytosanitary monitoring; III – examination of phytosanitary risks; IV – decisions making about plant protection.\(^8\)

National plant protection organisations, carrying out phytosanitary risk analysis (hereinafter referred to as PRAs), should rely on biological and other scientific and economic data in accordance with relevant ISPMs.\(^9\) When performing PRAs, it is also necessary to consider the threats to biological diversity that result from the impact on plants. It is the latest advances in science, technic and technological advances in electronics and information technology that allow to quickly receive and analyse any amount of necessary information. Express method of diagnostics of harmful microorganisms, field microcomputers, automatic weather stations, satellite navigation systems, electronic data warehouses, operational satellite weather maps, geo-information phyto-landscape maps, etc. are now widely available.

Today, many countries have developed and are using a variety of decision support systems to manage the protection of agricultural crops, including cereals, from harmful organisms. A DESSAC system has been set up in England to support decision-making to protect crops from disease. The system is installed on the user’s computer. At program start-up, system users automatically receive meteorological information from nearby meteorological stations, enter agroecological data, the degree of disease development and spread, and the cost of the fungicide.\(^10\) In the Netherlands, Dacom company has developed PLANT-Plus. The model used by the system takes into account information on plant status, disease development, preliminary and prognostic weather conditions. It advises when and how to treat fungicides.\(^11\) In the United States, MoreCrop system operates to manage protection of wheat and barley against disease in the Northwest Pacific. It is designed for thirty plant diseases that are spread throughout the United States and in individual regions. In total, 11 factors are analysed.\(^12\) In Denmark, the Landbrugsinfo system has been developed and maintained to help farmers make operational decisions to grow field crops, considering agro-meteorological and phytosanitary situations.\(^13\)

For Ukraine, the use of decision support systems for the protection of, for example, cereals based on phytosanitary expertise is particularly significant. Phytosanitary security of any state means the protection of its territory from the risks that arise in the event of the penetration, spread and mass reproduction of pests, diseases of plants and weeds. The latter poses a real danger and can cause significant economic losses in a very short time. It is known that, as a result of pest activity, national agricultural producers lose more than 30% of their gross harvest annually.\(^14\)

**Conclusions**

Developing national and applying international standards, as a key factor in creating a quality system in the field of plant quarantine, not only ensure full fulfilment by Ukraine of its obligations under the IPPC and SPS, agreeing on the phytosanitary safety of exported quarantine cargoes, but also increase the competitiveness of the domestic vegetal products in the world market. This creates a positive image of Ukraine as a reliable trading partner that does not violate the requirements of other countries and guarantees the conformity of product quality, phytosanitary procedures to internationally recognised standards. Therefore, for qualified phytosanitary examinations, the mechanism of guaranteeing compliance with national and international standards, amending legislation, introducing effective penalties for violation of the rules and procedure for conducting phytosanitary examinations should be a promising area.

**Acknowledgments:** None.

**Conflict of Interest:** There is not conflict of interest.

**Ethical Clearance:** All procedures performed in studies involving plant were in accordance with the ethical standards of the institutional and national
research committee of the International Plant Protection Convention. A study was performed in accordance with the Law of Ukraine “On Amendments to Certain Legislative Acts of Ukraine on Regulation of Some Phytosanitary Procedures”, February 2, 2019, No 2501-VIII.

Covid 19 Pandemic-
A Bane to Seeking Information in India

Ankit Gupta¹, Vikas Gupta²

¹Research Scholar of Ph.D in Law at Amity Law School, Amity University, Noida, Uttar Pradesh, India,
²Associate Professor of Law at Amity Law School, Amity University, Noida, Uttar Pradesh,
India and is Guide of Research Scholar

Abstract

Right to seek information is a right deeply embedded into Article 19 of the Indian Constitution and which generally cannot be suspended in the worst of the worst situations save exceptions. The right guarantees Indian citizens to seek information from the public authorities on the touchstone of informed citizenry, greater and transparent access to information, accountability, and optimum use of limited fiscal resources. The recent impact of COVID-19 has not only shaken the basic edifice in India but has also weakened the countries across the world in some or the other mode. In a way the pandemic has caused immense trench in the economic as well as social well-being of the citizens.

The Right to Information Act, 2005¹ was enacted by the Parliament in India with the aim to provide for setting out the practical regime of right to information for citizens to secure access to information under the control of Public Authorities. The basic objective of the Right to Information Act is to empower the citizens, promote transparency and accountability in the working of the Public Authorities, contain corruption, and make our democracy work for the people in real sense.

Therefore an attempt in this paper has been made to ascertain, whether the rights of citizen to seek information in this great despondency time of Covid-19 has been able to bolster or not. Weather the right to information as guaranteed by the Indian Constitution is available to citizen irrespective of the pandemic situation.

Keywords: Right to information, Legal knowledge, Covid-19 crisis, unavailability of information due to lockdown.

Introduction

The origin of the Right to Information Act, 2005 in India is dated back to the Mazdoor Kisan Shakti Sanghatan (MKSS) which was an organization developed for the purpose of empowering the workers and landless farmers and other rural poor in 1987. At that time nobody could ever thing of raising a legit brow before the government for their actions and inactions but this organization began its work regarding seeking information in the State of Rajasthan during the early 1990s by organizing grassroots movement by demanding access to government information with respect to wage workers and other small farmers who were not given their rightful wages or were devoid of obtaining other benefits under the different government schemes. MKSS introduced the innovative concept of jansunvai or public hearing through which the organization started demanding for more information from the local government authorities with respect to their wages, attendance rolls as well as the material used for road construction during the relief work done during famine². Political activists in India got a lot of inspiration from this small beginning in the village of Rajasthan and similarly started demanding information from the bureaucracy and the government. The struggle of the activists spread this fire across the country and increased the demand of the public to guarantee the right of information to every citizen. This movement received support from other social activists, professionals, and other media who support transparent and accountable governance and empowering people³.
The sense of gaining information and thereafter utilizing the information to ascertain the good and the bad use of it by government created pressure and demand to codify law related to seeking information and thus the same resulted in enactment of various legislations viz. The Freedom of Information Act, 2002 and thereafter the Right to Information Act, 2005. The judicial verdicts have time and again balanced as to what information is to be provided and what is to be no provided. Moreover the courts in India has been enthusiastic in coming to aid of people who seek information and are denied the same under the veil of exemption provisions in the RTI Act, 2005 by imposing cost and invoking penal provisions. Moreover the recent Right to information Act has been designed to provide information to applicant within 48 hours of application in case the information sought relates to life and liberty of any person.  

Covid-19 in India and Seeking of Information:

COVID-19 is the infectious disease caused by the most recently discovered corona virus. This new virus and disease were unknown before the outbreak began in Wuhan, China, in December 2019. The first case of the COVID-19 pandemic in India was reported on 30 January 2020. Since the first case of Covid-19 is reported in India, the government of India has taken steep steps to ensure that rapid expansion of this pandemic is not caused and has declared complete lock down in the nation, following which only the essential services were allowed to be undertaken and all the shops, malls, cinemas, public amusement parks, stadiums etc. were closed for public access.

According to the Right to Information Act, the appeals and complaints against public authorities of the Central government and Union Territories, Supreme Court and High Courts besides Public Sector Undertakings and autonomous Institutions set by Centre are heard by the Central Information Commission while those of State are heard by respective State Information Commissions.

Sadly, as per a study out of 29 Information Commissions in our country, 21 state panels did not hold any hearings to adjudicate complaints and appeals of RTI applicants during lockdown. The study said 21 commissions did not hold hearings. Only seven commissions, made provision for taking up urgent matters or those related to life and liberty during the period when normal functioning was affected due to the lockdown. These were the Central Information Commission and the state information commissions of Arunachal Pradesh, Haryana, Manipur, Punjab and Telangana. The State Information Commission of Rajasthan made provision for hearing such matters, though only from May 4, 2020.

The commissions also known as transparency watchdogs mandated to enforce proactive disclosure of information from government were found wanting on their website, according to the study, with websites of 11 commissions did not showing any information about the functioning of the Information Commission during lockdown.

The functioning of the state information commission is almost like the Central Information Commission.

When an RTI applicant is not satisfied with the response of the officer handling his query or with the appeal within the department against the decision, a second appeal is filed before the Information Commission, independent bodies to adjudicate the matter.

Eleven Commissions referred in the study are Assam, Bihar, Himachal Pradesh, Kerala, Madhya Pradesh, Manipur, Meghalaya, Mizoram, Nagaland, Sikkim and Tripura. The study also found that Jharkhand and Tripura did not have any commissioners for varying lengths of time and were completely defunct as the serving information commissioner in both retired during the period of the lock down. Four State Information Commissions were functioning without a Chief Information Commissioner - Bihar, Goa, Rajasthan and Uttar Pradesh.

COVID-19 and Judicial Intervention

- Constitution of High-Powered Committee in each state/union territory for release of prisoners on parole or interim bail (dated March 23, 2020)

In Suo Motu Writ Petition (C) No. 1/2020, In Re: Contagion of COVID-19 Virus in Prisons, a Bench of Chief Justice SA Bobde, and Justices L Nageswara Rao and Surya Kant directed that prisons must ensure maximum possible distancing among the prisoners, including undertrials.
The Bench also directed that the physical presence of all the undertrial prisoners before the courts must be stopped forthwith and recourse to video conferencing must be taken for all purposes. The transfer of prisoners from one prison to another for routine reasons was also prohibited, except for purpose of decongestion.

The Bench further directed that each State/Union Territory shall constitute a High Powered Committee comprising:

(i) Chairman of the State Legal Services Committee,
(ii) The Principal Secretary (Home/Prison)
(ii) Director General of Prison(s)

This Committee was empowered with determining which class of prisoners can be released on parole or on interim bail for such period as may be thought appropriate. The Bench suggested that each State/Union Territory consider the release of prisoners who have been convicted or are under trial for offences for which the prescribed punishment is up to 7 years or less, with or without fine and the prisoner has been convicted for a lesser number of years than the maximum.

• Directions for the interest of children who fall within the ambit of the Juvenile Justice Act (dated April 3, 2020)

In Suo Motu Writ Petition (Civil) No. 4/2020, In Re: Contagion of COVID-19 Virus in Children Protection Homes, a Bench of Justices LNageswara Rao and Deepak Gupta issued a slew of directions to prevent the spread of the Coronavirus in Child Care Institutions (CCIs). These include children in need of care and protection, children in conflict with the law in Observation Homes, and children in foster and kinship care.

The Child Welfare Committees were directed to monitor cases telephonically for children who have been sent back to their families and to coordinate with the District Child Protection Committees and Foster Care & Adoption Committees and establish online help desks and support systems for queries at the state level for children and staff in CCIs.

It was also directed that the Juvenile Justice Boards and Children Courts take measures for organizing online video sessions for conducting inquiries and to consider taking steps to release children alleged to be in conflict with law, unless there are clear and valid reasons for the application of the proviso to Section 12, JJ Act, 2015.

The authorities were also directed to ensure adequate budgetary allocation to meet the costs that are likely to arise for the effective management of the pandemic. CCIs were directed to take necessary steps to practice, promote and demonstrate positive hygiene behaviour and monitor their uptake, conduct regular screening of children lodged in institutions, and follow the Health Referral System.

- Guidelines for court functioning through video conferencing during COVID-19 pandemic (dated April 6, 2020)
- In Suo Motu Writ Petition (Civil) No. 5/2020, In Re: Guidelines for Court Functioning Through Video Conferencing During COVID-19 Pandemic, a Bench of CJI Bobde and Justices DY Chandrachud and LNageswara Rao directed that all measures shall be taken by the Supreme Court and by the High Courts to reduce the need for the physical presence of all stakeholders within court premises and to secure the functioning of courts in consonance with social distancing guidelines.
- It was directed that the Supreme Court of India and all High Courts are authorized to adopt measures required to ensure the robust functioning of the judicial system through the use of video conferencing technologies. It was directed that the district courts in each state shall adopt the mode of video conferencing prescribed by the concerned High Court, and the Court shall duly notify and make available the facilities for video conferencing for such litigants who do not have the means or access to video conferencing facilities.
- It was further directed that video conferencing shall be mainly employed for hearing arguments whether at the trial stage or at the appellate stage and the presiding officer shall have the power to restrict entry of persons into the court room.
- Conduct of COVID-19 tests should be done free of cost (dated April 8, 2020)

In Writ Petition (Civil) Diary No(s). 10816/2020, Shashank Deo Sudhi V. Union of India, a Bench of Justices Ashok Bhushan and S Ravindra Bhat directed that the tests relating to COVID-19, whether in approved government laboratories or approved private laboratories, shall be done free of cost. It was further directed that tests relating to COVID-19 must be carried out in NABL accredited labs or any agencies approved by WHO or ICMR.
• COVID-19 tests by private labs should be done free of cost only for EWS, those eligible under Ayushman Bharat Yojana (dated April 13, 2020)

Modifying its order dated April 8, the Bench directed that free testing for COVID-19 shall be carried out for persons eligible under Ayushman Bharat Pradhan Mantri Jan Aarogya Yojana and any other category of economically weaker sections of the society. It was also directed that the Ministry of Health and Family Welfare may consider as to whether any other categories of the weaker sections of the society were also eligible for the benefit of free testing.

The Supreme Court has risen to the occasion and has put its best foot forward to preserve the rule of law in our country envisaged by the Constitution of India, even at this cataclysmic juncture. The High Courts of our country have also taken steps in ensuring that access to justice remains ubiquitous and approachable.

The use of modern technology for enhancing justice dispensation has been profusely encouraged by the Supreme Court of our country so that hearings can be carried out effectively and successfully through virtual mode.

**Conclusions**

The RTI Act as introduced in the year 2005 lays down comprehensive statutory and procedural method in order to guarantee the right to freedom of speech and expression to Indian citizens and more necessarily “Right to Know”. The Supreme Court of India had, in several judgments prior to enactment of the RTI Act, upheld the Constitutional provisions to enshrine Right of Information as the fundamental right which is provided as right to freedom of speech and expression and also in right to life. Under the RTI Act, the government bodies and government-funded agencies are required to designate a Public Information Officer (PIO) whose responsibility is to make sure that the information which has been requested is disclosed to the applicant within the duration specified which is 48 hours in cases where information required is related to the existence or independence of a person, to up to 30 days. The Act has been seen to be inspired by earlier legislations which were enacted in states including Maharashtra, Goa, Karnataka, Delhi amongst others. The implementation of the RTI Act helped citizens in attaining the right to information of varying degrees with respect to activities of any state or central government body. Recently, there have been disclosures of various high-profile cases which have revealed corruptions in different schemes of government including scams in public distribution systems, disaster relief and construction projects amongst others. The law has been viewed as a milestone in the drive of India towards more directness, transparency and responsibility in the government.

But, despairingly the recent situation of pandemic COVID-19 has let the constitutional spirit behind the legislation to a halt and due to which the right as guaranteed by the Indian Constitution in the hands of the citizens has been severely hampered. Several Information commissions across the country have stopped or limited the working. The citizens are facing hard time to approach the information commissions for getting the information sought or to file appeal against the non-disclosure of information by the PIO of the CPIO due to non-availability of standard operating procedures in the tough time of pandemic which is experienced by the world for the first time ever.

Effect of Bosu Ball Versus Swiss Ball on Core Strength in Overweight and Obese Post Menopausal Working Women

Ankita Mane¹, Amrutkuvar Rayjade²

¹Intern, Faculty of Physiotherapy; ²Associate Professor, Department of Musculoskeletal Sciences, Faculty of Physiotherapy, Krishna Institute of Medical Sciences Deemed to be University, Karad, Maharashtra, India

Abstract

Background: During post menopausal period, many changes take place in women physiologically. Among them core muscle weakness, pelvic floor dysfunction. There can be some measures taken for improving core strength in women. It leads to the cessation of ovarian estrogen production concurrent to the deterioration of muscle function. So this study is an effort made to check either bosu ball is effective or swiss ball.

Aims and Objective: To find the effect of bosu ball versus swiss ball for core strengthening in post menopausal women. Objectives: to compare effect of bosu ball and swiss ball for core strengthening in post menopausal women.

Subject and Methodology: The experimental study was carried over a period of 12 weeks. Sampling size includes total 24 subjects. 12 in each group, materials used were bosu ball, Swiss ball, pen, paper. Study was conducted in Krishna college of physiotherapy.

Result: And it was found that for bosu ball; before protocol trunk stability test and abdominal curl test was performed and it was found that by 70% the strength had been improved in population who followed the bosu ball protocol. For trunk stability test the p value was <0.0001 which was extremely significant. For abdominal curl test the p value was <0.0001 which was extremely significant. The results for swiss ball by trunk stability test were, p value was <0.22 which was not significant. For abdominal curl test the p value was <0.20.

Conclusion: Bosu ball was effective than swiss ball.

Keywords: Post menopausal women, bosu ball, swiss ball, core strength.

Introduction

“PAUSE”

Yes, she just had her menopause.

Yes, she still yearns to live life to the fullest!

What exactly is menopause, Menopause is defined as the time when there has been no menstrual periods for 12 consecutive months¹. Also it occurs when there is complete, or near complete, ovarian follicular depletion of females ovaries. It generally occurs at a median age of 51.4 years and menopause before the age of 40 years is considered abnormal. The months and years leading up to this are called perimenopause. Hot flushes, vaginal dryness, depression, sleep disturbances, joint pain, and cognitive changes are some of the pre warning signs of menopause¹.

Physiologically, a female ovary has the largest number of gametocytes during the 5th month of gestation and has approximately 1 million of gametocytes at birth
as women ages normal openings or follicular tubes in the body are closed, which reduces the number of gametocytes. As a result, at the time of menopause a women may have a few thousand or a few hundred gametocytes left. As the ovary produces three hormones: estrogen, progesterone and androgens. Among the estrogens, estrone (E1), estradiol (E2) and estriol (E3) are the three produced estrogens. Estradiol is the most potent natural estrogen and is produced during the monthly menstrual cycle. Fluctuations and deficiencies in estrogen levels cause many of the menopausal signs and symptoms. Natural menopause, pre mature of early menopause, surgical or induced menopause are some of the types of menopause(1).

Strengthening core has become a major trend in rehabilitation. It is a description of the muscular control required around the lumbar spinae to maintain functional stability(2). Core training excluding the diaphragm for old individuals can also improve balance ability. Strength exercises for muscles are therefore hypothesized to help improve balance ability during sitting without support. Contraction of trunk core muscles increases intra-abdominal pressure, providing stability and stiffness of the body(3). The core programme should progressed and planned gradually as exercising the core muscles is more than trunk strengthening(4). A variety of core exercises are used to develop core strength and core stability which are believed to be important for women. Curls up and sit ups are the most common abdominal exercises. Unstable surfaces, such as swiss ball, bosu ball have been used to increase the neuromuscular stress in the core muscle compared with a stable surface. In rehabilitation, BOSU and swiss ball may be beneficial because the body responds to the instability of the ball to remained balanced, engaging many more muscles. Swiss ball abdominal crunch is one of the exercise for core strengthening(8). The greatest benefit of moving an exercise onto an unstable surfaced is achieving a greater activation of the core musculature(9). An unstable surface increases activation of the rectus abdominis muscle and allows for greater activity or exercises when compared to a stable surface. Core stability exercises on and off a swiss ball(10), Exercise such as a curl ups on an exercise ball yields a greater amount of electromagnetic field compared to exercise on a stable platform. Performing standard exercises, such as a push up on an unstable surface can be used to increase activation of core trunk stabilizers and in turn provide increased trunk strength and greater resistance to injury.

Aims: To find the effect of bosu ball versus swiss ball for core strengthening in post menopausal women.

Objectives:
1. To determine effect of bosu ball in post menopausal women.
2. To determine effect of swiss ball in post menopausal women.
3. To compare effect of bosu ball and swiss ball for core strengthening in post menopausal women.

Material: The experimental study was carried over a period of 12 weeks. Sampling size includes total 24 subjects. 12 in each group, materials used were bosu ball, swiss ball, pen, paper. Study was conducted in Krishna college of physiotherapy.

Methodology
The ethical clearance was taken from the institutional ethical committee of Krishna institute of medical sciences “deemed to be” university karad. A experimental study was conducted over period of 12 weeks in post menopausal women in musculoskeletal department of Krishna college of physiotherapy. Prior consent was taken and study was explained to the participants. The participant were attended and assessed personally with 15 to 30 mins of session per day. Major outcome measure were swiss ball and bosu ball.

Procedure: Exercises on swiss ball:
1. Stability ball crunch: ask the subject to lie face up on the ball, with the ball under low back. Keep feet on the floor, hip width apart, and behind ears. Brace core, tighten glutes and slowly crunch upper body upward, raising shoulders off the ball and tucking chin to chest. Slowly lower upper body down to return to start.
2. Stability ball oblique crunches: procedure same as above. Brace core by pulling navel toward spine. Tightens glutes and slowly crunch up and to the right. Ask to lift shoulder blades off the ball and rotate upper body to the right. Lower the back down and repeat on the left side.

3. Ball crunch: legs elevated, lie on back, calves on top of the exercise ball and arms across chest. Roll shoulder blades up and lower back down after a short pause. To avoid strain in neck, ask the subjects to look straight up instead of looking at knees.

Exercises on Bosu ball:

1. Bosu one leg bridge: ball flat on floor. Lie down on back and place feet on top of the ball. Raise one leg towards the ceiling and push hips up again before touching the floor. Repeat for 10-15 repetitions on each leg.

2. Crunch: lay on bosu ball and bring feet towards the body. Place hands behind head, engage the abs, and slowly raise the upper body (looking upwards).

3. Sit ups: lay over the bosu ball. Raise arms towards the ceiling, engage the abs, and then raise the upper body and towards feet. Hold for a secs and return to starting position.

Inclusion Criteria:

1. Age group beyond 45-50 years.
2. Post menopausal women who were willing to participate.
3. Only working women are considered for the study.
4. BMI with overweight and obese grade I, grade II

Exclusion Criteria:

1. Recent fractures
2. Soft tissue injuries
3. Episodes of mechanical or specific back pain.
4. Carcinoma
5. Cardiovascular conditions.

Limitation:

1. Only post menopausal women are taken.
2. Only working women were included.
3. Only grade I, II obese women were included.

Suggestions and Recommendations:

1. This study can be done on large populations.
2. This study can be made more precise with more details.
3. Non working women can also be included.

**Result**

After analyzing the data, significant effect was found on post menopausal women after the protocol by using bosu ball and swiss ball respectively. It was found that bosu ball was effective than swiss ball based on the tests such trunk stability test and abdominal curl up test. Before and after protocol reading were assessed accordingly. The results were as follows: Three exercises in each group were given i.e stability ball crunch, stability ball oblique crunch, and ball crunch on swiss ball and one leg bridge, crunches, and sit ups on bosu ball. The study was carried for 12 weeks. And it was found that for bosu ball; before protocol trunk stability test and abdominal curl test was performed and it was found that by 70% the strength had been improved in population who followed the bosu ball protocol. For trunk stability test the p value was <0.0001 which was extremely significant, t value was 9.62, standard deviation before and after protocol was 1.9 and 1.6 respectively. For abdominal curl test the p value was <0.0001 which was extremely significant, t value was 6.99 and standard deviation before and after was 2.2 and 4.4 respectively. The results for swiss ball by trunk stability test were, p value was <0.22 which was not significant, t value was 1.26, standard deviation before and after the protocol were 1.11 and 0.66 respectively. For abdominal curl test the p value was <0.20, t value was 1.30 and standard deviation before and after the protocol were 0.68 and 0.54 respectively.

**Discussion**

Menopause is defined as the time when there has been no menstrual periods for 12 consecutive months\(^1\). Also it occurs when there is complete, or near complete, ovarian follicular depletion of females ovaries. Therefore, the objective of this study was to find effect of bosu ball versus swiss ball exercises training and find whether bosu ball is effective or swiss is effective.

The study shows that how much the effect is caused by which treatment protocol in post menopausal women. The study is one of its kind providing basic information regarding the effect of bosu ball versus swiss ball on core strength in overweight and obese post menopausal working women. To our knowledge no such study is conducting to find out the effect of bosu ball versus swiss ball on core strength in overweight and obese post menopausal working women.

Two tests were carried out such as trunk stability test and abdominal curl test which were conducted among 24 subjects, 12 in each group over a period of 12 weeks.
was studied in the population including working women in any field. They were also examined according to the their age beyond 45 years, body mass index ranging from 25 to 39.9 according to the classification discovered by WHO. The results were achieved by performing the tests. In this study Age group beyond 45-50 years was included, only working women were considered and BMI with overweight and obese grade I, grade II were included. A exercise protocol was given which includes exercises such as Stability ball crunch, Stability ball oblique crunch and ball crunch for swiss ball. bosu one leg bridge, crunch and sit ups for bosu ball were performed. And a significant result was found. After that data analysis was carried. The readings were compared of before and after protocol as follows: based on two tests which were trunk stability test and abdominal curl test to check the core muscle strength. And it was found that for bosu ball; before protocol trunk stability test and abdominal curl test was performed and it was found that by 70% the strength had been improved in population who followed the bosu ball protocol. For trunk stability test the p value was <0.0001 which was extremely significant, t value was 9.62, standard deviation before and after protocol was 1.9 and 1.6 respectively. For abdominal curl test the p value was <0.0001 which was extremely significant, t value was 6.99 and standard deviation before and after was 2.2 and 4.4 respectively. The results for swiss ball by trunk stability test were, p value was <0.22 which was not significant, t value was 1.26, standard deviation before and after the protocol were 1.11 and 0.66 respectively. For abdominal curl test the p value was <0.20, t value was 1.30 and standard deviation before and after the protocol were 0.68 and 0.54 respectively.

In another study “The effects of training by virtual reality or gym ball on pelvic floor muscle strength in postmenopausal women: a randomized controlled trial” which was studied by Martinho N, Silva V. A randomized controlled trial was conducted with 60 postmenopausal women, randomly allocated into two groups: Abdominopelvic training by virtual reality APT_VR (n=30) and PFMT using a gym ball – PFMT_GB (n=30). Both types of training were supervised by the same physical therapist, during 10 sessions each, for 30 minutes. The outcome endurance was higher in the APT_VR group (p=0.003; effect size=0.89; mean difference=1.37; 95% CI=0.46 to 2.28). Conclusion: Both protocols have improved the overall PFM strength, suggesting that both are equally beneficial and can be used in clinical practice.

In the current study, it was seen that the treatment protocol given on BOSU ball was more effective than the treatment given on swiss ball. Many other etiological factors can be responsible for reduced core strength. however further studies are required with a large sample size to get a deep insight about the effect.

**Conclusion**

By this study, it was found that bosu ball was more effective than swiss ball with p value <0.0001 which was extremely significant.

COVID-19 in Children and Policy of the Indonesian Government to Begins New School Year

Anna Wijayanti¹, Ratna Dwi Wulandari², Agung Dwi Laksono³

¹Master Program in Health Policy and Administration, Faculty of Public Health, Universitas Airlangga, Indonesia, ²Researcher, Department of Health Policy and Administration, Faculty of Public Health. Universitas Airlangga, Indonesia, ³Researcher, National Institute of Health Research and Development, Indonesian Ministry of Health

Abstract

The New Coronavirus 2019 pandemic (COVID-19) is the world’s health crisis. Various aspects of the virus are still unknown. As the COVID-19 virus became more prevalent, the Government of Indonesia issued several types of policies, including in the education sector, by closing schools as an emergency measure to prevent the spread of infection. But when the start of the new school year, it makes parents who have school-age children start to worry, if it will start during this pandemic. The study aimed to find a picture of the impact of the Ministry of Education’s policy discourse on the start of a new school year for school-aged children. The study design was conducted with a descriptive analysis approach which was carried out through a literature review. The results of the study found that although children tend to have mild symptoms of COVID-19, it did not mean we should ignore those who have this disease. We still need to take steps to prevent them from becoming infected. Policies for reopening schools must be carefully considered. Among them were waiting for conditions to be safe from the impact of COVID-19 following the decisions of the COVID-19 Task Force and the Ministry of Health, as well as the local government as the person in charge of basic education.

Keywords: COVID-19, new school year, health policy.

Introduction

COVID-19 pandemic is a health crisis in the world. Various aspects of the virus are still unknown. Studies show that the transmission of the COVID-19 virus is through respiratory droplets and direct contact with secretions containing the virus. The cause of the high prevalence of this disease can be attributed to the long incubation period and its transmission in periods without symptoms, mild, or before it appears. It also found viral symptoms in people with chronic diseases, such as cardiovascular disease, diabetes, cancer, hypertension, and chronic respiratory diseases. The risk of viral infection increases with age¹.

As the COVID-19 virus became more prevalent, the Government of Indonesia issued several policies, including in the field of education. The government closed schools nationally as an emergency measure to prevent the spread of infection. Massive efforts were made by schools and teachers at all levels of education to create lectures, or provide course material, and examinations, online, in a short time. Online learning activities are not a new thing for school children, because before they were accustomed to doing semester tests online. It’s just that now they have to start adapting again by providing online subject matter. The virtual semester has also begun in many parts of the country that were affected first. This policy helps alleviate many parents’ concerns about their children’s educational attainment, by ensuring that school learning is largely uninterrupted. But when the new school year will start

e-mail: ratna-d-w@fkm.unair.ac.id
again, parents who have school-age children will start to worry, if it will start during this pandemic. Based on the background description, the study aimed to find out the impact of the Ministry of Education’s policy discourse on the commencement of the new school year in schools with children of school-age children.

Method

The method used in this research was the study of literature, which was the study of the object of research in the form of literary works, whether in the form of scientific journals, books, articles in the mass media, or statistical data. The literature would be used to examine research problems and how to deal with them. The nature of the study conducted was descriptive analysis which was to give a picture to the reader so that it could be a medium of public education. The type of data used was secondary data.

Findings:

COVID-19 in children: COVID-19 is a new type of coronavirus that has infected people from many countries in the world. Early reports indicate that children are relatively protected from this virus compared with adults. The mission of the World Health Organization’s collaboration with China in February 2020 on Coronavirus Disease found that only 2.4% of cases were in those under the age of 19\(^2\). Besides, the severity of the disease in infected children is less than the total infected population. Only 2.5% of children suffer from severe illness (compared to 13.8% overall) and 0.2% of children suffer from critical illness (compared to 6.1% overall). Severe illness is defined as dyspnoea, tachypnoea, hypoxia, or infiltrates that affect more than 50% of the lung space within 48 hours, and critical illness is defined as respiratory failure, septic shock or multi-organ failure. Although the number of reported cases is quite small, young infants appear to have a relatively low level of influence; one study of nine infected infants found that none needed intensive care or had significant complications. However, certain pediatric populations, such as babies born prematurely, tend to be very vulnerable, with one death confirmed in this subgroup. Further evidence is likely to emerge over time about how children globally will overcome this epidemic disease\(^3\).

The immune systems of children and adults are different, both in terms of their composition and functional responsiveness\(^4\). Besides, there are differences in the immune systems of very young children, preschoolers, and adolescents. During the early weeks of life, newborn human babies are faced with a series of exposures to new environments that undergo dramatic changes\(^5\). Another difference between newborns and older children is the presence of several maternal antibodies during the first months of life. These antibodies do not include new viruses such as SARS-CoV2\(^5\). One possible explanation for the presentation of COVID-19 milder disease in children is that children have a qualitatively different response to the SARS-CoV2 virus than adults. Another possibility is that the presence of other simultaneous viruses in the lung mucosa and airways, which is common in children, can limit the growth of SARS-CoV2 through direct virus-to-virus interaction and competition\(^7\). This is consistent with data emerging from the current pandemic, which has shown a relationship between the number of copies of the virus and the severity of COVID-19\(^8\). This condition could also explain some of the tragic deaths of health care workers, who may have been exposed to a large number of SARS-Cov2 viruses.

Another possible theory for mild COVID-19 infection in children is related to differences in the expression of angiotensin-converting enzyme (ACE) 2 receptors needed for binding to SARS-Cov2 infection. These receptors are expressed in the airways, lungs, and intestines, but not in immune cells\(^9\). Treatment with ACE inhibitors or angiotensin receptor blockers induces ACE2 expression. Both of these therapies are common in adults with hypertension and less frequently in children. This has led some to believe that increased ACE2 expression may explain worse results in adults infected with SARS-Cov2, but others have reported the protective effect of ACE2 during lung infections\(^10\). Although children tend to have mild forms of COVID-19 symptoms, that does not mean that we should ignore those who have this disease.

Government Policies in the Field of Education:

The government has issued a policy for education which is to close schools and provide subject matter and examinations online. Although these steps and efforts are highly commendable and necessary, there is reason to be worried because the closure of long schools and confinement at home during an outbreak may harm the physical and mental health of children\(^11,12\). This can be proven when inviting or when children leave school activities (for example weekends and school holidays), they are physically less active, have more time to play
with gadgets, irregular sleep patterns, and fewer dietary patterns. Resulting in weight gain, and loss of physical fitness\textsuperscript{13}. Such negative effects on health are likely to be far worse when children are locked up in their homes without outdoor activities and interactions with friends of the same age during the outbreak.

Perhaps this pandemic issue is more important, but don’t overlook the psychological impact on children and adolescents. Stress resulting from prolonged quarantine duration, fear of infection, frustration and boredom, inadequate information, lack of direct contact with classmates, friends, and teachers, lack of personal space at home, and family financial losses, can have more problematic effects and lasts long in children and adolescents\textsuperscript{12}. According to Sprang and Silman show that the average post-traumatic stress score is four times higher in children who have been quarantined than those who are not quarantined\textsuperscript{14}. Furthermore, the interaction between lifestyle changes and psychosocial stresses caused by confinement at home can further exacerbate the effects on a child’s physical and mental health, which can lead to recurring circles.

To reduce the consequences of confinement at home, governments, non-governmental organizations, communities, schools, and parents need to be aware of the downside of this situation and do more to deal with these problems immediately. The experience learned from previous outbreaks can be useful for designing new programs to overcome this problem in Indonesia\textsuperscript{15}.

The government needs to increase awareness of the potential physical and mental health effects of confinement at home during this unusual period. The government must also provide guidelines and principles for effective online learning and ensure that the contents of school subject matter meet the educational requirements. But it is also important not to burden students. The government might mobilize available resources, involve non-governmental organizations, and create a platform to gather the best online education courses on healthy lifestyles and psychosocial support programs available for schools. For example, in addition to innovative courses for a better learning experience, promotional videos can be useful to motivate children to have a healthy lifestyle at home by increasing physical activity, having a balanced diet, regular sleep patterns, and good personal hygiene. These actions make this educational material truly effective, appropriate for their age, and interesting\textsuperscript{16}.

The community can also function as a valuable resource in managing family difficulties. For example, a committee of parents can work together to bridge student needs with school requirements and advocate for children’s rights to a healthy lifestyle. Psychologists can provide online services to deal with mental health problems caused by domestic conflict, tension with parents, and anxiety due to this pandemic\textsuperscript{15}. Social workers can play an active role in helping parents deal with family problems arising from the situation if needed. Social safety nets or some kind of cooperative of parents can be very useful for disadvantaged families or single parents\textsuperscript{17}. These services make it easily accessible to them when needed.

Schools have an important role, not only in presenting educational material to children but in offering opportunities for students to interact with teachers and get psychological counseling. Schools can actively promote health-conscious schedules, good personal hygiene, encourage physical activity, proper diets, and good sleep habits, and integrate health promotion materials into the school curriculum\textsuperscript{11}.

In terms of quarantine or at home, parents are often the closest and best source for children to seek help. Closed or open communication with children is the key to identifying any physical and psychological problems and to entertain children in prolonged isolation\textsuperscript{18,19}. Parents often become important role models in healthy behavior for children. Good parenting skills are very important when children are locked up at home. In addition to monitoring children’s performance and behavior, parents also need to respect their identity and needs, and parents need to help children develop self-discipline skills. Children who are constantly exposed to news related to the epidemic, so having direct parent conversations with children about this problem can reduce their anxiety and avoid panic\textsuperscript{19}. Quarantine or home activities alone can offer a good opportunity to increase interaction between parents and children, involve children in family activities, and improve their independent skills\textsuperscript{18}. With the right care approach, family ties can be strengthened, and the psychological needs of children are met\textsuperscript{20}.

Indonesian Government’s Policy to Begin a New Academic Year: The Ministry of Education will reopen schools simultaneously, starting a new school year, but not with face-to-face teaching and learning method. The method of learning for the new school year will
depend on the conditions of each region. Terms related to this condition will later be announced by the Ministry of Education, and explain that the start date of the new school year can vary by region because the education calendar is made by the local government. Generally, the new school year begins in the third week of July. But this is only for areas in the green zone and eligible. In anticipation of the fact that the pandemic has not ended until the end of the year, the Ministry of Education prepares a home learning scenario until the end of 2020. To date 97.6% of schools conduct distance learning, 54% have done full distance learning, namely teachers and students teaching and learn from home. The remaining 2.4% have not done it because the area is not affected by the pandemic or do not have supporting devices. Besides, the Ministry of Education has made several programs such as Learning Houses, Learning from Home, on television, and radio to support the learning process.

Other news added that the reopening of schools is also awaiting safe conditions from the effects of COVID-19, following the decisions of the COVID-19 Task Force and the Ministry of Health. Therefore, optimistic estimates of schools opening in mid-July according to the education calendar, concerning the health protocol. If by mid-July the COVID-19 case was still high and large-scale social restrictions were still in place, distance learning for early childhood education, basic education, and secondary education would continue.

Conclusions

Even though children tend to have mild forms of COVID-19 symptoms, that does not mean that we should ignore those who have this disease. We still need to take steps to prevent them from becoming infected if we want to reduce the pandemic. Children may be able to transmit the virus, and they have been found to store large amounts of the virus, even without showing symptoms but they are not aware of it.

The policy to reopen schools must take into account the various related parties, including waiting for safe conditions from the impact of COVID-19 following the decision of the COVID-19 Task Force and the Ministry of Health and local government as the person in charge of basic education. The risk is too great for the education sector because what is faced is children. In addition to having a bad impact on students, the government will also get a bad spot, if it is mismanaged and results in new clusters.

The Kinetic Family Drawing Test for Evaluating Interpersonal Dynamics in Families: A Case Study

Anupama Bajaj1, J.M. Asgarali Patel2, Anuradha Kabra3

1Research Scholar, Department of Psychology, Annamalai University, Annamalainagar-608002, 2Associate Professor & Head in-Charge, Department of Psychology, Annamalai University, Annamalainagar-608002, 3Consultant Clinical Psychologist & Art Based Therapist, Department of Psychiatry, Manipal Hospital, Bengaluru-560008

Abstract

The purpose of this study is to evaluate interpersonal dynamics through Kinetic Family Drawing (KFD). Art Based Therapy (ABT) can be used in situations where talk therapies and counselling skills are least effective. It is especially helpful for people in crisis and those who are experiencing extreme psychological states. This case study has employed The Kinetic Family Drawing (KFD) to diagnose and treat 62 years old married woman with complaints of sadness, uncertainty & fear. This ABT program comprised of 3 sessions in which the Burns and Kaufman’s (1972) Kinetic Family Drawing (KFD) was used. In each session the client was made to draw a picture on a sheet of paper (8.5” x 11”) 4. The picture drawn by the client was subsequently analysed using focal points and the results were discussed with the client. The outcome of the present study helped the client to get insight into her problem and regain her self-confidence and improve relationship with her family members.

Keywords: Art Based Therapy, Kinetic Family drawing, Case study, Insight building, mental health, self–confidence, family dynamics.

Introduction

Diverse art forms have been an essential part of human life since primeval period. For generations art have been put into practice in every culture to articulate, generate, and communicate the needs, desires, and ideas among human beings. Arts-Based Therapy (ABT) is a term coined by World Centre for Creative Learning (WCCL) Foundation in 2001 to represent the use of multiple art forms and their combinations in therapy.

The formal practice of art therapy has its origins in the mid-20th century in Europe, with the coining of the term being attributed to British artist Adrian Hill in 1942. By working to bring the conscious, unconscious and subconscious into expressive and tangible forms, the creative processes involved in art therapy have been praised for their ability to encourage personal growth, mindfulness, and self-discovery. The client creates art images ‘to help express who they are, to express feelings and ideas, and to enhance life through self-expression’. Analysing the drawings of the client enables health professionals understand wide spectrum of client’s mental health issues.

The purpose of the present study: The main objective of this study is to enable the client to release her feelings, emotions, and worries and help her understand the family dynamics and improve relationship with family members.

Method

Sample: The client is a 62-year-old married woman (housewife) with prolonged history of psychological and familial issues. The client has a past history of psychological treatment which did not help her fully.

Tool: The Burns and Kaufman’s Kinetic Family Drawings (KFD) technique was used for the present study. The KFD was created as an extension of the Family Drawing Test 4. The directions given to the client is stated as follows: “Draw a picture of everyone in your family, including you, doing something, some kind of
action. Try to draw whole people, not cartoon or stick people. This picture is meant to elicit the person’s attitudes toward his or her family and the overall family dynamics.

Procedure: The kinetic family drawing was administered on the client. In each session the client was instructed to a draw picture based on KFD instructions on a sheet of paper (8.5” x 11”). The pictures were analysed and discussed using focal points.

1st Session: After the intake session, 1st session of art therapy was planned. “The client was instructed to draw her present family doing something.”

![Drawing 1: 1st session (November 2019)](image)

Session 1: Analysis of focal points: The client is a 62-year-old married woman (housewife) with prolonged history of psychological and familial issues. The family consisted of the client, her spouse (72, retired from business) and daughter (31, working as project manager). The client has a past history of psychological treatment which did not help her fully. The client has certain issues with her family members, and she is not happy with her present situation. The client appeared sad as her daughter has been facing issues in her marriage. The client had to leave her job to help her daughter.

In figure 1-seven characteristics dominated KFD-Lining on the bottom of the paper, Underlining, X’s, light (candle), placement of figure, Size of figures, elevated figure.

“Lining on the bottom of the paper is typical of children who feel instability in the home and are trying to maintain stability by creating a very solid foundation.” The client had drawn a table beneath her leg, which indicates that she feels instability in her house and she might be looking for some ways to create stability.

Underlining- “the instability reflected by such lining is focus on an individual figure, in which case only that figure will be heavily underlined. Underlining at the base of the drawing reflects the extreme tension in the family, unstable relationship symbol of that which links to source of nurturance.” Here the table drawn beneath the leg of the client’s spouse indicated underlining. May be the client’s spouse is undergoing lots of stress and instability, looking for attention and his need for nurturance is high. The client stated that she is not able to provide enough support to the spouse.
X’s indicates “the person is struggling for love and warmth”. The client has drawn two candles (energy) with the cross in the centre suggesting the need for love, warmth and direction in her life. There may be possibility that the client is inhabited by a strong conscience or superego. The client has also drawn source of light (Energy) suggesting “There is very little warmth and love in the family. The person must be of obsessive need for warmth and love.” Elevated figure—“A dominant person will be placed high above the rest of the figures”. The client has drawn her daughter elevated which shows that she is powerful and aggressive in the family.

“The placement and size of the figures in the drawing shows, large figures, perceptions of power or aggressiveness and small drawing of the self indicates poor self-concept and feelings of insignificance. When an individual draws the self-next to a significant other, it may indicate that the person likes that individual, wishes to be closer, and wants more attention.” The client drew herself, daughter and her spouse at distance from each other. The daughter has been drawn the largest, may indicate that she is powerful and aggressive in the family. The spouse is the smallest relative to family members suggesting that he may have feeling of insignificance and poor self-concept. The client has drawn herself next to her daughter suggesting that she is close to her and helping her deal with marital difficulties.

2nd Session: The first session of KFD was an eye opener for the client. The client decided to come again as the insights from the first session were very helpful. This session was approximately three months after the first session.

Session 2: Analysis of focal points: The second KFD (figure 2) defines the family dynamics and progression of therapy. The client is feeling much calmer & positive. The conflict with her daughter & spouse is still present as she has encapsulated them in the drawing. “Encapsulation is the encircling of individual family member, with an element of tension in the family. Theoretically it is thought to reflect isolation, rejection, threat and adjustment.”

The client depicts her daughter and spouse playing carom enclosed by large chair. Throughout the therapy the client was feeling unhappy about her daughter’s life and she was looking forward to get some help in that
direction. In drawing two the need for love and warmth has taken a form of sun\(^1\) (energy) instead of candles\(^5\). There is no X drawn in the second drawing suggesting that the struggle for love and warmth was resolved by the client by getting into religious practices. Placement of figures has changed; the client drew herself, daughter and her spouse around the dinner table which shows improvement in relationship. Daughter is still placed as an elevated figure. There is no line drawn at the bottom of the page suggesting that the client need for support has been taken care either by the family member or by the counsellor. Compartmentalization is “as an intentional separation of family figures through lining. This probably reflects the importance of boundaries and beginning of separation for the people living in the family”\(^4&5\). The client has used compartmentalization by separating the family figures through curtain lining. The client is trying to create a boundary between herself and her daughter. Some new elements like flowers and trees were added. “Flowers& trees represent love of beauty and the growth process”\(^4&5\). It symbolizes client’s religious and spiritual growth. Religious practises have made the client emotionally stable to handle her conflicts\(^11\). Table at the centre of the picture depicts obsessive need for attention and food.”\(^10\) This may suggest the client is not getting enough attention and acknowledgement from her spouse and daughter. In summary the second drawing reinforces several basic themes present in the first drawing but it also demonstrates a clear improvement, which was supported by client’s ve

3rd Session: After the second session of KFD the client has started looking at life with a different perspective. The client is feeling calmer & positive.

Session 3: Analysis of focal points: In drawing three, the client presents herself united with the family. The conflict with her daughter & spouse is still present as there is a need to encapsulate. The client depicts her daughter and spouse eating food enclosed by chair. The compartmentalization is removed, indicating the closeness & togetherness of the family. Placement of figures is around the table\(^10\) suggests need for attention. They all are eating dinner together shows the relationship has improved significantly. Absence of Elevation of figure (daughter) depicts improvement in her relationship. There is no line drawn at the bottom of page suggest stability in her family life. The need for love and warmth has taken a new representation in
form of light bulb. It indicates that the client is still striving for love & warmth. Absence of Flowers and trees suggests client’s satisfaction about her spiritual development. In summary the third drawing reinforces several basic themes present in the first & second drawings, but it also demonstrates an understandable change which was supported by client’s verbal reports.

**Discussion**

The aim of this case report was to explore the role of KFD, bringing in insight/understanding in family dynamics and relationship of a female client and help her improve relationship with family members. The finding on the first drawing indicated that the client feels that there is relationship and communication issue in the family. The client feels unheard. The client is looking for some support in the family and she is not fully involved in life. Even though the client is saying that her relationship with daughter is good but the distance shown between them is contradicting her statement. The findings were discussed with the client that helped her create insight and awareness about herself and the family which was taken up into the counselling. Family drawing assessments are an effective instrument for exploring more subjective, personal, and unconscious aspects of representational models of the self in relation to family. The second drawing shows united family. The struggle for love and warmth was resolved by the client by getting into religious practices. Religious practises have made the client emotionally stable to handle her conflicts. Some new elements like flowers and trees were added in drawing indicating client’s growth. The client has used Compartmentalization to create boundaries by separating the family figures through curtain lining. Finding on the third drawing shows the client can manage a much better relationship with her husband and daughter. There is lots of laughter and Happiness in the family, which was indicated by the picture of family having dinner together. Presence of encapsulation in the third drawing suggests the client still feeling suffocated and she needs boundary drawn among the family members. She wants family members to take up responsibility of their own life. This case study suggests that KFD resulted in insight building and conflict resolution among family members. Information found in KFD combined with clinical interviews, proved invaluable in setting therapeutic goals with the client, repeated themes and focal points suggest deep-rooted conflict and anxiety.

**Conclusion**

Diagnostic procedures such as the KFD offer easy and accurate access to information regarding attitudes and conflicts within the family. We believe that the KFD can be used as a valuable diagnostic tool to understand the intervention in more depth. The client indicated that she became more tolerant and accepting towards herself and family members. She noted a softened attitude towards herself and her complaints towards the end of art therapy.

A Study on the Patterns of Drowning Cases Brought for Medico-legal Autopsy

Ashim Teron¹, Biswadeep Paul²

¹Senior Resident, Deptt. of Forensic Medicine, Gauhati Medical College, Narakasur Hill Top, Bhangagarh, Guwahati -781032, Assam. ²Assistant Professor; Deptt. of Forensic Medicine, Jorhat Medical College, Kushal Konwar Path, Barbheta, Jorhat–785001, Assam

Abstract

Drowning is a form of death in which the atmospheric air is prevented from entering the lungs due to the submersion of the body in water or any other fluid medium¹,². Drowning can be classified as wet drowning (fresh or salt water), dry drowning, secondary drowning and the immersion syndrome or hydrocution (cold water drowning).²,³,⁴,⁵ Drowning is an important public health issue with major impacts on human resource which is a preventable phenomenon. According to National Crime Records Bureau, Ministry of Home Affairs in 2014, in India, death due to drowning was 6.6%, making it third largest cause of death in India. India is a vast country having plenty of water bodies and an extensive coastline and under such conducive circumstances, cause of death due to drowning is a frequent event where medico-legal experts are called upon to investigate. With a view to investigate the epidemiological factors, a study was conducted in the Deptt. of Forensic Medicine, Gauhati Medical College for a period of 1 year. In our study we found that most of the victims were males (82%) in the 31- 40 years age group (24.4%). Most of the victims had drowned in fresh water (94.5%) and running type (63.8%). A total of 34 cases constituting 26.77% had external injuries. Most of the cases were accidental in nature (78%). An exhaustive study to unearth these socio-demographical factors of drowning, hence should be conducted, to analyze their impact on population and its prevention.

Keywords: Drowning, fresh water, accidental, prevention.

Introduction

India is a vast country blessed with natural resources of water bodies. But often this has led to inevitable loss of human life by the act of drowning. Drowning deaths are often unpredictable and poses variety of questions for a forensic expert. The WHO reports nearly 3,60,000 drowning deaths each year⁶, of which approximately 90% occur in low-income and middle-income countries (LMIC)⁷. India contributes significantly to the global burden of drowning, with national drowning deaths accounting for 17% of global unintentional drowning mortality¹. With a coastline of over 8000km and extensive inland freshwater systems², a large proportion of India’s population is regularly exposed to water. Many waterbodies are located within or nearby community settings, particularly in rural areas. Cataclysmic weather events are common in many parts of the country, particularly in North-Eastern states including Assam and West Bengal. Over 12% of the country is prone to flooding and river erosion³. In India, accidental drowning is mostly common. Many valuable lives are lost during the period of floods. Sometimes accidental drowning can also occur in swimming pools due to jumping off from the high diving board causing to injury over the head after striking over solid surface, with resultant loss of consciousness and inhalation of water. In marine, air or rarely road transport accidents, the victim may be injured.

or killed before entering the water. Person falling from docks, bridges may get his body strike on any heavy and hard objects, such as rocks or some solid obstruction. After immersion, the body may strike the rocks, coral or marine structures thereby producing injuries and as the body floats along the bottom, injuries may occur over the head, face, backs of the hands, knees and the toes. Accidental drowning in shallow water can occur in intoxicated, insane or epileptic individuals. Despite a number of drowning risk factors being common in India, little empirical data are available on the burden or context of drowning-related morbidity or mortality within the country. A better understanding of the context and trends of fatal and non-fatal drowning is required to inform appropriate prevention strategies.

**Aims and Objectives:**

1. To evaluate the present trends of drowning by appropriate statistical analysis
2. To analyze the effect of various socio-demographic factors upon drowning
3. To study the injuries associated with drowning.

**Materials and Method**

The present study has been carried out in the Department of Forensic Medicine, Gauhati Medical College upon the 127 drowning cases out of total 3,367 cases brought for autopsy by police from within the district administrative area of Kamrup, Assam and few referral cases from the neighbouring districts. 24 cases excluded via exclusion criteria. The study period extended for 1 year from 1st July, 2017 to the 30th June, 2018. The data was collected in pre designed proforma from autopsies, interviews of accompanying attendants and police, which were subsequently analysed and represented in the form of tables, graphs and charts.

**Inclusion Criteria:** All the cases brought for medico-legal autopsy to the mortuary in the department of Forensic Medicine, Gauhati Medical College & Hospital within the study period, where the cause of death was drowning.

**Exclusion criteria:** Decomposed cases and cases where the actual death was not due to drowning.

**Results and Observation**

During the period from 1st July 2017 to 30th June 2018, a total of 151 cases of drowning were registered for autopsy out of which 127 were selected based on exclusion criteria. We found that most of the victims were males (82%), in the 31-40 years age group (31 cases). (Fig-1) and belonged to rural locality (63.77%). Most of the victims had drowned in fresh water (94.5%) (Table-1) and running type (63.77%), which comprises rivers, streams etc. There were 2 cases in which drowning occurred in a swimming pool. (Table-2). Majority of the incidents occurred near place of residence or work (54%). The months of July registered the highest number of cases with 18 cases. (Fig-2). A total of 34 cases constituting 26.77% had external injuries. (Fig-3). Most of the cases were accidental in nature (78%) and the rest were suicidal.

Discussion

The present study has been compared with similar studies conducted by various authors in different parts of the world. The comparison has been carried out in order to bring out similarity and variation of findings of the observation. During study, a total of 3,367 medico-legal autopsies were performed, out of which, 127 cases were considered based on inclusion and exclusion criteria. The study found that drowning cases mostly involved males with 82% cases similar to the works carried out by Donson H8 and Tokbi S9. The male preponderance may be attributed to the fact that males population outnumber females in our state and are more exposed to water sources such as irrigation and fishing. The age group 31-40 was the most commonly affected with 31 (24.4%) cases similar to the study of Chakraborty P et al10 but differs with Turgut A11 and Tokbi S9 who reported that for persons aged between 10–19 years, the death rate was the highest. The cause has been attributed to being the most productive population to earn livelihood. Most of the victims were from the rural background with 63.77% cases similar to Hossain M et al12 and Tokbi S9 but varying with the study of Auer A13 where urban dwellers (58.8%) was reported to be more. The findings are in expected lines owing to irrigation and fishing and abundant water bodies in rural areas. Fresh water drowning constituted nearly 94.5% of the cases. Palimar V14 and Tokbi S9 also noted similar findings. It is due to Assam having vast fresh water bodies with no coastline. Majority of the victims drowned in running water similar to findings of Tokbi S9 but varying with Chakrabarty P et al10 who found stagnant water bodies to be the most involved. Most of the victims drowned at a site near to their homes (54%). 51 cases drowned at a place near their work place. Racz E et al15 reported similar findings. Heavy rainfall in our state and floods and poor roads and demarcation attribute to these causes. The months of July registered highest 18 (14.17%) cases. Pal S K16 and Tokbi S9 reported similar findings to the study which is due to monsoon season and floods here. A few cases had injuries which mostly occurred in the head or face due to impact in the running water with underlying stones or objects similar to the study of Tokbi S9. Most of the cases were accidental in nature (78%). Mukherjee A A17 reported findings similar to the study. However Kumar A G V18 reported suicidal cases to be more common. The cause can be attributed to poor infrastructure and general lack of alertness amongst non-swimmers.

Conclusion

The present study was done with the aim of having an overview of the the epidemiology of all the ante-mortem drowning cases. Drowning cannot be stopped per se but few steps can be taken to prevent it. Drainage of unnecessary water accumulations, building flood control embankments, implementation and enforcement of mandatory isolation fencing for swimming pools should be done. Promotion of swimming programs for primary school children, increased awareness of drowning survival tactics, and train lifeguards for regular deployment in supervised swimming locations are the need of the hour. Increased education in boat safety regulations and training the general community in timely resuscitation manoeuvres can increase the survival prospects of drowning victims.

Abstract

Background: The populace is quickly expanding and has become a significant issue with the populace developing at a yearly pace of 1.2%. India will have more than 1.53 billion people before the completion of 2030 with the masses improvement rate at 1.58%.

Materials and Method: A Non-Experimental Descriptive Survey Research Design was used. A sample was comprised of 50 males and 50 females belongs to peer group of 20-45 years. Purposive sampling technique was utilized to gather sample for additional investigation. The data was aggregated by applying selected variables, Structured Knowledge Questionnaire and Attitude Rating Scale.

Results: The result showed a significant association of knowledge of males with their selected variables. The calculated p value of males and females with selected variables of knowledge and attitude was non significant which showed that there was no association between the level of knowledge and attitude of males and females towards tubectomy and vasectomy.

Conclusion: It was concluded that Knowledge of the males and females regarding tubectomy and vasectomy was in average and Attitude was moderately favourable. There was not any relationship between knowledge and attitude of males and females regarding tubectomy and vasectomy.

Keywords: Knowledge, attitude, males, females.

Introduction

India is a second largest country because of its population that is 1,311,559,168 (1.31 billion), on the other hand China is the top largest country because of its population 1,380,914,176 (1.38 billion). These figures show that India came to for all intents and purposes 17.74 of the all out populace, which shows that every person out of six social orders is has a spot with India. Be that as it may, the crown of the world’s most prominent nation is China’s obligation from a long time. India is additionally expected to take a similar circumstance by 2030. With the people advancement rate by 1.58%, India is typical for over than 1.53 billion people before the completion of 2030¹ (Taneja, 2014).

According to the world health organization, 1 million conceptions takes place every day and about 50% of these conceptions are unplanned and 25% of them are unwanted (ladipo, 1999). Everyday about 150,000 unwanted pregnancies are terminated. (Etuk, 2003).

In India, The national Family Planning Programme was started in 1952 to making it the first country in the world to do so. In spite of this about 56% eligible couples in India are still unprotected against contraception³. (Reddy, 2003).
The contraception alludes to the avoidance of the origination by the utilization of different sexual practices, surgeries, synthetic compounds and medications. The main purpose of seeking contraception is to prevent the women from becoming unwanted pregnancy. That’s why it is considered as a contraceptive. Its main aim is to attain privacy and comfort in the physical or sexual relationship. In the society, the couples are allowed to enjoy and fulfill their sexual desires without fear of unwanted pregnancies. (Jain R, 2011).

So couples now a days confronting clashes with objectives of accomplishing fulfilling sexual coexistence and keeping their little family. In the event that individuals neglects to keeping their family little outcomes in undesirable pregnancies and unsafe premature births. On the off chance that the premature birth looking for is late or in unhygienic conditions or in the hands of hazardous suppliers, it can prompt concepive horribleness just as maternal mortality. (Jain r, 2011).

**Methodology**

This study was done in the month of February, 2019 in the Panjab state of India. A sample of 100 (50 Males and 50 Females) participated in this study with the prior permission from the sarpanches of Respective Villages. A Non Experimental Descriptive survey research design in which Males and females aged 20-45 years having one or more children with alertness, oriented and comprehend to respond, speak and understand Hindi, willing to participate and residing in selected rural villages of Rajpura, Punjab were included. Males and Females who were not accessible at the hour of information assortment were prohibited. A Non-Probability Purposive Sampling Technique was owned for data collection from the participants through the medium of Structured Knowledge Questionnaire and Attitude Scale.

**Description of Tool:**

1. **Selected variables:** The selected variables include Gender, Age, Religion, Type of family, Educational status, Occupation, socio economic class, Number of children, Age at marriage, Married life, Have you ever heard about tubectomy and vasectomy, Source of information about tubectomy and vasectomy.

2. **Structured Knowledge Questionnaire:** This questionnaire was adopted to assess the level of knowledge of males and females toward tubectomy and vasectomy. It contains 20 multiple choice items regarding tubectomy and vasectomy covering the content area of:
   - Concept and types
   - Procedural knowledge
   - Assessment
   - Post care

   Each correct answer was graded with one point score and every incorrect answer was graded as no point. Consequently least score was 00 and greatest score was 20. The calculated Cronbach’s Alpha Internal consistency was 0.78 (Adequate range is 0.7-0.9).

3. **Structured Attitude Rating Scale:** This scale was used to measure the attitude of participants with regard to tubectomy and vasectomy. It consist of total 28 items used to measure the attitude of participants in terms of Strongly Agree, Agree, Uncertain, Disagree and Strongly Disagree and were graded from 1-5.

   Out of 28 items, 11 items were positive statements scored as 5,4,3,2,1 while 17 items were negative scored as 1,2,3,4,5.

   **Procedure:** In the wake of getting the formal regulatory endorsement, the last investigation was led in the period of April 2018 at chose villages of Rajpura, Punjab. Participants were selected by purposive sampling and information was gathered by utilizing tools of the study. A prior consent was taken from the participants. Earlier data was given to the subjects about the motivation behind the investigation.

**Data Analysis**

- **Descriptive statistics:** Frequency distribution was issued to show the selected variables.

  Correlation Coefficient test was utilized to find out the relationship between knowledge and attitude number score of Males & females towards tubectomy and vasectomy.

  Chi square Test was used to find out the Association of knowledge and attitude score of males and Females towards tubectomy and vasectomy with their selected variables.

**Results**

Frequency distribution in terms of level of knowledge score and Attitude scores of participants in
figure 1 and Figure 2 illustrates that furthermore half of the males 27(54%) had an moderate level of knowledge while 22(44%) of the males had low level of knowledge and only 1(2%) of male had high level of knowledge.

Out of the 50 females, Majority of them 30(60%) had average level of knowledge while 20(40%) had low level of knowledge as shown in figure 1.

**Figure 1: Percentage distribution in terms of level of knowledge among eligible couples towards tubectomy and vasectomy.**

Frequency and percentage distribution in terms of level of attitude of eligible couples towards tubectomy and vasectomy. Out of 50 males, Half of the males 25(50%) had moderately favourable attitude and 24(48%) of the males had favourable attitude while only 1(2%) of the males had unfavourable attitude towards tubectomy and vasectomy. Out of 50 females, majority of the females 35(70%) had moderately favourable attitude while only 15(30%) of the females had favourable attitude towards tubectomy and vasectomy as shown in figure 2.

**Figure 2: Percentage distribution in terms of level of attitude among males and females towards tubectomy and vasectomy.**
Table 1: Correlation between the knowledge and attitude of males and females towards tubectomy and vasectomy. N = 100

NS = Not Significant (p>0.05)

Discussion

In this study, From 50 males 22(44%) of the male’s knowledge was low while more than half of the males knowledge was average i.e. 27(64%) and only 1(2%) of male had high level of knowledge. Out of 50 females, 20(40%) of the females had low level of knowledge while more than half of the females 30(60%) had average level of knowledge and 0(0%) female had high level of knowledge.

In the present study, 24(48%) of the males had favourable attitude and half of the males 25(50%) had moderately favourable attitude while only 1(2%) of the males had unfavourable attitude. Out of 50 females, less than half of the females 15(30%) had favourable attitude and more than half of the females 35(70%) had moderately favourable attitude and no females had unfavourable attitude. These results were contradictory to the study conducted by Onasoga, 2013. The result showed that respondent’s knowledge of atleast one type of male family planning method, only 18(13.2%) had higher knowledge level and rest of the participants 33(24.3%) had lower knowledge regarding vasectomy. Most of the respondent also showed negative attitude towards vasectomy.

The mean knowledge score of males was 7.76+2.33 with obtained range of 2-13 and the mean knowledge score with standard deviation of females was also 7.76+2.33; median was 8 with obtained range of 2-13 whereas the mean attitude score of males was 96.26+12.71; median was 96.50 with obtained range of 73-125 and the mean attitude score of females was 97.6+ 12.49; median was 97.50 with obtained range of
These findings were contradictory to the results of the study by Gayathry, D., 2014 who observed that females had higher scores as compared to males which was not significant between the overall knowledge score (18.67+7.798 vs. 18.41+7.177)6.

In the present study, the computed p values of knowledge scores of the males with their selected variables were not significant except education i.e p-value 0.02 and occupation i.e p-value 0.01 which were highly significant. Hence knowledge of males towards tubectomy and vasectomy was dependent on educational status and occupation.

In this study, the computed p values of attitude scores of males with their demographic variables were non significant except Educational status i.e p value 0.00, occupation i.e p value 0.02, No. of children i.e p value 0.05, age at marriage i.e p value 0.03 which were highly significant at the 0.05 level of significance and computed p-value of females with all demographic variables were non significant at 0.05 level of significance. The findings are partially matches with the study conducted by Onasoga, 2013. The findings reveals that there was no significant association of academic scores of respondents and their attitude towards vasectomy, as well as between marital status and their attitude towards vasectomy significant association was found between the level of knowledge and attitude towards vasectomy5.

In the present study, computed p value of males and females with selected variables of knowledge and attitude was non significant at 0.05 level of significance. This shows there is no association between the level of knowledge and attitude of males and females towards tubectomy and vasectomy.

**Ethical Approval:** The moral leeway was gotten by taking consent from Sarpanch of Respective villages to direct the investigation in the rustic zones. The assent from the qualified Couples was gathered preceding the examination. The reason for doing research venture was clarified and affirmation of privacy was given to the members.

Health Care Professionals’ Pain in Pandemic COVID 19 in India

Ashok Kumar Rastogi¹, Binay Kumar², Avinash Kumar³, Amrendra Kumar¹, Prabhat Kumar³, Nawal Kumar Singh³, Himanshi⁴

¹Assistant Professor, ²Associate Professor, ³Senior Resident, ⁴Senior Resident,
Department of Forensic Medicine & Toxicology, All India Institute of Medical Sciences, Patna, Bihar

Abstract

Health care professionals are highly vulnerable for COVID 19 infection. It is due to frequent contact with COVID 19 positive patients, long time exposure with positive patients. There may be lack of personnel protective equipment’s (PPE). Indian health care professional taking many kinds of pain during the management of COVID 19 it can be hospital related problems during management, professional must wear PPE about 06 hours on duty time. Duty time with PPE personnel uncomforted and cannot have anything even water. PPE cannot change frequently. Socially persons do not comfort because society not accepting as normal people, they afraid of spreading of corona by health care personnel. Family isolation also necessary for the health care professional to avoid infection to their family members during COVID 19 management. Health professionals have tough time to manage pandemic. Government also active and full swing supporting providing extra care of health professionals, giving insurance and approved extra budget to fight with COVID 19.

Keywords: COVID 19, PPE, Pandemic, Isolation.

Introduction

Whole world fighting with pandemic COVID 19, this word given by WHO in January 2020, COVID 19 indicate corona virus disease 2019, (COVID-19) was outbreak from Wuhan, China January 2020.¹ on 30 January 2020 WHO declared outbreak of this disease and declare as Public Health Emergency globally.² In India 1st case of corona virus detected on 30th January 2020³ and fist case of COVID 19 reported in December 2019 from Wuhan city from china. Total cases in India till date 08 April 2020 for COVID 19 is 4714 Active Cases, 410 Cured/Discharged, 149 Deaths 1 Migrated.⁴ Indian health professional including doctors and paramedical staff providing the health care services in all over the India. in India all places not the protective measure available and in some higher institute protective equipment’s not in sufficient amount,⁵ we using these protective equipment cautionary as per the direction and availability of PPE . it should try make at local level by and low price, can make by raincoat/wind chitter material can be used. Scientific and technical approval can be taken. It should be in 3 layers, 1st layer -made up of material like wind cheater, 2nd layer- Absorbent like foam, so that if any respiratory droplets passes through 1st layer it gets absorbed in it, 3rd layer-again of the same material like the 1st layer Hydrophobic: non porous: non-absorbent. Devolved country also facing PPE kit shortage problem and India is developing country. Till 03 April in India about 50 health professionals affected by COVID 19.⁶ This insist to think about the future of our health professional COVID 19 case increasing day by day in this COVID outbreak, if health professional become sick who will treat the COVID cases. Frequently screening for the corona of health professional is suggested, by

Family related problems originated with the health care professional who are treating the COVID 19 patients. He avoids living with their family members because there are chances of spread of infection to their kin near and dear. That is health care professionals are worried about their family members and relatives. As we know that everyone has their family included kids to old members. study in china reported that it affects the all age group, 4 % affected less than 17 years aged peoples,12 % cases seen in more than 65 years age rest 84 %cases reported in middle aged 18 to 64 years age group population. in respect of family value, Two infected Italian nurses also committed suicide due fear of spreading of infection to the others.

Society related problems also came to notice in the Indian society, the health care workers ruined by the peoples, disgraceful behaviour with health care providers. Some part of India reported that when health workers went into the society for the screening of COVID 19 cases. They started fighting with them and there was mob attack over the few health care providers. They save yourself by run away, that’s life-threatening situation for the health care providers. health care professional residing at their home, those area public doing bad behaviour they are saying to health providers confined at your home do not move. Groceries shop keeper not supporting the health care providers not giving groceries to them and saying go away. you are more vulnerable to spread infection to us. Many health professionals are renters and their land lard insisting to vacate the house. They be afraid of that health professional can spread the COVID19 to others nearby.

Government giving full support to health care provider, who are indulging in management of COVID 19 cases as much as possible. In respect of this pandemic to fight with the situation, government given separate budget that’s one lakh seventy thousand crores. Other country also allocated separate budget to fight with COVID 19 tragedy, US allocation is two trillion US dollar to fight this pandemic. In Indiagovt also approved insurance for health care providers to encourage the moral and family support. It will provide an insurance cover of Rs. 50 lakhs for ninety (90) days to a total of around 22.12 lakh public healthcare providers, including community health workers, who may have to be in direct contact and care of COVID-19 patients and who may be at risk of being impacted by this. It will also include accidental loss of life on account of contracting COVID-19.
WHO considers ‘airborne precautions’ for medical staff after study shows coronavirus can survive in air.\(^2\)\(^3\)
Management of the corpse with suspect, probable or confirmed COVID-19 respiratory infection – Italian interim recommendations for personnel potentially exposed to material from corpses, including body fluids, in morgue structures and during autopsy practice.\(^2\)\(^4\)
Any post-mortem activities, from recovery, transport, to autopsies and handover to families and burial, should be therefore conducted with a focus on avoiding aerosol generating procedures, such as splashes of contaminated fluids;\(^2\)\(^5\)
Forensic pathologists beware: COVID-19 lives on in blood after death.

**Conclusion**

Indian Health care professionals are in awfully bad and painful condition; beside that they are serving the nation and they are providing hope to live to the COVID 19 patients. Indian government also supporting as much as possible by all the way to fight with corona dragon. Health care professional fighting everywhere in hospital,society as well as their home with family and relatives.

A Retrospective Study of Medico-legal Cases Coming to a Tertiary Care Hospital of Malwa Region of Punjab

Ashwini Kumar¹, Rajiv Joshi²

¹Associate Professor, ²Professor and Head, Department of Forensic Medicine and Toxicology, Guru Gobind Singh Medical College & Hospital, Faridkot, Punjab

Abstract

Background: Number of person suffering from some kind of illness is increasing day by day. In addition to the individuals suffering from various disease, person with medico-legal injuries or complaints are also admitted in the hospital. A hospital is a place where a patient gets required treatment, undergoes various investigations, procedures and medico-legal formalities when required. In a tertiary care hospital, Emergency Medical Officer is the first doctor to attend the patient. In any case first and foremost duty of a doctor is to save the life of patient. After providing the first aid and following the treatment protocol another duty is to do all medico-legal formalities like issuing Medico-legal reports and sending police information etc in a police case. A medico-legal case is a case where a patient has some assault injuries or having some complaint where a doctor thinks that some kind of information to police is required in the case.

Aims and Objectives: To prepare and evaluate complete demographic profile of medico-legal cases admitted at our tertiary care hospital.

Materials and Method: A one and half year retrospective study was conducted in department of Forensic Medicine at G.G.S. Medical College, Faridkot. This study was conducted on cases that came during the period under study i.e. from 1st January 2017 to 30th June 2018.

Results: A total of 1850 medico-legal cases got registered in the emergency during the period under study. Out of these, medico-legal reports were prepared in 1510 cases. Majority of cases in which MLR was issued were of assault followed by road traffic accident. Males dominated the females and commonest age group affected was 21-30 years in our study. Majority of victims got admitted in Surgery department followed by Orthopedics and Neurosurgery department. Most victims came during period from 8PM to 8AM. Maximum number of cases reported in months of summers than winters. Most of the victims were of rural background.

Keywords: Medico-legal case, Casualty, Tertiary Care, Assault.

Introduction

A doctor working in a government hospital or even in a private hospital has to perform duties which can be medical, surgical or medico-legal etc. A tertiary care hospital is a hospital that provides tertiary care, which is health care from specialists in a large hospital after referral from primary care and secondary care. A medico-legal case is a case of injury or having some complaint where a doctor after taking history and clinical examination of the patient thinks that some investigations by law enforcing agencies are essential so as to fix responsibility regarding the case.¹ It is classified as cases related to the crime against the human body like assaults, rape, burns, poisoning etc. Injury is defined under section 44 IPC as “any harm whatever illegally
caused to any person, in body, mind, reputation or property”. Profiling of Medico legal cases is an integral aspect for the prevention of preventable causalities in future and to study the crime rate in area.

Materials and Methodology
A one and half year retrospective study was conducted in department of Forensic Medicine and Toxicology at G.G.S. Medical College, Faridkot. This study was conducted on cases that came during the period under study i.e. from 1st January 2017 to 30th June 2018. Information regarding the date, time and place of the incident, age, gender and place of residence of the victims, time of admission etc was gathered from the available records. The relevant details were analyzed and tabulated by taking various parameters like age, sex, time of admission, cause of MLC etc. for obtaining observations.

Inclusion Criteria: This study included only those cases for which Medico-legal report was issued either on arrival or on request later on.

Exclusion Criteria: Those cases in which Medico-legal report was not issued or those went LAMA/referred to other hospitals were excluded from the study. Cases in which consent was not given or in which MLR was deferred due to unconsciousness or serious condition of victim were also excluded from our study.

Observations: A total of 1850 medico-legal cases got registered in the emergency during the period under study. Out of these, medico-legal reports were prepared in 1510 cases. Majority of cases in which MLR was issued were of assault followed by road traffic accident. (Table 1).

Discussion

In the present Study Medico-Legal reports were issued in 1510 cases. It was observed that most of the cases were of Assaults followed by Road Side Accident (RSA). This may be due to the reason that assault victims are keener for Medico-legal reporting than the RSA cases. Garg Vishal etal reported in his study that RTA was highest. SN Hussainietal reported that Burns constituted majority of MLC. Majority of cases belong to age group of 21-30 years, being the most active phase of life. This age group is more prone to go for outdoor activities and more prone for assault and accidents. Another reason for RSA is proximity of National highway to our college. Same was also reported by SN Hussainietal. In our study it was observed that majority of the victims (40.8%) reported to casualty in the evening to night period followed by afternoon period as people becomes more prone to assault and accidents due to more recreational activities and parties during that period. Garg Vishal etal reported that the majority of the incidences occur between 1601 to 2000 hours (33.5%)
followed by 1201 to 1600 hours (20.9%) and 2001 to 2400 hours (19.4%). Maximum cases were admitted in the month of July to September (49%) followed by months of April to June (39%). Garg Vishal et al reported in his study that maximum cases 92 (11.7%) were admitted in the month of September and 252 (32.1%) cases during July to September (monsoons). Present study shows maximum number of victim were males (73%) as compared to females (27%) as they are more active member of a family and still the main bread earners of the family as also reported by other various authors.5-11

Conclusion

The casualty department of any hospital not only gives treatment to the patients who reports in emergencies but also carry out legal responsibilities to examine and conduct medico legal cases which in turn puts a lot of burden on the concerned department. The basic principles of preventing injury are education, Law enforcement, pre-hospital care and the evaluation. The doctors who are involved in treatment of such medico-legal cases need to be more trained and skilled in this field. Also due to increase in accidents and violence cases, hospitals have the need for round the clock availability of such medico-legal experts in sufficient number to deal effectively with such cases to better serve judicial purpose.

Abstract

A role of health officer to prevent stunting rate was very significant, especially on first 1000 days of life. The role of health officer within program of stunting prevention was divided into three parts: basic role, the role on specific nutritional intervention, since the role on nutritional intervention was regarded as sensitive aspect. This research aimed to analyze the effect of implementation from health officer to the program of stunting prevention on the first 1000 days of life. This research was categorized into quantitative research which exerted case control approach, while the data analysis employed bivariate data analysis with logistic regression analysis test. The research sample was taken through cluster random sampling in approximately 275 respondents. The result of data analysis showed the effect of health officer basic role to the stunting prevention. Moreover, the analysis result from those three variables indicated p value ≤ 0.05, it referred that this variable did not get to be confounding factor in this research and it referred that the significant effect was not existed between health officer role and stunting prevention program on the first 1000 days of life in Indonesia. This result demonstrated that the variable of specific nutrition intervention became the most effective aspect to the program of stunting prevention on the first 1000 day of life, it produced OR value 0.703 (95% CI: 0.504-0.981). Therefore, the good specific nutrition intervention has the biggest chance as much as 0.703 times in order to prevent stunting rather than the poor specific nutrition intervention.

Keywords: Role of Health Officer, Stunting, Basic Role of Health Officer, Specific Nutritional intervention, Sensitive Nutritional intervention.

Introduction

The incident of stunting is recently the main problem which attacks to the toddlers in almost all parts of world. The impact which is caused by stunting incident was very vital, it not only affects to the toddler health, but is also potential to hamper the national development and advancement in the future. The bad impacts which are caused by the problem of stunting in short term: disruption of brain development, intelligence, physical growth disorder, and metabolism disorder in the toddler body. Whilst, the bad impacts in long term period from this stunting problem are decline of cognitive skill and learning achievement, decline of immune which causes to the client to easily ill, and the high risk will rise to diabetes, obesity, heart disease and vascular disease, cancer, stroke, and disability on the old age, as well as uncompetitive working quality which results to the low economic productivity. The huge of loss in case of stunting is due to the rise of government expenditure, specifically on the national health insurance⁶.

role of health officer as an attempt to realize maximal service in the first stage/primary service on a particular program is very important, since it is considered as a key of health development in Indonesia, thus, the health officer must have duties and responsibilities to run Minimal Service Standard of health sector in order to realize the healthy society in all society and affordable cost efficiency\(^1\). The prevention on stunting incident is focused on the role of health officer as it has been mentioned in the Laws, where the government has also implemented some policies and programs which are nationally executed by the Indonesian Government to the stunting incident. The health development during period of 2015-2019 has been focused on four priority programs, as decrease of death rate on mother and baby, decrease of stunting prevalence, management on transmittable disease and un-transmittable disease. The attempt to rise public nutrition status includes to stunting prevalence is regarded as a priority program of national development which is asserted in the main target of National Development Plans in Medium-term 2015-2019. The target of decrease on stunting prevalence (either short or very short toddler) in below age of 2 years old is 28\%\(^7\).

**Method**

This research was categorized into a quantitative research which employed analytic descriptive research method. This research exerted cluster random sampling as the data collection method. The total research sample were 257 respondents from 13 posyandu. The method of data analysis in this research was univariate analysis by exerting descriptive method, frequency table, while bivariate analysis by exerting logistic regression, which aimed to identify the effect of health officer role to the prevention of stunting. Moreover, the descriptive analysis of this research was employed to illustrate generally about the respondent characteristics who had babies in age of 0-23 months. Meanwhile, the logistic regression analysis was employed to test the effect of independent variable to the prevention of stunting incident.

**Research Findings:** The respondent characteristic in this research could be categorized into a number of groups: mother’s education, mother’s occupation, mother’s income, and child gender. The detail distribution of respondent characteristic in approximately 275 respondents could be seen on the table 1 below:

<table>
<thead>
<tr>

Based on the table 1, this research finding indicated that the majority of respondents were graduation of Senior High School Degree 80 respondents (29\%), employed category 159 respondents (57\%), having income more than UMK standard 179 respondents (65\%), and child of female gender 146 respondents (53\%).

**Cross Tabulation on role of health officer and stunting on Toddlers.** The total of respondents in 13 posyandu were 275 respondents. The result of this cross tabulation was to determine five evaluation categories, this was acquired from accumulation of all questionnaires from each indicator in a variable of basic role, and the result of cross tabulation on basic role effect of health officer to the program of stunting prevention could be seen on the table 2 below:

</tbody>
</table>

Based on the table 2, this research finding referred that the basic role of Health Human Resource in the attempt of stunting prevention was mainly good in approximately 142 (51.6%). The indicators which were used to arrange the basic role of Health Human Resource: communicator, motivator, facilitator, counselor. The role of specific nutritional intervention as an attempt to prevent stunting was mostly good in approximately 122 (44.4%). The indicators which were used to establish the role of specific nutritional intervention: Pregnancy record of mother which was influenced by the role of health officer and the role of health officer intervention on the toddler in age range 0-23 months. The role of sensitive nutritional intervention as an attempt to prevent stunting incident was mainly good in approximately 137 (49.8%). The indicators which were used to arrange the role of sensitive nutritional intervention covered to the role of clean water provision and sanitation, program of Keluarga Berencana, health insurance, basic childbirth assurance, and nutrient education.

The result of conformity model test from analysis of health officer role effect to the stunting prevention program on the first 1000 days was shown on the table 3 below:

Table 3. Analysis between independent variables and stunting

<table>
<thead>

</tbody>
</table>

The table 3 illustrated the analysis result from those three variables which showed p-value > 0,05, which referred that the variable was not a confounding factor in this research. Besides, this result indicated that the variable of specific nutritional intervention was a factor with the greatest risk which was related to the stunting incident prevention, since it delivered to the biggest Odds Ratio value 0.703 (95% CI: 0.504-0.981). Thus, the respondents who have received good specific nutritional intervention would have more chance 0.703 times to prevent stunting incident, if it was compared to the bad specific nutritional intervention.

Discussion

The basic role was covered to the role as communicator, facilitator, counselor, and also motivator. The basic role of health officer in stunting prevention was in line with this following theory, where the role as a communicator must be owned by all health officers. The health officer as a communicator must be able to deliver information, educate and teach individual, family, group and society, and other health officers according to their responsibilities(1). Further, the health officer as an educator must educate or conduct health counseling
to the clients and was completed by an evaluation which aimed to develop health learning\(^{(18)}\). The role of health officer as a motivator was also important as other roles. The health officer must be able to give motivation, direction, guidance, and increase awareness on the client\(^{(5)}\). The characteristics of health officer as a motivator were to provide assistance, bring client awareness, and encourage group to recognize potential and problem, and be able to develop the potential in order to solve the problem\(^{(7)}\). The role of facilitator must be also owned by every health officer within health promotion. As a facilitator, the health officer must be able to give technical guidance and empower the client to develop to the expected goal achievement. The facilitator must be skilful to integrated three important aspects, as optimization of facilities, time provision, and optimization of society participation\(^{(2)}\). The role of health officer as a counselor in aspect of health socialization or promotion was very needed, the health officer must be able to give approaches and trainings to the local public figure, help client to understand information take decision relating to the medical treatment, and facilitate the client and family as well as all society to improve optimal health situation\(^{(13)}\).

The role of health officer as an attempt of specific nutrition intervention was the direct role or involvement which given on 0-23 months\(^{(6)}\). It was indicated the effect of food intake which covered to energy intake protein intake, fat intake, carbohydrate intake, calcium intake, zinc intake to the stunting incident on toddler in the age range 6-35 months \(^{(8)}\). The toddler age should be introduced to many kinds of food, it was not only to give education relating to kind of food, but also to fulfill the nutritional need in order to help the process of growth\(^{(10)}\). The toddler who received non-exclusive breast milk have risk of stunting 16.5 greater than the toddler who received exclusive breast milk\(^{(6)}\). The role of Health Officer to give education which related to smoking habit was also crucial, it was in line with the theory from the center of social insurance of University of Indonesia, where the research finding had showed that the cigarette consumption on parent would affect to stunting children\(^{(10)}\). The smoking behavior on parent was estimated to influence the stunting children through two ways. First, through the cigarette smoke which was able to disturb nutrient absorption on children, second, aspect of cigarette buying cost which would affect the parent to reduce the nutritious food cost, health cost, education cost, etc\(^{(12)}\).

The role of health officer as an attempt of sensitive nutrition intervention was done by multi-sector. Furthermore, the role of health officer as an attempt of sensitive nutrition intervention has shown a good role result. The effect of health officer role on sensitive nutritional intervention to the stunting prevention program in the first 1000 days of life was an attempt to prevent and decrease nutritional problems indirectly\(^{(6)}\). Many studied have analyzed the access relation between clean water and stunting incident. Besides malnutrition, the bad water condition and sanitation would also affect to the high rate of stunting incident on children in Indonesia. The ground floor and sanitation could improve the stunting incident, since the children who lived in the house with ground floor and bad sanitation were tended to suffer illness, this condition was a leading factor of stunting\(^{(11)}\). The role of health officer was directed to prevention attempt, because the sanitation and clean water was regarded as a cross sectoral activity which involved the other role of housing ministry and irrigation sector in general \(^{(15)}\). The effect of Keluarga Berencana program was aimed to prevent stunting incident and was considered as an attempt of government in the stunting prevention program through National Population and Family Planning Board (BKKBN) \(^{(19)}\). The woman who have good access to the health service was who have received information regarding to that service from health officer as doctor, midwife, or nurse. For the society in low level of economic status, the cost limitation was often the biggest factor which hampered the woman access to the health service, especially the safe childbirth\(^{(14)}\). The effect of health officer role to the nutritional improvement of society has been employed in multisectoral, through socialization from the government and non-government regarding to the importance of nutritional intake on pregnant mother\(^{(17)}\).

**Conclusion**

Prevalence of stunting which was based on this research, indicated that the number was still high in approximately 36.7\%, it was valued as high level according to WHO standard, since it was above 20\%. The effect between basic role of Health Officer, the effect of Health Officer role, the effect of Health Officer role and stunting incident.

Abstract

Introduction: When girls get married, this heralds a major change in their immediate environment. There is a change of guardianship, separation from the parents and family and creation of a new family. All this creates a stressful environment around them, which is further aggravated by pregnancy, the upbringing of children, managing the household and office works. Eventually, when the tolerance breaks down, the brides are forced to take the extreme step of ending their miserable lives. In the majority of female unnatural deaths, the family members (parents, husbands, in-laws) may be directly or indirectly responsible for precipitating the circumstances leading to the death of the victim.

Methodology: Material for the present study comprised of all information from the relatives, guardians, police or investigating officers pertaining to the cases of ‘unnatural deaths of females within seven years of their marriage’, brought to the District Mortuary, Kanpur during the period of one year.

Conclusion: The incidence of unnatural deaths in females who died within seven years of their marriage was estimated to be 4.17% of the total cases autopsied. Maximum numbers of victims were rural Hindu housewives belonging to lower-middle or middle socioeconomic classes between 18-22 years of age and most of them had died within three years of their marriage. In cases of homicidal deaths burning and throttling/strangulation were found as the most common method used Dowry was the most common motive in homicidal deaths. As such husbands and in-laws were the most common human offenders in homicidal cases. Hanging was the most common method used in suicidal cases followed by burning. Whereas family quarrel and marital disharmony were the most common motives behind such deaths.

Keywords: Married female death within 7 years of marriage, dowry death, burning death, hanging, suicide in married female, homicide in married female.

Introduction

The rapid increase of unnatural deaths in newly married females in our population probably because of problems related to marriages, mal-adjustment and marital disharmony between the newly married women & the family of in-laws has caused great concern to our masses in last few decades. When girls get married, this heralds a major change in their immediate environment. There is a change of guardianship, separation from the parents and family and the creation of a new family. All this creates a stressful environment around them, which is further aggravated by pregnancy, the upbringing of children, managing the household and office works. Eventually, when the tolerance breaks down, the brides are forced to take the extreme step of ending their miserable lives. In the majority of female unnatural
deaths, the family members (parents, husbands, in-laws) may be directly or indirectly responsible for precipitating the circumstances leading to the death of the victim.

**Material and Method**

**Material:** Material for the present study comprised all the cases of ‘unnatural deaths of females within seven years of their marriage’, brought to the District Mortuary, Kanpur, during the period of one year from January 2017 to December 2017, that numbering 152 (One Hundred Fifty Two) cases. Information was gathered from their relatives, guardians, neighbors, investigating police officers after having informed and explained about our research and taken consent from the guardian.

**Exclusion Criteria:**

1. Unidentified bodies, where the relevant history was not ascertainable.
2. Cases in which, autopsy established a natural cause of death.
3. Cases of deaths, which occurred in mass casualties, like train accidents, major road accidents, explosions etc.
4. Cases of death, which occurred in road traffic accidents, even if not the case of mass casualty.
5. Cases of deaths, where the duration of marriage was found by history and interrogation, to be more than seven years.

**Observation and Results**

Present work is done to explore the epidemiology of deaths in married females, died within seven years of their marriage. The study is done from the cases of unnatural deaths, in such females, brought to District Mortuary of Kanpur, during the year 2017. Total number of cases autopsied were 3643, from January 2017 to December 2017. 152 cases were found of married females, who died within seven years of their marriage. The most of the victims were rural Hindu housewives. The observations thus recorded are tabulated after analyzing the collected data.

**Table 1. Age Distribution**

<td><strong>100</strong></td>
</tr>
</tbody>
</table>

Maximum number of victims were in the age group of 21-22 years, followed by the age group of 18-20 years (Table-1). This means that most of the victims were of very young age, died in the beginning years of their married lives. Because of the trend of early marriage in India and probably because the person becomes mature enough, no cases of unnatural deaths was found in more than 30 years age group, having completed less than seven years of marriage.

**Table 2. Socio Economic Status**

Low educational status has been found to be an important factor influencing such deaths (Table-6) as 60% of victims has no education or only primary level education.
It shows personal habits of the victims, as most of the victims belong to Hindu community, so is seen by their dietary pattern that most of them are vegetarian (80.92%). 19.07% cases were non-vegetarian either regular or occasional. Although such kind of dietary pattern is nothing to do with deaths, but it shows that most of the cases are occurring in Hindu families. 5 victims (3.28%) were regular smokers, while 15 of them (9.86%) were habitual of tobacco chewing. None of the victim was either alcoholic or drug addict. Personal habits reflect the mental status of the person. Most of the women were mentally normal (88.81%). Unstable personality and neurotic status were found in 3.28% and 2.63% cases respectively. 3 cases (1.97%) each, were found of hysterical behaviours and depressed mental condition. None of the females were drug addicted or had any other mental problem.

</table>

Most of the victims (47.36%), did not survive for significant period of time or died immediately after the incident (Table 6).

Discussion

The high incidence of unnatural death in young Hindu females belonging to rural areas, within 3 years of their marriage was most probably due to unending demands of dowry by their husbands and/or in-laws, for which they sometimes kill or torture the bride in such a way that she commits suicide, which is consistent with other authors findings1-8.

However, the study of Srivastava showed that incidence of death in married females was higher in lower-middle socioeconomic and middle socioeconomic strata and this dissimilarity with our findings could be due to more urban population in their study1.
With respect to the duration of married life, our findings were similar to the findings of Ambade & Aggarwal\textsuperscript{2,3}.

The higher incidence of unnatural death in illiterate and low-standard educated population was due to the more number of cases belonging to rural areas\textsuperscript{7,8} and lower as well as lower middle socio-economic strata\textsuperscript{3,4}. Agnihotri et al found 94.9\% Hindus, 4.22\% Muslims, 0.53\% Sikhs, and 0.35\% Christians in their study which is consistent with our findings \textsuperscript{1}. Burns as a major cause of death in females was also concluded by other authors in their study\textsuperscript{2-6}. The fact that in our study, more victims belonged to rural areas and constitute a major chunk to lower sections of the society. The high incidence of burn deaths, especially among young females is often attributed to cooking on open unguarded flames. Loose, highly inflammable, synthetic garments/saris of the victims are alleged to catch fire suddenly while cooking\textsuperscript{9}.

In India, many deaths are not registered as suicide due to fear of social and legal consequences associated with the same (IPC 306 and 309). The same was the opinion and findings of Batra, Ambade & Godbole\textsuperscript{2,5}. Drowning was found as a cause of death in 1.31\% cases, which was in variance with that noticed by Agnihotri et al in 0.7\% cases and this variation can be attributed to the fact that Kanpur is situated at and near the banks of rivers the Ganges and festivals like Ganga Mela, chhatth, etc., making people more prone for accidental and suicidal drowning\textsuperscript{1}.

Quarrel with husband/in-laws and dowry demand by the husband or his family members were two important reasons behind suicidal as well as homicidal deaths and this finding was consistent with other authors\textsuperscript{2}. Prajapati et al and Kailash et al observed that dowry demand, ill-treatment by in-laws, rash and negligent behavior of husbands and infidelity were the most common reasons for unhappy married lives in all such cases\textsuperscript{6,7}. The findings of the present study were similar to the findings of many other authors as far as age, community, habitat, and manner of alleged dowry death were a concern\textsuperscript{7,8}. India’s National Crime Records Bureau reported that 8,233 Indian women were killed in 2012 in dowry-related violence or nearly one per hour\textsuperscript{8}.

The Meshing between Epstein Barr Virus Nuclear Antigen-1 and P53 in Iraqi Malignant Breast Tissues

Bareq N. Al-Nuaimi

Assistant Lecturer (M.Sc. in Microbiology), Department of Biology, Madenat Alelem University College, Baghdad, Iraq

Abstract

In Iraq, breast cancer incidence exceeds any other type of cancers and the etiology not understood well. Epstein Barr virus is a gamma herpesviruses and one of carcinogenic viruses that may implicated to breast carcinogenesis. The nuclear antigen-1 (EBNA-1) protein is the sole EBV antigen that presented in all tumors related to EBV and plays pivotal roles in carcinogenesis of the virus. Examination applied by immunohistochemistry (IHC) to detect and demonstrate the correlation between (EBNA-1) and tumor suppressor protein (P53) expression. The study includes paraffin-embedded tissue blocks of ninety 90 malignant breast tissues and thirty 30 normal breast autopsies. EBNA-1 was significantly expressed in 40/90 (44.4%) of malignant tissues while its expression in normal breast tissues was negative in all tested cases. The tumor suppressor protein P53 was showed negative expression in all normal breast tissues and positive in 27/90 (30%) in malignant breast tissues. A significant negative relationship (r=-0.420; P<0.05) revealed between EBNA-1 and P53 expression. These finding reveal that EBNA-1 was evident in malignant breast tissues and demonstrate the interplay between EBV and p53 raising the possibility that viral infection may be involved in carcinogenesis process.

Keywords: EBV, EBNA-1, P53, and Immunohistochemistry.

Introduction

Malignancy of the breast is the top distributed cancer among females in Iraq with an estimation of 4,720 cases in 2015. The incidence of breast cancer generally exceeds any other type of cancers in Iraq (33.5% of all cancers in Iraq)[1]. The causality of breast cancer is not yet clearly understood, but its incidence related to some environmental factors like viruses such as EBV [2]. EBV belongs to the gamma herpesvirus family, affects over 90% of the world’s population and one of the main viruses to be directly involved in cancer genesis[2]. EBV has been involved as a causative agent of many cancers like Hodgkin’s disease, non-Hodgkin’s lymphoma, Burkitt’s lymphoma, as well as nasopharyngeal carcinoma, arising in immunocompromised individuals[3].

Researches revealed a strong relationship between EBV and breast carcinoma by showing strong evidences[4]. In both primary and metastatic tumors, the constant expression of some of EBV proteins suggests that these proteins are the key player in the EBV-associated tumorigenesis[5]. The tumor suppressor gene, p53 is frequently related to many human cancers because most of the human cancers have mutated p53 [6]. Mutations in p53 happened in breast cancer and are typically associated with more aggressive tumor characteristics, but the clinicopathological and epidemiological features of p53 protein expression is still not clear yet. Some studies suggested that EBV infection induces p53 expression in away or another without causing mutations [7]. Transformed cells by EBV are delicate to apoptosis by P53 mediated pathways[7]. EBV infection of primary cells usually induces a DNA damage-signaling pathway and inhibits cellular proliferation[6]. At the same time, EBV has the capacity to cancel the effect of p53 by multiple means. EBV has many genes that blocks p53-mediated apoptosis or downregulates the expression of p53[9,10]. Epstein-Barr nuclear antigen-1 (EBNA1), demonstrated in all tumors correlated with EBV, may act as the sole protein in many tumors and supposed to be implicated in tumorgenesis[20]. The present study used
to investigate the relationship between EBV-infected patients by testing (EBNA-1) antigen expression with p53 expression in Iraqi breast cancer patients.

Materials and Method

Patients and sampling: The present study have done in a period between January 2019 and October 2019 in Baghdad. Paraffin blocks of breast biopsies were obtained from patients of breast carcinoma after mastectomy. Blocks were collected by a pathologist from Al Alweiya teaching hospital according to ethical considerations and the hospital approval. Formalin fixed, paraffin embedded tissue blocks of (90) malignant breast tissue and (30) normal breast autopsies were obtained. A faculty pathologist re-examined all slides stained with Hematoxylin and Eosin (H&E) for histopathological diagnosis of the chosen blocks.

Immunohistochemistry (IHC): Paraffin-embedded blocks sectioned using a microtome to 4 μm and placed in tissue floatation bath (40C°) and then placed on positively charged slides. The slides were set in oven at 70C° for one hour followed by a series of sequential xylene/ethanol/water washes that remove the wax and rehydrate the tissue for subsequent antibody binding. Heat-induced epitope retrieval (HIER) was applied for antigen unmasking. Heating to boiling in buffer was applied for the slides using a pressure cooker for 30 minutes. Then, the slides were transferred to PBS (phosphate buffer saline) before immunostaining. The sections quenched in a hydrogen peroxide (H₂O₂) by adding drops on the slides for 10 minutes. Protein block solution were applied to each tissue section and allowed it to remain in place for 10 minutes. Then, antibody solution was added to the slides by using micropipette 100-200µl of diluted antibody solution. The slides were incubated overnight (18-22) hour at room temperature. Streptavidin peroxidase and biotinylated Goat Anti-Mouse was added to each slide and incubated for two hours each respectively. Washing of the slides by washing buffer should be applied after each stain. Freshly prepared DAB chromogenic solution was added to the tissue sections and incubated for 10 minutes. The slides washed by distilled water and counterstained by hematoxylin. Aqueous mounting media was added to cover slips where the slides laid on. The slides left for a while to be dried and be ready for examination under the light microscope.

Results

Patients and sampling: A number of (90) malignant breast tissues and (30) normal breast autopsies were included in this study for sampling. Formalin-fixed paraffin embedded tissue blocks of breast obtained from each woman included in this study and according to ethical approval.

Epstein-Barr virus nuclear antigen expression (EBNA-1): All malignant and normal tissue blocks were tested for EBV nuclear antigen (EBNA-1) expression. From 90 breast cancer samples, 40 cases (44.4%) were positively express the antigen while all the normal control cases were show negative expression (figure 1 and 2). Our results show that EBNA-1 expression is significant in malignant breast tissue as compared to normal control specimens (P<0.05).

Figure 1: 40X strong EBNA-1 antigen expression of nuclear and cytoplasmatic staining in breast carcinoma, brown colour is the positive result.

Figure 2: 10X negative EBNA-1 antigen expression in breast carcinoma. Brown colour is not present.
**P53 Expression:** P53 have been tested in all cases by immunohistochemistry (IHC). From (90) cases of breast carcinoma, a number of 27 (30%) cases were express P53 positively. Among them, 17 (18.8%) showed strong expression, 10 (11.1%) cases moderately express p53 (figures3, 4, and 5). According to ages, The protein expressed in 18.8% (n=17) females of age younger than or equal 50 years (≤ 50 years), While females of ages older than 50 years the results of expression 11.1% (n=10). A statistical significant (P<0.05) relation between patients ages and expression of p53. In addition, It was found 14.4% (n=13) of p53 positive expression were of the histological grade III, 12.2% (n=11) of histological grades II and 3.3% (n=3) of histological grade I. Statistical analysis was found to be statistically significant (P<0.05).

Mentioning lymph node involvement, 18.8% (n=17) of positive cases were correlated with lymph node involvement. P53 positive cases with no lymph node involvement recorded in 11.1% (n=10). No significant association have been observed (p>0.05). The tumor size also determined in the present study, It was found that the size range > 10cm was the highest (15.5%, n= 14) compared to other tumor size ranges of p53 expressed cases. Statistics of estrogen and progesterone receptors found in this study. From total number of malignant cases in the study, A percentage of (20%, n=18) that express p53 positively express estrogen negatively and only (10 %, n=9) express estrogen positively. The progesterone receptor negative cases show higher p53 expression (17.7%, n=16), whereas the positive cases seen only in (n=11). Statistical association of p53 expressed cases with hormone receptors, lymph nodes involvements and tumor size were statistically not significant (Table 1).

**Figure 3:** 40X Strong positive Cytoplasmic and nuclear expression of p53 in breast carcinoma. Dark color showing the positive result

**Figure 4:** 40X moderate positive Cytoplasmic and or nuclear staining of P53 in breast carcinoma. Dark color showing the positive result

**Figure 5:** 10X negative p53 expression in breast carcinoma, no dark brown color appeared
The Correlation between EBNA-1 and P53 expression: Significantly negative relationship (r=-0.420; P<0.05) was recorded between (EBNA-1) antigen expression and P53 protein expression in malignant breast tissues. No other relationships noticed between EBNA-1 antigen and the clinicopathological parameters of malignant breast tissues.

Discussion

The present study revealed that EBV significantly expressed in malignant breast tissues than in normal autopsies. EBNA-1 antigen demonstrated in 44.4% of the breast cancer cases, which indicated that EBV might have a role in breast carcinogenesis. A previous studies support the present indication, serological researches on breast cancer patients on EBV relation to disease using the traditional marker of EBV revealed that EBV IgG levels score (97/208; 96%)\[11\]. Another study tested for both anti-EBNA-1 IgG level by ELISA technique and EBNA-1 antigen expression by immunohistochemistry technique (IHC), the results show that 90.9% of breast cancer cases were seropositive for anti-EBNA-1 IgG and EBNA-1 was positively expressed in 28/51 cases (54.9%) by IHC\[12\]. The nuclear antigen 1 (EBNA1) protein is the only EBV protein that presented in all tumors that are associated with EBV and plays many important roles in the latency of the virus. The cellular processes that the viral protein play is to reduce apoptosis and increase cell survival\[15\].

Determining the P53 expression is important for aiding in diagnosis and helping to decide the best therapeutic way in addition to predicting prognosis\[13\]. Although our present study found significant association of p53 expression with tumor grade, it demonstrated non-significant relationships with other tumor parameters. Previous reports indicated that, P53 expression correlated with clinical grading of the disease and age of the patients significantly. No significant statistical correlations observed with lymph node involvement, tumor size, and expression of estrogen and progesterone receptors\[21,14\]. In spite, these associations were not significant in statistical manners of the present study, the contrasts in the results explained to genetic, environmental, and possibly social factors\[12,13\].

All the previous reports of p53 expression in malignant breast tissues extended approximately from 10% to 70%\[12\]. During this project, p53 demonstrated in 30% of the samples. These investigations can be compared to previous researches exclusively regarding the associations with histological grading and hormonal status. The relatively high expression of p53 could be related to genetic and environmental parameters that reveals the mutation type of P53. In addition, Most of the cases at relatively advanced stages of the disease when they diagnosed for the first time and are already at higher expression of P53. That may reflect the bad prognosis in many of the present study cases\[11\]. P53 is a tumor suppressor gene, mutations in gene commonly occur in breast cancer. Alterations in the gene lead to change the expression of many other genes that controlled directly or indirectly by p53. The results are malfunctioning of DNA damage repair pathways, cell-cycle arrest, and apoptosis\[16\].

The relationship between EBNA-1 and P53 is not clear yet. A study in Brazil found that there was a correlation between EBNA-1 and p63 expression, but not between EBNA-1 and p53\[17\]. Our present study revealed that there is a significant negative relationship between (EBNA-1) antigen expression and P53 in breast cancer patients meaning that increased expression of EBNA-1 lowers p53 expression. A study, dealt with a key regulator of p53 (USP7), determined that EBNA1 binding to USP7 lowers p53 levels and protect cells from apoptotic challenge\[18\]. A researchers in (2019) found that EBNA1 lowers p53 level in osteosarcoma cell\[19\].

Conclusion

The present study revealed Epstein Barr virus nuclear antigen-I was significantly expressed in malignant breast tissues and this raises the possibility that EBV may have a role in carcinogenesis of the breast. Tumor suppressor protein P53 expressed in about 30% of the malignant cases. The correlation between EBNA-1 and P53 expression was negatively significant which means that increasing the expression of EBNA-1 in malignant breast tissues may lower the tumor suppressor protein P53. This foundation may explain one the EBV roles in tumorgenesis of the breast in Iraqi patients.

Abstract

It has long been believed that cytokines have an important function in immunopathology during viral infection. Coronavirus disease 2019 (Covid-19) is a contagious viral disease caused by severe acute respiratory syndrome coronavirus 2. Covid-19 can be fatal because of an overactive immune response and release of cytokines. This review focuses on the role of cytokines in COVID-19.

Keywords: COVID-19, cytokines, Immune response.

Introduction

Coronavirus disease 2019: Coronavirus disease 2019 is the infectious disease caused by (SARS-CoV-2) severe acute respiratory syndrome coronavirus 2. First identified in December 2019 in Wuhan, and has since spread all over the world, resulting in the ongoing 2019–20 coronavirus pandemic[1]. Main symptoms include fever, dry cough and fatigue. It may be accompanied by runny nose, sore throat, vomiting and diarrhea. Most patients have mild symptoms, while a few develop into viral pneumonia and multi-organ failure. The incubation period of virus is generally 5 days however may range 2 to 14 days. The disease can spread from person to person through small droplets produced by coughing, sneezing, or talking. These droplets land on objects and surfaces being infectious over long distances[2]. Low protective immune response causes the virus to spread and destroy infected tissues, especially in organs that have high angiotensin-converting enzyme 2 expressions, such as intestine and kidney. The damaged cells induce innate inflammation in the lungs that is largely mediated by pro-inflammatory macrophages and granulocytes. Lung inflammation is the main cause of life-threatening respiratory disorders at the severe stage[3].

Role of Cytokine in COVID-19: Cytokines are inflammatory immunological proteins that act as molecular messengers between cells, which fight infections and ward off cancers. The overproduction of specific inflammatory cytokines is a hallmark of viral infection[4]. It has been suggested that the pathogenesis of COVID-19 is mediated by disproportionate immune responses and the ability of the virus to circumvent innate immunity[5]. When COVI-19 infects the upper and lower respiratory tract it can cause mild or highly acute respiratory syndrome with consequent release of pro-inflammatory cytokines². Chen and colleagues reported that COVID-19 might mainly act on lymphocytes, especially T lymphocytes, and induce a cytokine storm in the body, which is characterized by increased plasma concentrations of cytokines[6]. Mehta, et al recently stated there is accumulating evidence suggests that a subgroup of patients with severe COVID-19 might have cytokine storm syndrome. The authors suggest that patients with severe stage must be screened for hyperinflammation and subgroups of patients identified for whom immunosuppression therapy could improve mortality[7]. However, in most moribund patients, 2019-nCoV infection is associated with a cytokine storm[8].

DOI Number: 10.37506/mlu.v20i4.1779
In those who survive intensive care, these aberrant and excessive immune responses lead to lung damage and fibrosis, causing functional disability and reduced quality of life\textsuperscript{[9,10]}.

**Proinflammatory Cytokines:** Cytokine storm is a systemic inflammatory response that can be triggered by a variety of factors such as infections. Shimabukuro-Vornhagen et al., pointed out that during the cytokine storm, three important cytokines in the IL-1 family are involved IL-1\(\beta\), IL-18, and IL-33\textsuperscript{[11]}. Recent study declared that COVID-19 stimulate pro-inflammatory cytokines productions such as IL-1\(\beta\) and IL-6 via the toll like receptors that causes the release of active mature IL-1\(\beta\) which is a mediator of lung inflammation, fever and fibrosis\textsuperscript{[12]}.

It is well known that TNFs are key inflammatory factors that trigger a cytokine storm. They are attractive targets for controlling the cytokine storm. Similarly Qin and colleagues showed that most patients with COVID-19 had high serum levels of TNF-\(\alpha\) along with IL-1\(\beta\) and IL-6, elevation levels of these cytokines have also been found in patients with severe COVID-19 as compared to the non-severe ones\textsuperscript{[5]}. On the other hand Chinese medical researchers have found that the increased expression of interleukin-2 receptor and IL-6 in serum is expected to predict the severity of the 2019-nCoV pneumonia and the prognosis of patients\textsuperscript{[13]}. Likewise higher plasma levels of other inflammatory cytokines (IL-7, IL-8, IL-9, IL-10, MCP-1, and IFN-gamma etc.) were observed in patients with COVID-19 (2). IL-17 play a role in pathogenesis of COVID-19 infection and blocking it could help those patients who have high level of IL-17\textsuperscript{[14]}. Additionally, in severe cases, a reduction of CD4\(^+\) and CD8\(^+\) T cells and a decrease of regulatory T cells has been found, likely due to high expression of proinflammatory cytokines in COVID-19 patients\textsuperscript{[5]}.

**Anti-inflammatory Cytokines:** Anti-inflammatory cytokines, such as IL-1Ra, IL-37 or IL-38, can provide relief in both systemic inflammation and fever that occur after infection. Conti et al., demonstrate that the suppression of IL-1\(\beta\) by IL-37 in inflammatory state induced by COVID-19 can have a new therapeutic effect previously unknown. As well IL-38 is a potential therapeutic cytokine which inhibits inflammation in viral infections including that caused by COVID-19, providing a new relevant strategy\textsuperscript{[13]}. Dissimilar SARS patients, patients with COVID-19 also have elevated levels of Th2 cell secreted cytokines (such as IL-4 and IL-10), which inhibit the inflammatory response\textsuperscript{[3]}. However, infection with 2019-nCoV appears to be initially associated with an increased Th2 response, which might reflect a physiological reaction to curb overt inflammatory responses\textsuperscript{[2]}.

**Conclusion**

In conclusion both T-Th1 and Th2 cytokines underline the role of the immune processes in the pathogenesis of COVID-19.

**Conflict of Interest:** The authors and planners have revealed no possible conflicts of interest, financial or else.

An Anthropometric Study of Stature Estimation from Foot Morphometry in North Indian Population

Bhamini Sharma¹, Reena Singla², Vishal Verma³

¹M.Sc. Student, Department of Anatomy, ²Professor, Department of Anatomy, ³Asstt. Prof. Department of Anatomy, MMIMSR, MMDU, Mullana-Ambala

Abstract

Background and Objectives: The aim of present study is to find the correlation of foot morphometry with stature and to derive the regression equation for stature estimation among two endogamous (baniya and jats) groups of North India.

Material and Method: The present study was carried out at Department of Anatomy, MMIMSR Mullana–Ambala, on 400 subjects (100 males, 100 females of each group) belonging to known endogamous group (baniya and jats) of Haryana, age group ranged between 21-35 years. Height and foot length, foot breadth was measured. Foot index was calculated. Statistical analysis including mean, standard deviation for stature and foot morphometry of both sides were calculated separately for both sexes. Pearson’s correlation coefficient was calculated to find correlation between stature and different foot morphometry. To estimate stature from foot morphometry linear regression analysis was done.

Results: The mean and standard deviation for height in males was 173.68 ± 7.336 and in females was 160.73 ± 10.049 with highly significant p value. The mean foot length, foot breadth of males was higher than females with statistically significant p value. In males, the foot length and foot breadth of both sides have a highly significant correlation with height. In females the correlation of height was highly significant with foot length, foot breadth and foot index among both the groups.

Conclusion: A significant correlation coefficient was observed between height and foot length in males. In females, a significant correlation was observed between height and foot length and foot breadth. If either of the measurement is known (height or foot length/foot breadth), the other can be calculated. This would be useful for Anthropologists and Forensic medicine experts.

Keywords: Foot length, Foot breadth, Foot index, jats, baniya, correlation.

Introduction

Anthropometry is a series of systematic measuring techniques that express quantitative dimensions of human body and skeleton.¹ Forensic investigations use an anthropometric approach in the identification of victims.² Over the years, the anthropometric measurements of various anatomical structure for prediction and estimation of stature has become very useful, especially when the skeletal remains are often observed to be incomplete or extensively dismembered.³ Stature estimation has a very important role to play in forensic anthropometry for personal identification. Specifically, since each individual has different variations of body profile, estimating someone’s height can have an important role in an investigation.⁴ The stature of an individual is an inherent characteristic which varies with race and it is determined by genetic constitution.
of a person, geographical location, environment and the climatic conditions. With increasing frequency of mass disasters, it is essential to find out correlations between stature, age, and sex of an individual with variable information collected from different systems, organs or its parts which is of immense importance. Stature plays a key role in establishing the identity from unknown, decomposed and fragmented remains in medico legal cases. Human stature is an anatomical complex of linear dimensions, including skull, vertebral column, pelvis and lower extremities, so that it is assumed that significant association exist between the total stature and these individual body parts. Stature of a person is proportional to dimensions of various body parts. It is established that dimensions of lower extremity show higher association with stature than upper extremity.

Height estimation by measurement of various long bones has been attempted by several workers. Each worker has derived own formula to estimate height from long bones. In 1968, Rutishauser for the first time showed that the reliability of prediction of height from foot length was as high as that from long bones. Ossification and maturation in the foot occurs earlier than the long bones and therefore, during adolescence age, height could be more accurately predicted from foot measurement as compared to that of long bones.

Like other parts of body such as head, trunk, lengths of upper and lower limbs, the foot size also displays a definite biological correlation with stature on the basis of this relationship it is possible to predict the stature from foot and its segments. Various studies have reported a statistically significant positive association of stature with foot measurements. Some studies suggest the use of stature – foot index, multiplication factor method and regression equation method to estimate stature from foot dimensions. The aim of present study is to find the correlation of foot morphometry with stature and to derive the regression equation for stature estimation among two endogamous groups.

Material and Method

The present study was carried out at Department of Anatomy, MMIMSR Mullana –Ambala, on 400 subjects (100 males, 100 females of each group) belonging to known endogamous group (baniya and jaat) of Haryana, age group ranged between 21-35 years. Prior written consent for the study was taken from all the subjects both in English and in vernacular. Cases with foot anomalies, trauma, inflammations and surgery was excluded for the investigation.

Equipments used: Osteometric board, Flexible metallic measuring tape.

Height was measured by making the subject stand erect and barefooted on a flat floor and the vertical distance between the point vertex, (highest point on the head), when the head is held in the Frankfurt’s horizontal plane (which is obtained by joining the infra orbital margin to the upper margin of external acoustic meatus) and the heel touching the floor was measured in cms.

Foot measurements were taken with the help of osteometric board:

- Osteometric board: Osteometric board is an anthropometric instrument that consists of a flat board with two ends, one of which is movable and travels along a routed track. This is a preferred instrument for measuring long bones. The object to be measured is placed between the two end pieces and the movable end brought up to the object, where the measurement scale can be read.
- Foot length: Foot length was taken as a straight distance between the most posteriorly projecting points of heel (pternion) to the most anterior projecting point (Acropodion) of the first or the second toe whichever will be bigger when the foot is fully stretched.
- Foot breadth: Foot breadth was measured as a straight distance from metatarsaletibiale (the most medially placed point on the head of first metatarsal) and metatarsalefibulare (the most laterally placed point on the head of the fifth metatarsal) when the foot will be fully stretched.
- Foot index = foot breadth/foot length x 100

Statistical analysis: Data was analyzed using Statistical Package for Social Sciences (SPSS, version 20). Descriptive statistics including mean, standard deviation, minimum and maximum value for stature and foot morphometry of both sides were calculated separately for both sexes. Pearson’s correlation coefficient was calculated to find correlation between stature and different foot morphometry. To estimate stature linear regression analysis was applied.
Results

The mean and standard deviation for height in males was 173.68 ± 7.336 and in females was 160.73 ± 10.049 with highly significant p value. The mean foot length, foot breadth of males was higher than females with statistically significant p value. Table 1. In Baniya males, the foot length of both sides have a highly significant correlation with height at 0.01 level(2 tailed) and foot breadth of both sides is significantly correlated with height at 0.05 level(2 tailed). In Jat males, Right foot length and right foot breadth shows a correlation which is significant at 0.05 level (2 tailed) and left foot length and height are correlated and this correlation is highly significant at 0.01 level (2 tailed). The correlation of foot length, foot breadth and foot index in females of both the groups was highly significant at 0.01 level (2 tailed) as compared to the male group. Table 2 The linear regression equations were applied on the parameters, which were highly correlated with height. In males, foot length (right and left) and in females, foot length(right) and foot breadth(left side). From these parameters, certain equations to estimate stature (dependent variable) from foot morphometry (Independent variable) are derived as follows: Linear regression equation to estimate height for various parameters studied in male and female group:

In Jats:

Height = 126.597 + 1.979 (Left foot length)

In baniya:

Height = 109.262 + 2.457 (Right foot length)

Linear regression equation to estimate height for various parameters studied in females:

In Jats:

Height = 90.831 + 2.920 (Right Foot Length)
Height = 88.309 + 1.744 (Right Foot Length) + 3.318(Left Foot Breadth)

In baniya:

Height = 189.636 – 3.616 (Left Foot Breadth)
Height = 133.758 + 2.453 (Right Foot Length) – 3.520 (Left Foot Breadth)

Table 1: Descriptive statistics of Age, Height and Foot morphometry among study population

Discussion

The present study focused on foot morphometry and its correlation with stature among two endogamous groups (Baniya, jats) of North India. It was seen that a significant correlation was seen between height and foot length in male study group. Among females, height is showing significant correlation with foot breadth, foot length and foot index (in jats and baniya females). (Table 2) Various previous studies conducted to find correlation between stature and foot morphometry agrees with our study. They concluded that there is significant correlation between height and various foot parameters as shown in Table 3.

Stature estimation is considered as one of the important parameters in identification of a person. various body parts shows biological correlation with stature. Therefore, many workers have utilized this fact to use body parts or skeletal remains to estimate stature. A study by Qamra et al, measured height, foot length and foot breadth of 1015 adults (519 males and 496 females). They developed method for estimating height from foot morphometry. Sen et al studied the foot measurements and stature of Rajbanshis of West Bengal (150 males, 150 females) and derive various formulas to evaluate height from foot morphometry. Kanchan et al studied the relationship between stature and foot dimensions among Gujjars, a north indian endogamous group. They measured height, foot length and foot breadth on 100 males and 100 females and derive multiplication factors and regression equations from foot dimensions to estimate stature. Dhaneria et al, concluded that foot length and foot breadth showed positive correlation with stature. out of both these parameters foot length is a better predictor of stature they also derive linear regression equation for estimation of stature from foot length and foot breadth.

Conclusion

The present study has established a strong correlation between height, foot length and foot breadth among study groups. Regression equation have also been established. In males, the correlation between height and foot length was more than foot breadth. In females, both foot breadth and foot length has significant correlation with height. In baniya females in addition to foot length and foot breadth, a significant correlation was seen between height and foot index. To conclude, foot length can be considered as a better predictor of stature in males than in females. Among comparison between endogamous groups in baniya females besides foot length and foot breadth, foot index is also a good predictor of stature. If either of the measurement (foot length, foot breadth, stature) is known the other can be calculated. However, these equations are population specific and cannot be applied to other population. Therefore, population specific studies are suggested that may be useful in examining dismembered human remains in medicolegal cases.

Correlation between QT Interval with Left Ventricular Mass Index (Using M-Mode Echocardiography) and Blood Pressure in Patients with Hypertension

Budi Susetyo Pikir¹, Priscillia Myriarda²

¹Professor in Department of Cardiology and Vascular Medicine, ²Student in Department of Cardiology and Vascular Medicine, Faculty of Medicine–Dr. Soetomo Academic General Medicine, Universitas Airlangga, Surabaya, East Java, Indonesia

Abstract

Background: In patients with hypertension, the excessive blood pressure load correlates with neurohormonal activities and will lead to left ventricular remodeling. QT interval often occurs in patients with hypertension. The correlation between structural changes and repolarization remains unclear.

Method: This study involved 62 patients with hypertension (38 female and 24 male) to whom blood pressure, electrocardiogram and echocardiography examination were performed simultaneously. The correlation between QT interval with left ventricle mass index and blood pressure was statistically analyzed using Pearson correlation test.

Results: The mean of QTc interval in patients with hypertension was 390.40±30.73 millisecond. Based on the echocardiography examination results, the mean of left ventricular mass index was 75.38±12.36 with RWT of 0.36±0.06. Pearson correlation statistical analysis shows a correlation between QTc interval with left ventricular mass index (r=0.277; p value=0.030) and systolic blood pressure (r=0.317; p value=0.014).

Conclusion: QT interval correlated with increased left ventricular mass index and systolic blood pressure in hypertension patients with normal geometry and concentric remodeling.

Keywords: QT interval, left ventricular mass index, blood pressure, hypertension.

Introduction

Hypertension is considered the primary cause of morbidity and mortality in cardiovascular. In 2000, hypertension occurred in nearly 1,000 million people or almost 26% of adult population globally, 333 million people in developing countries and 639 million in underdeveloped countries(1). According to epidemiology data in America, hypertension prevalence in 2004 reached up to 29% and increased to 34% in 2006, while in Indonesia was 32.2%(2).

Hypertension is defined as the persistent increase of blood pressure to above 140/90 mmHg. High blood pressure is a long-term health problem that most frequently send people to health facilities(3). American Heart Association has predicted that the total cost for hypertension in 2010 would reach 76,600 million dollars. The data in America reported that of all the patients, 80% knew their diseases, 71% following routine medication and 48% could achieve controlled blood pressure(4).

Uncontrolled hypertension increase the risk of coronary heart disease, stroke and heart failure. Heart failure could occur due long-term hypertension or due to
secondary results of coronary heart disease. Continuous high blood pressure stimulus will lead to remodeling and left ventricular hypertrophy. Left ventricle remodeling is a structural changes (dimension, mass and form) of the heart as the response to the hemodynamic loads related to neurohormonal activation(5).

Until recently, electrocardiogram is still considered an important diagnostic tool in cardiology. Electrocardiogram examination in hypertension patients showed several abnormalities, i.e. QRS complex expansion (as the appearance of left ventricle hypertrophy), QT interval elongation etc. QT interval depicts the total amount of time required to activate and to relax the ventricle(6).

Clinically speaking, left ventricular hypertrophy is more often detected using echocardiography (EKG). In echocardiography, left ventricular hypertrophy can be detected more accurately by evaluating the wall thickness and/or left ventricular mass index towards body size. Several criteria of LVH in EKG are highly specific but less sensitive. Several previous studies showed a correlation between left ventricle hypertrophy and EKG repolarization changes, such as QT interval elongation(7). Although several evidences have confirmed that repolarization impairment is the initial process, but the correlation between the effect of light ventricular hypertrophy or left ventricular structural changes with EKG repolarization remains unclear. This study aims to analyze the correlation between QT interval with left ventricular mass index and blood pressure in patients with hypertension.

**Method**

This is an analytical observational study which used cross-sectional approach or design. It was conducted in Department of Cardiology and Vascular Medicine, Dr. Soetomo General Hospital Surabaya from October to December 2012. The samples of this study were patients with hypertension undergoing outpatient treatment in cardiology unit of Dr. Soetomo General Hospital Surabaya from November 2012 who met the inclusion criterion (having normal left ventricular ejection fraction with EF >55%) and were willing to be enrolled in the study procedure as shown by their signing the informed consent(8).

The samples were 62 patients with hypertension who were treated in outpatient cardiology unit and underwent echocardiography examination. The data were analyzed using SPSS 17.0 program for Windows (SPSS, Inc., Chicago, IL). One-sample Kolgomorov-Smirnov test was used to test the normality of data distribution. Intra-observer and inter-observer variability were evaluated using correlation test, Bland Altman test and variability percentage. The results were considered significant if the p significance value was <0.05(9).

The results of data normality conducted in the study’s variables showed a normal distribution in the variable QT interval based on Kolmogorov-Smirnov significant value (p >0.05). To find out the correlation between QT interval and left ventricular mass index, Pearson correlation test was performed on the respondents’ RWT and systolic blood pressure which were evaluated using M-mode echocardiography. The correlation between QT interval and blood pressure was tested using Spearman method.

Table 4. Correlation between QT interval with respondents’ left ventricular mass index and blood pressure

Table above shows that different test analysis was performed on the confounding factors, i.e. gender, age, hypertension period and obesity, in the respondents’ characteristics based on left ventricular remodeling. Left ventricular remodeling occurred if the LVMI in female was >97 g/m\(^2\) and 110 g/m\(^2\) >0.42.

**Discussion**

Hypertension was still considered the primary health problem among the society. People with hypertension often developed abnormal heart structure and functions including left ventricular remodeling and hypertrophy. Left ventricular remodeling was the structural changes (dimension, mass and form) in the heart as a response towards hemodynamic loads related to neurohormonal activation\(^{(10)}\).

Left ventricular hypertrophy occurred as a compensation to maintain to keep heart’s pumping function adequate towards the chronic increase of preload and after-load. The chronology of ventricular load increase until cellular hypertrophy occurred was due to interactions among several systems \(^{(11)}\). Myocardial strain due to excessive volume loads or pressure loads stimulate cardiac fibroblast and myocytes expressed a number of fibrotic and growth factors including angiotensin II, insulin growth factor I (IGF I), IL-6, TGF-β, and endotelin-1 \(^{(12)}\). All those humoral factors could trigger myocardial hypertrophy occurrence. Persistent hypertension stimulated RAAS (rennin, angiotensin II and aldosteron), endotelin-1 and TGF-β to trigger transition from fibroblast to myofibroblast. Myofibroblast then increase the production of extracellular protein matrix including fibronectin, laminin, collagen I and II which caused fibrosis progressivity\(^{(10)}\). The increase of cardiomyocyte size, extracellular matrix changes and fibrosis accumulation led to left ventricular remodeling. In echocardiography examination, left ventricular concentric remodeling occurred if the relative wall thickness (RWT) was >0.42 with left ventricular mass index was still within the normal range. The prevalence of left ventricular hypertrophy correlated with old age and the degree of hypertension severity, which ranged around 6% in young patients aged <30 years old, 43% in the age of >69 and 20-50% in mild to severe hypertension \(^{(13)}\).

From the respondents’ data in this study, the author obtained 62 subjects (24 were male and 38 were female) aged 40-75 years old. Their hypertension history period ranged between 0.5-15 years and they have undergone at least routine medication in polyclinic. Gender, age, hypertension history period and obesity affect the occurrence of left ventricular remodeling. Difference test analysis was performed on those four confounding factors using Chi-square and t-test statistical analysis and no significant result was obtained. In the respondents’ data, those four factors did not give any significant difference.

No left ventricular hypertrophy was found in EKG examination as well (based on Romilt Estes criteria). The results of M-mode echocardiography showed that left ventricular mass index was within the normal range with the mean of 75.38±12.63 g/m\(^2\) (the lowest was 49.44 and the highest was 97.92 g/m\(^2\)) while the mean of RWT was 0.36±0.06 (the lowest was 0.28 and the highest was 0.48). No left ventricular hypertrophy was found in the data. Left ventricular geometric changes in hypertension patients were still within normal size or left ventricular remodeling. All respondents showed normal left ventricular systolic functions with the mean of EF by Teich amounted of 68.59±5.04 (%). Normokinetic was also found in regional wall motion based analysis based on echocardiography \(^{(14)}\).

In this study on tested rats, there was QT elongation related to the rats’ blood pressure compared to the rats’ left ventricular mass index. Another studies also showed the correlation between the value of arterial blood pressure and the average blood pressure with QT interval elongation in patients with hypertension. A study conducted by Latea et al. (2010) confirmed that anti-hypertension therapy could decrease QT interval related to decreased blood pressure and left ventricular mass index \(^{(15)}\). The result of this study also supported that of the previous ones where there was a significant correlation between QT interval and left ventricular mass index in respondents with hypertension. The data above show elongated QTc interval that correlated with the increase of left ventricular mass index with weak correlation (r = 0.27, p value=0.030). The possible explanation on the weak correlation was because it was related to the hypertension period and the degree of hypertension severity. The respondents in this study had the hypertension period of 3-8 years and not very high blood pressure.

QT interval positively correlated with left ventricular mass index in hypertension patients who have not yet...
developed left ventricular hypertrophy. Repolarization impairment in this study might be due to left ventricular remodeling, i.e. fibrosis, extracellular matrix increase and perivascular fibrosis that caused conduction impairment. In this study, the QTc was longer in hypertension patients with left ventricular remodeling. In microscopic level, left ventricular hypertrophy including myocyte hypertrophy, fibrosis and increased interstitial collagen tissue would lead to action potential time elongation (16). The heart of rats with hypertrophy would experience action potential elongation and specific impairment in potassium repolarization (I_{op})(17).

Several studies showed data in which a correlation between QT interval and blood pressure in hypertension patients was found. This study showed a positive correlation between QT interval and systolic blood pressure ($r=0.312$, $p$ value=0.014). Systolic blood pressure affect QT interval more significantly that it did diastolic blood pressure. The primary factor that was responsible for left ventricular hypertrophy was excessive pressure loads. It would lead to myocardial changes, i.e. increased left ventricular mass index due to remodeling or left ventricular hypertrophy (18). Increased left ventricular mass index caused QT interval elongation. The previous studies showed a correlation between QT interval correlation and excessive sympathetic activities in essential hypertension patients (6). In this study, hypertension patients’ blood pressure evaluation results was still in control or increased up to level I (according to JNC VII), but the higher blood pressure correlated with QT interval elongation in respondents’ data.

Left ventricular mass index was examined using echocardiography in which there was a limitation compared to other examinations such as magnetic resonance image. LVMI examination using M-mode echocardiography resulted in variabilities with the difference of nearly 5% which might contribute to the difference of 50 gram. The variabilities particularly occurred in measuring of wall thickness and determining the myocardial lining limit. For reproducibility, it was a bit better to use ASE measurement method compared to Penn (19).

Based on Framingham data, RWT gave left underestimated ventricular hypertrophy measurement, which was 5%, since it only used posterior wall thickness. Systolic blood pressure affected ventricular repolarization (20). Blood pressure kept changing from time to time and therefore, a measurement in one time could not represent a patient’s blood pressure for 24 hours.

**Conclusion**

Left ventricular hypertrophy was rarely found in EKG examination of hypertension patients since this examination was highly specified but less sensitive. Another EKG impairment that often occurred in hypertension patients was QT interval elongation. The respondents’ mean of QT interval was 390.40±30.73 millisecond.

Echocardiography examination in hypertension patients showed normal left ventricular mass index (based on ASE recommendation, in female was <95 g/m$^2$ and in male was <115 g/m$^2$) and RWT of above 0.42 which indicated left ventricular concentric remodeling. A weak correlation was found between QT interval with left ventricular mass index and systolic blood pressure. QT interval elongation was proportional to the increase of LVMI and high systolic blood pressure in the respondents.

**Ethical Clearance:** The research process involves participants in the survey using a questionnaire that was accordant with the ethical research principle based on the regulation of research ethic committee. The present study was carried out in accordance with the research principles and was approved by the Ethics Committee of Faculty of Medicine Universitas Airlangga, Indonesia. This study implemented the basic principle ethics of respect, beneficence, nonmaleficence, and justice.

**Conflict of Interest:** The researchers reports no conflict of interest of this work.

**Source of Funding:** This research is done with individual money.

Relationship between Working Period and Knowledge Level to the Prevention of Work Accident through Work Stress on Milled Kettle Workers in Sugar Factory of Rejo Agung Baru Madiun

Caesar Kridha Bagus Prahartiko¹, FX Ady Soesetijo¹,², Ristya Widi Endah Yani¹,³

¹Graduate Student, Magister Program of Public Health Education, Jember University, East Java (Indonesia), ²Medical Doctor, Faculty of Dentistry, Jember University, East Java (Indonesia), ³Medical Doctor, Faculty of Dentistry, Jember University, East Java (Indonesia)

Abstract

Sugar factory labor was highly vulnerable to get work accident in work place. The objective of this research was to identify the relation between working period and knowledge level to the prevention of work accident through variable of work stress on mill and kettle workers. This research was quantitative in analytical observational method and cross sectional design. Total sample of research were 115 workers in the sugar mill and kettle at sugar factory of Rejo Agung Baru Madiun through total sampling. The research data was tested in SEM (Structural Equation Model) method by exerting instrument of Stata 13 to analyze the data. Based on the finding of research, on the sig value of working period 0.006 and sig value of knowledge level 0.023, it referred the relation in variable of working period through work stress, while no relation in variable of knowledge level through work stress to the prevention of work accident. Thus, it required to more stimulation to the knowledge level and more support to the workers in order to minimize their work stress.

Keywords: K3, Sugar Factory, Milled Kettle, Stress, Work Accident.

Introduction

Work accident is an unpredictable and unexpected situation by all workers which might occur, it is often unpredictable and cause to time and property loss, or even victim in the working world. This work accident is caused by a contact between energy sources as mechanical, chemical, physical, and kinetic which affect to injury on human, environment, or working tools. ISO 14001, 2004 has asserted that the work accident is defined as an incident which occurs on labor and causes to occupational illness, injury, or even death⁷.

Prevention of work accident can be implemented through strategies of work accident prevention which are addresses to working machine, environment, equipment and supplies as well as human factor. Environmental condition is needed to fulfill standards or safety and security, proper condition of work place according to the standard of work safety until the planning which needs extra attention to fulfill the safety standard¹⁰. The work accident also impacts to significant expense for the organization, employee, and even society in overall. The expense is varied based on lowest level up to the highest level, with the duration of sick leave because of work accident. The long duration of sick leave will impact to the organization, since the labor or employee will be less productive along that period of time. The sick leave of employee means that the organization must keep paying the salary along the leave period of employee (it appears to the expense proportionally over the work-days left). The alternative which can be implemented during employee’s leave is to look for the substitute as the part-time employee. However, this part-time employee must also be paid by the organization. This also might impact to the higher cost of expense in an organization, if the work accident is not minimized as good as possible³.

Working period is defined as a duration of employee to exert effort and time to the factory or organization as well as produce absorption from many kinds of...
human activity. The longer working period will make the employee have more experiences and be able to help the factory or organization to produce output and better performance. Working period can build skill of employee, so the work will be performed well. Therefore, the longer working period will identify better working skill of employee\[9\].

Knowledge is a result of knowing towards a particular object through five sense (eye, nose, ear, and other senses) or a production of human sensing. Naturally human sense produces knowledge which is very affected by the intensity of attention and perception on certain object. It mainly gotten through sense of hearing and sight\[6\].

Knowledge is mental components which has been resulted from whole process physically or connately which is derived from individual experience\[8\]. It is divided into several aspects, as 1) Know, as the reminder of subject which has been learned in the past. This level is considered as recall stage or re-remember on stimulus received. Thus, know is the lowest stage in the knowledge aspect, 2) Comprehension, as being able to explain well about particular object which is known as well as to interpret subject properly. It is also about to explain, mention, conclude, estimate the object which is being learned at that time, 3) Application, it aims to exert the subject as things that have been learned in the real situation or condition, 4) Analysis, the activity of information sorting into many parts or activities which examines and attempts to understand information, 5) Synthesis, an ability to put and relate parts within an overall form, or it is simply explained as the ability to arrange new formulation from some existing formulation, 6) Evaluation, where the individual has ability to value on particular object\[1\]. There are factors which can influence individual knowledge: age, educational level, working experience, up to the information which is obtained by the individual\[5\].

Work stress is a state of stress which impacts individual to have unbalanced psychological and physical condition that will influence the process of thinking, emotion, and condition of employee. The individual who often worries and feel nervous indicates signals of stressful individual, as a result, it will make the individual more aggressive, get angry frequently, unrelaxed condition, until uncooperative behavior towards the surrounding environment\[4\]. Generally, the phase of mild stress does not damage the individual or employee from their physiological aspect. The mild stress on individual in their daily life will make the employee be more alert and not cause to disease, next, the phase of severe stress, where the duration of severe stress is longer than the mild one. It can be in week or even years, thus, the severe stress can danger individual or employee. The example of severe stress is inharmonious relationship with family or partner of life, chronic disease, until financial difficulty. About responses which emerge from this severe stress are indigestion, asphyxia, tremor, and often feel confused or panic\[11\].

However, the stress can result positive things in the end, as calmness, high motivation, good perception, and high energy. Those responses also impact well to the employee as long as the stress management can be managed well, then, the task or work is finished well and relation with the surrounding goes well. On the other hand, if the individual response during work stress is negative, it will impact badly as decreased motivation, easy to get angry or offended, work absence, apathetic, easy to make mistake during working, and inability to take decision. Those negative impacts are very influential to the individual and their work environment. They are caused by the individual inability to manage the stress, so it cause problems among employees or even unfinished works\[12\].

The research is conducted on the milled kettle workers in sugar Factory of Rejo Agung Baru Madiun.

**Method**

This research was included into observational analytical research which exerted observational analytical method and aimed to identify the relation between knowledge level and working period to the prevention of work accident through variable of work stress. The researchers employed cross sectional research design on the total respondents 115 milled kettle workers in Sugar Factory of Rejo Agung Baru Madiun by using questionnaire sheets which have been valid and reliable to the variables of working period, knowledge level, work stress as well as prevention of work accident in questionnaire as the research instrument. Each variable questionnaire was consisted of 10 items for the knowledge level, 11 items for the work stress and 12 items for the prevention of work accident, while the working period was identified from standard of working period which has been determined by the organization. The research data was analyzed in SEM (Structural Equation Model) by exerting instrument of Stata 13.
Research Findings

1. Univariate Analysis

a. Working Period: Variable of working period was consisted of two categories: long working period and new working period. The 1st table would define the working period of milled kettle labor from the total respondents 103 workers where particularly 71 workers have long working period (62%), while 44 workers have new working period (38%).

<table>
<thead>
<tr>
<th>Working Period</th>
<th>Respondent (n)</th>
<th>Percentage %</th>
</tr>
</thead>
<tbody>
<tr>
<td>Long</td>
<td>71</td>
<td>62</td>
</tr>
<tr>
<td>New</td>
<td>44</td>
<td>38</td>
</tr>
<tr>
<td>Total</td>
<td>115</td>
<td>100</td>
</tr>
</tbody>
</table>

b. Knowledge Level: Variable of knowledge level was divided into two categories, good and poor category. 2nd table would illustrate data distribution which gathered from 115 respondents, that 67 workers have good educational level (58%), while 48 workers have poor educational level (42%).

<table>
<thead>
<tr>
<th>Knowledge Level</th>
<th>Respondent (n)</th>
<th>Percentage %</th>
</tr>
</thead>
<tbody>
<tr>
<td>Good</td>
<td>67</td>
<td>58</td>
</tr>
<tr>
<td>Poor</td>
<td>48</td>
<td>42</td>
</tr>
<tr>
<td>Total</td>
<td>115</td>
<td>100</td>
</tr>
</tbody>
</table>

c. Work Stress: Variable of work stress was divided into two categories, as mild and severe stress, 3rd table would explain that from the total 115 respondents, 65 workers have mild work stress (57%), while 50 workers have severe work stress (50%).

<table>
<thead>
<tr>
<th>Work Stress</th>
<th>Respondent (n)</th>
<th>Percentage %</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mild</td>
<td>65</td>
<td>57</td>
</tr>
<tr>
<td>Severe</td>
<td>50</td>
<td>43</td>
</tr>
<tr>
<td>Total</td>
<td>115</td>
<td>100</td>
</tr>
</tbody>
</table>

d. Prevention of work Accident: Prevention of work accident on milled and kettle workers in Sugar Factory of Rejo Agung Baru Madiun illustrated that workers section have prevented towards work accident in about 63 respondents (55%), while 52 respondents (45%) have not been good in preventing work accident as it was illustrated on the following table:

<table>
<thead>
<tr>
<th>Prevention of Work Accident</th>
<th>Respondent (n)</th>
<th>Percentage %</th>
</tr>
</thead>
<tbody>
<tr>
<td>Good</td>
<td>63</td>
<td>55</td>
</tr>
<tr>
<td>Not good</td>
<td>52</td>
<td>45</td>
</tr>
<tr>
<td>Total</td>
<td>115</td>
<td>100</td>
</tr>
</tbody>
</table>

2. Multivariate Analysis: Path analysis test was aimed to identify indirect relation between independent variable and dependent variable through intervening variable. Further, path analysis in this research exerted pat analysis in logistic regression base. The software of Stata 13 was used to analyze the research data in this research, it resulted:

<table>
<thead>
<tr>
<th>Variable</th>
<th>Log odd</th>
<th>Coefficient</th>
<th>S.E</th>
<th>Z</th>
<th>P Value</th>
<th>CI 95%</th>
</tr>
</thead>
<tbody>
<tr>
<td>Work Stress (Working Period)</td>
<td>-1.2</td>
<td>-1.157</td>
<td>0.425</td>
<td>-2.72</td>
<td>0.006</td>
<td>-1.99 up to -0.32</td>
</tr>
<tr>
<td>Work Stress (Knowledge Level)</td>
<td>-0.76</td>
<td>-0.762</td>
<td>0.431</td>
<td>-1.77</td>
<td>0.077</td>
<td>-1.61 up to 0.08</td>
</tr>
<tr>
<td>Prevention of Work Accident</td>
<td>0.87</td>
<td>0.875</td>
<td>0.384</td>
<td>2.28</td>
<td>0.023</td>
<td>0.123 up to 1.63</td>
</tr>
</tbody>
</table>

5th table Table of Estimation Result: Negative relation between working period and work stress incident was indicated by the log odd coefficient in each score unit of working period variable that could reduce work stress in about 1.2 unit, and significant relation statistically (CI 95% = -1.99 up to -0.32; p value = 0.006). Relation between knowledge level and work stress incident was negative. Moreover, the log odd coefficient in each unit of knowledge could reduce the work stress in about 0.76 unit, and did not show any relation statistically (CI 95% = -1.61 up to 0.08; p value = 0.077). It referred to the positive relation between work stress and prevention of work accident. Log odd coefficient in each score unit of work stress could improve prevention of work accident in about 0.087 unit, and have significant relation statistically (CI 95% = 0.123 up to 1.63; p value = 0.023).
indirect relation of working period through variable of work stress to the prevention of work accident resulted value -1.044. This indirect relation from the variable of working period -1.044, where the path analysis on direct relation value between working period and work stress -1.2. Whereas, the knowledge level and prevention of work accident through work stress -0.66 from the calculation result (-0.76) x (0.87) = -0.66. It was not indicated to significant relation statistically on the level of knowledge, due to the p value of knowledge level was higher than p value 0.077 > 0.05.

Direct relation was the relation between independent variable and dependent variable except through intervening variable. The relation of total working period in prevention of work accident -1.044 through formula (-1.2) x (0.87) + 0 = -1.044, while for the knowledge level (-0.76) x (0.87) + 0 = -0.66. Value score is 0 was derived because of no indication of direct relation between variable of working period and knowledge level to the prevention of work accident.

**Discussion**

Work stress and working period resulted to negative relation to the prevention of work accident. The result of path analysis showed that on log odd coefficient in each score unit of working period was able to decrease work stress of employee in about 1.2 unit, where the long period of working could reduce the severe level of work stress, then, workers who have been in the long working period could minimize possibility of severe stress than workers in new working period. Globally, either new working period or long working period could rise to work stress, surrounding environment was also able to be the trigger of work stress from the physical and social environment condition, as well as work target demand of the factory or organization. Monotonous activity in working and age factor due to the long period of work could impact tired condition that raised to work stress[2]. The longer experience indicated that the workers have undergone critical periods during working in the factory or organization, which affected the labor to be more calm during working. Therefore, the prevention of work accident was better and profitable for both parties.

Knowledg level and work stress was not related to prevention of work accident. Log odd coefficient in each score unite of knowledge level could reduce the work stress in about 0.76 unit. The worker who have good knowledge level could decrease severe stress level than worker who have poor knowledge level, but it did not indicate to significant relation statistically in this research, since the p value of knowledge level (0.077) was higher than the p value (0.05). Knowledge level in this research was not related to work stress which referred that knowledge level should pass variable of attitude. Attitude could determine whether decision should be taken or not. In addition to knowledge level, if on the average, worker have good knowledge level but bad attitude, the attempt of work accident prevention would not be appropriate to purpose. Intervening variable in this research is work stress which no relation with prevention of work accident. Knowledge level did not have any relation, because it was possible that knowledge level of workers was only to know, but did not reach to the evaluation stage where workers should understand or comprehend about the prevention of work accident.

**Conclusions**

Working period in this research showed relation to prevention of work accident through variable of work stress, while knowledge level did not show to any relation to prevention of work accident through variable of work stress on milled and kettle workers in Sugar Factory of Rejo Agung Baru Madiun. Next, the work stress as intervening variable resulted about relation to the prevention of work accident on milled and kettle workers in Sugar Factory of Rejo Agung Baru Madiun. Furthermore, researchers suggested that the workers with long working period should share their experience to new workers and remind them to keep focusing on how to minimize about possibility of work accident. Workers were expected to follow acceleration system to equalize the educational level. Since, the higher level of education would result to more knowledge. Stress management was also needed for the workers, so the work stress and work accident could be minimized.

Abstract

Objectives: To compare the effects of clonidine and moxonidine as add on therapy in patients of chronic kidney disease with hypertension.

Method: It is an observational study of duration of one year. Patient who fall under the diagnostic criteria of chronic kidney disease with hypertension were selected randomly from those attending the routine medicine outpatient department and medicine ward at S.N. Medical College and associated hospital.

Result and Conclusion: Study shows a slightly greater reduction in various parameters of chronic kidney disease like systolic BP, diastolic BP, pulse rate, blood urea, and serum creatinine with moxonidine group than clonidine group. But statistically there was no significant difference was found in both groups.

Keywords: Chronic kidney disease, hypertension, moxinidine, clonidine.

Introduction

Hypertension is a “life time” condition and, if left untreated, leads to lethal complications. High blood pressure went from being the 4th leading risk factor in 1990 and 1st risk factor in 2010 as quantified by DALYs.¹ According to a WHO report on Global Status of Non-Communicable Diseases 2010, 33% of the adult Indian men and 30% of adult Indian women have high blood pressure, implying that one in every three adult Indian is hypertensive.² Hypertension is one of the cause of chronic kidney disease (CKD). Hypertension in CKD increases the risk of important adverse outcomes, including loss of kidney function and kidney failure, early development and accelerated progression of cardiovascular disease (CVD), and premature death. CKD is an internationally recognized public health problem affecting 5–10% of the world population.³⁴

Clonidine is classified as a centrally acting α₂ adrenergic agonist and imidazoline receptor agonist that has been in clinical use for over 40 years.⁵ Clonidine suppresses sympathetic outflow resulting in lower blood pressure, but sudden discontinuation can cause rebound hypertension due to a rebound increase in sympathetic outflow. Treatment of clonidine withdrawal hypertension depends on the severity of the condition.⁶ Moxonidine is widely approved central antihypertensive drug that acts primarily by reducing central sympathetic nervous system activity via activation of imidazoline I-1 receptors in the rostral ventro-lateral medulla (RVLM). It is an orally administered imidazoline compound with selective agonist activity at imidazoline I-1 receptors, for which it has affinity >30 fold than α-2 adrenoreceptors.⁷ Thus, the unique profile of moxonidine and clonidine...
provides an opportunity to simultaneously cover a large number of factors crucially involved in the pathophysiology of the Chronic kidney disease associated with elevated blood pressure.

**Aim:** To compare the effects of clonidine and moxonidine as add on therapy in patients of chronic kidney disease with hypertension.

**Objectives:**
1. To study the efficacy and safety of clonidine and moxonidine in chronic kidney disease with hypertension.
2. To compare the efficacy and safety of clonidine and moxonidine during the study period.

**Material and Method**

Patient who fall under the diagnostic criteria of chronic kidney disease with hypertension were selected randomly from those attending the routine medicine outpatient department and medicine ward at S.N. Medical College and associated hospital after having taken approval from institutional ethical committee. It is an observational study of duration of one year. Informed consent was taken from all patients and strict compliance of prescription was ensured during the study.

**Inclusion Criteria:** Patients of either sex with following parameter:
1. Patients age >30 years and <60 years.
2. Patient who were diagnosed of chronic kidney disease by biopsy, USG, GFR or DMSA scan.
3. Patients whose systolic blood pressure is ≥ 140 mmHg or diastolic blood pressure is ≥ 90 mmHg

**Exclusion Criteria:**
1. Patients age <30 years and >60 years.
2. Patient who were not diagnosed of chronic kidney disease by biopsy, USG, GFR or DMSA scan.
3. Patients whose systolic blood pressure is <140 mmHg or diastolic blood pressure is <90 mmHg.

4. Patients who require renal transplant (Grade-5 CKD).

**Drugs:** Clonidine, Moxonidine

In this study patients were selected randomly on the basis of inclusion and exclusion criteria. These patients were already on standard treatment CCB(AMLODIPINE) +THIAZIDE DIURETICS+B BLOCKERS. Selected patients were divided randomly into two groups:

**Group-I:** Comprises 94 Chronic kidney disease patients with hypertension who were given Clonidine 0.1mg BD as add on therapy and dose was titrated to achieve target level along with their standard treatment.

**Group-II:** Comprises 87 Chronic kidney disease with hypertension who were given Moxonidine 0.2mg BD as add on therapy and dose were titrated to achieve target level along with their standard treatment.

Although study was started with 100 cases in each group but there was drop out of 6 cases in group A and 13 cases in group B after 8 weeks due to unknown reasons. These patients were excluded from the study.

**Observations:** One hundred eighty one cases of chronic kidney disease with hypertension attending Medicine OPD, and admitted in Medical wards in post graduate Department of Medicine, S.N. Medical College& hospital Agra, fulfilling the inclusion criteria constituted the material for the present study.

Overall incidence of distribution of cases is maximum in 41-50 years, followed by 30-40 years and least no of cases in 51-60 years. Youngest person in this study was 31 years and oldest person in this study was 58 years.

In group-I the male/female ratio was 1.3:1, and in group- II the male/female ratio was 1.48:1. This could be due to a larger number of male being treated.

Table 1 illustrates the baseline value of systolic blood pressure before and after 4 weeks, 8 weeks and 12 weeks of therapy in group I and group II. With clonidine therapy fall in systolic BP was statistically significant at 4 week in group I (t=2.8619, p< 0.01) insignificant thereafter. With moxonidine therapy, the fall in systolic BP was statistically insignificant at 4 weeks (t=1.542, p>0.05), but was significant at 8 weeks (t=2.235, p<0.05) and 12 weeks (t=2.797, p<0.05).

Table -4 illustrates the mean baseline value of blood urea before and after 4 weeks, 8 weeks and 12 weeks of therapy in group I and group II. There was a decrease in blood urea in both groups. In group I, the decrease however was significant at 4 weeks (t=2.8075, p<0.05) and 8 weeks (t=4.8045, p<0.05) and was insignificant at 12 weeks (t=0.2777, p>0.05). The decrease in blood urea level was significant at all intervals in group II.

Table 6 demonstrates the most commonly seen side effect was sedation in both groups. Other side effects were more common in group I as compared to that seen in group II.

**DISCUSSION:** The prevalence of chronic kidney disease has been increasing worldwide during the past years and is reaching epidemic proportion in industrialized countries. This problem represents an enormous burden on health care systems and most importantly, the quality of the affected individuals is substantially lowered. Even though extensive research and public awareness efforts have been made over the previous decades the proportion of people affected is still rising. Chronic kidney disease (CKD) is an important source of long term morbidity and mortality. It has been estimated that CKD affects more than 20 million people in the United States. Most patients were asymptomatic until the disease had significantly progressed, they remain unaware of the condition. Thus it is essential to have clinical practice guidelines aimed at early detection, evaluation, diagnosis and treatment of this condition. Hypertension was found in approx. 80% of the chronic kidney disease patients. Treatment of hypertension significantly reduces the progression of chronic kidney disease.

**Clonidine therapy (Group-I):** In clonidine therapy (group-I) there was significant reduction in mean systolic blood pressure and mean diastolic blood pressure. Our finding are similar to those of G. J. A. MACPHEE (1992) and V. Planitz (1984) who observed significant reduction in systolic blood pressure and diastolic blood pressure9,10. With clonidine therapy there was insignificant change in mean pulse rate while V. Planitz (1984) crossover comparison study found that there was no significant change in pulse rate after clonidine therapy10. After clonidine treatment major side effects observed are dry mouth and sedation and tiredness. V. Planitz (1984) observed that out of 20 hypertensive patients treated with clonidine 17 patients complained of dry mouth and tiredness10.

**Moxonidine therapy (group-II):** In moxonidine therapy (group-II) there was significant reduction in mean systolic blood pressure and mean diastolic blood pressure. Our finding are similar to those of G. J. A. MACPHEE (1992) and V. Planitz (1984) who observed significant reduction in systolic blood pressure and diastolic blood pressure9,10. With moxonidine therapy, there was insignificant change in mean pulse rate. These findings concurred with the observation of V. Planitz (1984)10. Our study demonstrate that the decrease the mean baseline value of serum creatinine, however V. Planitz (1984) observed that there was no significant change in s. creatinine level after moxonidine treatment10. After moxonidine treatment main adverse effect was sedation, tiredness, pallor and dry mouth. Planitz, V. et. al. (1987) reported that moxonidine produces a hypotensive response similar to that of clonidine, at an equivalent dose, but with a significant reduction in adverse effects particularly sedation and xerostomia11.

**Conclusion**

Study shows a slightly greater reduction in various parameters of chronic kidney disease like systolic BP, diastolic BP, pulse rate, blood urea, and serum creatinine with moxonidine group than clonidine group. Side effects like dry mouth, sedation, dizziness, and headache are more common with clonidine group than moxonidine group. Moxonidine was better tolerated by patients.

Viability Test of the Gourami Scales Collagen Extract (Osphronemus Goramy) on the Human Gingival Fibroblast Cells

Chiquita Prahasanti¹, Widya Rizqi Romadhona², Shafira Kurnia S.², Aristika Dinaryanti³

¹Professor in Department of Periodontics Dental Medicine, Faculty of Dental Medicine, Universitas Airlangga, Surabaya Indonesia, ²Dental Medicine Professional Program, Faculty of Dental Medicine, Universitas Airlangga, Surabaya Indonesia, ³Research Center for Stem Cell Research and Development Institute of Tropical Disease, Universitas Airlangga, Surabaya Indonesia.

Abstract

Background: Periodontal disease is a pathological inflammatory condition of the periodontal tissues which surround the teeth, including Human Gingival Fibroblasts (HGF). HGF regeneration is through the accelerating proliferation of tissue engineering therapy needs. Generally, the tissue engineering uses regenerative materials from cow or pig as the therapies, but these materials have some flaws. Thereby, this research aims to find the alternative materials regenerative tissue engineering scaffold collagen type 1 derived from the gourami fish scales. This research is also conducted to test the viability of fish scales collagen gourami against the Human Gingival Fibroblasts for 24 hours.

Objective: To determine the concentration of fish scale collagen gourami which can maintain the viability of human gingival fibroblast cells for 24 hours.

Method: HGF is taken from the healthy gingiva and planted in 96 well plates. Fish scales collagen gourami with a concentration of 0.32 mg/ml, 0.16 mg/ml, 0.04 mg/ml, 0.02 mg/ml and 0.01 mg/ml were added to each well and incubated during 24 hours. MTT Assay is performed to see the viability of fibroblast cells.

Results: The viability of HGF were increased after the addition of fish scales collagen gourami on the concentration 0.32 mg/ml until 0.01 mg/ml. The viability of the cells after the addition of fish scale collagen gourami was shown above 100%.

Conclusion: Fish scales collagen gourami has the potential in tissue engineering and the concentration of 0.01 mg/ml shows the highest viability of HGF.

Keywords: Collagen extract, gourami scales, human gingival fibroblast cells, MTT assay, viability.

Introduction

Periodontitis is an inflammation caused by infection of the supporting tissues of the teeth, progressive damage to the periodontal ligament, and alveolar bone. This disease is caused by the induction 90% of facultative anaerobic bacteria and 75% of negative bacteria. Fibroblasts are stem cells that play a role in forming and placing fibers in the matrix, especially collagen fibers. These cells secrete small tropocollagen molecules that combine in the basic substance to form collagen fibers. Periodontal disease is a dental and oral disease with a high prevalence rate. It is also a disease in the oral cavity that affects almost all humans in the world as well as reaches 50% of the adult population.

Engineering tissue technology is needed to
accelerate the regeneration and healing of periodontal tissue. The tissue engineering approaches to bone and periodontal regeneration combines three key elements to improve the regeneration, namely progenitor cells, scaffold or supporting matrix, and molecular signal (growth factor). Scaffold serves to provide structure and substrate for the tissue growth and will be degraded after that healthy tissue grows. Cells are needed as inductors of cells (fibroblasts) for adhesion, regeneration, and differentiation from the primitive cells to the specific ones needed in the scaffold to form a healthy new tissue. Growth factor functions for biophysical stimuli and keeps cell growth and differentiation in the scaffold.

Fish can be used as raw material to produce collagen. Collagen sourced from the skin, and fish bones has a smaller molecular structure compared to collagen made from cows or pigs, so it is easier to absorb. Collagen from the fish scales is derivative collagen from fish, and extracted from the fish scales. Therefore, there is no need to worry about mammalian diseases, such as mad cow disease or bird flu virus. Based on research of Nagai et al., (2004), there are components of fish scales including 70% water, 27% protein, 1% fat, and 2% ash. Organic compounds consist of 40-90% in the fish scales, while the rest are collagen.

Viability is the ability of a cell to survive. The viability test was determined by 3- (4,5-Dimethylthiazol-2-yl) -2,5-diphenyl-tetrazoliumbromide) MTT. This study aimed to determine the concentration of fish scale collagen gourami which can maintain the viability of human gingival fibroblast cells for 24 hours. Human gingival fibroblast cells were used because fibroblast cells were the most important cells in human periodontal tissue.

Material and Method

This type of research is a laboratory experiment with the design of The Post-Test Only control group design. This research was conducted in the Stem Cell Research and Development Center, Airlangga University and the hemical engineering laboratory, Politeknik Negeri Malang.

The tools and materials used are 200μl micropipette, small test tube, used tube, 96-well plate, cone tube, yellow tip and blue tip, ELISA reader, tweezers, petri dish, incubator, tissue, aluminum foil. Saline phosphate buffer (PBS) 10%, complete media (MK) (α-MEM 500 mL, FBS 10%, Penicillin, Streptomycin 2%, fungizone 0.5%), DMSO 7.5 mL, MTT 5 mg/mL PBS (50 mg MTT and 10 mL PBS), 10% SDS in 0.1 N HCl, Gourami scales, Human Gingival Fibroblast Cells (HGF), and 10% bovine serum albumin (FBS), Tripsin 0.25% as much as 2 mL, Aquades.

The Making of Gourami Scale Collagen Extract:
The addition of chelanting agent (EDTA) 1 N for the decalcification process as well as the addition of 0.5 M acetic acid (acid solubility collagen) are conducted. The next one is the addition of pepsin (pepsin solubility collagen) 0.1 gr. Stirred it with an ultrasonic device at 4°C for 18 hours, and then filtered it. The addition of 0.5 M NaCl was then conducted by centrifugation in the small tubes with a speed of 4000 rpm. Afterward, washed with distilled water and then removed (salting out) it. The lyophilization process with a freeze dryer to remove the water with a condenser temperature of -76°C and ambient temperature of 23.6°C for 12 hours until the water runs out.

The Stage of Fibroblast Cell Management:
The gingival tissue was washed for 3 times with PBS containing penicillin and streptomycin antibiotics in order to avoid the possibility of bacterial contamination. Afterward, it was cut to approximately 1mm3 and covered with deckglass. The collagenase was added later on for 30 minutes at 37°C. The tissue was then washed and centrifuged for 6 minutes. The cells obtained were cultured with a growing and incubated medium in a 5% CO2 incubator with a temperature of 37°C for 3 days. Moreover, it was observed every day until the cells are confluent. In addition, the culture medium is replaced every three days until the cell is confluent and passages are performed.

The Stage of Fibroblast Cell Culture:
Primary human gingival fibroblast cell culture in the Alpha Modified Eagle’s Medium (αMEM). Culture was added with 150 µg/ml Fetal Bovine Serum (FBS) 10%, 10 µg/ml Fungizone 0.5%, 100 µg/ml 2% Citrate. Afterward, the confluent cells dipasase to be propagated. The cell medium is removed and washed with PBS. The next one, that cell is released with a 2 ml trypsin enzyme and incubated safely 5 minutes at 37°C and 5% CO2. After that cell is removed, then added a stopper and resuspended, centrifuged 25000 rpm for 6 minutes. Finally, pellets are planted on a 10 cm plate with αMEM medium.

Harvesting Cells: The human gingival fibroblast
cells were taken from CO₂ incubators and then cell conditions were observed (80% confluent cell cultures were used for harvesting). Those cells were harvested according to the harvest protocols. In addition, the cells are seen using a microscope. Finally, the container is tapped so that the cell is floating.

The Stage of Treatment and Readings: The microplate with concentrations of 0.32 mg/ml, 0.16 mg/ml, 0.04 mg/ml, 0.02 mg/ml, 0.01 mg/ml. The last microplate was filled with αMEM culture, Fetal Bovine Serum (FBS) 10% and Pen-Strep 2% as much as 100µL as media control, the next one, the microplate contained only human gingival fibroblast cell culture and αMEM culture because it is used as cell control. The microplate is removed from the incubator. The 20 µl of MTT solution are added to each and finally is well ready to be used.

Results

% life cells: According to the results of reading OD (Optical Density), the average results of the research shown in table 1 are as follows.

Statistical Analysis: It can be concluded that the data are normally distributed. Afterward, from the homogeneity testing using Levene’s Test with Sig. >0.05 can be concluded that the data is homogeneous. In addition, the statistical tests were carried out using ANOVA One Way at the significance level of Sig. <0.05 and significant differences were obtained. It then continued by performing multiple comparisons using post hoc test Tukey HSD which concluded that all groups had significant differences except the concentration group control cell against 0.16 mg/ml and 0.32 mg/ml.

Discussion

Periodontal tissue has many important constituent components, such as collagen and fibroblasts. Fibroblast cells function as producers of connective tissue. The coats produced by fibroblast cells include collagen fibers, reticulum fibers, oxytalan fibers, and elastic fibers. Fibroblast cells secrete large amounts of protein, such as collagen, and abnormal collagen deposition in which it is a feature of the scarring process involving TGF-β1 and PDGF as a migratory fibroblast medium. Fibroblast cells secrete cytokines and several growth factors (growth factors) which can stimulate cell proliferation and inhibit the process of differentiation.

Proliferation of fibroblasts can be accelerated by giving tissue engineering. Tissue engineering functions as returning, regenerating, maintaining, or improving defective or lost tissue function. One type of engineering tissue is scaffold. Scaffold is a porous solid biomaterial that functions as (1) promoter of interactions between cells and biomaterials; cell adhesion; extracellular matrix deposits; migration media and fibroblast cultures; as well as niches for stem cell proliferation (2) supplying gas for cell survival, proliferation, and cell differentiation, (3) can adjust to the rate of tissue regeneration, (4) and relieve the inflammation.
The basic principle is the work of mitochondrial enzymes in active cells that metabolize tetrazolium salts, so that the tetrazolium ring is broken down by the dehydrogenase enzyme which causes the tetrazolium to turn into an insoluble and purple formazan. The color change of tetrazolium salt is caused by a decrease in the metabolic activity of cells that form NADH or NADPH. This purple color will be measured by absorbance.

Statistically, the comparison of the cell control group with the concentration group of 0.04 mg/ml, 0.02 mg/ml and 0.01 mg/ml experienced a significant value. Meanwhile, the concentration of 0.32 mg/ml and 0.16 mg/ml did not have a significant value. This shows that the plateau effect occurs at exposure to concentrations of 0.16 mg/ml and 0.32 mg/ml, so that exposure to these concentrations does not significantly affect cell proliferation. The research data is in accordance with the loading-dose theory of drugs, namely the higher the dose given, the therapeutic effect on target cells is no better than the lower dose.

Scaffold composition consists of polymer poly (alpha-hydroxyl) which can be degraded in the body (PLA, PGA, PLGA) and natural polymers. Natural polymers are divided into proteins (collagen, silk, fibrinogen, elastic, creatine, or actin), polysaccharides (cellulose, amylose, dextran, chitosan (chitosan), and glycosaminoglycans), and polynucleotides (DNA and RNA).

Among the various types of scaffold that has been mentioned, collagen-based scaffold (mainly type I) is widely used. This is because it has more advantages than the other scaffold constituents both natural and synthetic, including those identical to the extracellular matrix, adaptable in various forms, biocompatible, having biodegradation power, increase proliferation, and trigger cell differentiation.

Fibrillar type I collagen was chosen because it is the gold standard in the formation of biomaterials and is a type of collagen that is widely found in the human body – 90%. The telopeptides found in the collagen scaffold can cause mild inflammatory reactions that can affect the regeneration process. Cells interact with scaffold through the Arg-Gly-Asp (RGD) ligand that is similar to the natural extracellular matrix on its surface. The biodegradation properties of collagen scaffold can trigger the restoration of tissue structure and function. The degradation of collagen scaffold based on the type I collagen to type III by MMP-9 will induce the attraction of chemotaxis from human fibroblasts.

Collagen derived from gourami scales can be an alternative material consideration for the tissue engineering because of its abundant collagen content and good biocompatibility.

Conclusion

Collagen extract of gourami scales was viable on Human Gingiva Fibroblast cells, with the highest yield of viability at a concentration of 0.01 mg/ml is 137.82%.

¹Professor in Department of Periodontics Dental Medicine, Faculty of Dental Medicine, Universitas Airlangga, Surabaya Indonesia, ²Dental Medicine Professional Program, Faculty of Dental Medicine, Universitas Airlangga, Surabaya Indonesia, ³Research Center for Stem Cell Research and Development Institute of Tropical Disease, Universitas Airlangga, Surabaya Indonesia

Abstract

Background: The role of type I collagen is as a matrix of extracellular proteins with characteristics of increased cell proliferation which directly affects the physiology and morphology of cells. Type 1 collagen can be obtained from fish scales. Thus, this research aimed to support engineering tissue used for the treatment of periodontal disease in the regenerative surgery by utilizing collagen derived from gouramy scales. As an initial step, the researchers wanted to conduct a study used collagen extract derived from gouramy scales (Oshpronemusgouramy) which was applied to bone marrow mesenchymal stem cell cultures to see viability in vitro.

Objective: To determine the viability of collagen from fish scales (Oshpronemusgouramy) to bone marrow mesenchymal stem cells. Method: Bone marrow mesenchymal stem cells are taken from mice and planted in 96 well plates. Collagen extracted from gouramy scales using the enzymatic method was dissolved in a condition medium with each concentration of 0.01 mg/ml, 0.02 mg/ml, 0.04 mg/ml, 0.16 mg/ml, 0.32 mg/ml was put into the well prepared and incubated for 24 hours for the MTT assay.

Result: Collagen from fish scales can increase the viability of bone marrow mesenchymal stem cells with a percentage above 90% and the highest viability concentration at 0.01 mg/ml. Conclusion: Collagen from fish scales is viable against bone marrow mesenchymal stem cells. Collagen scales of gouramy soaked in medium had the highest viability with an optimum dose of 0.01 mg/ml.

Keywords: Bone marrow mesenchymal stem cell, gouramy scales collagen, viability.

Introduction

The regenerative material used in the field of dentistry has grown rapidly now. Regeneration of periodontal tissue with regenerative materials is expected to work at the cellular level. Used of regenerative materials can trigger cell proliferation and differentiation that are useful for the development of various cells.

Type I collagen is as a matrix of extracellular proteins capable of increasing cell proliferation. Type 1 collagen can be obtained from fish scales. Fish scales contain components including 70% water, 27% protein, 1% fat, and 2% ash. Organic compounds consist of 40% -90% in fish scales and the rest are collagen.²-⁴

Gouramy (Oshpronemusgouramy) is one of the aquaculture products whose production increases every year⁵. The amount of gouramy consumption reached
33.89 kg/capita/year in 2012 and in 2013 it increased to 35.14 kg/capita/year. Zhang’s 2011 study showed collagen derived from freshwater fish scales was safer to use than collagen sourced from other materials such as cattle and pigs and collagen derived from freshwater fish scales containing high type 1 collagen. Hence, this research aimed to the development scaffold to support tissue engineering to treat periodontal disease in the regenerative field by utilizing collagen derived from carp scales. As an initial step, the researchers wanted to conduct a study using collagen extract derived from gouramy scales (Osphronemus gouramy) which was applied to bone marrow mesenchymal stem cell cultures to see viability in vitro.

Materials and Method

The extraction of gouramy fish scales into collagen was conducted at the Instrumental Analysis Laboratory of the State Polytechnic Chemical Engineering Department, Malang. Culture of bone marrow mesenchymal stem cell and viability tests conducted at the Stem Cell Institute of Tropical Disease Research and Development Center, Surabaya.

Collagen Extracted from Gouramy Fish Scales: Gouramy scales were washed with water and dried under the sun to dry. After that, soaked in 1 M NaOH solution, 4°C for 24 hours to remove non collagen protein. NaOH solution was replaced every 8 hours and occasionally stirring. Washing with distilled water was performed to neutralize the pH followed by immersion in isobutanol to remove fat and added chelating agent (EDTA) 1N for decalcification. Followed by the addition of acetic acid (acid solubility collagen) as much as 0.5 M and the addition of the enzyme pepsin (pepsin solubility collagen) as much as 0.1 gr, then stirred with an ultrasonic device at 4 °C. Then filtering, then added NaCl 0, 5 M, and centrifugation in small tubes with a speed of 4000 rpm, after that washed with distilled water and then disposed (salting out). The lyophilization process with a freeze dryer to remove the water content with a condenser temperature of -76 °C and ambient temperature of 23.6 °C for 12 hours until the water runs out. The results of collagen extract of carp scales are sterilized.

Preparation of Conditioned Medium: Collagen extract of gouramy scales was soaked in α-MEM medium for 24 hours.

MTT Assay Test on Bone Marrow Mesenchymal Stem Cell: Samples were calculated by using the Federer formula with 5 treatments, 1 cell control, 1 medium control, and 4 replications were obtained. The concentrations used in this study were 0.32 mg/ml, 0.16 mg/ml, 0.04 mg/ml, 0.02 mg/ml and 0.01 mg/ml. Microplate containing cells was incubated for 24 hours in a 5% CO₂ incubator at 37°C. Microplates were removed from the incubator, culture media and scales of gouramy were removed then cell cultures in well washed with PBS. In each well, 100 μL of MTT solution was added. Cells were incubated for 4 hours in a 5% CO₂ incubator at 37°C. After the incubation period was complete, discard the medium and sample. Then stop by giving DMSO to each well. The value of formazan optical density was read by using ELISA reader with a wavelength of 590 nm. The live cell percentage was calculated and the CD50 price was analyzed by SPSS. The reading results were converted into% by using the formula to determine the percentage of cell viability:

\[
\% \text{ of live cells} = \frac{\text{Treatment} + \text{Media} \times 100}{\text{Cell} + \text{Media}}
\]

Note:

\% of live cells = Percentage of live cell count after the test

Treatment = Optical density value of formazan in each sample after the test

Media = Optical density value of formazan on media

Cell = Optical density value of formazan on control cells.

P value was lower than the alpha significance level in all treatment groups, so there was a significant difference in concentration of one with the other concentrations.

Data analysis is continued by using Mann-Whitney Test to compare differences between concentration groups. Mann-Whitney Test statistical tests showed that there were significant differences between each medium control group with a concentration of 0.32 mg/ml, 0.16 mg/ml, 0.04 mg/ml, 0.02 mg/ml, 0, 01 mg/ml. Significant differences were also found in cell control and concentration of 0.04 mg/ml, cell control with a concentration of 0.01 mg/ml, concentration of 0.32
mg/ml with a concentration of 0.04 mg/ml, 0.02 mg/ml, 0.01 mg/ml. While the cell control group with 0.32 mg/ml, the cell control group with a concentration of 0.16 mg/ml, the cell control group with a concentration of 0.02 mg/ml, a concentration of 0.16 mg/ml with a concentration of 0.04 mg/ml, 0.02 mg/ml, 0.01 mg/ml, concentration of 0.04 mg/ml with a concentration of 0.02 mg/ml and 0.01 mg/ml, concentration of 0.02 mg/ml with a concentration of 0, 01 mg/ml, there is no significant difference.

**Discussion**

Collagen is a biopolymer that is well used in the field of tissue engineering and it have a high level of biodegradability. Since, its high biodegradability, scaffold does not only support, but will unite with cells has a biological function as a medium for attachment, migration and proliferation of cells that can increase viability without affecting gene expression.

The viability test aims to see the ability of cells to be able to live by showing cell responses in the short term and showing the ability of cells to survive from the process of apoptosis and necrosis triggered by the exposure of a material. The viability test in this study uses a culture of bone marrow mesenchymal stem cell which is part of an adult stem cell that is able to make copies of cells that are identical to themselves for a long time and proliferate and differentiate into mature cells with morphological characteristics and certain functions for bone formation.

Based on the results of this study, it appears in table 1 that the average absorbance value is higher than the average absorbance value of the cell control group. Bahi states that the absorbance value of the treatment group which is smaller than the absorbance value of the control group indicates that the cell’s ability to proliferate is low. If the absorbance produced is higher than the control, then the cell’s ability to proliferate is high, but if the level of proliferation is too high, so it will result in cell death due to the possibility of changes in cell morphology.

In this study, the concentration of 0.01 mg/ml had the highest percentage of living cells of 116.502% and at a concentration of 0.32 mg/ml the lowest percentage of living cells was 93.184%. The research data is in accordance with the theory of loading-dose on drugs, i.e. the higher the dose given, the therapeutic effect on target cells is no better than the lower dose. The absorbance obtained is influenced by several factors, including the type of solvent, pH, temperature, high electrolyte concentration, and the presence of intruders from external properties of fish that can survive at various water temperatures and pressures, making collagen extract of fish scales resistant to physical and chemical damage.

Collagen derived from gouramy scales consists of various amino acids, especially the amino acid glycine. Collagen bonds from collagen extract of carp scales induce procollagen formation and cell proliferation. The bonds that form type 1 collagen from gouramy scales consist of proline, lysine, glycine, and other amino acid components. Proline and lysine from type 1 collagen extract gouramy scales will form new collagen fibers.

Collagen extract is rich in amino acids glycine, proline, glutamic acid, and aspartic acid and various kinds of peptides. These components have the ability to actively regulate cell function. Glycine can regulate the proliferation and differentiation of progenitor cells, proline can induce differentiation of embryonic stem cells. Glycine, glutamic acid, and alanine can influence signal transduction in the differentiation of osteoblastic bone marrow stem cells.

Type 1 collagen taken from gouramy scales can improve cell viability as indicated by the MTT test. The results of this study are in accordance with the research conducted by Zhang et al (2011) which states that Nano-fibrous type 1 collagen can support the growth of mesenchymal stem cells and is used for tissue engineering, and collagen material obtained from fish scales is used as engineering tissue as a potential candidate for bone collagen-based graft. The conclusions of the results of this study are gouramy scales collagen soaked in the medium condition has good viability that is above 90%. It has the highest viability with an optimum dose of 0.01 mg/ml.

Abstract

Background: Recent alarming increase in breast cancer, especially in younger women, has been attributed to the increasing usage of mobile cellular phones and their placement in contact with the body especially the breast region. The bio-effects of high frequency electromagnetic radiations accompanied by thermal damage to the tissues play an important role in tumor initiation and progression.

Method: The study was carried out in 260 working women from Pondicherry. They were questioned about mobile phone keeping behavior using a three item questionnaire.

Results: Women involved in unskilled job kept their mobile phones more proximal to the breast region when compared to the women engaged in white collar job. However the duration of mobile phone usage was higher in the latter group.

Conclusion: Longitudinal studies to follow up the relationship between mobile phone keeping behavior and development of breast cancer need to be undertaken. Hence we propose researchers to ask for history about mobile phone keeping behavior while dealing with breast cancer patients.

Keywords: Breast, cancer, cellphone, keeping behavior, mobile phone.

Introduction

Globally mobile phone usage among the younger generation has increased drastically over the recent past with the number of subscribers crossing 725 million.¹ Radiowave and microwave radiations of frequency ranging between 0.1-300,000 MHz are used in radio communication, radio location centers and cellular phones.² Electromagnetic radiation from mobile cellular phones draw immense attention and its contribution as an environmental factor in the development of various health issues including breast cancer in young women is still a debatable issue. Some studies claim the direct thermal energy emitted from mobile phones to be the cause while a few other studies have reported non-thermal biological effects due to electromagnetic radiations to be responsible for the disease pathogenesis.³ Electromagnetic radiations emitted from mobile phones during signal transmission are generally high frequency.

radiowaves. Extremely low frequency electromagnetic waves, emitted during battery discharge that occurs merely when the device power is switched on, may also be involved in carcinogenesis.\(^4\)

Understanding environmental and behavioral risk factors play an important role in identifying and preventing the increase in disease incidence. One such factor of concern is the increasing usage of mobile cellular phones and their placement in contact with the body especially the breast region.\(^3\) Breast cancer hits third in the list of common cancers worldwide. India along with China and United States contributes to about one-third of the global breast cancer disease burden.\(^5\) There exists a lacuna in the awareness of risk factors for developing breast cancer among the public. In most instances disease in young women less than 40 years of age seems to carry a genetic predisposition with positive family history of breast cancer. Sporadic occurrence of breast cancer is common among women in the post-menopausal age group without any family history. of late there appears a rise in the number of breast cancer cases under 40 years of age in the absence of family history.\(^5\) There has been over emphasis on the genetic factors causing breast cancer; however in reality, environmental and lifestyle factors do play a considerable and huge role in cancer pathogenesis. Even a small increase in the incidence of cancer due to mobile phone usage would be considered an issue of significant public health importance.\(^4\)

In India, most women culturally prefer to wear saree (a traditional dress) especially those working in fields or construction works. They are more prone to slip their mobile phones into their blouse. There exists a lacuna among Indian studies that explore the effect of keeping mobile phones in proximity to the breast region and the effects of electromagnetic radiations as a possible risk factor in the development of breast cancer.

**Aims and Objectives:**

1. To compare the difference in body region in contact with mobile phones between women engaged in white collar jobs and women engaged in unskilled jobs
2. To compare the duration of mobile phone usage between women engaged in white collar jobs and women engaged in unskilled jobs
3. To compare the duration of keeping mobile phone in contact with the body parts among women engaged in white collar jobs and women engaged in unskilled jobs

**Materials and Method**

The study was conducted in Puducherry, India, an old French territory between May 2019 and January 2020. The study was designed as across sectional comparative study among 260 women included from both urban and rural population. Women who possessed a mobile phone with them were recruited for the study using snow ball sampling technique. An informed consent was obtained from the participants in vernacular language.

**Questionnaire:** Those women who consented to participate in the study were administered a simple 3 item questionnaire to provide information regarding mobile phone keeping behavior and usage duration. The following items were presented in English/Local vernacular language (Tamil) based on the participant’s choice.

(i) In which region of your body do you keep your mobile phone when not using it for talking or texting or browsing?
(ii) How many minutes in a day do you use your mobile phone for talking or texting or browsing?
(iii) How many minutes in a day do you keep your mobile phone in contact with your body?

**Statistical analysis:** The categorical data were described as frequency and percentage [item (i)]. The data obtained as minutes per day was described as mean ± SD and comparison between groups were done using unparied t-test [items (ii) and (iii)].

**Results**

The mean age of women who participated in this study was 38.58 years. The women who were engaged in white collared jobs such as teaching, health care, clerical jobs reported that they keep their mobile phones in hand while not using it (53.4%), in contrast, the women engaged in unskilled jobs such as construction site workers, house maids and agricultural laborers slip their mobile phones in their blouses, near their breast (50%); and hip region (24.3%). Apart from the above mentioned body regions 41.4% women engaged in white collar job and 43.6% of women engaged in unskilled job reported that they keep their mobile phone in contact with the other regions of the body (Table 1).
Table 1: Frequency and percentage distribution of body region in contact with mobile phone while not using it

| Body region in contact with mobile phone | Type of work | White collared job (n=116) | | | Unskilled job (n=144) | | |
|-----------------------------------------|-------------|---------------------------|-------------|---------------------------|
|                                         |             | Frequency                  | Percentage  | Frequency                  | Percentage  |
| Hands                                   |             | 62                        | 53.4        | 3                         | 2.1         |
| Hip                                     |             | 5                         | 4.3         | 35                        | 24.3        |
| Near Breast                             |             | 1                         | 0.9         | 72                        | 50.0        |
| Others                                  |             | 48                        | 41.4        | 34                        | 23.6        |

When comparing the duration of mobile phone usage between white collared and unskilled workers, the former were found to use their mobile phones for 92.37 min per day while the latter used only 15.53 min per day. There was a statistically significant difference (p<0.001) found in the duration of mobile phone usage between the two groups (Table 2).

When the participants were asked “How long you keep your mobile phones with you while not using it?” women engaged in white collared job responded they keep about 495 min (8 hours) while unskilled workers keep their mobile phones for 327.52 min (5.5 hours). There was a statistically significant difference in duration of keeping the mobile phone with them (p<0.001).

Discussion

The concern about mobile phone being involved in carcinogenesis is due to two reasons. One is the electromagnetic radiations emitted due to signal transmission and the other is thermogenic effect produced by the device. The cellphones with 2G support emit electromagnetic radiations in the range of 890-960 for Global system for mobile communications (GSM).\(^7\) 3G/4G supported mobile phones tend to emit higher EMR. Biological stress responses to these radiations have become an important public health concern.

The result of this study revealed that women engaged in white collar jobs preferred to keep their mobile phone proximal to hand and other regions. On the other hand, women who were engaged in unskilled job preferred to keep their mobile near their breast and hip without knowing the fact that proximity of cellphones to the body and their contact with breast tissue especially in young girls probably carry a high risk of tumourogenesis.

Human breast cancer cells when exposed to electromagnetic frequencies under laboratory conditions grow faster when compared to low environmental exposure.\(^3\) As per WHO/ICNIRP Environmental Health Criteria (1993) non-thermal intensity of microwaves can be considered to have weak biological influence.\(^8\) The international expert panel of IARC (International Agency for Research on Cancer in Lyon) concluded that non-thermal radiofrequency exposure is a possible...
carcinogen (group 2B) for humans.\textsuperscript{9} Bio-effects of high frequency EMR are accompanied by thermal damage to the tissues.\textsuperscript{4} Non-ionized electromagnetic radiations induced oxidative stress due to imbalance in free radical production and antioxidant protective mechanisms cause cell damage and apoptosis. Kahya et al observed a rise in cytosolic reactive free radicals accompanied by increase in enzyme caspases levels that are pro-apoptotic in breast cancer cell lines exposed to 900 MHz radiations. However the mechanism of EMR induced biological cell response is yet to be uncovered.\textsuperscript{10}

Mobile phones produce local heating effect emitting a total peak output power of about 2 watt contributing to an average specific absorption rate (SAR) of 2.0 W/Kg. SAR is a measure of rate of energy absorbed by the human body when exposed to a radio frequency (RF) electromagnetic field.\textsuperscript{11} Distribution of radio-frequency energy and SAR is non-homogenous inside the body for different organs and tissues leading to difference in propensity to develop DNA damage causing cancer. Moreover the absorption of EMR is proportional to the heat generated at the interphase of biological tissue in contact with mobile phone.\textsuperscript{4} This study also revealed that the duration of mobile use was different between white collared working women and women engaged in unskilled job hinting that white coloured women are more vulnerable to the ill effect of mobile phone. The duration of keeping mobile phone with them also showed that there was significant difference between two groups studied, white collared women carry the mobile phone with them for longer duration when compared to women engaged in unskilled job. A few studies concluded that mobile phone usage though likely to produces deleterious biological response, do not demonstrate statistical significant harmful changes.\textsuperscript{12,13} Though the biological responses largely depend on the duration and frequency of exposure to EMR emitted from mobile phones, inter-individual variations do occur commonly. Safety guidelines and regulations for exposure of wireless communication devices including mobile phones are fixed based on their thermal bioeffects, not considering non-thermal effects of electromagnetic radiations. Existing public safety standards remain unmatched with the adverse health outcomes due to radiofrequency radiations from mobile phones. Attempts to assess adverse outcomes from EMR lower than the existing public exposure safety limits need to be undertaken to prevent future health risks especially cancer. Curtailing the exposure to excessive handling and usage of mobile phones should be considered as a vital initial step towards reducing the risk of developing cancer and other health hazards. Cumulative absorption of electromagnetic energy depends greatly upon the cumulative hours of usage of mobile phones.\textsuperscript{9} A few investigators also expressed their opinion that EMR play a role in tumor initiation and progression. Tumor progression is aided by increase in tumor growth rate and inhibition of involution.\textsuperscript{14,15}

Controversies in the results obtained from previous studies however need to be addressed due to the short study period and recall bias among the participants. Mobile phones are relatively a new technology and demands future studies on long term exposure before conclusions can be drawn on their tumorigenic effect in humans. The long induction and latency period of carcinogenesis raises concern on accuracy of association between mobile phone usage and development of cancer.\textsuperscript{16}

\textbf{Future Persepectives:}

Many of the studies conducted in the past focus on the development of brain cancer with little emphasis of breast cancer and testicular cancer. Future studies should be designed to study the bioeffects of EMR on infertility and risk for developing breast cancer.

The urgent need for the present Indian scenario is preventive approach in the form of health information programs to promote safe usage of mobile phones even though the 10 years studies do not reveal any significant carcinogenic effect.\textsuperscript{17} This study is an eye opener intends to provide researchers in breast cancer to include mobile phone keeping behavior as a possible environmental risk factor in the development of breast cancer. Considering the long latency prior to overt appearance of cancer, immature conclusions that electromagnetic radiations from mobile cellular phones are not involved in breast cancer pathogenesis should be discarded. As retrospective studies may be accompanied by patient and interviewer bias to a larger extent, longitudinal studies should be undertaken to prove or disprove the association. Administration of health education to instill awareness among the public regarding hazards of excessive mobile phone usage and its contact with their body surface occupies prime importance.

\textbf{Limitations of the Study:} Details of the network 2G/3G/4G and the type of mobile phone were not questioned.
Ethical Clearance: Ethical clearance for the conduct of study was obtained from International center for psychological counseling and social research, Puducherry.

The Policy of Large-Scale Social Restriction (LSSR): Prevention Effort of COVID-19 and Community Compliance in Indonesia

Dewi Kurniawati¹, Thinni Nurul Rochmah², Agung Dwi Laksono³

¹Master Program in Health Policy and Administration, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia, ²Researcher, Department of Health Policy and Administration, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia, ³Researcher, National Institute of Health Research and Development, The Indonesian Ministry of Health, Jakarta, Indonesia

Abstract

Covid-19 prevention efforts in Indonesia are carried out through several policies taken by the Government. One of them is the policy of conducting Large-Scale Social Restriction (LSSR) for regions that meet the requirements. LSSR and other policies that require community participation and discipline. The case curve is still high. Many violations still occur. The easing discourse has been LSSR rolled out. The study was aimed at evaluating the picture of the impact of LSSR policies in efforts to prevent the spread of Covid-19 in Indonesia concerning current public discipline. The study was conducted with a descriptive approach that was carried out through a literature study. The type of data used was secondary data. The results found that the policies issued in the Covid-19 prevention efforts, both in the form of policies on physical distancing, the use of masks, washing hands, to LSSR, all were related and depended on the level of community discipline to carry out and obey them. But the reality in the field of discipline that occurs both personally and collectively was still at a low level and requires further support. So that this also has an impact on the increasing occurrence of Covid-19 cases in various regions, even though the area has implemented an LSSR policy. It could be concluded that community discipline was the key to success in preventing Covid-19. The LSSR policy can also be successful if the community was able to discipline it obediently.

Keywords: Large-Scale Social Restriction, Health Policy, Community Compliance, Preventive.

Introduction

Covid-19 is a new type of virus so that not many people know and understand how to handle it. In the current condition Covid-19 is not a virus that can be ignored. This group of viruses can cause disease in birds and mammals, including humans. In humans, Covid-19 causes infections of the respiratory tract. If seen from the symptoms, people will think only limited to the common symptoms of influenza, but according to analysis in the world of medicine this virus is quite dangerous and deadly¹.

At present, in 2020, the development of transmission of this virus is quite significant, its spread is worldwide and even all countries have felt its effects including Indonesia. The transmission of this massive virus makes the whole world uneasy. Even the WHO since January 2020 has declared the world into a global emergency related to this virus².

As the outbreak of the Covid-19 virus became more prevalent, the Government of Indonesia issued several types of policies to anticipate and reduce the number of sufferers. Among them is determining the status of
disaster emergency starting from 29 February 2020 to 29 May 2020 with a total time of 91 days. Besides, several health protocols have also been disseminated to be followed and implemented properly.

The steps in the health protocol that were delivered did indeed require the participation of the discipline of the community, including the application of physical distancing, the use of masks and always doing proper handwashing. This concept aims to break the chain of transmission. But apparently in the field, this concept is often not obeyed, so there are still many violations of this health protocol. As there are still many people who are clustered in physical activity both in markets, shopping centers, and in other public areas. Doing activities without using a mask, and not doing hand washing before and after doing activities.

The behavior of the community in responding to Covid-19 caused the spread of this virus to become more widespread and difficult to deal with, thus making the Legislative Body urge the Government to immediately form a National Team to deal with the centralized Coronavirus outbreak. So that new policies emerged to limit movement society, namely the Large-Scale Social Restriction (LSSR) policy, another version of the lockdown policy carried out by other countries in the world, which is adjusted to the conditions of the people in Indonesia. New policies and commitments for implementation are needed to produce positive results.

The implementation of the LSSR policy is based on Government Regulation Number 21 of 2020, which is an embodiment of Law Number 6 of 2018 concerning health quarantine. Some regions have received approval from the Ministry of Health to implement the policy. However, after it has been carried out in several places and sometimes, then an evaluation is conducted, there is a discourse to relax the LSSR policy. On the other hand, according to the University of Indonesia epidemiologist, Syahrizal Syarif, this easing should not have been carried out.

Based on the background, several questions arise that are the focus of the research, namely how to address public discipline related to the Covid-19 preventive health protocol in Indonesia? And how are the positive and negative impacts if LSSR eased on the efforts to prevent the spread of Covid-19 in Indonesia related to the current level of public discipline?

Material and Method

The method used in this research was the study of literature, which was the study of the object of research in the form of literary works, whether in the form of scientific journals, books, articles in the mass media, or statistical data. The literature would be used to examine research problems and how to deal with them. The nature of the study conducted was descriptive analysis which was to give a picture to the reader so that it could be a medium of public education. The type of data used was secondary data.

Findings:

The Covid-19 Case in Indonesia: Today the Government of Indonesia continues to make efforts to minimize people infected with Covid-19. Initially the government did not want to provide information related to the coronavirus that entered Indonesia. This was done to avoid public panic and also avoid issues that are not clear.

Regarding the development of Covid-19, the Government made several policies. The first policy, in the form of Physical Distancing health protocol. This is intended to prevent transmission from patient to non-patient through droplets or small splashes of mucus from the walls of the respiratory tract of someone who is sick when sneezing and coughing. For this reason, it is strongly recommended that you set the distance and do not conduct meetings or activities that gather large numbers of people so that there is a build-up or opportunities for people to intersect or be nearby can be avoided. Then the next policy is a health protocol that requires all people to carry out healthy and clean behavior by always washing their hands using soap or hand sanitizer both before and after carrying out activities related to others. Then the next policy related to the use of masks, both in the middle of a sick or healthy condition, which aims to reduce up to 70% of transmission through droplets.

Besides, there is also a policy regarding the Covid-19 virus inspection, which is hoped to be carried out on a massive scale and to cover the entire Indonesian population. Several kinds of inspection method are evaluated from its sensitivity, namely by using molecular method using PCR or immunoglobulin examination method as an initial screening test and can be carried out en masse. The purpose of this policy is to quickly find out the condition of the people exposed
to Covid-19 so that further isolation can be carried out, both independently and in health care facilities.

To date, the number of people who have confirmed positive for Covid-19 is increasing and the number of deaths is still being found. To avoid confusing news, the government is also preparing reports that can be accessed online by the public through the official website.

**Large-Scale Social Restriction (LSSR) as an alternative policy in Indonesia:** To prevent the spread of Covid-19 in Indonesia, the government finally decided to implement the Large-Scale Social Restriction (LSSR) on March 31, 2020. LSSR or which could be interpreted as partial lockdown or quarantine was one of the alternative interventions carried out by the Indonesian government after previously issuing policies related to health protocols that must be obeyed by the Indonesian people. This LSSR policy limits community mobility, one of which is by closing public areas such as schools and offices, to cut the spread of the SARS CoV-2 virus, the cause of Covid-19.

This LSSR policy is given by the Central Government (in this case the Ministry of Health’s approval) to the Regions whose applications are deemed to meet the requirements. The legal basis for implementing this LSSR is Government Regulation number 21 of 2020 which is the manifestation of Law number 6 of 2018 concerning health quarantine.

**The Discipline of the Indonesian Society:** During the Covid-19 pandemic, as now, every citizen is expected to survive and adjust to life patterns. Collective discipline and behavior guided by health protocols are needed when they are active, especially in the public sphere.

According to the Government Spokesperson for Handling Covid-19, Covid-19 can only be prevented by strong discipline and cooperation spirit carried out by all elements of society as a whole without interruption. This discipline is related to compliance with government recommendations and policies to reduce the risk of the spread of Covid-19 becoming more widespread.

According to the Big Indonesian Dictionary, discipline means the exercise of mind or character with the intention that all actions always obey the order, disciplined means to obey the provisions or rules according to applicable regulations. Discipline can not arise directly, it needs learning and gradual habituation until everything will be implemented spontaneously and become part of the soul. The application of discipline in society is important and needs to be fostered and enforced. Because discipline is the success capital of every activity. By upholding discipline in the community is one of the efforts to prepare people (the community), concerned so that they can develop their potential. With the theoretical discipline will be able to provide stimulation and encouragement so that they can become productive people.

---

**Figure 1. Discipline Level**

Source: Masitoh, 2006
From Figure 1 it can be seen that forming a disciplined attitude in society is not easy. There is a need for learning or familiarity for every member of the community to be able to apply it. This attitude can be applied to start from someone since he was a child, namely through educators provided by parents or starting from the smallest environment, the family because the family environment has a central role in shaping the attitudes and behaviors of a person and the rest they will be formed or influenced by the environment that is around them namely the social environment of the wider community. The attitude of self-discipline based on awareness and because of a sense of caring and responsibility can certainly work well because it is not based on coercion from others. Discipline in each individual is what will form a collective discipline in the middle of society. People often have their own views, which are sometimes different from the perception of health workers.

Impact of LSSR Policy and Community Discipline Level: In several countries in the world, many lockdown policies have been revoked. Activities related to the public interest began to be held again. The economy was revived after a long dormant period.

The Indonesian government, who learned this, also felt that limiting the movement of the people would no longer be an effective policy, because this policy had an impact on many things. Even in several discussion sessions, the team leader of the National Covid-19 taskforce handling team stated that socially we will experience something new normal or have to adapt when we are active and working. Besides, the community is also required to avoid physical contact with others or avoid the crowd at work, as well as comply with existing protocols, such as health protocols. Still, according to him, this transformation is to organize life and new behavior, when the pandemic, which will then be carried forward in the future until the discovery of this vaccine for Covid-19.

However, this is less agreed by epidemiologists, according to the analysis of the epidemiologist curve in Indonesia it does not meet the standards, so it is difficult to do an assessment. Case curves that continue to show an increase should also be taken into consideration. If there is a discourse about the LSSR policy easing, some conditions must have been fulfilled, such as related to the number of cases, the shape of the epidemiologist curve, and the minimum number of examinations that must be performed on the Indonesian population.

Public discipline is also an important benchmark before the easing of the LSSR policy is rolled out. Disciplined society will be the main key to preventing the spread of Covid-19. The reality in the field, at some point, the accumulation of people is still often found, even becoming the national news headline, even though it is happening in areas that are being applied LSSR policy. Besides, according to the results of several social studies, people show that they act according to their desires and do not heed health protocols that the government calls for, such as not wearing masks, not washing hands, and still carrying out social activities that involve many people.

If this condition is not immediately corrected, this will be a time bomb against efforts to prevent the spread of Covid-19 which is touted by the government. Not wearing a mask as protection will cause droplets to spread easily from one person to another, which means that it will cause the affected person to become a carrier of the virus or even become a new sufferer. Not doing handwashing properly will also be a medium for massive viral growth. In addition to the absence of movement restrictions, the spread of viruses that have been carried by these undisciplined hosts can become more widespread across distances and boundaries. As a result it is not impossible to see a significant increase in the number of cases, especially in several key areas.

For this reason, if Covid-19’s prevention efforts are to be successful, the government should re-evaluate these conditions in the community, if necessary the community must do intensive coaching in advance, be prepared until it is fully ripe to apply the health protocol in a disciplined manner until collective discipline formed throughout all elements of society. Only after that, the discourse about the LSSR policy can be evaluated for its existence and success.

Conclusions

The essence of this paper is that discipline was the key to success in preventing the spread of Covid-19 in Indonesia. Personal discipline would shape the collective discipline, which would have a wide impact on society. This discipline also could not be done by only one component but requires cooperation and the willingness of all parties to participate.

The ongoing LSSR in several regions also has not shown significant results. Repeated evaluations still need to be made regarding their effectiveness. Community
participation in the implementation of LSSR was very necessary. LSSR which was implemented without any discipline from the community will take place without meaning.

The Effect of Vitamin D3 and its Relationship with the Level of White Blood Cells in Women Spontaneous Miscarriage Undergoing Intracytoplasmic Sperm Injection (ICSI) Technique

Dhirgam F. Hassan Al-Shimerty¹, Alaaualdeen S.M. AL-Sallami²

¹Associate Professor, ²Professor, Department of Biology, Faculty of Sciences/Kufa University, AL-Najaf Province/Iraq

Abstract

Women were studied undergoing ICSI for 84 who suffer non-pregnancy at the Fertility Center, Al-Sadr Medical Hospital in Najaf Governorate, Period between January 2019 and March 2020. WBC, Vitamin D3 and β-hCG were measured, The pregnant women was divided into (Pregnancy Group, and spontaneous miscarriage) and then demonstrate the immunological effect on pregnancy of women after ICSI technique.

Current results study showed a significant increase (p<0.05) in hormone level β-hCG is evidence of the presence of high success rates for pregnancy in women who performed operations IVF, where the success rate at the beginning of the matter reached 61.9%, after which it decreased to 33.3% after the first three months due to the occurrence of spontaneous miscarriage of pregnant women due to various immunological and physiological reasons, a positive correlation between the level of β-hCG and other parameters in the study (Vitamin D3 -WBC). Also The current results showed a significant decrease in a groups (pregnancy failure) and the group (spontaneous miscarriage) compared with the control group (continued pregnancy) in relation to the level of vitamin D3 Also, The current results showed a significant increase in (pregnancy failure) and (spontaneous miscarriage) compared with control groups (continuation of pregnancy) in relation WBC numbers, and the present study founds a negative relationship between the level of vitamin D3 and WBC.

Keywords: Miscarriage, ICSI technique, vitamin D3, white blood cells.

Introduction

Infertility is a widespread disease worldwide and it means “the inability of the spouses to achieve pregnancy within one year of marriage” and the estimated rate of infertility in the world is around 15-20%¹. In vitro fertilization, intracytoplasmic sperm injection (ICSI), and intrauterine insemination (IUI) be are the main method of assisted reproductive technology (ART). Found a several Various studies in recent years have indicated that occur risk factor for implantation failure of women after ICSI which may be immunological parameters or biochemical parameters may be affected on In ICSI results²,³.

Measuring hematological parameters is one of the factors that affect pregnancy and its effect because it is a reliable indicator, and it is a simple, fast, and effective test since increasing the number of leukocytes in the event that infection is not detected that leads to important damage ⁴,⁵. Several studies have reported that pregnancy
in sometimes accompanied by leukocytosis, but complete chain changes to the different types of cells responsible for this observed leukocytosis number has not been clearly identified in all studies related to pregnancy\textsuperscript{6,7}. White blood cells (WBCs) are an important part of the immune system in a pregnant woman’s body as high white blood cells for some reason during pregnancy may lead to spontaneous abortion due to increase infection in the urinary tract or immune system problems\textsuperscript{8,9}.

The most important source of vitamin D is the skin’s synthesis of vitamin B from ultraviolet B, and any process that reduces the entry of ultraviolet B photons into the skin will reduce the production of cholecalciferol (vitamin D-3). Melanin absorbs skin pigment with UVB photons and can reduce vitamin D-3 synthesis by\textgreater 90\%\textsuperscript{10,11}. Vitamin D also worsens in the winter months (November to March), when latitudes reach above 37 °C ultraviolet B radiation decreases to Earth and little or no vitamin D can be synthesized in the skin, as vitamin D plays a prominent role in Calcium and phosphorous stabilization, and its deficiency has been shown to increase the risk of osteoporosis, fractures, and muscle weakness\textsuperscript{12,13}. Also, female reproduction is a one of the areas in which the role of vitamin D has not been extensively examined. However, early evidence from basic research strongly indicates the potential role of vitamin D in human reproduction, especially women\textsuperscript{14,15}. It turns out that the effects of a lack of Vitamin D3 on pregnant women expose them to the problems of spontaneous abortion or premature birth due to failure of the placenta function, pre-eclampsia, gestational diabetes, bacterial vaginitis, and poor growth and development of the fetus and childhood, as preserving must be maintained at sufficient levels throughout the period Pregnancy\textsuperscript{16,17}. The aim of this study was to study the relationship of white blood cell count in pregnancy and its relationship to vitamin D3 for aborted women under ICSI.

### Materials and Method

This is this study in the laboratories of the Department of Biology, College of Science, University of Kufa, and in the Laboratory of Fertility Center in Sadr City Medical City in Najaf Governorate/Najaf Health Directorate/Ministry of Health/Iraq. Venous blood samples were taken from women at three times, the first stage 14 days after the right, the second stage after spontaneous abortion in the third trimester while the third stage for women who are pregnant continuously and using a needle and syringes is used once from each patient and observer. The β-hCG level and the vitamin D3 level were measured using the ELISA method and the white blood cell count was measured by the GENEX blood analyzer. The research was approved by the ethics review committees of Al-Sadr Education City and the College of Sciences at Kufa University.

### Statistical Analysis:

The popular statistical system (Graph Pad prism ver. 5) was adopted, and a one-way analysis of variance table - Anova method (by Tukey’s multi-comparative test) was used to compare the groups divided into the measured parameters. The results are expressed as (Mean ± Stander Error). Correlation coefficients were calculated to estimate the correlation between tags and parameters. Descriptive statistics and correlation coefficients were performed using mega stat (V10.12 version) for excel 2010 (18).

### Results

**Results of β- Human chorionic gonadotropin hormone test:** In this test showed found significant difference (p<0.05) between pregnant women which was 52 (4.24±0.25) and non- pregnant women (Implantation Failure) (2.56 ±0.10) which was 32 from women which undergoing intracytoplasmic sperm injection technique as shown in figure (1).
Figure (1): Result β-Human chorionic gonadotropin hormone test which differ between pregnant women which was 52 and non- pregnant women (Implantation Failure) which was 32 from women which undergoing intracytoplasmic sperm injection technique.

Results of White Blood Cell Count

In this test showed found significant difference (p<0.05) between Continuous pregnant women (control group) which was 28 women and non- pregnant women groups which was 56 from women which undergoing intracytoplasmic sperm injection technique (Implantation Failure (32) and found non significant difference with spontaneous miscarriage (24)) as shown in figure (2).

The correlation between Vitamin D3 with White blood cell count: The study showed the presence of a negative correlation between Vitamin D3 with White blood cell count Figure (4).

Figure (4): The correlation between Vitamin D3 with Wbc.
Discussion

The results of the current research showed a significant increase in the level of significance (p<0.05) in the level of the β- Human chorionic gonadotropin hormone, and the reason for this is that this hormone is evidence of the presence of pregnancy in women who underwent ICSI operations may be because it is excreted mainly from the placenta during the formation of the fetus and this study is consistent with what reached 19. in this regard and that the increase in the level of this hormone is evidence of high success rates of pregnancy for women who conducted ICSI operations, where the success rate initially reached 61.9%, after which it decreased to 33.3% after the first three months due to the occurrence of spontaneous abortions for women. Pregnant women for various immunological and physiological reasons, as this study indicated, and these results are consistent with what was reached20,21,22.

The results of the current study also showed a significant difference at the level of significance (p <0.05) between the groups (pregnancy failure - spontaneous abortion) compared to the control group (continuous pregnancy) in vitamin D3 level. Also, the current study showed a significant difference in the vitamin D3 level between the pregnancy group, and spontaneous abortion group, and perhaps the reason for this is that vitamin D3 has a major role in miscarriage in women because the lack of vitamin D3 leads to the accumulation of white blood cells in Capillaries in the utrine of women, which leads to a decrease in blood flow to the uterine layers which leads to a weakening of the uterine layer Which leads to uterine weakness in women, which leads to pregnancy failure or spontaneous abortion. This study is consistent with the findings of 25,26. And this result may be explained that is the reason for this is that pregnant women have a lowered white blood cells count level compared to abort women This may be because white blood cells count is evidence of the presence of infections in the genital and urinary tract as a result of the abortion process, where these results are consistent with what was reached 27,28. Where he explained the presence of a significant increase in white blood cells women abortifacients and pregnancy after a period when the failure of vaccination compared to non- spontaneous miscarriage women.

The current study also showed a negative correlation between the level of white blood cells, and vitamine D3 level perhaps the reason for this is that vitamin D3 has a major role in miscarriage in women because the lack of vitamin D3 leads to the accumulation of white blood cells in Capillaries in the utrine of women, and increase in the white blood cells which leads to a decrease in blood flow to the uterine layers which leads to a weakening of the uterine layer Which leads to uterine weakness in women, which leads to pregnancy failure or spontaneous abortion. This study is consistent with the findings of 29,30, where it was explained that a lack of vitamin D3 in pregnant women leads to an increase in the level of white blood cells as an immune reaction and thus leads to miscarriage as a result of the accumulation of these cells in the blood vessels, which leads to a lack of flow Blood to the womb and weak endometrium.

Conclusions

From the result of this study showed a positive effect between a deficiency of vitamin D3 and the chances of infection of pregnancy in women who underwent ICSI.

Ethical Clearance: Guidelines of the Ethical Committee of the human and animal Research at the university of kufa were followed, which conform to the recommendations on confidentiality and privacy of human samples were followed throughly.

Conflict of Interests: The authors declared they have no competing interests.
Funding: This project was privately and equally funded by all authors in the manuscript.

Acknowledgements: The authors in this research would like to thank all the staff at the faculty of medicine for their assistance and valuable contribution to this project.

Abstract

Background: Stature estimation is one of the four pillars in the anthropological identification protocol. During this time, stature estimation uses long bones, but if no long bones are found, tooth dimensions begin to be examined as a tool in stature estimation.

Purpose: The aim of this study was to be able to determine the percentage of success in using tooth dimensions to estimate height in the Mongoloid population in Indonesia, using the Carrea’s Index method.

Method: The study was carried out by measuring the dimensions of arch and chord, then put into the Carrea formula, the results were compared with actual height, then calculated the frequency of predictions of success and non-success, compared to gender, and quadrant side of jaw.

Results: The results of predictions of success for both women and men on both sides of the mandibular were a successful prediction of 69.6% and a non-successful prediction of 30.4%. In each sex, the success rate was different for each side, without a statistically significant difference (right p value 0.186; left p value 0.713) using Chi-square test. The results of the Pearson Correlation Coefficient test have a positive correlation (p <0.05) indicating that there is a significant relationship between height and the results of height estimation obtained from tooth dimension measurements.

Conclusion: Based on the successful rate of the Carrea’s Index method in this study shows that the Carrea’s Index method can be used in the Mongoloid population in Indonesia as a tool for human identification.

Keywords: Anthropology, carrea’s index, forensic identification, odontology, stature estimation.

Introduction

Indonesia is the most disaster-prone country in the world according to data compiled by the United Nations Agency (UN) in the field of the International Strategy for Disaster Risk Reduction (UN-ISDR) because it is included in the five most populous countries in the world, so there are potentially many victims threatened the risk of loss of life in the event of a disaster¹. In addition, geographically Indonesia is an archipelago that crosses the equator and is included in the Eurasian Circum Pacific Ring of Fire and is located at the confluence of four tectonic plates namely the Asian Continent, the Continent Australia, the Indian Ocean, and the Pacific Ocean, so that they are potentially at the same time prone to disasters such as volcanic eruptions, earthquakes, tsunamis, floods, and landslides². Disasters can be caused by natural factors (natural disasters) and by human actions (man-made disasters), such as crime,
terrorism, transportation accidents. These disasters are undeniably caused many victims, both alive and dead.

Every person who has died and cannot be identified or without identity must take the forensic identification stage, as stated in article 118 paragraph (1) of Law no. 36 of 2009 concerning Health, which reads “Unknown bodies must be made an effort to identify”3. This identification process is something important because it involves medicolegal and human rights aspects4. Identification of individuals will be easy to do if visuals can be recognized, but in cases that cause death, often the individual’s body becomes difficult to recognize due to the trauma, such as being cut into pieces (mutilated), damaged by severe accidents for example in transportation accidents (Air Asia 2014, Zahro Express ship, deadly accident at Puncak 2017, Lion Air 2018), fragmented/crushed5, decayed6, burnt because of fire accident, bomb blast, or only human skeletal remains that left to identify.

Estimating body posture is an important step in reconstructive identification of skeletal remains or body remains that are difficult to recognize. In anthropology, height estimation can be obtained from various parts of the body7 and, most commonly, using long bones8. But in some cases, not all parts of human bones can be found, especially if only jaws and leftover teeth are found. So under these conditions, investigators and researchers began to pay attention to the estimation of height through the skull and tooth dimensions9. But until now, only a few studies have evaluated the possibility to estimate height through the dimensions of the tooth. The main consideration regarding the reason teeth can be used for height estimation is that no two individuals have identical teeth and there is a presumption in society that a person with high body posture has large dental dimensions and arches, as well as the nature of teeth that are resistant to changes in perimortem and post-mortem, so these characteristics make teeth have an important role in the process of individual identification10.

In an effort to examine the use of teeth to estimate height11, researchers from outside Indonesia, have conducted several studies using a variety of method using tooth dimensions as parameters (odontometric parameters), both using permanent maxillary teeth5,12–15, permanent mandibular teeth9,10,16,17, as well as a combination of maxillary and mandibular permanent teeth18, some have even examined using deciduous teeth19. Odontometric parameters that have been used include tooth length, crown length, mesiodistal width, labiolingual/buccolingual width, and relationship to facial measurements. In studies using maxillary permanent teeth parameters, the results show that the mesio-distal width of maxillary canines has a significant correlation with height12,15,20, however, with linear regression formula that varies depending on the population and sample. According to Yadav et al.’s research, the regression equation generated from odontometric parameters can be used as an additional approach to estimating body height if the bone extremity is not available, but only in the same specific population15. Interestingly, for mandibular permanent teeth parameters, some researchers used the same method using a formula called the Carrea’s Index9,10,16,17. Although the study was conducted in different populations, the significant results obtained are the same, namely Carrea’s Index method can be used to estimate the height in their population. Carrea’s Index method is a method that was discovered by Carrea in 1920, which uses the parameters of the mandibular anterior permanent teeth by measuring two dimensions namely arch and chord16. Based on previous research using the Carrea’s Index method the advantages of this method are easy and simple because the formula is already found, it can be used in normal and crowded tooth conditions, and because the measured dimensions are horizontal dimensions (mesiodistal width of teeth and dental arch), so they are not affected by changes in the vertical dimensions of teeth, for example, due to attrition, as well as due to local cultural rituals that change to condition of the tooth (for example, pangur). In addition, when observing the findings of cases in the field, the anatomical position of the mandibular anterior teeth crowns is behind the anterior maxillary teeth so that they are adequately protected from trauma and damage before and after death.

Because the Carrea’s Index method is based on the previous study, the accuracy of the results is good, namely above 70% used in some populations9,10,16, so in this study, the writer wants to examine the accuracy of the estimated height using the Carrea’s Index method on the Mongoloid population in Indonesia. It is hoped that later the results of this study can be an inspiration or further study to develop related method or other method in estimating body height using dental dimensions to support the process of identifying bodies in the forensic field in Indonesia in particular.
Materials and Method

This study is an observational analytic with a cross-sectional design. The subjects in this study are the Mongoloid population - the largest group found in Indonesia - who are clinical patients of the Orthodontic Residents in Orthodontic Residency Program (PPDGS), at Oral Medical Education Hospital (RSGM-P), Faculty of Dental Medicine, Airlangga University, over the past year, with the following inclusion criteria:

- The age range of patients is 21-25 years
- Complete mandibular anterior teeth
- There are no anatomical, morphological abnormalities or pathological conditions and healthy periodontal tissue.

The sampling technique uses a total sampling method. The total sample is 46 subjects with mandibular dental molds, with a sampling unit that is one side of the mandibular quadrant, so that the total number of samples was 92 samples (for the right and left quadrants). While the exclusion criteria for the sample in this study as follow:

- Not willing to be the subject of the study.
- Not getting approval from the treating dentist.
- Not from the Mongoloid population.
- Have a history of mandibular anterior restorative, crowded teeth, or diastema.
- Have a history of abnormalities related to growth, such as abnormalities in the number of teeth, tooth size and shape, tooth eruption time, and abnormalities in tooth structure.

Each subject has explained the intentions and procedures in this study, and each subject fills informed consent. This study has also received Ethical approval from the Ethics Committee of the Faculty of Dental Medicine, Airlangga University. The procedure of this study as follow:

1. **Actual body height (BH) measurement**: The subject was measured using a One Med stature meter with the subject standing upright in a horizontal plane, barefoot, in an anatomical position according to the Frankfurt field, holding the breath, aligning the posterior surface of the heel, hips, shoulders, and nape in the vertical plane. Height is recorded in the subject’s identity form. Measurements were made by one person, the author himself. For intra-examiner variability, the height measurements were repeated for 12 subjects.

2. **Arch and chord measurement**: Arch is the sum of mesiodistal widths of one side of the mandible anterior measured from the labial surface, while the chord is the distance between the mesial edge of the central incisors and the distal edge of the canines on the same side measured from the lingual surface. It was measured using a sliding caliper according to the Carrea’s Index in the mandibular mold for each side of the mandibular quadrant, then the measurement results are entered into the Carrea formula to determine the estimated minimum and maximum height. Calculation results in millimeters are then converted to centimeters. For intra-examiner variability, the arch and chord measurements were repeated on 12 sample.
**Carrea Formula:**

\[
\text{Max BH} = \frac{\text{arch (in mm)} \times 6 \times 3.1416 \times 100}{2}
\]

\[
\text{Min BH} = \frac{\text{chord (in mm)} \times 6 \times 3.1416 \times 100}{2}
\]

**Comparison of estimated results with actual BH:**

The Max BH and Min BH values are the estimated range of the subject’s height which will then be compared to the actual body height of the subject, with the following conditions:

- **Successful Prediction**: if the actual height measurement results are in the range between the estimated minimum height and maximum height measurements.
- **Unsuccessful Prediction**: if the actual height measurement results are not in the range between the measurement results of the estimated minimum height and maximum height.

Then the frequency of successful prediction and unsuccessful prediction in both men and women, both right and left side is calculated.

**Data analysis:** The proportion of accuracy is compared by sex, and the jaw quadrant side uses the Chi-square test. Carrea’s Index method reliability was tested with Pearson’s coefficient and Kappa Index to determine intra-examiner reliability. This study uses a 95% confidence level, with a p-value <0.05 considered statistically significant.

**Results**

In this study, according to the results of the intra-examiner test, obtained reliable results with a Kappa Index coefficient of 0.897, which means that there is a very strong consistency (coefficient value close to 1) between the first and second height measurements in 12 subjects and arch and chord dimension measurements of 12 mandibular mold by the authors. Based on the Kappa Index test, a significant p value was obtained at 0,000 using a 95% confidence interval, where a p value <0.05, so this indicates that there was significant consistency between the first and second measurements.

Descriptive statistics of gender-related subjects consisted of 38 women (82.6%) and 8 men (17.4%) so that the sample was 92 (for a total of 2 sides of the mandibular quadrant with 46 samples each).

</table>

Based on table 1 above, the mean value of the subjects of the study, both female and male, was 22 ± 1.16 years. The table also shows the comparison of the actual average height of the subjects with the estimated height obtained from the arch (maximum height) and chord (minimum height) values in each sample calculated by the Carrea’s Index formula. It appears that of the 46 subjects, male subjects had higher average height and the estimated height than female subjects. Meanwhile, when viewed from the calculation of the estimated height between the sides of the mandibular quadrant, in female subjects, the estimated height results on the right side are higher than the results of the calculation of the estimated height of the left side. In contrast to male subjects, the estimated height results on the left side are higher than the results of the estimated right side height estimates. The total estimated height of the right side in female subjects (158.67 ± 10.92 cm) differed by 1.53 ± 3.44 cm from the actual height of the female subjects (157.14 ± 7.48 cm), and the total estimated height the left side body in the female subject (157.55 ± 10.94 cm) differed by 0.41 ± 3.46 cm from the actual height of
the female subject (157.14 ± 7.48 cm). Meanwhile, the total estimated height of the right side in male subjects (163.06 ± 12.32 cm) differed by 4.47 ± 7.6 cm from the actual body height of male subjects (167.53 ± 4.32 cm), and the total estimated left-side height in male subjects (163.94 ± 10.20 cm) differed by 3.59 ± 5.48 cm from the actual height of male subjects (167.53 ± 4.32 cm).

Table 2 below shows the distribution of successful and unsuccessful prediction results from the calculation of estimated height using the Carrea’s Index method to the actual height of the study subject based on gender and the side of the mandibular quadrant using the Chi-square test. From 38 female subjects, on the right side, 28 subjects (73.7%) showed successful predictions, while the remaining 10 subjects (26.3%) showed unsuccessful predictions. From 8 male subjects, on the right side, the results of a balanced and successful prediction were obtained, namely, 4 subjects (50%) had successful predictions, and 4 subjects (50%) had unsuccessful predictions. Thus it can be seen that a higher percentage of success was found in female subjects compared to male subjects on the right side, but there was no statistically significant difference (p = 0.186). Overall on the right side, there were 32 samples (69.6%) with successful predictions and 14 samples (30.4%) with unsuccessful predictions.

There was a slight differences found on the left side, where there were fewer female subjects who had success predictions compared to the right side, namely 26 subjects (68.4%), while 12 subjects (31.6%) had unsuccessful predictions. In contrast, in male subjects, on the left side of the number of samples with more successful predictions than the right side, namely 6 subjects (75%), while those who have unsuccessful predictions are 2 subjects (25%). Thus, on the left side, it appears that male subjects have a higher percentage of success than female subjects, but there is no statistically significant difference (p = 0.713). Overall on the left side, the percentage of success is not different from the right side, that is, there are 32 samples (69.6%) with predictions of success and 14 samples (30.4%) with predictions of no success.

**. Correlation is significant at the 0.01 level (2-tailed).
Table 3 above shows the results of the correlation analysis between actual height and estimated maximum and minimum height on both the right and left sides. From this table, it is known that the Pearson correlation coefficient value between the height variable and each estimated height variable is greater than zero to maximum body height of the right side is 0.471; to the maximum body height of the left side is 0.476; to the minimum body height of the right side is 0.452, and with a minimum body height of left side is 0.515. The Pearson correlation coefficient value which is getting closer to 1 indicates a stronger correlation, so from the four estimated height variable, the minimum body height of the left side coefficient is closest to 1 which means that the variable has the strongest correlation to the height variable compared to the another estimated height variable.

*. Correlation is significant at the 0.05 level (2-tailed).
a. Jenis Kelamin = Perempuan

In addition, to determine the strength of the correlation, it is also possible to see the value of p compared to the level of significance used in this study. The p-value between the actual height and the estimated maximum height (right) and the maximum height (left) is 0.001 (<0.05), which means that there is a significant correlation between the actual height and the estimated maximum height of the right side and left side respectively. Similarly, between the actual height and estimated minimum height (right), a significant correlation was obtained with a p-value of 0.002 (<0.05), and between the actual height and an estimated minimum height (left) obtained a significant correlation with a p-value of 0.000 (<0, 05). Based on the results of the Pearson correlation coefficient, marked by (**) on all estimated variables of maximum height and minimum height both right and left side with the information below the table which states that there is a significant positive correlation with actual height at a significance level of 1% or 0.01 (2-tailed). Although the significance level used in this study is the 0.05, it does not mean the results of this test indicate that it does not correlate at the 0.05 if the 0.01 is significantly correlated, then, of course, the 0.05 level will also be significantly correlated.

b. Jenis Kelamin = Laki-laki
Table 4 and Table 5 above show the results of correlation test for each sex, and there are slight differences in the strength and significance of the correlation. In female subjects (Table 4), there were three significant correlation results at the 0.01 level of significance (**), namely the maximum height of right side variable with a Pearson correlation coefficient of 0.455 (p value = 0.004); maximum height of left side with Pearson correlation coefficient 0.425 (p value = 0.008); and the minimum height of left side with the Pearson correlation coefficient of 0.430 (p = 0.007). While there is one variable with significance at the 0.05 (*) significance level, namely the minimum height of right side with a Pearson correlation coefficient of 0.409 (p = 0.011). So from the four variables, the maximum height of right side variable is the one with the strongest correlation.

In Table 5, it shows that in male subjects there is one variable that correlates at the 0.01 (***) significance level, that is, the maximum height of left side variable with a Pearson correlation coefficient of 0.862 (p value = 0.006). In the table, there is one variable that correlates at the 0.05 (*) significance level is the maximum height of right side variable with a Pearson correlation coefficient of 0.771 (p = 0.025). From the two variables, although both have coefficient numbers that are very close to 1 and show that they have a very strong correlation, the level of significance of the two is different, it can be seen in the results of each p value, so that from these two variables the strongest correlation is found in maximum height of left side. The other two variables also have a correlation coefficient number that is larger and closer to 1 when compared to female subjects, namely the minimum height of right side variable of 0.556, and the minimum height variable of left side (0.667), which means there is a strong correlation between these variables on actual height, but the correlation between these two variables is not significant at the level of significance used in this study. This is because both of these variables produce a value of $p > 0.05$, namely the value of $p = 0.152$ for the minimum height of right side variable and the value of $p = 0.071$ for the minimum height of left side variable.

**Discussion**

In this study, from 46 research subjects with 92 right and left mandibular quadrant samples, the mean of estimated minimum height was lower than the mean of the actual height, and so was the mean of estimated maximum height was higher than the mean of actual height. The mean of actual height (female and male) is 158.95 ± 8.08 cm, the difference is 0.49 ± 3.08 cm from the total estimated height from the right side (159.44 ± 11.16 cm), and a difference of 0.29 ± 2.92 cm from the total estimated height from the left side (158.66 ± 11.00 cm), so this means that the mean of overall height is actually within the range of the mean of total estimated body height (minimum height - maximum height) obtained from the Carrea’s Index calculation.

In this study, based on the results of height measurements, it was found that the mean value of the male subject’s height had a higher value than the female subject. It was also found when calculating the estimated height from the dimensions of the teeth, and it was found that the mean of male subject’s height had a higher value than female subjects, thus indicating that in subjects who were taller, the dimensions of the teeth were also greater. This discovery shows that the dimensions of the teeth are directly proportional to height. Therefore, the dimensions of the teeth are considered to be a measurement tool for estimating height.

A comparison of the successful prediction results in female and male subjects and in both quadrants as a whole in this study had the same percentage of success. However, in each gender, the percentage of success was different for each side of the jaw quadrant, although both were without statistically significant differences (right p-value (0.186); left p-value (0.713)). This difference can be caused by the results of the estimated height for each gender for each side of the jaw quadrant, where the female subjects, have higher body height estimates in right quadrant than the left quadrant, in contrast, in the male subjects, estimated body height in left quadrant is higher than the right quadrant, so this causes the range to be wider and had a higher chances of the actual height being within the estimated range.

In this study, between the genders, there are differences in the percentage of success on the right and left sides, but in previous studies\(^9,10,16\) found that the percentage of success in the male subject is greater than women on both sides, with no statistically significant difference. This could be due to the small number of male subjects in this study, so further study on a larger sample and a balanced proportion of gender are needed. Similar to what was found in the study of Silva et al. (2014) where the number of female subjects was higher than that of male subjects, and the success percentage of female subjects was higher than male subjects.
In this study, a similar percentage of successes on the right and left sides and no statistically significant differences were found in each sex on each side of the jaw quadrant indicating that the Carrea’s Index method can be used on both women and men on all sides of the jaw quadrant, without affecting the percentage of success. Comparison with previous studies, namely, in a study by Lima et al. (2011), with normal dental structure, the results was higher percentage of success on the right side, as well as in research by Sruthi (2016), while in research by Silva et al. (2014), with normal dental structure, the percentage of success was higher on the left side, as was the study by Rekhi et al. (2014). This can be caused by differences in population and race that are used as research subjects. Although there is a difference in the percentage of success on each side of the jaw of previous studies, there is no statistically significant difference overall, so it can be concluded that the Carrea’s Index method can be used on any side of the jaw, of course with normal dental structure conditions as examined in this study.

From the results of the correlation test between actual height and estimated height (maximum height and minimum height) obtained from the Carrea’s Index method can be used on both women and men on all sides of the jaw quadrant indicating that the Carrea’s Index method in this study shows that the Carrea’s Index method can be used in the Mongoloid population. Therefore, the dimensions of the tooth are considered to be alternative to long bones, especially in forensic cases where no long bones or other body parts are found.

Based on the results of the Pearson correlation test for each gender, there are strong Pearson correlation coefficient numbers in both female and male subjects. But from each correlation coefficient in each gender, there are differences in the level of significance. If on the female subjects, the correlation of actual height to the estimated height is a strong correlation at the 0.01 (with p value <0.01 on the maximum height (right), and the minimum height (left)) and 0, 05 (p <0.05 in the minimum height (right)), whereas in male subjects, there was only a strong correlation according to the significance level of 0.01 (p <0.01 in the maximum height (left)) and 0.05 (p <0.05 in maximum height(right)). In the estimation results of the minimum height (left & right), although it shows a strong Pearson correlation coefficient, there is no significant correlation at the the significance level of 0.05 or 0.01. This can be due to the very small number of male subjects compared to women, so that more male subjects are needed to be able to see the significance at the expected level of significance. As explained in the study by Alwi (2010), that the smaller the significance number, the larger the sample size needed. Conversely the greater the significance number, the smaller the sample size. To get a good significance number, usually a large sample size is needed. Conversely, if the sample size gets smaller, then the possibility of more errors arises.  

**Limitation:** This study still has some limitations including small sample size and gender imbalance, narrow age range, still limited to normal tooth structure, general and less specific population, and the study carried out on living subjects, therefore further research is needed to address all the limitations of this study.

**Conclusion**

The conclusion obtained from this study is that based on the percentage of success of the Carrea’s Index method in this study shows that the Carrea’s Index method can be used in the Mongoloid population.
in Indonesia to estimate the height of an individual as an aid for individual identification. In addition, there were no statistically significant differences between the gender and the mandibular quadrant side to predict the success of height estimation so that these factors did not correlate or influence the percentage of success in height estimation using the Carrea’s Index method.

Abstract

Purpose: To evaluate the efficacy of nurse assisted distraction strategies on postoperative pain, parent pain catastrophizing, mother and child anxiety and physiological parameters.

Method: The present study included a total of 160 mother-child dyads (2-7 years) inpatient to paediatric surgical unit. The study participants are randomized into intervention and control group. The intervention group will receive age appropriate NADS along with the standard care for three postoperative days and the control group will receive only standard care. The participants will be followed from day of admission to postoperative day 3.

Results: NADS will be delivered for three postoperative days to the children in the postoperative unit. Children received intervention had shown improvement in the postoperative pain and anxiety in these three postoperative days.

Conclusion: The findings of the study will empower nurses and health care professionals to practice distraction strategies in the postoperative unit which will decrease postoperative pain, anxiety and reduces the dosage of analgesics among children.

Keywords: Postoperative pain; Anxiety; Children; Nursing, Distraction; RCT; Protocol.

Introduction

A hospitalized child experience pain more frequently and it is a leading concern of parents and caregivers.¹ Postoperative pain involves multiple physiological mechanisms precipitated by surgical trauma.² It is associated with autonomic, endocrine, metabolic, physiological and behavioural responses.³ Evidence suggests that inadequate relief of postoperative pain results in harmful physiological and psychological consequences that eventually lead to significant morbidity, which may delay recovery and return to daily living and mortality.⁴ It is found that 64% of the
post-operative children experience moderate to severe pain and among them 29% experience unbearable pain after surgery and at least 24 hours after surgery.\textsuperscript{5} However, pharmacological method are usually practiced in all health care setting to reduce pain which is administered through different routes.\textsuperscript{6} Meanwhile, non-pharmacological techniques are commonly considered additional strategies which are used alone or in combination with pharmacological treatment.\textsuperscript{7} Non-pharmacological interventions provide relaxation and balance the physiological indicators such as blood pressure, pulse rate and respiration and also prevent the post-operative complications such as pain, sleep disorder and anxiety.\textsuperscript{8} To ensure proper management of pain in the post-operative period the pain must be assessed by using the age appropriate tools.\textsuperscript{9} The pain expression of the children is the most appropriate indicator in the assessment of pain and the children those who are not able to communicate pain must be measured by using behavioural pain scales.\textsuperscript{10} Nurses play an effective role in identifying and controlling post-operative pain and teaching the non-pharmacological interventions to the parents and caregivers\textsuperscript{11}. Non-pharmacological intervention is often used to guide attention away from painful stimuli.\textsuperscript{12} It is most effective when adapted to the patient’s developmental and cognitive level\textsuperscript{13}. Most of the studies have reported that non-pharmacological interventions are effective among children when used along with pharmacological treatment.\textsuperscript{14-20} By reviewing the literature, the researchers identified that there are non-pharmacological interventions for pain but structured interventions need to be developed and used for the children to reduce postoperative pain. However, there are research studies conducted in the area of pain assessment but interventions to reduce postoperative pain among younger children is a new concept.

**Study objectives:**

**The objectives of the study are to:**

- assess the pain, anxiety and physiological parameters of the child inpatient to surgery.
- assess the anxiety and pain catastrophizing among mother of child inpatient to surgery.
- evaluate the efficacy of NADS on pain, pain catastrophizing, anxiety of child and mother and physiological parameters.

**Hypotheses:** All research hypotheses will be tested at 0.05 level of significance.

\[
\frac{2 \left[ z_1 - \frac{z_2}{\sqrt{2}} + \frac{z_2}{\sqrt{2}} \right] \sigma^2}{d^2}
\]

\textbf{H1:} There will be significant difference in pain, anxiety, physiological parameters and use of pain medication among child undergoing surgery in the intervention group from that of the control group.

\textbf{H2:} There will be significant difference in anxiety and pain catastrophizing among mother of child undergoing surgery in the intervention group from that of the control group.

**Method**

**Study design**

A cluster randomized controlled trial

**Inclusion and exclusion criteria**

**Inclusion criteria:**

**Child:**

- inpatient for a minimum three postoperative days
- in the age group of two to seven years
- undergoing urogenital & other surgeries
- not had any developmental or behavioural disorders
- able to understand and speak Kannada or English
- accompanied by the mother

**Mother:**

- able to understand and speak Kannada or English

**Exclusion criteria:**

**Child:**

- undergoing cardiac, head and neck, orthopaedic surgeries.
- mentally retarded and physically challenged
- posted for emergency surgery

**Mother:**

- who speaks other than Kannada or English
Sample size:

Sample size is calculated by using the following formula,

The total sample for the study is 160 (80 each for experimental and control group).

Data collection:

Mother in the intervention or control group: On the day of admission, the purpose of the study will be explained to the mother and subject information sheet will be given. Written informed consent will be obtained from the mother which records mother and child participation in the study. The anxiety of the mother is assessed on day of admission and postoperative day 3 by administering the STAI Scale to the mother. On postoperative day 1 and 3 the thoughts and feelings of the mother when her child is in pain is assessed by administering the PCS-P Scale.

Child in the intervention group: On the day of admission the anxiety of the child is assessed by the researcher using mYPAS Scale. On postoperative day 1 the pain and physiological parameters will be assessed after 2 hours of surgery. Next pain and physiological parameters will be assessed every fourth hourly. After 6 hours of surgery the researcher will assess the sedation level of the child using Ramsay Sedation Scale and the child receives an age appropriate distraction intervention for thirty minutes. Each day a new distraction activity is provided for the child. To avoid cross-infection all the toys will be cleaned with the help of Dettol solution and the contaminated toys will be replaced with a new kit. After completion of distraction activity, the child is asked to relax and the pain and physiological parameters will be reassessed after 15 minutes. On postoperative day two and three the pain and physiological parameters will be assessed every seventh hourly and the distraction activity is given twice a day.

Child in the control group: All assessments are done same as the intervention group but the child receives no any distraction activity and the child will receive standard care in the postoperative unit.

Data collection tools:

1. Demographic Proforma: Demographic Proforma was developed by the researcher to collect data on sample characteristics. The tool was divided into sample characteristics and clinical data. Sample characteristics measured: age of mother and child, gender of the child, income, education of parents, previous history of surgery. Clinical data measured type of surgery, type of analgesic, demand for analgesics, pre-medications and duration of surgery.

2. Developmental psychopathology checklist for children: It is a standardized scale developed by Malavika Kapur to measure the behavioural/developmental disorders among children. For the present study the tool has been modified with the permission of the author. The checklist consists of 56 items which contains dichotomous questions (yes/no) and the areas assessed are developmental history, developmental problems, attention deficit hyperactivity, conduct disorders, learning difficulties, emotional disorders and OCD. Inter-class correlation co-efficient via analysis of variance was 0.965.

3. State trait anxiety inventory (STAI): It is a standardized tool developed by Charles D Spielberger to measure the state and trait anxiety. STAI form Y1 is composed of 20 items to measure state anxiety. State anxiety identifies the anxiety in the person by verbalizing the stress, tension and feeling “at that moment”. STAI-Y2 is composed of 20 items concerning trait anxiety which indicates the “general feeling of the person”. The higher the score is the greater the anxiety. The reliability obtained in the present study was STAI Form Y1=0.93, STAI Form Y2=0.91.

4. Modified Yale preoperative anxiety scale (mYPAS): It is a standardized tool developed by faculties of Yale University School of Medicine. The scale consists of 22 items divided into five subscales: activity, vocalizations, emotional expressivity, state of apparent arousal and use of parents. Each of the 5 categories has an individual score, ranging from the least anxious, to the most anxious behaviours. The higher the number indicates the more anxious behaviour of the child. Reliability of the tool revealed that inter observer agreement ranged from 0.68 to 0.86. Researcher has assessed the reliability of the tool by using inter-observer method and agreement was 0.92 which shows the tool is reliable.

5. Ramsay sedation scale (RSS): It is a standardized scale which is used to monitor the level of sedation. The tool contains six items and the scoring of the tool
and higher the score indicates high level of sedation. Cronbach’s alpha of the tool showed internal consistency $\alpha= 0.82$. In the present study the researcher has assessed the reliability of the tool by using Cronbach’s alpha and the internal consistency was 0.8 which reports the tool is reliable.

6. **Evendol pain scale**: It is a standardized instrument developed by Fournier-Charriere to measure the postoperative pain among younger children. The tool is composed of five subscales: vocal or verbal expression, facial expression, movements, postures, interaction with the environment. The scale contains score from 0 to 3 for each item: 0 indicates sign absent, 1=sign weak or transient, 2=sign moderate or present about half the time, 3=sign strong or present almost all the time. Inter-rater reliability showed kappa 0.7-0.9. On postoperative day 1 the researcher will take the pain measurements after 2 hour of surgery and then every fourth hourly. On postoperative day two and three pain is measured every seventh hourly. If the analgesic is administered to oral or rectal route pain is assessed after 45 minutes, 10 minutes if administered through IV route.

7. **Pain catastrophizing scale-Parent version (PCS-P)**: It is a standardized scale developed by Michael JL Sullivan to assess the negative thinking associated with pain. It includes 13 items which are rated on a 5-point scale ranging from 0= “not at all true” to 4= “very true”. The items are divided into three subscales: rumination-4, magnification-3 and helplessness-6. Items are summed across subscales to derive a total score ranging from 0-52. Higher scores reflect higher levels of catastrophic thinking. In the present study the researcher has assessed the reliability of the tool by using Cronbach’s alpha and the internal consistency of the tool is 0.9 which reports the tool is reliable.

8. **Physiological parameters**: The Heart rate, Respiratory rate and Oxygen saturation is measured by using Philips cardiac monitor (Intellivue MP5). Researcher has assessed the reliability of the monitor by using inter-observer method and agreement was 1 which shows that it is reliable.

**Data analysis**: EZR software will be used for data analysis. Descriptive statistics will be used for analysing sample characteristics. Repeated measure ANOVA to compare effect of intervention on continuous outcome.

**Ethical Clearance**: The protocol has been approved by the institutional Ethics Committee (IEC: 35/2019). The study has been registered under Clinical Trial Registry India (CTRI/2019/05/019174).

Discussion
Standardized age appropriate distraction strategies have a potential to reduce postoperative pain and anxiety among the child undergoing surgery. The current study presents an opportunity to evaluate such program among the children in the postoperative unit. The strength of the study is using standardized scales for measuring the outcomes. This is the first study where the pain is assessed using Evendol pain scale and the child receives standardized age appropriate distraction strategies intervention for postoperative pain among children. The outcomes of the study will support the training of nurses and health professionals regarding the use of pain scale for assessing postoperative pain and delivering the age appropriate distraction strategies for the child in the postoperative unit.

Conclusion
NADS will help to reduce postoperative pain and anxiety. The findings of this study will motivate the health professionals to practice distraction strategies in the postoperative unit which benefits the child and family undergoing surgery.

Abstract

Posyandu is one form of Community-Based Health Efforts held together with the community in obtaining basic health services. The cadre’s role is to provide health information to the community, as a community mobilizer to come to Posyandu and a motivator to realize maternal and child health. The research was aimed at developing an effort to improve the performance of Posyandu cadres based on an analysis of empowerment in Tulungagung Regency. The study was conducted using observational analytic method with a sample of 32 Posyandu. The study was conducted in Tulungagung Regency in January-March 2020. The results showed that there was a relationship between the process of empowering and capability empowerment with the performance of Posyandu cadres (0.019; 0.001). There was a relationship between cadre training and alignment (0.002); the relationship between the availability of facilities and the role of the village with capability (0.042; 0.028) and the relationship between the development of cadres and trusts (0.028). It could be concluded that the performance of Posyandu cadres was influenced by the process of empowering alignment and capability. While trust was not related to the performance of Posyandu cadres. The process of empowering alignment was influenced by cadre training; capability was influenced by the availability of facilities and the role of villages.

Keywords: Posyandu, cadre performance, empowerment.

Introduction

One of the 2015-2020 Sustainable Development Goals (SDGs) goals is to end hunger, including overcoming malnutrition¹. Achieving these targets through health efforts and community empowerment, including Posyandu (Pos Pelayanan Terpadu/Integrated Service Posts)². Posyandu is one form of Community-Based Health Efforts (CBHE) which is held together with the community in obtaining basic health services.

Posyandu activities consist of maternal and child health services, family planning, immunization, nutrition, prevention, and prevention of diarrhea. One of the benefits of Posyandu for the community is that the growth of children under five is monitored so that it improves the health status of the community³. Early detection of nutritional cases can be done by weighing toddlers. This is intended if the child’s weight does not rise, recovery and prevention efforts can be made immediately, so as not to become malnourished. Handling according to the management of nutritional cases will reduce the risk of death so that mortality due to malnutrition can be suppressed⁴.

Cadres have a large role in the smooth running of Posyandu activities. The task of planning various activities that exist in the Posyandu, implementing, evaluating, and controlling Posyandu activities, and
reporting on Posyandu activities is carried out by cadres. The role of cadres as providers of health information to the community, community mobilizers to come to Posyandu, and motivators to help realize maternal and child health. Looking at the Posyandu cadre’s tasks, it can be concluded that the Posyandu will be implemented optimally if the Posyandu cadre’s performance is good.

Empowerment cadres for Posyandu for Toddler can be studied with an empowerment approach consisting of Alignment, Capability, Trust, and Participation, adapted from the theory of Tenner and Detoro in 1992 in Total Quality Management (TQM). The results of several studies indicate that community participation in Posyandu is influenced by cadre performance as a dominant factor and availability of facilities. There is a link between Posyandu cadre guidance and trust, capacity with Posyandu cadre participation, education, and mother’s work with the presence of toddlers in Posyandu.

According to data from the Tulungagung Regency Health Office, in 2018, there were 27 Health Center out of 32 Health Center (84.4%). If seen from the total achievement of recording-reporting indicators, the community participation in Posyandu has not yet reached the 80.0% target. Not yet achieved community participation in Posyandu or the arrival coverage of 74.7% of the 80.0% target in Tulungagung Regency in 2018, is likely due to the performance of Posyandu cadres and toddlers factors. New policies and commitments for implementation are needed to produce positive results.

The results showed that the performance of Posyandu cadres in the good category was 84.4%. The performance of Posyandu cadres is cadres carrying out their duties, both before, during, and after the opening of Posyandu, namely: disseminating information about Posyandu opening days; register; child health services (the measurement of body weight, height, head circumference of children, monitoring of immunization status of children); recording of measurement results; counseling; make home visits; provide counseling; holding discussions with mothers of toddlers; learn Posyandu Information System.

**Materials and Method**

The study was conducted for 3 months, namely from January to March 2020 in the Work Area of the Tulungagung Regency Health Office. This study uses a cross-sectional approach. The instrument used in this study was a questionnaire. The population in this study were Posyandu cadres and mothers of toddlers with a large sample of 32 Posyandu. The research sample was taken using multistage random sampling.

Primary data was taken through a Likert scale questionnaire. Data were analyzed descriptively and using the Spearman Correlation test. The scientific discussion is held to produce recommendations on the emergence of strategic issues.

**Findings:** The results showed that the availability of adequate category facilities was 71.9%, and the development of Posyandu cadres in the category was sufficient 24.0%. The availability of Posyandu facilities is: weigh tools, length/height measurements, extension media, register books. While the efforts to develop Posyandu cadres are related to the improvement of Posyandu functions and performance. The guidance covers aspects of the program, institutional, and power aspects. The results showed that the role of the village category was 68.8%. The village is responsible for providing policy support, facilities, and funds; coordinating community mobilization to attend Posyandu; coordinating cadres, Posyandu administrators, and community leaders; following up on Posyandu results; Posyandu training.

The results showed that cadres had received 62.5% training. Posyandu cadre training aims to create quality Posyandu cadres. Training is to improve skills so that cadres can participate as Posyandu managers. Posyandu cadre training is expected to improve cadre performance. The results showed that the alignment of the good category was 65.6%, the capability of the good category was 75.0%, and the trust of the good category was 68.8%. Alignment is the stage of convincing employees to understand their vision, mission, values, policies, goals, and method. Capability is the stage of building employee capacity that is increasing the knowledge, abilities, and skills of each individual and the availability of resources, method, and technology to build systems. While trust is the stage of superiors trust in subordinates raises employee confidence to do work.

The results showed that the performance of Posyandu cadres in the good category was 84.4%. The performance of Posyandu cadres is cadres carrying out their duties, both before, during, and after the opening of Posyandu, namely: disseminating information about Posyandu opening days; register; child health services (the measurement of body weight, height, head circumference of children, monitoring of immunization status of children); recording of measurement results; counseling; make home visits; provide counseling; holding discussions with mothers of toddlers; learn Posyandu Information System.
Relationship between Training and Alignment: The results of the analysis of the relationship between training and alignment can be seen in Table 1. Table 1 shows that the training, tested by Spearman Correlation with alignment, obtained Sig. (2-tailed) = 0.002 which means there is a relationship between training and alignment. Increased knowledge and skills of cadres are influenced by training so that cadres can manage Posyandu according to their competencies. This is in line with the results of research on training related to increasing cadre knowledge\textsuperscript{12}.

Table 1. Relationship between Training and Alignment in Tulungagung Regency, Indonesia, 2020

Relationship between Availability of Facilities and Capability: The results of the analysis of the relationship between the availability of facilities and capability can be seen in Table 2. Table 2 shows that the availability of facilities, tested by Spearman Correlation with capability, obtained Sig. (2-tailed) = 0.042 which means there is a relationship between facility support and capability. According to the results of interviews with respondents, counseling media (flip sheets, posters, leaflets) have been given much damage and missing. This is in line with research on the relationship between facilities and infrastructure and the practices of cadres in Posyandu, namely to improve the ability of cadres in Posyandu, the availability of facilities and infrastructure that supports\textsuperscript{13}.

Table 2. Relationship between Availability of Facilities and Capability in Tulungagung Regency, Indonesia, 2020

Relationship between Village Roles and Capability: The results of the analysis of the relationship between the role of villages and capability can be seen in Table 3. Table 3 shows that the role of villages, tested by Spearman Correlation with capability, obtained Sig. (2-tailed) = 0.028 which means there is a relationship between the role of the village with capability. This is in line with the results of research on the relationship between the village’s role and the empowerment of Posyandu cadres, namely the Village Head’s role in providing facilities, monitoring and supervising cadres’ tasks, considering the ability of cadres before giving assignments, giving rewards, and developing Posyandu\textsuperscript{14}.

**Relationship between Posyandu Cadre Development and Trust:** The results of the analysis of the relationship between the development of Posyandu cadres and trust can be seen in Table 4. Table 4 shows that the Posyandu cadre development, tested by Spearman Correlation with trust, obtained Sig. (2-tailed) = 0.028 which means there is a relationship between the formation of Posyandu cadres with trust. Trust between the Health Center and cadres is well established with frequent cadre refreshing activities. The Health Center felt that cadres who often received coaching had been able to carry out their duties properly, resulting in trust. Cadres become more confident in carrying out their duties because they have won the trust of the Health Center. This research is in line with research that developing cadres can increase self-confidence in Posyandu cadres15.

**Relationship between Alignment, Capability, Trust and Posyandu Cadre Performance:** The results of the analysis of the relationship of alignment, Capability and Trust with the performance of Posyandu cadres can be seen in Table 5. Table 5 shows that the alignment was tested by Spearman Correlation with the performance of Posyandu cadres, obtained by Sig. (2-tailed) = 0.019 which means there is a relationship between alignment and the performance of Posyandu cadres. A person’s behavior is determined by a person’s knowledge and attitude16. This is consistent with research that Posyandu cadre knowledge is related to cadre participation17.

</tbody>
</table>
Table 5 shows that the capability was tested by Spearman Correlation with Posyandu cadre performance, obtained by Sig. (2-tailed) = 0.001 which means there is a relationship between capability and performance of Posyandu cadres. The procurement of facilities from the Health Center and villages should be able to support cadres to do their jobs properly. This capability is not yet maximal, possibly because cadre training is still not comprehensive. So that the soft skills of cadres are not honed and cause the cadre skills are still lacking. This is consistent with research that cadre competencies, especially in the competency of cadre knowledge, attitudes and skills related to cadre performance, and research on the availability of facilities related to cadre performance.

Table 5 shows that trust was tested by Spearman Correlation with the performance of Posyandu cadres, obtained by Sig. (2-tailed) = 0.658 means there is no relationship between trust and the performance of Posyandu cadres. Trust in this case is the mutual trust between the Health Center and the village with cadres. Overall cadre trusts are in a good category (68.8%). Tenner and Detoro stated that the trust of superiors can lead to the confidence of employees to carry out responsibilities so that the commitment to contribute to the maximum.

Conclusions
The better the process of empowering alignment and capability, the better the performance of Posyandu cadres. The alignment empowerment process is in line with the increasing frequency of Posyandu cadre training. The process of empowering capability will be better if the availability of facilities is more complete and the role of the village is getting better. Meanwhile, cadre trusts will be better if Posyandu cadre guidance is also increasing in quality and quantity. Various ways can be done by several parties to help in improving cadre performance by increasing factors related to cadre performance.

Abstract

The COVID-19 virus, emerged at the end of 2019 began threatening the health and lives of millions of people within few weeks. At present all regions of the world, declared lockdown for controlling highly contagious and pandemic virus. During this lockdown period people are restricted to stay at home, for few weeks. During the idle stay at home for very long hours, will cause mental health problems, like stress, fear, anxiety, depression and sleep problems. In this present study, the researcher, made an attempt to study the impact on mental health of individuals during the lockdown period. The basic aim of this study: is to find out the viz. “Mental health problems” and its influence on ‘Gender, Age, Marital status and Occupation’ differences. The data has been collected through online questionnaire and analyzed using “one way analysis of variance”, t-test and Correlation. The study found that significant mental health problems attributed more in female than male folk. There is significant social dysfunction in female than male. Middle age group i.e. (30-44) have more stress and pressure of future and job shortening are creating depression.

Keywords: Anxiety, Social Dysfunction, somatic problems, Depression.

Introduction

Corona viruses are a large family of viruses that cause diseases ranging from the common cold to more serious ones. The COVID-19 Coronavirus was first detected in China in December 2019 and has since spread into all countries in the world. The present study observed, that, ‘the messages for the general population’, the World Health Organization (WHO) in January 2020, declared the outbreak of COVID-19, to be Public Health Emergency of international concern. WHO made the assessment that COVID-19 can be a characterized as a pandemic, which generates stress throughout the population.¹⁴

The people also have affected by COVID-19, they deserved our support, compassion and kindness in order to reduce stigma. The public in general experiencing invisible, fear, pressure, strain and strain. But the stress and strain with Psychosocial wellbeing is as important as managing physicalhealth. To avoid the Covid-19, take sufficient healthy food, engage in some physical activity and stay in contact with family and friends creates, pleasure, happiness, which helps to avoid the pressure and strain. As a responsible citizen, you must know how to “De-stress” and keeping yourself psychologically well. This is “Not a Sprint, It’s a Marathon”.

This Corona virus has quickly alerted governments and its public health systems, Countries have initiated preventive measures to limit the spread of virus. As Millions of lives have been significantly impacted, efforts are being made at a global, multi-level, to address through stress-coping-adjustment processes. Accordingly, in our country, the national government have taken stringent measures and the Andhra Pradesh Government have also implemented all these measures.

Corona viruses are a group of inter-related viruses that spread diseases among the public in general and birds. The COVID-19 symptoms are fever, tiredness and dry cough, throat pain, aches and pains, nasal congestion,
running nose, or diarrhea, smell less, tasteless and eye infection. These symptoms are usually started mild and begin gradually. Some people become infected but don’t attribute any symptoms about feel unwell. About 80% of the people recover from the disease without any special treatment if the patient detected early. Around 1 out of every 6 people who got tested as positive, of COVID-19 becomes seriously ill and develops difficulty in breathing. Older people and those with underlying medical problems like high blood pressure, heart problems or diabetes, are more likely to develop serious illness. People with fever, cough, throat pain and difficulty in breathing should seek medical attention.

People can perceive COVID-19 from others who have tested positive. The disease can spread from person to person through their micro-splinters delivered from the nose, mouth or eye drops are strong agents to spread of Covid-19 from person to person or person to a group. These emitted splinters land on objects and surfaces around the person, stay alive for five to ten minutes. The people in and around that area, perceive that virus and infected with COVID-19 by touching these objects or surfaces, then touching their eyes, nose or mouth. People can also catch COVID-19 if they breathe in droplets from a person with COVID-19 who coughs out or exhales droplets. This is why it is important to stay more than 2 meter (6 feet) away from a person who is sick.

Maria Oquendo (2020) said that those who are already suffering from any kind of psychiatric problem are going to have a heightened anxiety response. Moreover these conditions increase the risk for suicidal behavior. Indian Psychiatry Society (2020), found that sudden rise in those suffering from mental illness is up to 20 per cent. And also at least one out of every five Indians is suffering from mental illness.

Raju MVR (2020) said that setting goals, minimizing distractions, building trust, reducing the use of social media, reading books, watching comedy videos, playing indoor games would help in offering comfort to those coping with Anxiety. Zandifan and Badrfan (2020) stated that ‘the role of unpredictability, uncertainty, seriousness of the disease’, misinformation and social isolation in contributing to stress and mental health.

Shigemura (et al). (2020) Emphasized the economic impact of covid-19 and its effect on wellbeing, as well as the likely high levels of fear and panic behavior such as hoarding and stockpiling of resources, in the general population. Dong and Bovey, (2020) Pointed out that wide scope and spread of covid-19 could lead to a true mental health crisis, especially in countries with high case loads which would require both large scale psychosocial crises interventions and incorporation of mental health care in the future. According to Thiyamkiransingh and Raju MVR (2020) the psychosocial consequences from the fallout of the pandemic like Depression, Anxiety, stress, loneliness financial loss, rise domestic violence are a cause of worry, especially those working in the mental health community.

Duran and Zhu (2020) Pointed out that while western countries have incorporated psychological intervention into their protocols. Bao (et. al) (2020) Highlighted the services that were already being provided in china and also provided a list of strategies for general public to minimize out break related stress. a) Assessment of accuracy of information b) Enhancing social support c) Reducing the stigma associated with disease d) Maintaining as normal a life as feasible while adhering to safety measures e) Use of availability of psycho social services when needed. Raju MVR (2020) said communication is the key for parents to educate children about the impact of corona virus and the safety standards to follow in order to keep the virus at bay. This can also take an interesting format such as a story telling. The fear of losing dear ones and the possibility of getting infected is high among youngsters. We need to build confidence among them and help them erase their untold fears.

Ho et al., (2020)Discussed the role of improved screening for mental disorders, improving links between community and hospital services and providing accurate information to general public in order to minimize maladaptive responses such as panic and paranoia regarding the disease and its transmission. Li, Z.et al., (2020) Highlighted the role of anxiety as dominant emotional response to an outbreak and the need for adequate training of mental health care personnel and optimal use of technological advances to deliver mental health care. Raju MVR (2020) said, intends to provide counseling to 1) COVID-19 affected people and their families. 2) Those quarantined at home and their family members, 3) doctors, nurses and paramedical, personal of frontline department Revenue, police and Municipal Corporation etc. 4) Those working from home, people away from home and their kin, 5) critically alcohol dependent, 6) those vulnerable to acute attacks of Blood pressure and Diabetes and 7) people in depression.
Objectives of Study:

• To find out gender difference and marital status on mental health problems.
• To find out differences among various age groups and occupations on mental health problems.
• To find out the relationship among sub variables of mental health problems.

Method

Sample: The sample of 107 (Male 67 and 40 Female) participants with age range from 18 to above 45 years. Participation was voluntary and anonymous. The purposive sampling method was used to include participants in the study. The data was collected through what’s app and email of the respondents in Andhra Pradesh.

Measures: The questionnaire developed by Sarvani, G. and Raju, M.V.R. (2020) “The Mental Health Problems”, “Lifestyle during lock down period” and “Awareness of covid-19” covered in the questionnaire, was classified into three broad categories. First category items related to Mental Health Problems during the lock down period (COVID-19), reliability 0.38. Second category items related to Lifestyle during lock down period, reliability 0.27. Third category items related to Awareness of covid-19, reliability 0.33. A total 34 items are listed in this questionnaire. It was a three point Likert scale - one indicated strongly dis-agree and three indicates strongly agree, with intermediary score of undecided. Reverse scoring was given for some of the negative statements present in the questionnaire.

Result and Discussion

The data analyses, under table -1 showed that female (M=4.70) have high mean score than male (M=3.94) in social dysfunction, while, t- test value 3.7 at 0.01 level which indicates that women have difficulty to overcome the problems at work place, difficulty to take decisions and difficulty to face future situations.

Remaining factors like anxiety and depression mean values are more in female than male but not significant. Which means female group is suffering with anxiety, insomnia and stress and pressure due to house hold chores.

Table-2 results indicated that Anxiety mean (M=15.2) value high in 30-44 age group compare with other groups, social dysfunction mean (M=4.32) value and somatic problems mean (M=1.34) high in above 45 age group. Depression Mean value (M=4.69) high in 30-44 age group and also this group is significant t-test value 3.36, significant at 0.01 level. Which means 30-44 age group is middle adulthood group has stress and pressure due to uncertainty of future and extending lockdown period.

It is noticed from Table 4 showed that Anxiety mean value (M=14.7) and somatic problems mean value (M=1.35) high in employees (government, private, professionals and self employed). It indicates that due to anxious about future, uncertainty of job all these increase somatic problems like head ache stomach ache etc. Others (home makers, retired, unemployed) have high mean value in social dysfunction (M=5.00) and depression (M=4.62) which indicates that uncertainty in lockdown; unemployment and home makers have more workload at home, all these factors increase social dysfunction and depression. More over others have (F=3.57) significant effect on social dysfunction.

**p<0.01,*p<0.05

Moreover there is significant relation between somatic problems and depression at 0.01 level of significance (r=0.22). It is indicated that anxious feelings effect on social dysfunction, somatic problems and depression. Social dysfunctions like future uncertainty and difficulty to face the situations are creating pressure and stress and its lead to depression. Moreover somatic problems like head ache and stomach ache effect on depression. So all these mental health problems are inter related and it’s create mental illness during the lockdown period.

Conclusion

During the lockdown period, under Covid-19, brought huge change in our routine habits and in our life styles. People are facing many problems, due to non-availability of vegetables, milk and other domestic needs. The researcher collected data for about 20 days during the lock down period. In this study significant mental health problems attributed more in female than male folk. There is significant social dysfunction in female than male. Others (home makers, unemployed)
have workload at home and increase unemployment etc are creating social dysfunction. Middle age group i.e. (30-44) have more stress and pressure of future and job shortening are create depression.

Suggestions: The Social networks should not encourage “spreading of false rumors or news”.

The Social Networks should promptly and truthfully inform about Covid-19.

The Central/State Governments and The Police Department must actively counter the discriminatory attitudes and behaviors that emerge as a result of misrepresentations.

Accept the medical support provided by the state/central governments.

Need to introduce Psychological counseling services

Social support is very important to create confidence and to develop good mental health, well being, to avoid the fear among their public.

Abstract

Attention deficit/hyperactivity disorder (ADHD) is one of the common emotional, cognitive and behavioral disorder in primary school children and it affects on children socially and academically, welfare. An important role in identify of AD/HD due to their daily contact with students in a range of related situations. Basically, elementary school teachers’ need to knowledge and enhance their positive attitude on pupils with ADHD to create a positive learning environment. Consequently, the present investigator made an insight into the aim of the study as follows: to assess teachers’ Knowledge and attitude toward pupils with ADHD and to find out the correlation between knowledge of primary school teachers’ regarding ADHD. As well as to find out the relationship between the teachers’ knowledge and their demographic data. The study was conducted on at governmental primary schools at Al-Najaf City, Iraq. A total of the (10) governmental primary schools selected randomly from total (253) governmental primary schools in Al-Najaf City. A purposive (non-probability) sample of (70) primary school teachers’ were selected from the candidate schools were included in the present study. During the period of 1st September 2018 to 30th May 2019. The data was collected by questionnaire which consisted of two parts, first part consists socio demographic sheet. Second part is about knowledge and attitude which consist of (53) items scale of teachers’ knowledge and attitude about children with ADHD. In the present study. Findings revealed a poor in teachers’ knowledge of as well as satisfied responses attitude (negative)to pupils with AD/HD among elementary school teachers. Fondly the our main findings indicate that there is a significant positive correlation between the teachers’ knowledge and the teachers attitude toward children with AD/HD. And there is a significant relationship between demographic characteristics and do of knowledge for the sample such as: (age, education level, years of experience, main sources of information). Thus, it is recommended for responsible parties to notes the need for greater efforts to provide teacher training specifically in identifying and managing children with ADHD.

Keyword: Attention deficit/hyperactivity disorder (ADHD); Teachers; knowledge; Attitude; perception; Primary school.

Introduction

Early childhood is one of the most important stages of development in a person’s life, as the character begins to develop through the child’s interaction with the environment.¹ Mental process (attention), plays an important role in his intellectual development. Some of the children may have a deficit in their attention associated with hyperactivity. This condition may lead to them to do inappropriate behavior, the disorder is characterized by severe difficulties in one or more of the three regions; lack of attention, impulsivity and hyperactivity.² ADHD is one of the most behavioral disorders widespread among students affecting an estimated of 8% to 12% of school-aged children and impact roughly 1-2 students in each classroom over United States.³ The estimated of ADHD among elementary school children in Baghdad/Iraq is approximately 10%.⁴ In another recent study conducted in Najaf/Iraq on several primary school, the prevalence rate among children of school age was approximately 25% according to teacher reports.⁵ Given
that school teachers are often the first to notice behavioral difficulties in children, it is surprising that relatively little research has been done with teachers. According to the Diagnostic and Statistical Manual of Mental Disorders, Fifth Edition (DSM5), major types of AD/HD have been found including mostly ADHD presentation “ADHD-PI”, Hyperactivity disorder and attention deficit are often hyperactive, and this type is higher in females than in males. “ADHD-PHI”, this type we attribute to males is higher than for females and ADHD combined presentation Hyperactivity “ADHD-C”. Based on these results, the researcher suggested that comprehensive screening for other problems that occur with ADHD is important and treatment profiles should be tailored by comorbidity status and levels of functional impairment in school settings.

**Material and Method**

A descriptive analytic study was carried throughout present study to assessment of knowledge and attitudes toward attention deficit/hyperactivity disorders among primary schools’ teachers. The study is conducted from 1st September 2018 to 30th May 2019. A purposive (non-probability) sample of (70) primary school teachers’ were selected from the candidate schools were included in the present study. The study was conducted on at governmental primary schools in (northern and southern) of Al-Najaf City, Iraq. A total of the (10) governmental primary schools selected randomly from total (253) governmental primary schools in Al-Najaf City. Instruments used in the study are an assessment tools. The data are collected through the use of self administered technique as means for data collection, by using a questionnaire consists of three parts. First part socio-demographic; the second part contains Knowledge of Attention Deficit Disorder Scale -36- items developed by 8. To measure teachers’ knowledge and of perception on ADHD and part three, teachers’ attitudes scale (25-items) is a measure of attitude toward pupil with ADHD developed by9,18. The researcher adopted foreword/backward translation for the study scales (knowledge and attitude), i.e. the English version of the scales are translated into Arabic version and then an experts from the English specialty are selected to translate the Arabic version into an English one and to compare the two versions of English instruments. Some modifications are needed to complete the study instrument as the experts suggestions. After review and evaluation by the experts, reveal that the instrument has adequate content and major changes have been done such as number of alternative become multiple selection questions to all items according to their suggestions. Reliability of the questionnaire is determined through a pilot study and the validity is achieved through a panel of (22) experts. The data was described statistically and analyzed through use of the descriptive and inferential statistical analysis procedures.

**Results**

This figure shows that the participants’ experience varied from 11-21 years of experience (38.60 %, n=27).

![Figure 1. Distribution of the sample of the study according to their experience.](image)

This figure shows that the participants 10 or less years of experience (38.60%).
Figure 2. The main source of information about ADHD.

This figure shows that 24.7% and (11.4%), their information obtained from the Internet and social media.

The study results shows a significant association between teachers’ knowledge with age, their education level, years of experience and main Sources of information source information at p-value less than 0.05.

Discussion

The carried result revealed most of the teachers were a young age (31-40) years old category. This finding reflect two important approach, one, young teachers’ has been found to be challenging for the attentional and meta cognitive capacities of most primary school pupils. This is similar to the results of,10 entitled “Effect educational program on elementary school teachers knowledge, attitude and classroom management techniques regards ADHD”, who found that the most ages of teachers were at (31-40) years old. The results of this study show that the majority of participants’ teaching experience of study sample were at 10 or less years,(38.6%) (Figure 1). This result of the study was do not agree with the study11, who found more than one third (46.7%) of them had more than 15 years teaching experience. Regarding the main sources of acquiring information about ADHD, the present study showed that 24.7% of teachers acquired knowledge about ADHD from the Internet followed by 11.4% from social media and (10%) from television programs (Figure 2). This result reflects the tremendous availability of information on the internet in this era, however, reliance on the internet as a source of information is not appropriate, as all information available online is not from original sources and when it comes to information about the disease, one must be careful.13. (Table 1,2)Distribution of the sample regarding total Knowledge and total attitude about ADHD. The result of the study revealed that most of the participants have poor knowledge and negative satisfied attitude toward pupils with ADHD. Recently, several studies conducted that this result may be due to the teachers not knowing about this disease and how to deal with the child who suffers from it and it cannot appreciate its importance, so the child neglects. Probably, The shortfall in the quality of teacher preparation and standards in Iraq, which makes it difficult in completing the assessment schedules that professionals need in the diagnosis of ADHD, it is necessary to fully know the characteristics and criteria of ADHD as a neurobiological disorder. Several studies,13,12,15, found that the study reveals that most of the teachers’ had poor knowledge regarding general information of ADHD as well as inadequate knowledge about general information and symptom diagnosis and, treatment, teachers scores on KADDS were poor (knowledge general information domain (57%); symptom diagnosis domain (59.1%) and treatment domain 63%), pointing to a significant lack of knowledge about ADHD. Second, teachers’ level of knowledge of ADHD correlated positively with their level of confidence in teaching a student with ADHD. Third, teachers level of knowledge of ADHD was positively related to their prior training about ADHD. (Table 3). Fondly the our main findings indicate that there is a significant positive correlation between the teachers’ knowledge and the teachers attitude (r = 0.468, P<0.0001). Because teachers with better knowledge, As we expected, the teachers could be less negative attitudes towards ADHD. This result is congruent with a large group of research studies such as the one by13, “Knowledge and attitude of male primary school teachers about ADHD in Riyadh, Saudi Arabia”, reported the significant correlation between a teacher’s knowledge and attendance of a structured training.
course, attendance of structured training courses affected the teacher’s knowledge and attitude toward pupils with ADHD. Moreover, it found that there was a significant positive correlation between knowledge and attitude. Also, “Teachers’ perception and attitudes toward ADHD in primary school”. Their findings indicate that there is a significant correlation between the teachers’ knowledge and the teachers attitude \( (r=0.249 \text{ and } P=0.000^*) \). Table (4). The study results show a significant association between teachers’ knowledge with age, education level, years of experience and main Sources of information source information at p-value less than 0.05. Perhaps, many younger teachers using a new train for knowledge and culture such as I pad and pc computer technology making them more acceptable for education program than older teachers. This result was supported by, “who to the study examines and compares general and special education teachers’ knowledge and misconceptions about ADHD. In addition, it seeks to investigate the role of specific demographic variables. They found that “statistically significant relation between teachers’ knowledge and their age. The finding of this study contradicts that of, who found that education level of teachers did not have significant influence over their knowledge of ADHD. While the finding of this study asserted that of, who found that the education level of teachers did have a significant influence on the knowledge and attitude of primary school teachers towards pupils with ADHD, teachers’ attitudes towards ADHD children are already sufficient because they often meet with their students and know the best way to deal with them. This result agrees with, after teachers gain classroom experience, the study recommended that knowledge of ADHD develops rather than during their education, classroom experience may evoke greater knowledge of ADHD due to contact with pupils who have ADHD, in-service training on ADHD and information gained from parents, other teachers, or individual study. Conclusion: A poor in teachers’ knowledge of as well as satisfied responses attitude (negative) to pupils with AD/HD among elementary school teachers. Fondly the our main findings indicate that there is a significant positive correlation between the teachers’ knowledge and the teachers attitude toward children with AD/HD. And there is a significant relationship between demographic characteristics and do of knowledge for the sample such as: (age, education level, years of experience, main sources of information). Thus, it is recommended for responsible parties to notes the need for greater efforts to provide teacher training specifically in identifying and managing children with ADHD. At least one, the teachers should participate in a training session about how to dealing with children suffer from ADHD. A mass media approaches should be used in population in order to increasing the teachers’ knowledge and enhance their attitude about the ADHD.

Feasibility of Activating Electronic Health Care System in Ibn Rushed Hospital

Hassan Naeem Kareem¹, Lujain Anwer Abood²

¹PhD Student/Community Health Nursing Department/College of Nursing–University of Baghdad/Iraq, ²Assistant Professor/Community Medicine Department/College of Al-kindiy Medicin–University of Baghdad/Iraq

Abstract

A descriptive study was conducted on health care providers them use electronic health care system and patients or clients in Ibn Rushed Teaching Hospital in Baghdad-Iraq. To evaluate the feasibility of activating electronic health care system, Data was collected using a developed self-administrated questionnaire; data was collected from March 20th, 2019 to May 6th 2019.

A purposive sample (non-probability sample) were selected (N=115) the study sample was divided into two parts, the first part is healthcare providers and their number (65), the number of physicians is (32) and the number of nurses is (33). The second part of the sample is patients or clients and their number (50).

Data were analyzed through the application of descriptive and inferential statistical approaches by using Statistical Package for Social Science (SPSS) version 19.

For health care providers, the findings for revealed that most of the respondents were males with age’s range from (31 to 39) years old, most of the respondents were physicians with (8 to 17) years’ experience. Most of the responses regarding of feasibility of activating electronic health care system, there are feasibility from activating electronic health care system (83%).

As for results patients and clients Most of the respondents were males with age’s range from (35 to 55) years old, level education for respondents were Primary and Preparatory education. Most of the responses regarding of feasibility of activating electronic health care system, there are feasibility from activating electronic health care system (90%).

The study recommended the government should be well informed about the benefits and latest innovation in e-Health so as to encourage appropriate allocation of budget, so that e-Health policy implementation can be taken more seriously. Highly recommendation the Ministry of Health to impose and generalize the experience of the electronic health care system in all hospitals in the country. Highly recommended that the educational sector inculcate e-Health into the curriculum for the integration of IT solutions into healthcare to flow successfully, this will provide health care givers graduating from learning institutions systemic training and education on the use of the e-Health. Recommended for further studies to adopt both quantitative and qualitative research approaches in similar studies to generate more responses from participants. This would help reveal whether or not the intended benefits of the implemented E-Health to patients are actually realized.

Keywords: Feasibility, electronic health care system.

Introduction

Electronic health (E-Health) is one of the 21st century innovations in healthcare. It is an umbrella term, which portrays the joined utilization of electronic correspondence and data innovation in the health/wellbeing division as well as the use of digital data transmitted, stored and recovered electronically for clinical, educational and administrative purposes, both at the local site and at distance². Since the inauguration of e-health, it has transformed the healthcare sector
and embraced it’s description by Intel as a concerted effort undertaken by leaders in health care and hi-tech industries to fully harness the benefits available through convergence of the Internet and health care (2). E-Health or health information technology (IT) as the case may be has the potential to improve the health of individuals and the performance of providers, yielding improved quality, cost savings and greater engagement by patients in their own health care (3).

E-Health is the use of information and communication technologies (ICT) for health as defined by the World Health Organization (WHO). E-Health has been a priority for the World Health Organization (WHO) since 2005, when the World Health Assembly resolution WHA58.28 was adopted: “e-Health is the cost-effective and secure use of information communication technologies (ICT) in support of health and health related fields, including health-care services, health surveillance, health literature and health education, knowledge and research” (4).

**Methodology**

A descriptive study was conducted on health care providers them use electronic health care system and patients or clients in Ibn Rushed Teaching Hospital in Baghdad-Iraq. To evaluate the feasibility of activating electronic health care system, Data was collected using a developed self-administrated questionnaire; data was collected from March 20th, 2019 to May 6th 2019.

The tool of the study is the questionnaire, which has been constructed and design for the purpose of the study after extensive reviews of available literature and related studies. The study instrument consists of two parts. The first part includes health care providers questionnaire, the second part includes patients or clients questionnaire, A purposive sample (non-probability sample) were selected (N=115) the study sample was divided into two parts, the first part is healthcare providers and their number (65), the number of physicians is (32) and the number of nurses is (33). The second part of the sample is patients or clients and their number (50).

Data were analyzed through the application of descriptive and inferential statistical approaches by using Statistical Package for Social Science (SPSS) version 19.

This table show that the study results that indicate overall assessment for the responses of study samples are most of their responses about feasibility domain is feasibility (83%) for healthcare providers about application of electronic health system.
Discussion

The study finding depict overall assessment of responses for study samples were most of their responses (clients or patients) about feasibility domain was there is feasibility about for application of electronic health system. A similar study that indicates the impact of e-Health technologies more effectively, a fresh way of thinking is required about how technology can be used to innovate health care through application e-health that increase feasibility and quality of health care services (5). Other study is consistence with the current study that indicate feasibility and quality of health care by use electronic health system as Moreover, eight RCTs found improvement in patient symptoms following e-Health tool use, especially in adolescent asthma patients. Furthermore, three RCTs showed that e-Health tools might improve patient self-efficacy and self-management of chronic disease. Little or no evidence was found to support the effectiveness of e-Health tools at improving medication recommendations and reconciliation by clinicians, medication-use behavior, health service utilization, adverse effects, quality of life, or patient satisfaction(6).

The study results that indicate overall assessment about the sample responses (health care providers) about feasibility domain was there is feasibility for application of electronic health system. These finding is consistence with that found use of e-Health requires a certain degree of technical proficiency from both health care professionals(7).

Conclusions

Conclusions for patients and clients results, most of the respondents were males with age’s range from (35 to 55) years old and with Primary and Preparatory education. Nearly all participants found that activating electronic health care system were feasibility.

As for Conclusions for health care providers results, most of the respondents were males with age’s range from (31 to 39) years old, most of the respondents were physicians with (8 to 17) years’ experience. Most of the participants found that activating electronic health care system was feasibility.

Abstract

COVID 19 or CORONA as we know it has not only become a global pandemic but a real threat to humanity which is proving itself as a third world war for the world. Everyone is talking about the basic preventive measures for fighting with this situation let it be proper hygiene, social distancing or allied healthcare measures. The basic symptoms of the covid-19 patients, the virus attacks healthy as well as immune-compromised individuals. The onset of virus starts from inhalation of droplets impregnated with virus which shows its effect on larynx and via it, progresses to lungs covering the respiratory system causing acute respiratory infections. Once in lungs it makes it as a strong hold on ground for further deterioration of immunity and respiratory functions which leads to fatal conditions like pneumonia acute respiratory distress syndromes. Now if by various respiratory physiotherapeutic practices if we can increase the strength of lungs it can actually increase the recovery of the patients with the aim of maintaining the bronchial hygiene and strengthening the respiratory muscles at various stages. Bronchial toileting, positioning can be helpful in dealing with complications like pneumonia and ARDS, where pursed lip breathing and ACBT can be helpful in dealing with breathlessness in early stages.

Keywords: COVID 19, Pneumonia, ARDS, Bronchial toileting, Positioning, Pursed lip Breathing, ACBT.

Introduction

The recent COVID -19 outbreaks has been declared as the global health emergency, India till date has already registered 909 covid-19 positive cases with 19 deaths and 40 cured cases¹. Indian government has taken various preventive measures against the virus and has taken a major step by locking down the whole country. Still we are getting various positive cases of covid-19¹. India is at a brink of entering at tertiary level. Various preventive measures for the people in India and intervention are getting implemented with the cases who are positive COVID 19. Since the complications of COVID 19 affects directly the respiratory system it has become important that the few strong measures should be highlighted for prevention and rehabilitation.

Method

Various international research articles have been reviewed for this study so that a standard protocol for the intervention of respiratory care should be inoculated as well as to establish the importance of respiratory therapy as the preventive measure.

Findings: The incubation period of covid-19 is from 1 day to 14th day the symptoms which are initially seen are fever, sore throat, dry cough, breathlessness and headache. The cases which have been resolved spontaneously are the one who were not having any secondary issues like diabetes, hypertension, any renal diseases, or who were not immune-suppressed³. However rest of them who are undergoing fatal complications like organ failure, septic shock, pneumonia & acute respiratory distress syndrome. Notably people who intensive care, are with multiple co morbidities including cerebro-vascular diseases, cardiovascular diseases and endocrine disease, digestive and respiratory disease⁴. More symptoms which were reported from ICU are severe dyspnoea, dizziness, anorexia and abdominal pain⁴. Few doctors from the city Jaipur, Rajasthan has
treated the patients with drugs used in HIV and they found it to be useful as no effective anti-viral treatment for covid-19 is available or researched till now. Whole community of doctors and pharmacist are rigorously researching for antidote of covid-19. On a temporary note the doctors are treating patients symptomatically via anti pyretic therapy, cough expectorants for non productive cough. Broad spectrum antibiotics are used in cases diagnosed with sepsis post covid-19 within an hour. Patients are also reporting with various fungal & bacterial infections are also treated with the same protocol.

According to World Health Organization acute respiratory syndrome is the first sign along with temperature => 38 degree Celsius(1). Preventive measures which taken are social distancing and regular hand hygiene where nobody is talking about bronchial hygiene. By maintaining bronchial hygiene we can save the patient from being collapsing(7).

Preventive measures in medical setups are nearest distance is 2 meters for 15 minutes as such patients are recorded with the temperature of more than 38 degree Celsius. No passive bronchial toileting can be indicated in acute respiratory infection or acute stages of patients with covid-19 pursed lip breathing (where the patient is asked to purse his lips and to breathe in via nose and exhale with the pursed lips), positioning and relaxation technique can help patient with symptoms of shortness of breath(7,9).

The Active Cycle of Breathing Technique consisted of 4–6 breathing control breaths, 3–4 thoracic expansion exercises and the forced expiration technique including 4–6 breathing control breaths combined with 2–3 huffs followed by cough(11). It can also be used as a respiratory therapy if the patient is in condition to perform as it has proved as a great measure to deal with respiratory failure(10), it can be a preventive measure for further stages of covid-19.

Where as in pneumonia along with covid-19 in acute stages bronchial drainage is contra indicated, the patient being ill & lung being totally consolidated and unproductive(7). Breathing exercises to maintain maximum ventilation in all areas of lung plus foot exercises (ankle pump) can be useful(12). Once entered the hepatization stage physiotherapy is to aid in cleaning the exudates is required(7).

In cases with ARDS of covid-19 frequent changes of positioning must be used in order to bring improvement in ventilation/perfusion ratio in certain parts of lungs and to prevent prolong dependency on any one section of lung(7). This improvement is only temporary but often leads to temporary improvement in oxygenation(7). Few study also have documented that prone positions significantly increase oxygenation and decrease driving pressure in patients with ARDS(13).

In general people can use various breathing exercise which can help in maintaining the bronchial hygiene and strength of respiratory system on a daily basis which will be a preventive measure on a larger note(8).

**Conclusion**

In such unprecedented situations which the whole world is facing, we as a developing country not only have to work on our primary health care system but simultaneously we have to develop the second line of health defense measures so that we not only reduces the risk of primary infections but also strengthen the respiratory system to fight this virus effectively in case one get infected be it a healthy individual or a immune-compromised one.

Exploring the Factors Responsible for Delay in Delivery of Justice in India

Hiranmaya Nanda¹, Shyamantak Misra²

¹Assistant Professor, Faculty of Legal Studies, Siksha ‘O’Anusandhan University, Bhubaneswar-751003, Odisha, India, ²Research Scholar, KIIT School Of Law, Bhubaneswar-751004, Odisha

Abstract

Albert Einstein once said in relation to justice that, “in matters of truth and justice, there is no difference between large and small problems, for issues concerning the treatment of people are all the same”. The Preamble of the constitution of India states that,“We, the People of India having solemnly resolved to constitute India into a Sovereign, Socialist, Secular, Democratic, Republic and to secure to all its citizens; Justice, social, economic, political;Liberty of thought, expression, belief, faith and worship;Equality of status and opportunity; and to promote among them all;Fraternity, assuring the dignity of the individual and the unity and integrity of the nation.” But still after so many years of Independence we have several rules, regulations and mechanisms but those are not adequate to give justice. The establishing father of our constitution placed Justice at the highest level and India is considered to be the largest democracy still we are not getting fair justice. It is a still remain a demand and need to be resolved soon.

Keyword: Delay, Justice, Judiciary, Case Backlogs, Pendency.

Introduction

The Judiciary of India time and again emphasized the significance of the timely delivery of justice. The Supreme Court of India made it eloquent many years ago that “speedy trial is of essence to criminal justice and there can be no doubt that the delay in trial by itself constitutes denial of justice”.¹ In this research article the author after having extensive review of literature has identified and discussed with the help of supporting case laws and views of the judiciary few factors for causing delay in delivery of justice. They are as follows:

1. Delay in disposing cases is a hindrance to good governance, moral integrity and deterioration in standard of public life.

2. Practicing Advocates are the principal agents in causing the delay in delivery of justice.

3. Procedural laws create the scope for delay in disposal of cases.

4. Lack of adequate infrastructure (both physical and man power) is responsible for delay in disposal of cases.

5. Justice delivery system and rights of the individual are not supplementary to each other.

Good governance, moral integrity and deterioration in standard of public life: The first contention which states that, “Delay in disposing cases is a hindrance to good governance, moral integrity and deterioration in standard of public life.” There is a famous quote that, “Justice delayed is Justice denied”. This quote has no meaning if it cannot be given in proper time. At the same time, it is exposes that, if justice cannot be rendered on time what would be the use of such a multifaceted judicial system. Justice V D Tulzapurkar of the Supreme Courts has observed that, “if an independent judiciary is regarded as the heart of a republic, then the Indian republic is at present suffering from serious hear aliment.
In fact, the superior judiciary of the country has of late been under constant onslaughts, external as well as internal which are bound to cripple the health, welfare and progress of our body politic, as an ailing heart cannot ensure vigorous blood supply for the sound health of its people.” Thus a very perilous question arises is the faith in judiciary which is being condensed by the public because it affects the governance and standard of public life.

In the words of Dr. Cyrus Das “Justice is a consumer product and must therefore meet the test of confidence, reliability and dependability like any other product if it is to survive market scrutiny.2 It exists for the citizenry, ‘at whose service only the system of justice must work’. Judicial responsibility, accountability and independence are in every sense inseparable. They are and must be, embodied in the institution of the judiciary.” Now a day to get justice has become a dream of a litigant. Even though he gets it, it is not in his life, it may come after his life. This syndrome of getting justice is taking the judiciary far away from the faith and public life and creating a hindrance for good governance. In the landmark case, popularly known as Uphaar Tragedy Case, it took six years to establish that, 59 people have lost their life and more than 100 people have injured out of criminal negligence on the part of the cinema management and the Delhi Government. There are series of cases where prolonged delay defeats justice. Some of them are, in Safdar Hasmi Murder Case, for example, who was killed by political opponents, the criminals were punished after a long 15 years. In Tanduri Murder Case, the accused a Delhi Congress Leader Susil Sarma was convicted with death sentence after long 8 years 6 months. In Model Jesicalal Murder Case and Madhumita Sarma Murder Case, the accused persons were punished and justice rendered to the victims after a long legal scuffle.

**Role of Practicing Advocates:** The next important contention is “Practicing Advocates are the principal agents in causing the delay in delivery of justice.” The role of lawyers is the most imperative aspect in the justice delivery system. The strength and the promises of these legal professionals can make a revolution in the whole set-up. Regrettably, they are prominently responsible for triggering delay in the justice delivery system. There are many reasons such as “firstly they are not precise; they indulge in lengthy oral arguments just to impress their clients, secondly they take adjournments on frivolous grounds. The reasons range from death of the distant relative to family celebrations. With every adjournment the process becomes costly for the court and for the litigants; but the Lawyers get paid for their time and appearance. More often than not, lawyers are busy in another court. They have taken up more cases than they can handle, hence, adjournments are frequently sought. Thirdly many times it is seen that, lawyers do not prepare their cases. A better preparation of the brief is bound to increase the efficiency of the system. Fourthly, it is a trend that lawyers often resort to strikes. The reasons could be any-it ranges from misbehaviour with their colleague both inside court and outside the court to implementation of some enactment. The strike by lawyers against the decision of the government to enforce an amendment in the Civil Procedure Code is an example. This was very unfortunate because the main objective behind these amendments was to curtail delays in disposal of cases. However, the Supreme Court’s Judgement in Harish Uppals v Union of India, that lawyer had no right to go on strike or give a call for boycott not even a token strike, will certainly discourage the lawyer to go on strike unless they really had a strong cause.” Gandhiji has also in several times given light in these issues, in his words “throughout my career at the bar I never once departed from the strictest truth and honesty. The first thing which you must always bear in mind, if you would spiritualize the practice of law, is not to make your profession subservient to the interests of your purse, as is unfortunately but too often the case at present, but to use your profession for the service of your country. The fees charged by lawyers are unconscionable everywhere. I confess, I myself have charged what I would now call high fees. But even whilst I was engaged in my practice, let me tell you I never let my profession stand in the way of my public service. And there is another thing I would like to warn you against. In England, in South Africa, almost everywhere I have found that in the practice of their profession Lawyers are consciously or unconsciously ‘led into untruth for the sake of their clients. An eminent English Lawyer has gone so far as to say that it may even be the duty of a lawyer to defend a client whom he knows to be guilty. There I disagree. The duty of a lawyer is always to place before the judges and to help them to arrive at, the truth, never to prove the guilty as innocent (Young India, 22-12-1927).” Lord Denning also observed that, “the real reason for delay of lawyers is not slackness or dilatoriness, They are as a class most hardworking of all professional men. It often lies in their choice of priorities. Each case is important and must be dealt with. Each letter must be answered the same day...
or at any rate the next. A sudden call puts something else out of mind (Due Process of Law, 1980 edn. p. 89).” Therefore, the need of the hour is that, the lawyers must prove themselves to be the duty bound citizen of India by curing the diseases that are spread in the judiciary.

**Old Procedural laws:** Another important contention is “Procedural laws create the scope for delay in disposal of cases.” There are mainly two types of laws Substantive laws and Procedural Laws. The Substantive laws express the rights and liabilities. Nonetheless the procedural laws provide the instrument to implement these rights and liabilities. There are many laws still in force which are drafted since more than hundred years back. With present pace of the time and society those old laws are not getting their momentum to dispense and creating the biggest blockages in the whole judicial process. Therefore, the valuable time of the court is wasted on the arguments of jurisdiction, cause of action, sufficiency of notice, amendments of plaint and other procedural matters. The Law Commission of India has also time and again have highlighted this major problem through its 14th, 27th, 41st, 48th, 54th, 71st, 74th, 77th, 79th & 144th report for necessary reforms in the legislations. Moreover, there are certain difficult terms used in the legislation which is difficult to interpret and understand. Sometimes the judiciary takes time to construct the actual meaning of the term used in the legislation. Hence procedural laws need to be simplified, howsoever good the substantive laws may be to define the rights and liabilities but it won’t be fruitful if procedural rules are not simplified. The complexity and rigidity of the procedural laws are the pivotal reason the delay in judicial process. Our varied philosophies, languages, customary practises, religions, apparent in a variation of cases create an intimidating mission before the Judiciary. Adding to it, the statutes are so abundant and slackly drafted, ambiguous and capable of a manufacturing hundreds of interpretations.

**Inadequacy of Infrastructure:** Further, it is to be noted that “Lack of adequate infrastructure (both physical and man power) is responsible for delay in disposal of cases.” The next factor for delay is the inadequacy of judicial infrastructure in physical as well as in the judicial human resources. From the Ministry of Law and Justice, the data published which evident that, before the Supreme Court of India the approved strength is 31 but 25 numbers of Judges are working creating 6 vacant posts, in all the high courts the approved strength is 1079 but only 676 numbers of judges are working creating 403 numbers of vacant posts (Ministry of Law and Justice, Report Published, Vacancy as on, 01.02.2018). This crisis in judiciary is rising from time to time. Many times it has been advocated by law commission reports and through judicial statistics of annual reports, Judicial reform committees that, the strength of the judiciary can be increased by filling up the vacant post and also recruiting more numbers of judges to deal with overloaded case docket. But in a situation where even the prevailing approved strength is not filled to the maximum then obviously there will be a docket explosion with backlog of cases. It would be relevant to mention that as per the Constitutional structure of India, the selection and recruitment of judges in subordinate courts is the responsibility of State Governments and High Courts.

The Supreme Court has discussed and delivered in a series of cases highlighting this subject. This includes, *All India Judges Association Case*, where the Supreme Court directed that, “the number of judges should be increased, in the first instance by filling up the existing vacancies followed by an increase in the judge strength in a phased manner.” In an another case, *Malik Mazhar Sultan Case*, the Supreme Court “devised a process and time schedule to be followed by the High Courts and State Governments for the filling up of judicial vacancies.” The Supreme Court has issued a direction in the *Brij Mohan Lal Case* demanding that 10% added posts should be generated in the subordinate courts of judiciary.

The next vitiating element under this hypothesis is judicial infrastructure. The judiciary in India, mainly the subordinate judiciary are facing more trouble by existing infrastructure they are provided for dispensing of justice. As per the statistics collected from the various High Courts (As of June, 2014), there were 15,419 numbers of court halls or court rooms available for district and subordinate judiciary. Adding to it, 1003 numbers of court rooms were accessible in hired buildings. Now it is high time to relocate adequate judicial infrastructure as per the need system. This necessity is closely connected to the allocation of budgetary planning for the judiciary. The state is also required to make some eye marked steps by making judiciary even more powerful.

**Rights and Justice:** It is pertinent to mention here that “Justice delivery system and rights of the individual are not supplementary to each other.” The justice delivery system is dependent upon the
governance of a country. This ‘governance’ literally means steering. It refers to the processes and systems by which an organization or society operates; the processes by which decisions are made that define expectations, grant power, or verify performance. The duty is not only with judiciary but it also with the legislatures and the executives. A litigant in the whole process got squeezed and ruined by the intimidating factors. Former Chief Justice P N Bhagwati has said that, “I am pained to observe that the judicial system in the country on the verge of collapse. Our judicial system is crashing under the weight of arrears. It is trite saying that justice delayed in justice denied. We often utter this platitudeous phrase to express our indignation at the delay in disposal of cases but this indignation is only at an intellectual and superficial level. Those who are seeking justice in our own Courts have to wait patiently for year and years to gets justice. They have to pass through the labyrinth of one Court to another until their patience gets exhausted and they give up hope in utter despair. The only persons who benefit by the delay in our Courts are the dishonest who can with impunity avoid carrying out their legal obligations for years and each affluent person who obtains orders and stays or injunctions against Government and public authorities and then continues to enjoy the benefits of such stay or injunction for years, often at the cost of public interest.”

The constitutional mandate of safeguarding to all its citizens justice, social, economic and political, as guaranteed by the Preamble of the Constitution cannot be appreciated unless the three wings of the government i.e. legislature, executive and judiciary join together to find ways and means for providing to the citizens equal access to its justice delivery system. It is very common that in a criminal case to drag on for years the accused travels from the zone of “anguish” to the zone of “sympathy”. The witnesses are either won over by muscle or money power or they become sympathetic to the accused. As a result, they turn hostile and prosecution fails which certainly defeats the justice to the victims. Judiciary today is more deserving of public confidence than ever before. The judiciary has a special role to play in the task of achieving socio-economic goals enshrined in the Constitution while maintaining their aloofness and independence. The whole justice delivery system should be aware of the social changes in the task of achieving socio-economic justice for the people so that there will be reciprocity in rights and justices.

**Conclusion**

Justice-social, economic and political is a preambular principle of the Constitution of India. The pledge of equality before the law and equal protection of law lies at the spirit and heart of the judicial administration system. The judiciary is a co-equal stem of governance within the framework of the constitution and the courts are formed not only to deliver judgments or to adjudicate disputes between disputant parties, but also often designate normative doctrine in which institutions are bound by. These doctrines are not merely formulated, but recurrently redefined and adapted to suit changing times, even while assuring that, the hub Constitutional morals are avowed.

**Ethical Clearance:** Not required, as the research article is based on origin of factors responsible for delay in delivery of justice. The research is doctrinally undertaken.

Nursing Students’ Awareness, Knowledge and Attitudes on Child Abuse

Hyun-Jung Kim¹, Dahye Park²

¹Professor, Department of Nursing, Daewon University College, Jecheon-si, Chungbuk, 27135, Korea,
²Professor, Department of Nursing, Semyung University, Jecheon-si, Chungbuk, 27136, Korea

Abstract

Background/Objectives: This study was designed to explore nursing students’ awareness, knowledge, attitude on child abuse.

Method/Statistical analysis: The descriptive research design was conducted by administering online questionnaire to 299 nursing students at two university in J city. Data analysis was performed using SPSS WIN 25.0 program.

Findings: The mean scores of child abuse awareness, knowledge and attitude were 175.42±10.69, 3.89±1.83 and 28.94±6.57 respectively. Awareness, knowledge and attitude on child abuse were significantly positively correlated. In addition, the number of education on child abuse was positively correlated with awareness, knowledge and attitude on child abuse. Factors influencing child abuse attitude were frequency of child abuse education, awareness and knowledge (R² = .222).

Improvements/Applications: Based on this results, the development of education programs and guidelines to help nursing students detect child abuse and improve reporting rates is important. Thus, we suggest that nursing students be provided with educational protocol for detection, including report of child abuse.

Keywords: Child Abuse, Awareness, Knowledge, Attitudes, Nursing Students.

Introduction

In recent years, the number of child abuse cases has increased steadily with a total of 33,532 cases of suspected child abuse reported by 60 child protection agencies nationwide in 2018[1]. To prevent child abuse, which is continuously increasing, early detection of abuse cases can be the best way to save children from the greater damage. As the preventive measure against child abuse, the government is trying to find and protect abused children early and as part of this, the reporting system of child abuse can be found[2]. Reports by person in occupations that are likely to discover child abuse play an important role in prevention of child abuse[3].

Nurses are included in the report duty of 24 occupations specified in the Special Act on Punishment of Child Abuse Crimes, etc.and are obliged to report to child protection agencies or investigation agencies if they become aware or suspect of child abuse crimes while performing their duties[4]. In particular, nurses frequently come into contact with children of all ages due to their special characteristics such as immunization, growth test and development evaluation. Therefore, they should play the most important role in identifying and reporting abuse among occupations of reporters[5].

It has been reported that the obstacles that hinder child abuse reporting are the symptoms and signs of abuse or lack of knowledge of the reporting process and
legal process\textsuperscript{[6]}, attitudes that it was not serious enough to report or not help\textsuperscript{[7,8]} and perceptions such as the thought that it will have a negative effect on parents or children and that parenting is the parent’s own authority and cannot be interfered with\textsuperscript{[9,10]} are preventing report.

Even in this situation, education and guidelines on child abuse for nurses are insufficient. This condition is due to the lack of clear agreement on the role of nurses in child protection and prevention of abuse, as well as the limited view that the role is still needed only at the individual level or in some areas of care. However, considering that all nurses, as well as nurses specialized in child care, are required to report child abuse and this duty is one of the important roles of nurses, it is urgent to provide education and guidance for nurses. In addition, the need for accurate education should be further emphasized to consider that the reason for the low report rate of nurses is that they do not accurately identify abused children and that they are afraid of legal liability.

Nursing students as well as nurses should be subject to systematic education of child abuse. Therefore, we intend to use this study as a basis for improving awareness and early detection of child abuse and to prepare the basic data for education of nursing students.

The purpose of the study is as follows.

- To grasp the general characteristics of nursing students
- To grasp awareness, knowledge and attitudes on child abuse by nursing students.
- To grasp perception, knowledge and attitudes of child abuse according to the general characteristics of nursing students.
- To grasp the correlation between child abuse awareness, knowledge and attitude of nursing students.
- To identify the factors influencing the attitude of child abuse in nursing students.

**Method**

**Research Method:** This study is a descriptive research study to confirm perception, knowledge and attitude on child abuse in nursing students.

**Data collection:** The period of data collection was from February 15 to March 13, 2020. The online survey was conducted for 299 nursing college students who understood the purpose of the study and agreed to participate. For ethical consideration of the study subjects, data was collected after approval through the deliberation (IRB No: D **-2020-01-004-02) of Institutional Review Board (IRB) of D university. In addition, approval for using the tool in the study was obtained from its developer. The research assistant without conflict of interest explained the purpose, the method, the outcome and the potential problems of the study to the subjects and explained that they may wish to remain anonymous and refuse to participate if they do not. The survey was conducted after obtaining the informed consent from subjects who agreed to participate in the study and the complimentary product was provided in return.

**Research Tools:** The survey consisted of general characteristics and child abuse perception (38 questions)\textsuperscript{[11]}, knowledge (13 questions)\textsuperscript{[12]} and attitude (11 questions)\textsuperscript{[13]}.

**Awareness of Child Abuse:** In order to grasp the awareness of child abuse among college students, the child abuse awareness tool developed by Korea Institute for Health and Social Affairs (KIHASA) was used\textsuperscript{[11]}. This tool consists of 12 questions of physical abuse, 9 questions of mental abuse, 10 questions of neglect and 7 questions of sexual abuse. In addition, the higher the score from 0 “not abuse at all” to 4 “definite abuse” on 5-point Likert scale, the higher the awareness of child abuse. At the time of development, the tool’s Cronbach’s $\alpha$ was .95 and the tool’s Cronbach’s was 89 for this study.

**Knowledge of Child Abuse:** The knowledge of child abuse was measured using the knowledge scale of the Child Abuse Report Intention Scale (CARIS), totaling 13 questions\textsuperscript{[12]}. For each question, one point was given only for the correct answer and if the answer was ‘I don’t know’ or the answer was incorrect, it was treated as an incorrect answer and given a score of 0, then the scores for the 13 questions were combined and used as the knowledge score. The Cronbach’s $\alpha$ of the original tool was .61 and the Cronbach’s $\alpha$ of the tool for this study was .63.

**Attitudes towards Child Abuse:** Questions about child abuse attitudes are whether you think positively or negatively about the act of reporting. The measurement was performed by the knowledge scale of Fraser et al.
total of 11 items\(^{13}\). The response method of each item was composed of 5-point Likert form (1 point= not at all, 5 points= very so) and the scores for 11 items were added and used as the attitude score. The Cronbach’s α was .84 for the original tool and .80 for the tool of this study.

**Data analysis:** The collected data were analyzed with SPSS 25.0 and general characteristics of the subjects were identified by frequency, percentage, mean and standard deviation. According to characteristics of the main variables, recognition, knowledge and attitude were analyzed by t-test and ANOVA while the post-test being analyzed by Scheffe’ test. The correlation between variables was obtained by Pearson’s correlation coefficients. The multiple regression analysis was used to identify the extent and factors affecting the attitudes of child abuse.

**Result**

**Subject’s general characteristics:** The study subjects were 45 (15.1%) male students and 254 (84.9%) female students. Religious subjects were 113 (37.8) and non-religious 186 (62.2%). 19 (6.4%) had child abuse experience and 106 (35.5%) had experience in child abuse education. There were significant differences in knowledge of child abuse according to gender (\( t = 4.52, P = 0.034 \)), but the remaining variables showed no significant differences [Table 1].

**Subject’s Perception, Knowledge and Attitude on Child Abuse:** The perception of child abuse in nursing college students got 4.61±0.28 points and the physical abuse 4.75±0.22 points, mental abuse 4.67±0.40 points, neglect 4.18±0.61 points and sexual abuse 4.91±0.18 points. Child abuse knowledge 3.89±1.83 points while attitude attaining 28.94±6.57 points [Table 2].

**Table 1. Differences in Awareness, Knowledge and Attitude on Child Abuse according to General Characteristics (N = 299)**

| Variables                  | Categories | n(%)  | Awareness |  | Knowledge |  | Attitude |
|----------------------------|------------|-------|-----------|  |           |  |          |
|                            |            |       | Mean±SD   | t/F (p) | Mean±SD   | t/F (p) | Mean±SD   | t/F (p) |
| Gender                     | Male       | 45(15.1) | 173.29±11.71 | 2.12(.146) | 4.42±2.36 | .05(.148) | 28.51±8.51 | .22(.636) |
|                            | Female     | 254(84.9) | 175.80±10.47 | 3.80±1.70 |           |           | 29.02±6.18 |          |
| Religion                   | Yes        | 113(37.8) | 176.69±10.97 | 2.55(.111) | 4.15±1.91 | .11(.111) | 29.17±7.36 | .21(.640) |
|                            | No         | 186(62.2) | 174.66±10.46 | 3.73±1.77 |           |           | 28.80±6.05 |          |
| Experience of being abused | Yes        | 19(6.4)  | 172.58±10.06 | 1.44(.231) | 3.79±1.78 | .06(.806) | 29.00±6.60 | 1.44(.231) |
|                            | No         | 280(93.6) | 175.62±10.72 | 3.90±1.83 |           |           | 28.94±6.58 |          |
| Experience of education    | Yes        | 106(35.5) | 176.92±11.22 | 3.21(.074) | 3.86±1.61 | .04(.828) | 29.24±6.23 | .33(.565) |
|                            | No         | 193(64.5) | 174.61±10.32 | 3.91±1.94 |           |           | 28.78±6.75 |          |
| Frequency of child abuse   | 0          | 195(65.2) | 174.73±10.35 | 3.92±1.94 |           |           | 28.72±6.75 |          |

Predicting factors of child abuse attitudes in subjects: The stepwise multiple regression analysis was conducted to identify the predictors of child abuse attitudes. As a result of the analysis, the number of education, the awareness and the knowledge were found to be influential variables in the attitude of child abuse. Especially, the number of child abuse education showed high F value. As a result of the final analysis, it was found that the number of education, the awareness and the knowledge accounted for 22.2% of attitudes toward child abuse ($R^2 .222, p < .001$) (Table 4).

Discussion

This study attempted to grasp awareness, knowledge and attitudes of child abuse in nursing students and to confirm the correlation between these variables. First, the child abuse awareness score was 175.42 points. Child abuse awareness is known to be influenced by gender, child abuse experience and child abuse prevention education[14,15]. In this study, it was found that the score was affected by gender. When analyzing child abuse perception by type, the perception of sexual abuse was the highest with the score of 4.91 out of 5, followed by physical abuse, mental abuse and neglect. The perception of child abuse also appeared in the same order as in the study of Ha[14] and Moon[15] using the same tool.

The level of knowledge on child abuse was 3.8 out of 13. Comprehensive research results of Lazenbatt and Freeman[6] for nurses show low overall knowledge of child abuse in nursing students. In addition, the ability to select abused children and the perception of professional content related to legal reporting systems were insufficient. Professional knowledge of child abuse with reporting method should be provided to nursing students as the systematic educational program.

The attitude on child abuse was 28.9 points. Nursing
students were found to have a high degree of professional responsibility for abused children. In other words, they tended to agree that they should advocate for abused children and that they should work to identify and discover abused children in clinical trials [10,13,16]. We need to avoid ambiguous decisions and make reporting more responsible by planning specific strategies for child abuse.

Recognition, knowledge and attitude showed the significant statistical correlation with education frequency as a result of examining the correlation result of child abuse awareness, knowledge, attitudes and the frequency of child abuse-related education. This result is similar to the one of the previous study [17], in which the number of education related to child abuse has the significant effect on attitudes. In this study, it can be confirmed that the attitude toward child abuse can be improved as the experience of education increases. In addition, the perception of child abuse showed the significant positive correlation with knowledge along with attitude. Considering the results of previous studies [17] that the prevention education of child abuse influenced knowledge and attitude through mediation of child abuse perception, education related to child abuse should be provided as the program that can increase the awareness of obligatory medical reporter and influence reporting.

Lastly, the number of education, the awareness and the knowledge about child abuse were influential variables as factors affecting the attitude of child abuse in nursing students. If these factors are considered, the development of the curriculum or the program related to the reporting obligation to prevent child abuse should be prepared in nursing college curriculum to correct knowledge and attitudes about child abuse.

**Conclusion**

This study explored perceptions, knowledge, attitudes and correlations of child abuse among pre-medical reporter, nursing students. The general characteristics of nursing students did not differ in their perceptions and attitudes toward child abuse. In the gender, the child abuse knowledge scores were significantly higher. The awareness of child abuse was highest in the order of sexual, physical, mental and neglect by type. The higher the number of child abuse education, the higher recognition, knowledge and attitude. In addition, the number of education, the awareness and the knowledge on child abuse were found to have the impact on child abuse attitudes.

This study was conducted on nursing college students and has limitations in the generalization of research results. However, the results of this study provide educational and practical usefulness to increase awareness, knowledge and attitudes of child abuse by preliminary medical reporters and the following suggestions are made. First, it is necessary to provide child abuse education repeatedly in the education process of preliminary medical reporter. Second, we suggest the follow-up study that compares and explores the differences and impacts of child abuse perceptions as well as reporting intentions in nurses and health teachers working in clinical practice.

**Ethical Clearance:** For ethical consideration of the study subjects, data was collected after approval through the deliberation (IRB No: D **-2020-01-004-02) of Institutional Review Board (IRB) of D university. The informed consent was obtained from the subjects before data collection. Confidentiality of data collected was ensured.

**Source of Funding:** Self-finance

**Conflict of Interest:** Nothing specific-can use the study findings with proper citation of authors name.

Health Promotion Strategy for Improving Men’s Participation in Family Planning Program in the Underdeveloped Areas, Borders and Islands and Poor Urban Areas

Indah Eka Novita¹, Lutfi Agus Salim²

¹Undergraduate Student in Department Biostatistic and Demography, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia, ²Associate Professor in Department Biostatistic and Demography, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia

Abstract

The participation of men in family planning in Indonesia is still very low, where the men who use the Medical Male Operations (MOP) method are only 0.2% while the condom use is 3.1% (IDHS 2017), Likewise in East Java only 3.7% of the total new KB participants in 2019. The conditions most in need of attention are in underdeveloped areas, borders, islands and poor areas, which are in dire need of appropriate strategic breakthroughs. The conditions most in need of attention are underdeveloped areas, borders, islands and poor areas, which are in need of appropriate strategic breakthroughs. Strengthen the advocacy efforts for new regional leaders so that the family planning program can continue to run in the regencies/cities without having to start from zero again, provide training to male family planning motivators so that the information provided to prospective acceptors is more detailed and accurate and follows up the results of training of medical personnel and midwives.

Keyword: Men’s participation in family planning, Health promotion strategies.

Introduction

The development of a nation is closely related to population problems. One indicator of the success of the nation’s development is said to be achieved if it is supported by the subject of development, namely residents who have optimal quantity and quality.¹

East Java Province is used as a pillar and a buffer for the implementation of the national family planning program which is run by all provinces in Indonesia. Even though it has been called a buffer zone, the challenges of implementing the family planning program remain.² The population of East Java which is predicted to reach 40 million this year and also the decentralized system is a small obstacle to the implementation of the program in East Java Province.³

FP programs that have been running for almost 40 years in Indonesia must pay more attention to the issues of justice and gender equality after the ratification of the Cairo Declaration.⁴ This certainly also had an impact on the family planning program. The level of family planning participation in general is still dominated by women. The number of male FP participation is still very low. The active participants of male birth control using the Medical Operation Method for men (MOP) are only 0.2% while the use of condoms is 3.1% while in East Java the numbers are only 3.7% of the total new FP participants until November 2019. Thus the number of male family planning participation in the province of East Java is still low.

In order to deal with the problem of male birth control, the BKKBN has a Directorate of Family Planning Participation in the Regional Path and Special Targets. This directorate was formed to increase male participation in family planning programs and also reach special areas that are included in underdeveloped, border and island areas and also urban poor areas.⁵

Based on the various reasons above, an analysis of the Family Planning Program for Men in Underdeveloped, Border and Islands and urban poor areas is needed in the BKKBN Representative of East Java Province to
see efforts to increase the participation of male family planning, especially in the province of East Java.

**Method**

This research uses quantitative research method with a secondary data analysis approach. This study uses data sourced from the BKKBN monthly report and also the policy for the implementation of the BKKBN Men’s FP. Analysis was also carried out on policies relating to the implementation of male birth control in East Java, specifically at Underdeveloped, Border and Island areas (UABI) and also urban poor areas.

---

**Result**

**Overview of Achievement of Men’s FP Program in Underdeveloped, Border and Islands and Urban Poor Areas in East Java Province:** As one of the buffer zones of family planning programs in Indonesia, East Java Province through its BKKBN Representative routinely reports on the achievements of the program each month, including the Male FP program.

![Figure 1: Trends in Active Family Planning Participants in UABI and Urban Poor Areas in East Java Province 2019](image-url)

Figure 1 show that the tendency of PA is quite stable, but in the condom method there was a decrease in users in July. This shows an increase in the rate of discontinuation of condom contraception in July.
Figure 2: Results of Achievement of New Male FP Participants in UABI and Urban Poor Areas in East Java Against 2019’s Targets

Targets data used is MOP and Condom PPM data that must be achieved by every Regency/City in East Java, including UABI and urban poor areas. PPM data used is MOP and Condom PPM data that must be achieved by every Regency/City in East Java, including UABI and urban poor areas. Achievement results that continue to increase are quite good and indicate improvements in each month, but when viewed from the figures, the results are still unsatisfactory especially in the MOP method which until the end of the year only reached 28.2% of the target set by the central government.

Discussion

Health Promotion Strategy: Health promotion aims to promote health programs in order to realize a new Indonesian society that is cultured with a clean and healthy life and participates directly in the health movement. To achieve the goal of realizing health promotion, a good strategy is needed. Strategy is a way to achieve and realize the vision and mission of health effectively and efficiently (7).

To achieve the goal of realizing health promotion, a good strategy is needed. Strategy is a way to achieve and realize the vision and mission of health effectively and efficiently. Decree of the Minister of Health Number 1193/Menkes/SK/X/2004 regarding the National Health Promotion policy and Decree of the Minister of Health Number 1114/Menkes/SK/VII/2005 Regarding the Guidelines on the Implementation of Health Promotion in the Regions (8). The strategies needed to realize health promotion are as follows:

Advocacy: Advocacy is an effort or a strategic and planned process with the aim of getting commitment and support from the parties concerned (9). The aim of this health advocacy is to increase the number of health-oriented public policies, to increase public opinion in supporting health and to solve health problems together and integrated with regional health development through partnerships and the support and care of regional leaders (10). The targets of health advocacy are decision makers as well as policies at the provincial, city or district level, as well as at the central level. For health advocacy activities, it consists of various forms, both formal and informal.
Government support for the Men’s FP program is one of them manifested by the support of policies that favor the implementation of the Men’s FP in UABI and urban poor areas.(11)

**Supporting policies include:**

1. Constitution No. 52 Year 2009 About Population Development and Family Development
2. Constitution No. 1 Tahun 2014 about Changes of Constitution No. 27 Year 2007 About Management of Coastal Areas and Small Islands.
3. Presidential Republic of Indonesia Regulation No. 78 Year 2005 About the Management of the Outermost Islands
5. Regulation of the Head No.10 Year 2018 About the Implementation of Mobile Family Planning Services
7. Presidential Republic of Indonesia Regulation No. 82 Year 2018 regarding Health Insurance in article 52 describes health services not guaranteed by Health Insurance.

BKKBN Representatives of East Java Province each year formulate a Work Plan which will later be advocated to the Central BKKBN in order to get support and approval. Besides that, they also routinely hold Regional Work Meetings with all representatives of Regencies/Cities in East Java Province to discuss work programs and plans for the next year’s activities.

**Social Support:** Health promotion will be easy to do if you get social support. Social support is an activity with the aim of seeking support from various elements (community leaders) to bridge the health program implementers with the community as recipients of the health program.(12) The main target of social support or community development is community leaders at various levels (secondary targets), while for other social support or community development targets consist of health care groups, religious leaders, health professionals, health service institutions, mass organizations, community leaders, mass media groups and non-governmental organizations.(13)

One of the ways to bring access closer is manifested by the existence of mobile family planning services. This mobile family planning service is based on conditions in regions where health facilities are not yet available that meet the requirements, there are no competent medical personnel available, areas that require assistance with mobile family planning services such as in the context of social service activities and the like.(12)

BKKBN Representatives of East Java Province through cooperation in the Field of FP-RH have routinely held Mobile FP Services through service visits and also use mobile FP service facilities or commonly referred to as “Muyan KB”.

One of the most important things in conducting Mobile Family Planning Services is the presence of competent doctors or midwives. The presence of competent medical personnel is very influential in service in the field, so this must continue to be optimized. Of 161 MOP doctors/providers who have been trained in 2012-2015, only 34 doctors/providers have been able to serve MOP, in other words only 21%. This certainly will greatly affect the achievement of male birth control especially with the MOP method in East Java.

**Community Empowerment:** Empowerment is a process of providing information to families or groups and individuals continuously and continually ambungan by following the development of the community and the process of helping the community so that the community changes from being ignorant to knowing or aware and from knowing to being willing and from wanting to be able to implementing the introduced health program.(14)

There are two health promotion objectives that are linked to community empowerment. First, empowerment is a way in which the community is expected to be able to carry out their lives. Second, it can improve healthy living behavior in the community and third, it can increase the role of the community in health efforts.(10)

Community empowerment related to male family planning is a motivator for male family planning and also male family planning groups. Male Family Planning Motivators are those who have used MOP contraception method in their environment and are expected to become MOP acceptors in their experience and can invite people around to keep the same things. The Male FP Motivator is in charge of communicating the existing
Male FP Program to the people in his neighborhood, providing information related to the Male FP Program and educating the surrounding community about the same thing. The male family planning motivator is also an extension of the BKKBN in the community so that its presence can be felt by all levels of society, especially those in disadvantaged areas, borders and islands as well as urban poor areas. At present, East Java Province has 199 FP Family Motivators.

It is different only with the male FP group, this group is an association of men who have used the MOP contraceptive method. The purpose of the formation of this group is so that fellow acceptors can update information related to the impacts and effects of using MOP method. In addition, the acceptor can also find answers to the obstacles that might occur in him. At present, East Java Province has 127 male family planning groups.

Partnership: In empowerment, community development and advocacy, the principles of partnership must be upheld\(^\text{(15)}\). Partnerships are developed between health workers and their targets, and developed because of the awareness that to improve the effectiveness of health promotion. Health workers must collaborate with various related parties, such as professional groups, religious leaders, NGOs, mass media, etc.

Partners are needed in the continuity of the family planning program. Therefore, the BKKBN collaborates with several parties to support the acceleration of achieving the KB program targets. These institutions include:

a. Partnership with Indonesian National Army

b. Ministry of Villages Development of Underdeveloped Regions and Transmigration Synergy of the KKBPK Program in the Village Fund for the KB Program; The use of Village Funds in supporting the availability of KB Extension Offices and Improving the economy through the productive capital of the local community; KB CIE and Reproductive Health in Disadvantaged Areas and Transmigration by involving transmigration instructors at the time of debriefing prospective transmigrants; Family Planning and Reproductive Health services in health facilities in transmigration areas.

c. Ministry of Maritime Affairs and Fisheries: Conducting advocacy and IEC and KKBPK program services and the movement to promote fish eating for the community; Community empowerment and resource utilization on the coast and small islands towards prosperous families, especially in the FP Village; Exchange of data and information; Joint utilization of supporting facilities and infrastructure; Increasing access and quality of family planning and family planning; Facilitating increased use of long-term contraceptive method through fisheries counselors; Promote family planning and family planning programs and family planning services.

d. Partnership with Interfaith Forum for Religion Cares About Family Welfare and Population

e. Perkumpulan Kontrasepsi Mantap Indonesia (PKMI) Vasectomy and Tubectomy training for doctors; Provide medical assistance/visiting specialists during vasectomy services; Giving material for male birth control Ikatan

f. Partnership with Indonesian Urologist

g. Indonesian Population Coalition East Java Provinceto assist scientific studies of advocacy and policy analysis

h. Indonesian Ulama Council, to assistance about the rumor of a vasectomy male birth control

i. National Disaster Management Agency IEC about FP and Health; Reproduction through information media; Provision of contraceptive devices and medicines in disaster conditions; Family Planning Services in the affected areas.

j. Head of Regional Apparatus Organization FP

If described the health promotion strategy in increasing men’s participation in family planning is as follows (8):

\[^\text{(15)}\]
Figure 3: Health Promotion Strategy Chart

Conclusions

The results of the analysis of the Men’s Family Planning Program in Underdeveloped, Border and Islands and urban poor areas in the BKKBN Representative of East Java Province, can be concluded as follows:

1. Advocacy has been carried out with the support of policies from the central government, cross-sectoral, as well as the head of the agency namely BKKBN. BKKBN has also routinely drawn up work plans and held regional work meetings.

2. Community development has been carried out by bringing access to family planning services closer to areas in need (Underdeveloped, Border and Islands and urban poor areas). Efforts made by way of service visits and using mobile FP service facilities (Muyan KB).

3. Community empowerment is done through the formation of motivators for male birth control and also for male birth control groups.

4. Partnerships are needed to optimize efforts to improve men’s participation in family planning, especially in specific areas. Partnerships that have been established, among others professional groups, religious leaders, NGOs, mass media, etc.

Recommendation:

1. Strengthen advocacy efforts for new regional leader candidates so that the KB program can continue to run in the Regency/City without having to start from scratch again.

2. Provide training to male family planning motivators so that the information provided to prospective acceptors is more detailed and accurate.

3. Register the reasons for doctors/providers who have been trained but do not want to provide services so they can be followed up again.

Conflict of Interest: The authors have no conflict of interest with the material presented in this paper.

Sources Of Funding: NILL

Ethical Clearance: NILL. My paper is an idea and policy analysis to solve population problems, without any treatment to the respondent/informant.

Epidemiology of Fatal Road Traffic Accidents: A Six Year Retrospective Study in the Medico legal Centre of a Tertiary Care Health Set Up in Western Maharashtra

Janender Baghel1, Sarala M.2, K.V. Radhakrishna3, Ravi Rautji4

1Ft Lt (Dr) Janender Baghel, Senior Resident, 2Lt Col (Dr) Sarala M, Assistant Professor, 3Col (Dr). KV Radhakrishna, Professor, 4Brig (Dr) Ravi Rautji, Professor and HOD, Dept. of Forensic Medicine and Toxicology, Armed Forces Medical College, Pune-411040

Abstract

Road Traffic Accident (RTA) is a public health concern globally. Rapid urbanisation and increase in the number of motor vehicles, lack of discipline and violation of traffic regulations has led to a rapid rise in the deaths in vulnerable road users. A retrospective study was undertaken in the autopsy centre of a tertiary care hospital to observe the pattern and trends of deaths between 2013-2018 due to RTAs. Out of 248 RTA cases analysed in this study, 75.4% were male and 24.6% were female. The most vulnerable age group was 21-40 years in both two-wheeler and four-wheeler accidents while in pedestrians it was 41-50 years. High rate of accidents was seen during summer in afternoon in cases of pedestrians as well as motor vehicle occupants and in the evening after 6 PM in two-wheeler motorcyclists. Observation of the pattern of head injuries showed fracture of the skull was a common occurrence in two and four-wheeler accidents whereas a greater number of pedestrians reported no skull fracture. Non helmet users suffered higher mortality in the age group of 21-30 years. Subdural haemorrhage caused maximum deaths in two-wheeler motorcyclists and pedestrians while sub arachnoid haemorrhage was seen in four-wheeler accidents. Our study agreed with the WHO report of 2018 and various other studies from India and abroad. Increased number of fatalities was found to occur at a particular time of the day with seasonal preference. Two-wheeler motorcyclists without a helmet suffered maximum deaths. Real time analysis of data in various parts of the country would help in ensuring safe road user practices.

Keywords: Road traffic accidents, head injuries, helmets.

Introduction

Road Traffic Accident (RTA) remains a major public health concern at a national level and worldwide. The World Health Organisation (WHO) in its Global Status Report on Road Safety 20181 stated that 1.35 million people are killed in road traffic accidents worldwide with 90% of casualties taking place in the developing countries. As per the annual report “Road Accidents in India 2018 “by the Ministry of Road Transport and Highways2, a total of 1,51,417 deaths were attributed to traffic accidents on the road. India is signatory to the Brasilia Declaration to half global deaths due to RTAs by 2020. Though the country has been trying to honour the commitments to minimise the loss of young productive lives by enactment of Motor Vehicle Amendment Act 20193 the fatalities continue to rise due to the lack of discipline and responsible attitude amongst road users.

The most vulnerable of the road users are the pedestrians, cyclists and motorcyclists. Risk factors in them include speed, drunken drivers or pedestrians, neglecting road rules, failure to use helmets and seatbelts.
The victims of RTAs die due to head injuries, spinal injuries, crush injuries, abdominal injuries. Head injuries are the leading cause of trauma and death especially in motorised vehicles. Traumatic skull and brain injury manifests in these victims as Extradural, Subdural and Sub arachnoid Haemorrhage (EDH, SDH and SAH) with or without a fracture. Usage of standardised helmets by cyclists and motorised two and three wheelers reduce the percentage of head injuries and thus death in these group of road users.

NCRB in their 2014 report\(^4\) declares, ‘it is of vital consequence to understand the tendency and patterns of traffic accidents’. This study tried to analyse the patterns and trends in road traffic accidents over a period of time in an urban part of the country to aid in the data collection for a causative real time analysis of road accidents.

**Material and Method**

A retrospective observational study of deaths due to fatal road traffic accidents brought to the medico legal centre of a tertiary care setup in Western Maharashtra between 2013 and 2018 was undertaken. A total of 248 cases involving two-wheeler and four-wheeler motor vehicle occupants and pedestrians were included in the study. For the purpose of this study, an RTA was defined as an accident on the road between two or more objects, one of which must be any type of moving vehicle.

Data collected from autopsy reports was analysed according to the kind of road users (pedestrian, two-wheeler motorcyclists and four-wheeler motor vehicle occupants). Age & sex wise distribution, time and season of the mishap, use of helmets and the pattern of cranio-cerebral trauma were studied. Medico legal post-mortem records and fatal case documents of the victims were referred to for collecting information and cross checked. Data was analysed by using Microsoft office excel.

**Results**

During the study period, total number of autopsies performed was 1467, of which the number of RTAs was 248 (16.9%). Of these, 187 were male victims (75.4%) and 61 were female (24.6%). The male/female ratio was approximately 3:1. Number of pedestrian fatalities was 45 (18.2%) and fatalities by two-wheeler and four-wheeler motor vehicles were 144 (58.1%) and 59 (23.8%) respectively. [Table 1].

<table>
<thead>
<tr>

When the time of the accident was taken into consideration, large number of RTA cases (43.8%, n=68) were reported to occur by two-wheelers between 6 PM to 12 midnight. Pedestrian (44.4% n=24) and four-wheeler motor vehicles (41% n=16) accidents were found to occur from 12 noon to 6 O’clock in the evening. [Table 3].

Summer (36.3%, n=90) accounted for the maximum number of RTAs followed by rainy and winter seasons (31.9%, n=79).

Age group between 21-30 years has the highest death rate and most of these victims did not use helmets. Helmets were reportedly used by a majority of the individuals in the age group of 31-40 years [Table 4]
Fracture of the skull was a common occurrence in two and four-wheeler accidents whereas a greater number of pedestrians reported no skull fracture. Communal fracture (29% n=45) followed by linear fracture (23.9% n=37) was predominantly seen in two-wheeler RTAs and 29% (n=45) of the cases were seen to have no fracture of the skull. Linear skull fractures (25.6% n=10) were maximum in four-wheeler motor vehicle occupants followed by basal fracture (17.9% n=7) and 33.3% (n=13) had no evidence of fracture. 42.6% (n=23) cases of pedestrians had no fracture of the skull with 20.3% (n=11) cases having a comminuted fracture followed by 16.7% (n=9) cases having a linear fracture. [Table 5].

Traumatic brain injury was observed in all victims of RTAs irrespective of the category of road user. In the two-wheeler motorcyclists, 69.8% were found to have subdural haemorrhage (SDH) followed by extradural haemorrhage (EDH) in 66.6% of cases. Subarachnoid haemorrhage (SAH) was seen in 48.9% of cases. In all these cases intracranial haemorrhage was found with no evidence of fracture of skull. In cases of two-wheeler motorcyclists with skull fracture, SDH was found in 26.6% cases, EDH in 33.3% and SAH in 36.1% cases. In the four-wheeler occupants EDH was not seen on autopsy. SDH accounted for the maximum cases in both skull with (58.8%) and without fracture (41.1%). SAH was seen in 66.7% of cases with skull fracture and 33.3% cases without fracture. In pedestrians without skull fracture 85.7% of SDH, 75% of EDH and 64.2% of SAH was seen and in those with skull fractures maximum number of cases had SAH (35.7%) followed by EDH (25%) and SDH (14.2%) [Table 6].

Discussion

We observed that the most vulnerable category of road users in our study were males probably due to gender ratio on the streets. WHO in their gender wise comparison in RTAs between 2016-2018 revealed a much higher ratio of males (86%) compared to our study. Male preponderance is noted in other studies in various parts of India by Kumar A et al. and Saksham et al. Singh D et al. observed a ratio of 3:2 between the genders.

Recent report by WHO show that two-wheelers constitute the maximum share of road crash deaths (36.6%) in the year 2018. Four wheelers are the next higher contributors (16.6%) followed by pedestrians (15%). Similar findings were found by us with Pathak SM et al and Kumar. S et al substantiating us in their studies while Singh et al and Toro et al found maximum deaths in pedestrians.

21-40 year old individuals suffered the maximum fatalities in our study which is consistent with various other studies available from India. In its report the WHO observes that age profile with maximum fatalities between 18-45 years remain constant from 2016-2018 accounting for 69.6% of all RTAs which is much higher than what we found in that age group. In contrast the study of Toro et al found that victims belonged to an older age group and died of trauma difficulties after hospitalization.

As per the data given by WHO, afternoon and evening witnessed the maximum fatalities. We reported more two-wheeler accidents in evening after 6 PM, whereas maximum incidence of four-wheeler accidents and pedestrian injuries were seen in the afternoon hours with a peak in the summer.

Durkin et al. reported that peak incidence of pedestrian and motorcyclist injuries occurred during the summer months. In studies conducted in Mangalore most of the accidents took place during the afternoon and evening hours. Singh D et al reported more fatalities between 12 to 4 PM but in the months of September to October. Pathak et al observed most cases occurred in the monsoons and between 6 and 10 PM. Kumar S et al found that January and evening was the time of the day with maximum accidents.

In 2018 not wearing helmets caused 28.8% of total road traffic deaths. In our study the mortality rates were more in non-helmet users (49.2) than in helmet users (4%) in the age group of 21-30 years but in the age group between 31-50 years helmet users (40%) had more fatalities than non-users (19.2%) probably because of use of sub standardised devices and improper fastening of chin straps. Most commonly found intracranial haemorrhage was subdural haemorrhage and subarachnoid haemorrhage while extradural haemorrhage was observed in the least which is consistent with the findings by other researchers. Use of standardised head protective devices decreased the mortality as suggested by Cawich SO et al and Nzegwu et al in their studies. Aowen et al in their six-year study in China found that 75.2% suffered both skull fracture and intracranial injury while 24.1% have an intracranial injury with no skull fractures and that helmets improved the chances of survival in head injuries. Tripathi et al found that helmeted users suffered a smaller number of head injuries compared to non-users. Sola Kim et al observed preventive aspects of helmets much more in low impact crashes.

Conclusion

This study again emphasised the fact that fatal head injuries were common among two wheelers motorcyclists due to lack of standardised protective head gear. Responsible attitude of road users will avert a majority of road traffic accidents. This observational data on fatalities might be helpful in a real time causative analysis of road traffic accidents essential in the design and implementation of road safety programmes.

Limitations: This study took into account only those cases received at our centre and may not represent the entire region.

Declaration of conflicting interests: The authors declare that there is no conflict of interest.

Funding: None.

Ethical approval: Necessary ethical approval was obtained.

Positive Versus Negative Framing of Information

Jisun Lee

Professor, Department of Nursing, Honam University, Republic of Korea

Abstract

Background/Objectives: The message is being used as a mode of intervention leading to preventive health behaviors and can lead to modifications in knowledge, attitudes and behaviors in a large proportion of health behaviors. The purpose of this study is to identify the effective and persuasive message types among positive and negative message types in information on specific health behaviors, to evaluate the effects by systematically classifying and analyzing related studies and to lead evidence-based practices.

Method/Statistical Analysis: In this study, meta-analysis was conducted to evaluate the trends and reporting levels of the study in order to evaluate and systematically classify the effects of message types in information on health behavior. Only clinical studies with randomization comparing the effects of positive and negative message framing with respect to health behavior were selected. In addition, a case where the interventions were compared by dividing them into two groups was selected.

Improvements/Applications: Among the final selected papers, 7 papers were included in the included studies through methodological quality evaluation. Comparison of the positive and negative message interventions is related to health behaviors related to breast cancer (SMD -0.04 (95% CI -1.57 to 1.50), health behaviors related to vaccination (MMR, HPV)(SMD 0.20 (95% CI -0.69 to 1.08), cancer screening, vaccination, physical activity and all health activities related to Type 2 diabetes screening (SMD -0.21 (95% CI -0.89 to 0.47). All of these were not statistically significant. In order to confirm the change in health behavior according to message framing, a study considering the same target population and outcome indicators is necessary.

Keywords: Message Framing, Positive Message, Negative Message, Health Behavior.

Introduction

The message is being used as a mode of intervention leading to preventive health behaviors and can lead to modifications in knowledge, attitudes and behaviors in a large proportion of health behaviors. In order to enhance the persuasive effect of messages, various types of fields have been studied to see if there is a difference in the effect of persuading a subject depending on the type of message. Message types are categorized according to message framing, message appeal, etc. Among them, message framing refers to a series of processes that select and make certain elements of a message stand out and recommendations provide prisoners to achieve the same purpose. It refers to the method of manipulating the messages of profit framing that highlights the potential benefits and benefits of choosing and loss framing that highlights the negative consequences of not choosing[1].

In general, decision making of health behaviors varies greatly depending on how the problem is presented. In this case, the method of expressing the problem is called a ‘frame’ in judgment and judgment or selection changes as the frame changes. It is said to be a ‘framing effect’. However, since there are differences in approaching framing research on health behavior, there is a need to establish evidence-based practice by checking the message framing effect through systematic consideration. In general, in the case of messages that

Corresponding Author:
Jisun Lee
Professor, Department of Nursing, Honam University, Republic of Korea
e-mail: leezggo@naver.com
motivate health-related behaviors, negative messages are perceived more effectively than positive messages[2,3].

Indeed, in various studies, the persuasive effect of loss framing was more pronounced. In Meyerowitz & Chaiken[4], the breast cancer self-diagnosis recommendation showed that the loss framing showed a higher self-diagnosis will. While prisoners did not adopt breast cancer self-diagnosis recommendations in profit framing because of their tendency to evade risk, loss framing strengthened their risk-seeking tendencies, making it more favorable to adopt recommendations. This is the result of prisoners handling self-discovery information that takes risks through actions that may find lesions. In the HIV recommendation study [5]. Loss framing was highly effective among recommendations for health-promoting behaviors to detect lesions.

On the other hand, according to the Expectancy-Consistency Hyposis proposed by Smith & Petty [6], in the condition that the audience expects negative information, positive messages have more attention and have more influence on attitude formation.

As discussed above, there are differences in the effects of positive and negative message types in information on specific health behaviors and there is a need to identify effective and persuasive message types. This is to lead evidence-based practice by systematically classifying and evaluating research related to message framing.

Method

Criteria for considering studies for this review

Types of studies: Randomized controlled trials(RCT), controlled before and after studies

Types of participants: The subjects were not limited and all students, patients and the general public were included.

Types of interventions: We looked at studies comparing the effects of positive and negative messages in information to lead the same health behavior. Exclusion factors were excluded when the two framings could not be compared with counseling and single intervention therapy, not the type of message.

Types of outcome measures: There were no restrictions such as changes in actual behavior, behavioral intentions and attitudes and perceptions.

Search method for identification of studies:

Electronic searches: As for the data search, the search engines of Ovid MEDLINE(1966 to 2018), EMBASE(1980 to 2018), CINAL(1982 to 2018), PsyINFO(1887 to 2018) and Cochrane Central Register of Controlled trials(Issue 4, 2018) were used for overseas data search and KAMJE, Koreamed, KISS and related journals were used for domestic data search. We also looked at the list of references related to the subject in this document.

Searching other resources: Among the searched papers, a method of retrieving relevant papers among the papers that met the selection criteria and the references of the selected research was used.

Data collection and analysis:

Selection of studies: In this study, published randomized controlled trials with a high level of evidence and minimal bias were selected as the target literature for systematic review and meta-analysis. As a result variable, there was no restriction and papers that were compared by mediating positive and negative messages on the same health behavior were selected.

In order to evaluate the suitability of the selection criteria among the collected documents, the title and abstract were primarily reviewed. After extracting the data, the research method, participants, intervention, evaluation results and research results were selected and data related to the subject were selected.

Data extraction and management: Documents that did not compare the effects of message framing in the same health behavior or that did not provide the mean value, standard deviation and sample number of efficacy evaluations necessary for meta-analysis were excluded.

Assessment of risk of bias in included studies: In order to prevent the risk of prejudice, blind extraction was performed prior to comparison between evaluators with the help of one doctor and there was no part of disagreement or disagreement during the comparison. Methodological quality assessment method Grading of Recommendations Assessment, Development and Evaluation (GRADE) approach was used and the data selected for the analysis were selected based on the following method.

- Randomization.
• Allocation concealment
• Objectivity and directness of outcomes:

Assessment of heterogeneity: The $I^2$ test was used to confirm the heterogeneity of the compared paper and the degree of heterogeneity is as follows.

- < 25% : low
- 25%~ 75% : moderate
- 75% < : high

Data synthesis: Each paper has random effects models and SMD was used.

- < 0.40 represents a small effect size
- 0.40 to 0.70 represents a moderate effect size
- > 0.70 represents a large effect size

Data Analysis: $I^2$ test is used to check the heterogeneity of the paper and each paper is analyzed using random effects models and SMD.

Result and Discussion

Description of studies

Results of the search: A total of 233 papers were searched through the search engine and among them, 40 related papers were selected by checking the title and outline. For the selected papers, 16 papers were selected after reading the full text. Looking at the classified aspects of the selected papers through quality evaluation of the papers, 2 breast cancer screenings, 1 colon cancer screening, 1 diabetes screening and vaccination, 2 breast cancer screenings, 1 colon cancer screening, 1 diabetes screening and vaccination, 7 in total. The selected paper was a study conducted in the United States and the United Kingdom and the number of subjects was usually 100 to 300 and the results of the study reported the attitudes, perceptions and behavioral intentions of health behavior.

Included studies: All 7 papers were conducted on health consumers and the response rate was high in Part 2 (> 50%) and low in Part 1 (≤ 50%). Response rates were not reported in the three studies. Seven papers were compared in three ways according to the health behaviors associated with the message type.

- Comparison of all 7 health behaviors
- Comparison of 3 cancer screening health behaviors
- Comparison of two vaccination health behaviors

As a result of the study, papers using standardized mean difference (SMD) were selected and papers used as odds ratio were not included.

Excluded studies: Nine papers were excluded and the reasons are as follows. SMD to compare the effect of the results was not used (n = 6) and the total subjects were shown, but the number of subjects according to positive and negative message types was not compared to compare the two interventions.

Risk of bias in included studies: Of the 7 papers, randomized 2 (30%), 1 randomized (15%) and 4 (55%) unclear, randomized and objective in all 7 papers Result indicators were used.

Effects of interventions

[Positive versus negative framing]

Comparison 1. All health behaviors: The changes in awareness, attitudes and intentions according to message framing were examined for all health behaviors (physical activity, cancer screening, vaccination, diabetes screening). The combined estimates were statistically insignificant with SMD -0.22 (95% CI -0.89 to 0.47) and among the combined papers, Bigman (2010) and Nicholson (2008) were qualitatively superior papers, respectively, with SMD 0.64 (95% CI 0.33 to 0.96) and SMD 0.38 (95% CI 0.15 to 0.61) showed that the negative message type was statistically significant in leading health behavior changes than the positive message type. The heterogeneity of the study combined with ($I^2 = 98\%$) was found to be very severe. Figures 1 and 2 show forest plots and funnel plots for all health behaviors.
Comparison 2. Cancer screening: Among the seven selected papers, we examined changes in perception and intention according to message framing in relation to cancer screening behavior. Combined estimates were statistically insignificant with SMD -0.044 (95% CI -1.57 to 1.50) and among the combined papers, Gallagher et al. [8] was positive with SMD -1.26 (95% CI -1.49 to 12.04). The message showed statistically significant perceived sensitivity to examination rather than negative message. On the contrary, Nicholson (2008) showed that SMD 1.15 (95% CI 0.91 to 1.39) showed that the negative message type showed a statistically significant change in cancer screening intention rather than the positive message type. The heterogeneity of the study combined with (I² = 99%) was found to be very severe. Figures 3 and 4 show forest plots and funnel plots for cancer screening.

Comparison 3. Vaccination: Among the seven selected papers, changes in perception and intention according to message framing were examined in relation to vaccination (MMR, cervical cancer vaccine) behavior.
The combined estimates were statistically insignificant with SMD 0.20 (95% CI -0.69-1.08) and among the combined papers, Bigman et al.[7] was a qualitatively superior paper with SMD 0.64 (95% CI 0.33 to 0.96). Negative message type was statistically more significant in vaccination perception change than positive message type. The heterogeneity of the study combined with (I² = 93%) was found to be very severe. Figures 5 and 6 show forest plots and funnel plots for vaccination.

![Figure 3. Forest plot of comparison 2: Cancer screening](image)

![Figure 4. Funnel plot of comparison 2: Cancer screening](image)

![Figure 5. Forest plot of comparison 3: Vaccination](image)
Discussion

In order to prepare evidence-based practice, we looked into effective message framing in the decision process of health behavior. However, through the selected paper, the difference between the positive message and the negative message effect was not statistically significant. This does not take into account different population and outcome measurement method, variable definitions, tracking periods and estimates. It is confirmed that the quality of the data is low because it was induced. Nevertheless, among the combined papers, it was possible to identify the types of messages that statistically significantly influenced health behavior. In Bigman et al. [7], a negative message type was found to be more effective than a positive message type in the perceived benefit associated with uterine cancer vaccination of college students and the change in adult colon cancer screening intentions in Nicholson et al. [8]. In addition, in the perceived sensitivity associated with breast cancer screening in adult women, positive messages were found to be more effective than negative message types.

Of the 7 selected papers, only 2 (30%) of studies with cover-ups were assigned and 1 (15%) with no cover-ups, but 4 studies (55%) appeared to be unclear. As the allocation concealment was not clearly seen in more than 50% of the papers, it would have been a risk factor for bias in analyzing and synthesizing data.

The quality of the selected papers was evaluated based on the GRADE approach and randomized and objective result indicators were used for all 7 papers. The combined paper evaluated the estimated values with SMD and CI and the I2 test was used as an important evaluation index to give the meaning of SMD. The papers used for combining were highly heterogeneous and there was no difference between positive and negative messages in the estimated values.

All of the studies selected in this paper were excluded from the selection because the domestic papers did not select randomization and concealment of sampling.

Although studies with theoretical backgrounds such as message framing are being conducted both domestically and abroad, differences between domestic
and foreign studies have been found. In Korea, studies have been active in the field of health and crisis behavior, which focuses on eating habits, smoking, exercise, skin health, drugs and decision making. In foreign studies, various disease areas such as cancer prevention and screening, influenza and glaucoma and physical activity was working on framing.

The estimates from the selected papers were not statistically significant. Three studies in the sub-region showed statistically significant differences according to message framing. Each is as follows.

In the Gallagher et al. [9], study, the positive message type was more effective than the negative message type in breast cancer screening intentions for adult women, which is contrary to those of Block & Punam [2] and Meyerowitz & Chaiken [4] showed.

In the study of Nicholson et al. [8], in the intention to screen for colon cancer in adults, the negative message type was statistically significant in leading to changes in health behaviors rather than the positive message type and the Bigman et al. [7], study targeted female university students. In the intention to inoculate the cervical cancer vaccine, the negative message type was statistically significant in leading the change in health behavior than the positive message type.

The limitation in this study is that the previous studies have not been sufficiently progressed, so there is a problem that it cannot be analyzed in consideration of the same population and the same outcome variables, so it is not possible to accurately predict the prediction of the framing effect in the prevention and examination of diseases. In addition, even in the same framing type, differences may occur depending on the type of educational materials (document, audiovisual, etc.) and the method of education (persuasive, explanatory, etc.) and depending on the individual characteristics of the recipient, in addition to the message involvement and recommendation characteristics Framing effects can vary, so it is necessary to measure individual perception and characteristics.

In addition, this study has difficulty in developing discussions because it did not look at the similarities or differences with research trends in other fields that can be compared while conducting research on the framing of health-related messages.

Conclusion

The effect of message framing on the macroscopic part that affects population health as well as on health risk behaviors and disease-related choices should be studied. If we can grasp the effect of message framing on health behavior through these studies, we will be able to prepare an effective and useful theoretical framework for constructing the message of the health campaign, which will contribute to establishing evidence-based practice.

A Comparison of Symptoms, Functional Status and Quality of Life by the Survivor Stages of Pancreatic Cancer Patients

Jisun Lee

Professor, Department of Nursing, Honam University, Republic of Korea

Abstract

Background/Objectives: The purpose of this study was to identify the difference of symptoms, functional status and quality of life (QOL) according to the survival stage of pancreatic cancer patients.

Method/Statistical analysis: Descriptive, cross-sectional design. A sample of 139 patients was surveyed. The participants were as patients who were diagnosed with pancreatic cancer in Republic of Korea. The data collected was analyzed with descriptive statistics.

Findings: Nausea and vomiting symptoms were significantly higher in acute survival stage than in extended survival stage and insomnia and diarrhea were significantly higher in extended survival stage than in acute survival stage functional status and QOL were significantly higher in extended survival stage than in acute survival stage.

Improvements/Applications: The differences in symptoms, functional status and QOL by the survival stage of pancreatic cancer patients were grasped and the empirical evidence was given for performing differentiated nursing interventions by each survival stage.

Keywords: Pancreatic cancer. Survival stages, Symptoms, Functional status, Quality of life.

Introduction

Pancreatic cancer is one of the major diseases that rank fifth in cancer mortality rates in Republic of Korea, the 5-year relative survival rate of pancreatic cancer is 11.1%, which can be found as very low compared to the overall cancer survival rate of 70.6%[1]. Pancreatic cancer which is a low survival rate, nursing that prioritizes the quality of life (QOL) is required not from the last day to a couple of weeks, but from the day of diagnosis[2]. Most of the patients with pancreatic cancer would be threatened their QOL by unfavorable prognosis[3,4,5].

QOL is a subjective well-being condition that individuals feel about their lives and it is raising its head as an evaluation index of the treatment of cancer[6]. To maintain the highest level of well-being of the subject which is the main purpose of nursing and help, identify the factors affecting the QOL of pancreatic cancer patients and develop ways to mediate them is cancer patients experience a variety of symptoms and changes in functional status as they undergo physical, psychological and cognitive changes in the treatment and progress of the disease, among them, the symptoms play an important role in functional conditions and QOL[7]. The functional status of patients diagnosed with pancreatic cancer is reported to be very low compared to other cancer diseases[8], so efforts should be preceded to verify the patient’s functional status and to understand the nursing needs of those diagnosed clearly.

Mullen[9] classified the cancer survival stage into three stages based on changes in cancer condition and treatment process after cancer was diagnosed and argued that the required intervention method for each stage was different. These survival stages are a complex process
that occurs continuously and dynamically in the begins with the diagnosis of the cancer[10]. Therefore, assessing and interpreting the symptoms, functional status and QOL of survivors at each stage and differentiated arbitration by each survival stage should be applied.

The purpose of this study was to identify the difference of symptoms, functional status and QOL according to the survival stage of pancreatic cancer patients and to use it as evidence for developing differentiated nursing intervention according to the characteristics of survival stage.

Method

Research Design: This study is a descriptive-cross sectional study.

Research Subjects: The participants were as patients who were diagnosed with pancreatic cancer and visiting outpatient departments of one general hospital in Republic of Korea for treatment and further care. The inclusion criteria for this study were (a) adults >20 years old, (b) diagnosed patient with pancreatic cancer and (c) patients capable of understanding the contents of the questionnaire and responding directly to the questionnaire. The exclusion criteria for this study were (a) patients with psychiatric anamnesis or those receiving medication, (b) non-protopathic pancreatic cancer and (c) serious comorbid diseases requiring treatment other than pancreatic cancer.

The sample size of this study was calculated as a total of 126 people by using the G*power program when it set as t-test significance level (α)=0.05, effect size=0.5 and verification power (1- β) = 80[11].

Among data from 140 people which considered the dropout rate of 10%. 139 people were used as final analysis data except for one questionnaire which was insufficiently responded. As a result of the classification by survival stage, It was 100 people in the acute survival stage, 31 in the extended survival stage and 8 in the permanent survival stage that, the number of subjects in the permanent survival stage was not enough so the survival stage was reclassified to 2 stages by including the permanent survival stage in the extended survival stage based on previous research[11]. Finally, the patients were divided into 100 people in acute survival stages that less than 2 years after diagnosis of pancreatic cancer and 39 people in extended survival stages that more than 2 years after diagnosis of pancreatic cancer.

Measurement:

Symptoms: In this study used the sub territory of the QOL related to symptoms among the Korean version tools of EORTC QLQ-C30 (version 3). It is composed of 4 point scale and calculated from 0 to 100 points as perfect score according to the scoring instructions of the tool. Lower scores indicate better symptoms. At the time of development, it was Cronbach’s α=85 and in this study, it was Cronbach’s α=.87.

Functional status: In this study, using the sub territory of the QOL related functional status among the Korean version tools of EORTC QLQ-C30 (version 3). There are totals of 15 items, including five items of physical function, two items of role function, two items of cognitive function, two items of emotional function, two items of social function. It is composed of 4 point scale and calculated from 0 to 100 points as perfect score according to the scoring instructions of the tool. Higher scores indicate better functional status. At the time of development, it was Cronbach’s α=90 and in this study, it was Cronbach’s α=.91.

Quality of life: In this study used the Overall QOL among the Korean version tools of EORTC QLQ-C30 (version 3). There are totals of 2 items including 1 item of general health condition and 1 item of QOL and It is 7 point scale and calculated from 0 to 100 points as perfect score according to the scoring instructions of the tool, which means that the higher the score, the better the QOL. At the time of development, it was Cronbach’s α=84 and in this study, it was Cronbach’s α=.86.

Data Collection: The data collection of the study was conducted from June 15, 2018 to August 30. The list of patients visiting the outpatient department of a general hospital. The survey was conducted by including those who voluntarily agreed to participate in the study after the researcher explained by orally and in writing of the purpose and procedures of the study to the selected person, then conducted through the way of the subject directly filling out the questionnaire.

Data Analysis: The collected data were analyzed using the SPSS/WIN 25.0 program as follows. The differences in general characteristics, disease-related characteristics, symptoms, functional status and QOL were analyzed with χ2 test and t-test. Substantial missing data, one questionnaire were excluded from analysis. p-values <0.05 were considered significant.
Result and Discussion

The differences in general characteristics and disease-related characteristics: The number of people in acute survival stages was the largest at 100 (71.9%) and the number of people in extended survival stages was 39 (28.1%). As a general characteristic, the largest number of the gender was men as 100 (71.9%) and the largest number of age was between 56 and 65 as 59 (42.4%). In disease-related characteristics, the largest number of pancreatic cancer locations was in the head of the pancreatic as 89 people (64.0%) and metastasized cases as 75 people (54.7%). As for the treatment method, It was shown that 104 people (74.8%) took surgical treatment and 76 people (54.7%) took chemotherapy and 123 people (88.5%) did not take radiation therapy. There was no significant difference between the acute survival stage and the extended survival stage according to the analysis result of the difference in general characteristics and disease-related characteristics according to the survival stage of pancreatic cancer patients.

Differences in symptoms, functional status and QOL: [Table 1] shows the differences in symptoms, functional status and QOL in pancreatic cancer patients. Nausea and vomiting were significantly higher in acute survival stage as 56.38±13.15 than in extended survival stage as 45.82±10.91 (t=-4.45, \(p<.001\)) and insomnia was significantly higher in extended survival stage as 52.59±11.72 than in acute survival stage as 42.59±11.72 (t=-4.70, \(p<.001\)) and the diarrhea was significantly higher in the extended survival stage as 55.51±7.40 than the acute survival stage 50.60±4.87 (t=-4.70, \(p<.001\)). As a result of analyzing the difference of functional status by survival stage, the physical function was significantly higher in extended survival stage as 57.69±8.25 than in acute survival stage of 53.47±9.99 (t=-2.55, \(p=.013\)), the role function was also in extended survival stage as 48.8±13.47 than in acute survival stage of 42.79±10.62 (t=-2.50, \(p=.015\)) and the cognitive function was significantly higher in extended survival stage as 49.01±13.27 than in acute survival stage as 40.46±0.116 (t=-3.63, \(p=.001\)). As a result of analyzing the difference in the QOL in patients with pancreatic cancer showed that the extended survival stage was 55.40±6.35, significantly higher than the acute survival stage of 51.54±4.67 (t=-3.45, \(p=.001\)).

Discussion

This study was conducted to identify symptoms, functional status and differences in QOL according to the survival stages of pancreatic cancer patients.

In this study, as a result of looking into the difference of symptoms according to the survival stage, was found that in the acute survival stage was more complain of nausea and vomiting symptoms than in the extended survival stage and in the extended survival stage more severe insomnia and diarrhea symptoms than in the acute survival stage. Result of this was similar to a study that reported in the Cohort study of 564 pancreatic cancer survivors that pancreatic cancer survivors complained of symptoms such as nausea, vomiting, insomnia, fatigue, pain and loss of appetite\(^{12}\). In particular, the symptoms of nausea and vomiting are accompanied by symptoms of appetite loss and based on studies that report that 75% of patients with pancreatic cancer complain of appetite loss\(^{13}\), it is necessary to evaluate the status of food intake and nutrition absorption and to make efforts for continuous management in order to confirm the nutritional status as well as the intervention for relieving symptoms according to the survival stage of pancreatic cancer patients. Especially in the case of undernourished cancer patients, symptoms such as electrolyte imbalance, infection and fatigue were accompanied, consequentially a negative impact on the survival rate and QOL of cancer patients appeared\(^{12}\). Hence, evaluate the nutritional status of the individual and to organize a nutrition program to so that the necessary nutrients can be properly consumed in order to control their symptoms and improve nutrition intake and efforts that continuously watch and support the dietary intake and nutritional state are required.

Meanwhile, the symptoms of cancer patients are multiple symptoms at the same time, especially for pancreatic cancer patients, there are 5 ~ 10 symptoms exist at the same time and it appeared that they are interrelated\(^{14}\). As such, it is necessary to verify whether there is a difference in the survival stage of pancreatic cancer patients with the symptom cluster in which exists two or more symptoms at the same time is different in the survival stage of pancreatic cancer patient.

The functional status according to the survival stage was significantly higher in physical function, role function and cognitive function in the extended survival stage than in the acute survival stage. These results can be predicted as the patient would be faced anxiety and shocked by sudden diagnosis in the early stages of diagnosis, but with the passage of time, they adapt and handle disease and treatment and become better functional status.

\(^1\)Acute survival stage; \(^2\)Extended survival stage

Meanwhile, in the study of Carrato et al.[2] reported that patients who took pancreatic cancer resection showed the longest average survival rate in the 11 ~ 25.7 months range and that patients who took chemotherapy, radiation therapy, palliative surgery or exploratory laparotomy had an average survival period of between 2 ~ 8.1 months and 1.1 months for patients who took no surgery or active treatment. Compared the prognosis and survival rates of these pancreatic cancers with the results of this study, it is predicted that the overall functional status was measured as low due to the poor prognosis in the acute survival stage and numerous survivors who are focused on treatment.

This study confirmed the contents what Mullen[9] argued that the intervention method required by the cancer survival stage was different. In addition, the differences in symptoms, functional status and QOL by the survival stage of pancreatic cancer patients were grasped and the theoretical basis was given for performing differentiated nursing interventions by each survival stage.

Conclusion

This study aims to identify the differences in symptoms, functional status and QOL depending on the survival stage of pancreatic cancer patients and to utilize them as basic data for the development of differentiated nursing interventions program considering the characteristics of each survival stage.

The study result has shown that in the symptoms of pancreatic cancer patients by survival stage, symptoms of nausea and vomiting in patients with pancreatic cancer are significantly higher in the acute survival stage than in the extended survival stage and that insomnia and diarrhea in the extended survival stage are significantly higher than in the acute survival stage. Functional status (physical function, role function and cognitive function) and QOL were significantly higher in the extended survival stage than in the acute survival stage. Based on the above results of this study, the following suggestions are proposed. As a result of this study, although there were differences in symptoms, functional status and QOL according to the survival stage, it is difficult to
generalize the study results because the clinical stage, metastasis or not and treatment conditions of pancreatic cancer survivors who configured for each survival stage, are not identical. Therefore, further studies that collect and compare the same subjects need to be conducted.

Caring Behavior of Health Professionals: Its Implication to Clinical Practice

June II A. Kiblasan

Dean of Nursing, Mountain Province State Polytechnic College, Bontoc, Mountain Province, Philippines

Abstract
Health professionals’ behavior play a vital role in the care patient for it has been assumed that effective behavior promotes a caring relationship leading to an outcome that is therapeutic to both. The purpose of this study was to ascertain the caring behavior demonstrated by the health professionals based on the perspectives of allied health students and its propositions to clinical practice though patients’ point of view. Sequential Explanatory Strategy of the mixed method research design was employed where survey and conduct of key informant interview were the strategies employed in the collection of data. Weighted means were used to represent how caring behavior was demonstrated by the health professionals. Independent T-test was utilized to validate the difference of caring behavior demonstrated while thematic data analysis for the data collected during interviews. It was found that caring behaviors of health professionals were demonstrated the same and has no difference. Indeed, caring behavior of academicians is an essential element in developing a learner’s personality as future health professional. It is a must to uphold and disseminate the critical aspects of the caring behavior among learners in developing them as future health professional practitioners.

Keywords: Health Professionals, Caring behavior, Clinical practice.

Introduction
Caring emerged as a significant aspect has to possess in response to the environment. It greatly influences how an individual be nurtured and socialize. In education, caring is an approach that is based on reciprocal relationship between the teacher and students on ethical and human principles where caring based interaction of teachers and students’ action and feeling are equally considered.\footnote{1} It is widely accepted that good student-teacher relationship is important in increasing students’ sense of attachment to school that facilitates academic success. The objective patterns in learning to in planning and development of learning situations applies evidences and instances in educational processes that will help students to have meaningful learning experiences and introduce patterns of caring behavior to students.\footnote{2} At this point, caring as a behavior is essential in promoting the welfare of students. It is a teaching-learning approach that is formed based on constant teacher-student interactions at which, the nature of this educational strategy focuses on caring.\footnote{1} Moreover, previous research finding provides additional insight that teacher’s behavior as desired by students contributes to their educational success.\footnote{3}

Studies in higher education show the significant of a learning atmosphere that is caring, confident and welcoming are favorable to academic growth for all students.\footnote{4} Moreover, students’ achievement of self-esteem and peace reduced anxiety, developing self-esteem and increased the sense of empowerment in students are the outcomes of inducing caring concept in educational system.\footnote{5} Further, instructors’ caring behaviors influenced nursing students’ caring behaviors positively\footnote{6} and it is most important to show caring as a behavior for it can boost nursing students’ interests in learning caring behaviors by incorporating diverse teaching strategies to enhance the effectiveness of caring behaviors.\footnote{7}

Moreover, caring relation is an appropriate framework for guiding and creating ethical education\footnote{8} though some health care professionals are comfortable and competent users of technology, they must also preserve a focus on professional-patient relationship.
to achieve quality health care. A relationship that involve reflection on practice to increase recognition and demonstration of caring behaviors because it was concluded that, caring behavior is essential in clinical practice. One thing, a study showed that the concept of caring has been applied in designing curriculum based on the concept of caring instrument development and as a criterion to measure caring behavior.

On the other hand, the realization of this craft derived from a belief that effective caring promotes health and a higher level of wellness. It is considered a universal need and an important component in the delivery of health care. However, a study revealed no congruence on the perceptions of nurses and patients when it comes to demonstration of caring behaviors. This bring additional interest to discover how mentors’ caring behavior affect learners as future practitioner.

**Method**

Sequential Explanatory Strategy of the mixed method research design was utilized. This method composed of two phases of data gathering that is a combination of quantitative and qualitative strategy. Clustered-purposive-convenience sampling was used for all participants are known and was organized into groups where each group has own part in the accomplishment of this endeavor. It is purposive because the selection of participants was criterion based and convenience for it relied on available allied health students enrolled in Bachelor of Science in Nursing (BSN), Bachelor of Science in Physical Therapy (BSPT), Bachelor of Science in Medical Technology (BSMT) and Bachelor of Science in Respiratory Therapy (BSRT) who were currently enrolled during data gathering, and the patients confined in a healthcare facility during the scheduled data collection being cared by Registered Physical Therapist (RPT), Registered Nurse (RN), Registered Medical Technologist (RMT) and Registered Radiologic Technologist (RRT). Tools used were self-made Caring Behavior Instrument for students (CBIS) and Caring Behavior Assessment (CBA) tool based from Watson’s ten Carative Factors. CBA tool was translated to “Ilocano” for it is the common dialect spoken by Cordilleran aside from other local dialects they are using. Both instruments were pretested to determine its reliability making use of Kuder-Richardson 20 (KR20) coefficient and were declared valid for the coefficients of reliability were 0.99 and 0.98 respectively with a descriptive equivalent of “very reliable”. Meanwhile, Semi-structured interview guide was also employed to substantiate the findings.

It is a mere fact that statistics is dealing with the collection, analysis, interpretation, presentation and organization of data. Average weighted mean was used to interpret and analyze the surveyed data and Independent sample T-Test was used to validate differences on caring behavior. Use of words during interview were the basis of analysis where reasoning flows from the words provided by the participants toward themes that are patterned from the data or ideas that were repeated by more than one participant. This reasoning process and inductive thinking guides the organizing, reducing and clustering of data at which once themes are identified, the researcher uses deductive reasoning when considering the fit of data to the themes.

**Results and Discussions**

In learning or in practice, caring behavior of mentors or practitioners is an attribute that is essential in dealing with the environment. Table 1 presented how health professionals as mentors demonstrated their caring behavior that is imperative to learner’s personality, academic and non-academic achievement for it influences them how to get into it.

There were seven identified caring behaviors of mentors extended to learners. These are presence, guidance, competence, psychosocial support, commitment, confidence and conscience which was generally perceived as frequently demonstrated. Learners perceived that mentors were committed greatly in teaching with competence and confidence. Their moral as a mentor always touches their conscience leading them to properly guide and sparingly support their learners’ psychosocial wellbeing. However, there presence is minimal due to their complex responsibilities as educator. This result corroborates with the level of nursing instructors’ caring behavior during teaching students was medium to high with the mean and standard deviation of 4.65 which means that clinical instructors deeply cared for their students. However, looking into consideration the weighted means of the findings, commitment of mentors was nearly to be constantly demonstrated. Studies in higher education show the significant of a learning atmosphere that is caring, confident and welcoming and favorable to academic growth for all students. The pedagogic context of caring involved developing rapport and going out of one’s way to provide learning experiences geared toward students’ attributes while in caring-based interactions, the actions and feelings of instructors and students are considered equally. These literatures proved commitments of the mentors. Moreover, the findings itself reflected that each academic program had their own focus of learning needs and observations as to caring capabilities of their mentors. This can be a good indicator in deciding what attitude and strategy or method in teaching or educating learners to be inculcated in mentoring.

On the other hand, Table 2 revealed how health professionals as clinician demonstrated their caring behaviors to their patients.

Table 2: Caring behavior of allied health professionals as perceived by patients in a healthcare facility

Legend: Descriptive Interpretation (DI); Average Weighted Mean (MEAN); 4.20 – 5.00 = Constantly Demonstrated (CD); 3.40 – 4.19 = Frequently Demonstrated (FD); 2.60 – 3.39 = Occasionally Demonstrated (OD); 1.80 – 2.59 = Rarely Demonstrated (RD); 1.00 – 1.79 = Scarcely Demonstrated (SD)
As gleaned from the table, the seven scales on how a health practitioner exhibits caring to their patients. Generally, it was perceived as frequently demonstrated which the same with the mentors is. This shows that health care professionals regularly, routinely or oftentimes perform these caring behaviors to their patients. However, the result of this study negates the finding of a study that recommends empowering nurses to engage in positive health behavior through education.17

Moreover, health trend now is to foster a healthy, safe and supportive environment. Everywhere people go especially in healthcare facilities, signs of safety first are posted. However, from the seven scales of caring behaviors, only six were demonstrated frequently that is something to look upon. Expression of positive or negative feelings and existential/phenomenological/spiritual was the one perceived as occasionally demonstrated. Existential can be a reference to survival while phenomenology is the inquiries that addresses the practices of professionals in everyday life and spiritual force is the faith to practice profession. This is somewhat unbelievable because this is referring to sincerity and commitment of a health professionals related the services they can give to their patients.

To validate if there is an implication of the caring behavior of health educators in the academe on how health practitioners exercise their vocation in the clinical area, independent sample t-test was used. The caring behavior of health professional were fully demonstrated as perceived by students and patients. Table 3 presented the inference if there is significant difference on caring behaviors of health care professionals that implicates clinical practice. As gleaned from the table, caring behavior of health academician (M = 3.95, SD = 1.72, N = 4) was not significantly different from the health practitioners (M = 3.86, SD = 0.09, N = 4), t-value = 2.664, p = 0.154.
The finding revealed that, how a learner be educated depicts how they will practice their profession in the future. The good portrayal of caring behaviors by the educators to their learners will determine how learners be molded that will affect how they will practice after graduation. This is because of its influence that is crucial to the learning process. One thing, caring behavior is imperative to learner’s personality, academic and non-academic achievement for it influences them how to get into it. That influence will implicate how they will practice once they will graduate.

To substantiate the interpreted and analyzed numerical data, ten patients from the respondents in the quantitative part of this study were subjected to follow-up interview after confirmation of participation. Patients were asked about their experiences and the traits they observed from the health professionals during interaction that made them listen, participate and follow instructions. Responses were transcribed as basis in coming up with initial coding and was categorized. Finally, three categories were foster wellbeing, ensuring proficiency and patient’s engagement while the themes drawn were human needs assistance, competence, commitment and psychosocial support.

The findings show a good impact and proves that “how an individual be learned and nurtured depicts how they will perform”. However, it is still a need to constantly demonstrate those caring behaviors for it was suggested that health education should be delivered to patients according to their learning style in order for patients to comprehend and retain information provided.\(^\text{18}\)

**Conclusion and Recommendation**

The findings show a good impact and proves that “how an individual be learned and nurtured depicts how they will perform in the future”. Therefore, demonstration of caring behaviors is fundamental to uphold to learners for it significantly contribute a great impact on their behavior as future professional in the healthcare arena. One thing, caring behavior of health professionals as academician is an essential element of developing a student’s personality as future health professional practitioners. Thus, it is highly recommended to uphold and disseminate the critical aspects of caring behaviors among learners in developing them as future health professional practitioners.

**Conflict of Interest:** There is no professional, personal or family allegiance, bias, inclination, obligation or loyalty which may in any way affects the objectivity, independence or impartiality in the accomplishment of this study.

**Funding:** This research did not receive any specific grant from funding agencies in the public, commercial, or non-for-profit sectors.

**Ethical Clearance:** Guidelines for the protection of human rights outlined in the American Nurses Association\(^\text{19}\) was observed.

Community-Based Rehabilitation Program in the Municipality of Bauko, Mountain Province, Philippines

June II A. Kiblasan¹, Garry B. Tukaki², Rexton F. Chakas³

¹Dean of Nursing, Mountain Province State Polytechnic College, ²Public Health Nurse, Guinzadan National High School, ³SUC President III, Mountain Province State Polytechnic College

Abstract

Community-based rehabilitation is a beneficial treatment of addiction as it provides opportunities to learn how addiction settles into a healthy mind and body and how it can be beleaguered. At this point, Bauko municipality in the Mountain Province, Philippines designed a community-based rehabilitation program to cater the health needs of drug surrenderees or scholars under the government program “TOKHANG”. No visible impact was determined that made this study to assess its effectiveness for possible enhancement. Qualitative method was utilized where focus group discussion, key informant interview and observation were employed where thematic strategy was utilized in data analysis.

There was an improvement noted to wellness of the scholars after the implementation of the said program. Moreover, the program contributed best to the peace and order, strong family relationship and to the health and safety of the surrenderees. On the other hand, four significant areas were considered to enhance the program and strong support of stakeholders is vital. Indeed, high satisfaction with the program was noted.

Keywords: Drug surrenderees or scholars, community-based rehabilitation program, physical and psychosocial wellness, Bauko Municipality.

Introduction

Addiction to prohibited substances was one of the major problems that the Philippine Government is facing nowadays. It was considered a complex but treatable disease affecting brain functions and behavior. Thus, addiction can be treated but it has to undergo processes through rehabilitation. At this point, project “Tokhang” was developed by the Philippine Government that is a practical and realistic means of accelerating the drive against illegal drugs in affected barangays. This concept involves the conduct of house to house visitations to persuade suspected illegal drug personalities to stop their illegal drug activities.¹ Project “Tokhang” was launched by the Philippine National Police (PNP) to target the drug-infected barangays in coordination with the local government units² through the Philippines Dangerous Drugs Act of 2002 (Republic Act No. 9165) and the Philippines Local Government Code (Republic Act No. 7160) reinforced by Executive Order No. 4 of 2016 to provide establishment and support of drug abuse treatment and rehabilitation centers throughout the country.

In rehabilitation, the residents learn new lifestyle, principles and coping mechanisms that will help them overcome drug addiction.³ Treatment should include development of specific cognitive skills to help the offender adjust attitudes and beliefs that lead to drug abuse. This includes skills related to thinking, understanding, learning and remembering.⁴ Further, its the behavioral interventions designed to influence the behavior changes in a way that benefits addicts and the society for its goal is to return people to productive functioning in the family, workplace and community.⁵ Furthermore, community-based treatment is a specific integrated model for people affected by drug use...
and dependence in the community which provides a continuum of care from outreach and low threshold services, through detoxification and stabilization to aftercare and integration in coordination of health workers, social and other non-specialist services with strong support by family and the community to ensure efficient and long-term results.

In the Philippines, drug addiction is a major concern where rehabilitation facilities are not enough to accommodate surrenderees. Indeed, the Philippine Government challenged everyone to devise own rehabilitation program to cater the health needs of people involved. At this point, the Local Government Unit (LGU) of Bauko conceptualized a community-based rehabilitation program (CBRP) in rehabilitating the surrendered drug personalities. However, the impact of the program is not visible that made this study to furtherly assess if how effective its implementation and the possible recommendations as basis for enhancement.

**Methodology**

Descriptive qualitative method of research was used and participants were the drug surrenderees of the entire municipality. Purposive-convenience sampling was utilized where selection of participants is criterion-based and though participants are entirely known, available drug scholars during the scheduled data collection were considered. Focus group discussion was the primary technique in gathering data. The question revolved on the implementation of CBRP focusing on its effectiveness, contributions to the community and suggestions on how the program can be enhanced. Moreover, an open-ended interview guide and an observation checklist based on the foci of this study were utilized to evaluate the effectiveness and contributions to scholars and the community, and recommendations for the enhancement of the program. Gathered data were transcribed into categories, synthesized then analyzed by themes and quantified.

**Results and Discussions**

Use of prohibited drug involves serious risks at which, the more a person use, the greater the risks become. At this point, provision of a comprehensive therapy not only the mental and emotional but foremost its physical wellbeing is vital. One thing, psychological wellbeing is related to emotional and social knowledge that influenced the overall ability to effectively cope with environmental demands. The CBRP is a comprehensive therapy that was implemented with five steps. Organizing is the first where a Community Rehabilitation Network (CRN) was developed and oriented on how the program is implemented. Next is enrollment of drug surrenderees which requires medical tests by the Department of Health (DOH) for only low and medium risk users are allowed. This was supported by a that “low- or mild-risk” drug users need not be admitted in the rehabilitation centers but can be catered through community-based treatment.

Third step is program orientation of both enrollees and their families followed by the rehabilitation proper. In this segment, patient’s care involved sessions on the understanding of the individual as patient, sharing of experiences, lectures/seminars, individual and group counseling, skills training, physical activities and community service. Evaluation is the final step that requires drug recovering patients to undergo an unannounced drug test while they will be assessed on how well they fared with the activities done.

**Effect of Community-based Rehabilitation Program to wellbeing of scholars/drug surrenderees:**

Wellbeing is essential to everybody’s life. It denotes health, happiness and satisfaction. In this study, there were three (3) categories involved which are physical, psychological and social wellbeing. Initially, the effectiveness of CBRP on physical wellbeing shown in table 1 was more on the body physique followed by their aura then by their body strength and comfort. Moreover, there was low percentage of responses noted from the participants. This is for the reason that only 67 out of 90 scholars were available the time of follow up after the implementation of the said program. Based from the program implementers, those who were not available are with their family at home to immerse in more complex community environment.

Meanwhile, rheumatoid arthritis was last seen because minimal number from the scholars experienced the case. However, it should not be ignored. Indeed, the findings proved that having physical exercise such as jogging, push-up, sit-up from 5:00 to 7:00AM before breakfast and wash up, tree planting and gardening are effective remedies for regaining physical wellbeing. Further, the regular check-up conducted by the Municipal Health Unit and proper food intake also contributed to the physical wellbeing of the scholars.

On the other hand, table 2 reflected eight common psychological disturbances experienced by the scholars. It was noted that being shameful was the most reduced followed by being suspicious which is just the same with the most one after the program. Nice to know that self-esteem of scholars was regained and boosted because, this is the most important characteristic of an individual to live in this world freely and confidently.

Furthermore, Sleepiness is one of the common manifestations of psychological disturbance that can lead to psychosis if prolonged. Other notable observations were reduced such as craving for drugs; improved values and character of being respectful is evident;active participation in the activities;obedient with camp rules; developed leadership skills; and improved self-esteem.

Though there were some negative feedbacks, the positive effect of CBRP was noted from most of the scholars.

As to social wellbeing, table 3 revealed that lower levels were found to be the strongest predictors of negative mental health.
It has been noticed that improvement in socialization was the first observed and reported followed by their self-esteem which was more developed. Good to know that their spiritual life was given an importance for only GOD our creator knows what is best for us. Though respect to elders was the least that was managed, CBRP is still considered an effective for the reason that, as per culture, not only Cordillerans but most of Filipinos are hospitable. No matter what kind of situation or occurrence, respect to elders is still being practiced. Hence, social wellbeing can cope more successfully due to the social nature of human life and their challenges and it cannot be ignored to pay attention of the social aspect of health.

**Contributions of the Community-based Rehabilitation Program:** Peace in the Philippines related to drug abuse consistently ranked in the top five urgent national concerns in nationwide surveys since 2004.9 At this point, community plays a vital role in resolving conflicts and promoting peace most especially in terms of drugs and abused drugs.

Table 4 revealed that CBRP is an advantage to peace and order of concerned citizen because most of the major factors disturbing the social welfare of the people in the community were reduced and minimized. Scholars became a part of the community’s activities that were worthwhile and the usual violations they do were reduced and eliminated. The community became safer and more peaceful because no more troubles happened and some people even stayed late at night for bonding and public disturbance and drunkenness were also reduced as reported.

The effectiveness of the program to peace and order is somewhat a standpoint to remember. If this program is effective to drug addicts that made changes to the community, how much more if it will also be applied to other community related problems that affects the peace and order of a locality.

On the other hand, good community relationship is the basic and most important social skills that came from families. It has a great impact on the society and the society influences the operations of a country.

Table 5 showed contributions of the program to family relationship. There were factors affecting the relationship of scholars to their family brought by prohibited drugs or substances that made their personality different of who they are prior to involvement. As gleaned from the table, most of them found to be more responsible with closer family ties which is opposite to who they are before the therapy. Moreover, changes in the life of scholars were almost 360 degrees as to its angle. This means that CBRP plays a vital role in the promotion of relationship of the scholars with their families.

Indeed, family gives the strength needed to get through the bad times and celebrates the good times. Strong relationships among family members are essential to keeping a family together for it is the basic glue that holds society together.

Furthermore, people who are affected by drug use and dependence will be offered help to improve the overall quality of their life and wellbeing through social support for rehabilitation and reintegration. With this, CBRP is a social support that can promote the health and safety of drug scholars. It was gleaned from table 6 that health and safety of drug scholars were improved, managed and minimized. There were great changes on their health and safety wherein most regained their physical energy that made them comfortable and started to forget bad habits. These denotes the great contribution and signifies the effectiveness in the implementation of the program.

Recommendations to Enhance the Effectiveness of Implementation: There are four (4) significant areas recommended to enhance the effectiveness of the program implementation. First is Holistic Approach that integrated physical, mental and spiritual model. This approach helps in preparing the surrenderees’ reintegration with the community. Next is the Family Support and Involvement which is significant during the stay-in program contributing a positive impact on psychological wellbeing.

Third is Community Support and Involvement which is a patient-centered style of therapeutic interaction that facilitates support wherein, treatment becomes faster if community people understand the situation. And the last is Partnership with stakeholders and community in support to the restoration of wellness of drug scholars for this initiates a collaborative effort.

Conclusion and Recommendations

Effectiveness in the implementation of the community-based rehabilitation program was noted for it has great contributions to peace and order, family relationships and health and safety of the community. Further, it is contributory to the development of good physical outlook, worthy relationship with family and community members showing positive spiritual values, respect and sense of responsibility. Therefore, it is highly recommended that sustainability of the program should be maintained to cater those who are not able to avail; the four significant areas of concern should be considered; intensive anti-drug campaign, community awareness and capability-building should be seriously implemented; and strengthen the community support system for drug prevention by building healthy public policy that foster the health of the community.

Conflict of Interest: This has no impartiality in its accomplishment.

Source of Funding: Personal

Ethical Clearance: Guidelines for the protection of human rights outlined in the American Nurses Association10 was observed.

Effects of Health-Related Perception, Physical Activity Practice Rate and Stress on Health-Related Quality of Life for Middle-Aged Women: Based on the Seventh Korea National Health and Nutrition Examination Survey (KNHSNES 7-3), 2017, Korea Centers for Disease Control and Prevention

Jung Nam Sohn¹, Hae-Kyung Chang¹

¹Professor, Department of Nursing, Hanseo University, Republic of Korea

Abstract

Background/Objectives: The purpose of this study was to identify the factors which may influence a health related quality of life in middle age women in Korea.

Method/Statistical Analysis: This study used the 7th (2017) primitive data disclosed by the National Health Nutrition Examination Survey. Considering the design features of the sample data, it is analyzed with a complex sampling method by reflecting stratas, clusters and weight. The data were analyzed using descriptive statistics of the complex sample, general linear model of the complex sample and multiple regression using the SPSS/WIN 18.0 program.

Findings: As a result of conducting the regression analysis, the explanatory power of above 3 variables appeared to be 16% including subjective health status (β =-.055, p<.001), Perceived stress (β =. 016, p=.007) and subjective body shape (β = .011, p = .012).

Improvements/Applications: This study will be used as basic data for developing nursing intervention programs that can improve health related quality of life of middle age by establishing factors that affect well-being of middle age using variables of multilateral aspects.

Keywords: Mid-life Women, Quality of life, Perceived health perception, physical activity.

Introduction

The average life expectancy in 2018 was 82.7 years, 3.5 years longer than the average of 79.2 years in 2007[1]. The interest in health-related quality of life, which intends to maintain a healthy life in accordance with the life extension. Women, in particular, evaluated their health conditions worse than men[2]. Women’s health profile was reported to be weaker than men[3]. In many studies, as women are reported to have a lower quality of health-related life compared to men[4-5], the management plan should be prepared for the quality of women’s health-related life. Middle age is a transition period from adulthood to old age, which is a period feeling psychological crisis due to the decline in physical health, changes in family life cycles and loss of social roles[6]. These changes and health problems in middle-aged women reduce the quality of life of them[7].

Health-related quality of life is the levels of health in terms of physical, psychological and social aspects according to personal experiences, beliefs, expectations, or cognitive levels[8]. Health-related quality of life is one of the resulting indicators of the health-related
intervention[9] and can be judged as a result of health-related quality of life for middle-aged people or as a result of nursing interventions. As factors affecting the health-related quality of life, the more obese, the lower the health-related quality of life[10-11], the higher the social activities[12] or the better the walking practice rates[11,13], the higher the health-related quality of life. It was reported that the lower the standard of living[12,14], the lower the perceived health condition[15] the higher the stress, the lower the health-related quality of life[16].

Most studies on the health-related quality of life so far have targeted elderly people[12,15] or focused on middle-aged menopause symptoms[17] or related to certain diseases[18]. Therefore, focusing on middle-aged women among the relevant factors reported so far, an integrated analysis of the relevant factors up to date is needed.

Therefore, the study sought to look at how health-related perception, physical activity practice rates and stress affect health-related quality of life. Through this, we would like to present basic data on the development of nursing intervention programs that can systematically manage the health-related quality of life of middle-aged women. The specific purpose of the study is first to identify differences in the health-related quality of life according to the demographic characteristics and related variables of middle-aged women. The second is to identify the effects of health-related perception, stress and physical activity practice rates on health-related quality of life in middle-aged women.

**Method**

**Subjects:** This study used the 7th (2017) primitive data disclosed by the National Health and Nutrition Examination Survey in accordance with regulations for disclosure and utilization of primitive data from the Korea Centers for Disease Control and Prevention. The sample design of the National Health and Nutrition Examination Survey was extracted using two-stage stratified cluster sampling[19]. The number of 7th survey subjects was 8,127. Among them, 1,367 women aged 45 to 64 were the final subjects for this study.

**Instruments:**

**Health-related Quality of life:** Health-related quality of life is a tool developed by Euro QOL of group that evaluates from one point to three for five dimensions: mobility, self care, usual activities, pain/discomfort and anxiety/depression. EQ-5D Index is calculated by multiplying each score in five dimensions by weight value and closer to 1, the higher the health-related quality of life[20].

**Health-related perception:** Health-related perception consist of subjective health status and subjective body shape. Regarding the subjective health status, ‘very good, good’ was defined as ‘good’, ‘normal’ as ‘normal’ and ‘bad, very bad’ as ‘bad’. The Subjective body shape was reclassified as ‘obese, average’ and ‘thin’.

**Perceived stress:** Stress refers to perceived the stress rate, which is that the numerator was categorized into the group that felt ‘very a lot’ and group that felt ‘a lot’ of stress in their daily lives and the denominator was categorized into the group that felt ‘less’ and group that felt ‘a lot’[19] of stress, with a number calculated as the number of subjects aged 12 or older.

**Aerobic physical activity practice rate:** The aerobic physical activity practice rate was categorized depending on whether medium-intensity physical activity with more than 2 hours and 30 minutes, or whether high-intensity physical activity with more than 1 hour and 15 minutes, or whether combined with medium-intensity and high-intensity physical activity per week[19].

**Data collection:** The data was surveyed by the surveyors from January to December 2017 with interviews and questionnaire.

**Ethical consideration:** Regarding the National Health and Nutrition Examination Survey, since 2015, the study directly for public welfare has conducted without the review by the Research Ethics Committee in accordance with the Bioethics Law and the Enforcement Rules of the same Law[19].

**Data analysis:** To establish the representative nature of the samples for the population, the complex sampling method was used by reflecting the strata, cluster and weight in consideration of the sample design characteristics of the data[19]. The data were analyzed using descriptive statistics of the complex sample, general linear model of the complex sample and multiple regression using the SPSS/WIN 18.0 program.
Result and Discussion

General characteristics of subjects: The average age of subjects was 53.95 years old. The average health-related quality of life for all subjects was 0.96. The health-related quality of life showed significant differences in accordance with the income level (F=5.74, \( p=.001 \)), education level (F=12.90, \( p<.001 \)), subjective health status (F=8.06, \( p<.001 \)), subjective body shape (F=9.16, \( p<.001 \)), perceived stress (F=4.06, \( p<.001 \)). On the other hand, the aerobic physical activity practice rate (F=-0.59, \( p=.550 \)) showed no significant differences in the health-related quality of life [Table 1].

Factors affecting health related quality of life of subjects: To identify the factors affecting health-related quality of life, the income level and education level were adjusted and the general linear model analysis of complex sampling was conducted. The result showed that subjective health status (\( \beta = -.055, p<.001 \)), perceived stress (\( \beta = .016, p=.007 \)), subject body shape (\( \beta = .011, p=.012 \)) were appeared as influencing factors on health-related quality of life. The explanatory power of these variables on health-related quality of life accounted for 16 percent. The most influential of these variables was subjective health status [Table 2].

*Adjusted for income, education

**Discussion**

In this study, the effects on the health-related quality of life of middle-aged women were analyzed using the National Health and Nutrition Examination Survey data in Korea. Health-related quality of life is the perception of what one’s life is like in a health system that is related to the purpose, expectations, standards and interests of an individual[8]. In this study, the level of health-related quality of life for middle-aged women was 0.96, higher than the result of 0.91 in women in their 50s[3] or 0.95 in men and women in their 40s or 0.92 in their 50s[4]. However, it is difficult to compare directly because the subjects of the study are different and the figures can vary depending on the weighted model applied to the EQ5D Index.

Subjective health status among health-related perception under adjust of income levels and living standards was found to be the most influential variable in health-related quality of life, which is similar the results that the lower the subjective health status of middle-aged women, the lower the health-related quality of life[17] and subjective health conditions are the factors affecting health-related quality of life[4,15,18,22]. As the health-related quality of life is directly and indirectly affected by an individual’s health condition, physical, mental, social health status, etc[8]. It is thought to be the most influential.

The second most influential variable was perceived stress and the lower the perceived stress, the higher the health-related quality of life. This is explained in the same context as the results[4,16,18] of perceived stress as an influence variable of health-related quality of life among the influencing variables of health-related quality of life of middle-aged women. Middle-aged women experience many conflicts and stresses by experiencing internal and external life events while playing the main role of family members, resulting in the low quality of life[16]. As stress increases, the quality of life decreases due to decreased physical and mental functions and decreased social-psychological adaptability[4].

The Third influential variable in health-related quality of life was subjective body shape, which showed high levels of health-related quality of life in average-sized people. This is similar to the result that obesity was a factor influencing health-related quality of life[10]. In some studies, It is a contrary result to the result that there was no difference in the health-related quality of life[12] in accordance with the result of BMI, but it is thought
that it was difficult to objectively evaluate satisfaction and dissatisfaction with the BMI value. For that reason, it did not appear as an influencing factor when the BMI value was selected as a variable. As the health-related quality of life depends on how individuals perceive their body shapes rather than on the figure itself, such as BMI, it is thought that the satisfaction of body shape in this study was a variable affecting the health-related quality of life.

Aerobic physical activity practice rate has been shown not to affect health-related quality of life, which differs from the results of health-related life quality studies\(^\text{[11,13]}\). This is believed to have not affected the health-related quality of life as the subjects of this study are middle-aged women, not feeling much of the limitation of physical activity compared to the elderly. There were significant differences in health-related quality of life depending on general characteristics, education levels and income levels. This is similar to the study results\(^\text{[10,12,18,21]}\), which showed that the health-related quality of life is the influencing factor in accordance with the education levels. It is believed that education affects the economic, psychological and social aspects of our lives. It is similar to the study results\(^\text{[12]}\) that showed that the standard of living is a factor affecting health-related quality of life. Low economic standards do not satisfy the needs for survival, as the satisfaction with life decrease through comparison with people around.

This study is significant in the sense that it is representative as it utilized the country’s primitive data and that it compared and analyzed factors related to health-related quality of life in middle-aged women. Therefore, in order to improve the health-related quality of life in middle-aged women, the development of intervention programs such as education and stress management programs that can affect health perceptions and changes in health behavior for body shape management are necessary.

**Conclusion**

This study sought to identify the relative importance of the influencing factors by identifying those of health-related quality of life for middle-aged women. Factors affecting the health-related quality of life for middle-aged women include subjective health perception, stress and subjective body shape and these variables explain 16 percent of health-related life quality. Therefore, management of these variables should be considered in strategies for improving the health-related quality of life for middle-aged women. It is significant in the sense that the results of this study compare and analyze factors related to the health-related quality of life for middle-aged women in Korea. However, due to the low explanatory power for the health-related quality of life, it is suggested to explore factors affecting the health-related quality of life not included in this study and to identify direct and indirect effects by building models.

Study on Pattern of Lip Prints and its Relation to Sex and Blood Groups in Telangana Population

K. Srinivasulu¹, Padma Sri Katikaneni², Vaidarshi Abbagoni², Sowmya Bhashini Popuri², T. Rahul Reddy²

¹Professor & Hod, ²Internee, Mediciti Institute of Medical Sciences, Medchal

Abstract

A cross sectional study on the pattern of lip prints was conducted among the population of Telangana region. A sample of 140 individuals comprising of 70 males and 70 females were taken from both medical and nursing students of the Mediciti Institute of Medical Sciences, Medchal, Telangana.

The present study showed type-1 (vertical groove running across the lip) is the most common pattern present in all the quadrants of the lip in both males and females. In the left upper quadrant, it is found to be 51.4%, followed by 37.1% in the left upper right quadrant, 49.3% in the lower left quadrant and 53.6% in the lower right quadrant. Type-2 pattern (vertical partial length groove) is the second common pattern, in the upper left quadrant, it is 37.1%, in the upper right 42.1%, in the lower-left 34.3% and lower right quadrant 27.9%. Type-3 (Branched groove) observed as the third common pattern in the study population, in the upper left quadrant it is 11.4%, upper right 18.6%, lower left 15.7%, lower right quadrant 17.9%. Type-5 (Reticular pattern) is noticed in the upper right quadrant in 1.4%, lower left 0.7%, lower right 0.7% and not found in the upper left quadrant. The type-6 pattern is found upper right quadrant in 0.7% of study population and Type-4 pattern (intersected groove) is not found in our study group.

Our study revealed that the pattern of lip prints for each individual in each quadrant is unique. According to our study, there is no sex difference with lip print patterns. Study also revealed that there is no relation between lip print patterns and the blood groups, a near significant relation observed with the chi-square test in one quadrant, but not considered as significant.

Lip print patterns are constant, do not change with time and the uniqueness of its nature in each individual, it can be used for personal identification in various medico-legal issues.

Keywords: Lip prints, Personal identification, Crime investigation, Relation to sex, Relation to blood groups.

Introduction

Lip prints have a great significance in medico-legal issues. Identification plays a major role in any criminal investigation. The external surface of lips has many elevations and depressions forming a characteristic pattern called lip prints, examination of which is known as cheiloscopy. The lip prints are unique and distinguishable for every individual like fingerprints.¹

R. Fischer in 1902 was the first anthropologist to describe the furrows on the human lips.² In 1932, a French criminologist, Edmond Locard recommended the use of lip print for identification of a person.³ The idea of using lip print for identification was first suggested by Le Moyne Snyder in the year 1950.⁴ In 1972, Mc Donell reported that two identical twins seemed to be
indistinguishable by every other means, but their lip prints were different\(^1\) like fingerprints.

The lip prints, being uniform throughout life and it is the characteristic to a person, it can be used to verify the presence or absence of a person from the crime, provided there has been consumption of beverages, drinks, usage of cloth, tissues or napkin etc., at the crime scene. However, studying in-depth and establishing further facts and truth in lip prints will certainly help as useful evidence\(^5\) in crime investigation.

The present study aimed, to study the lip prints of different individuals in both upper and lower lip and find out the various patterns in the study population, to identify the most common pattern of Lip prints in the region of Telangana, to observe any gender differences and to find out any relation with the blood group. Several studies were conducted worldwide and in many parts of the country, but very few studies are available in the region of Telangana.

To classify lip prints we chose the classification scheme proposed by Suzuki and Tsuchihashi in 1970\(^6\) which is as follows: Type-1: A clear-cut groove running vertically across the lip.

Type-2: Vertical Partial-length groove.

Type-3: A branched groove.

Type-4: An intersected groove.

Type-5: A reticular pattern.

Type-6: Other patterns.

**Materials and Method**

A cross sectional study on pattern of lip prints was conducted in Telangana region in the year 2019. A sample of 140 individuals comprising of 70 males and 70 females, both medical and nursing students of Mediciti institute of Medical sciences, Medchal of Telangana area were taken in the study. All healthy individuals in the age group of 18 to 25 years with known blood groups were selected for this study. Individual Lips free from any pathology and having absolutely normal transition zone between the mucosa and skin were considered in this study. Individuals with any disease, cuts, injuries and deformities on lips were excluded. Informed consent was taken from all the individuals before commencement of the study.

The materials used in this study were Brown colored lipstick (Revlon), Cellophane tape, White chart paper and Magnifying lens.

Method adopted for collection of lip prints as follows: Both upper and lower lips of the individual were cleaned and a brown colored lipstick was applied on the lips uniformly. Over the lipstick, a white paper was used for impression of the lip prints. Subject was asked to make a lip impression in a normal resting position of the lips by dabbing it in the center first and then pressing
it uniformly towards the corners of the lips. The Glued portion of cellophane strip was pasted on the imprinted white paper for better preservation. The lip print patterns were examined by magnifying lens.

Lip prints of both upper and lower lips were divided into four quadrants, each quadrant was examined carefully and the pattern was identified according to the Suzuki classification. Lip print patterns were also compared with sex and Blood groups.

All the data was analyzed statistically using a SPSS software current version 21.0 for determining the pattern of prints in each quadrant of the lip.

**Figure 1: Lip print pattern divided into four quadrants.**

A total number of subjects are 140 in which males are 70 and females are 70. The following results were observed in our study showing that no two lip print pattern matched with each other, thus establishing the uniqueness of lip prints.

**Results**

A cross sectional analytical Study on Lip print pattern was conducted in the Telangana region among the population of the age group between 18-25 years. A total number of subjects are 140 in which males are 70 and females are 70. The following results were observed in our study showing that no two lip print pattern matched with each other, thus establishing the uniqueness of lip prints.

(Ul- Upper left, Ur – Upper right, LL- Lower left, LR – Lower right)
A Chi square test was done and it revealed a p value of more than 0.05 that was considered as insignificant. In our study there was no significant difference in the lip print patterns in both males and females and no significant correlation was observed between blood groups and lip print pattern.

Discussion

Lip prints are essential for identification of an individual and is an important tool in crime investigation similar to fingerprints and DNA analysis. Lip print impressions were obtained from both the sex with known blood groups of Telangana region and were classified by Suzuki’s classification. The lip print patterns of all the four quadrants of both upper and lower lip in relation to the sex and blood group were analyzed.

In our study it revealed that in upper left quadrant three types of patterns (Type-1, Type-2 and Type-3) were observed, among those patterns Type-1 is the most common variety in both males and females, 45.7% in Females and 57.1% in males and a total of 51.4% is observed. The second most common is Type-2 pattern observed in 41.4% of females and 32.9% of males and a total of 32.9%, followed by type-3 with, 12.9% in females and 10% in males and a total of 11.4%. The remaining lip print patterns, type 4,5,6 were not found in the upper left quadrant.

In upper right quadrant Type-2 is the predominant pattern, observed in 45.7% in females and 38.6% in males and a total of 42.1%. The next common is found to be Type-1 with 37.1% in females and 37.1% in males and a total of 37.1%, the third pattern is type-3 which is 15.7% in females and 21.4% in males and a total of 18.6%. Type-5 pattern observed in a total of 1.4% and Type-6 in 0.7%. The remaining Type-4 pattern not observed.

In the lower left quadrant, type-1 is the most common one, with 50% in female and 48.6% in male and a total of 49.3%. Type-2 is the second common pattern with 38.6% in females and 30% in males and a total of 34.3%, followed by Type-3 11.4% in female and 20% in male and a total of 15.7%. Type-5 is not found in females, whereas found in 1.4% males and a total of 0.7% is observed. The remaining patterns, Type 4 and 6 were not observed.

In the Lower Right quadrant, the commonest pattern is type-1, which is 55.7% in females, 51.4% in males and a total of 53.6%. Type-2 is observed in 30% in females and 25.7% in males and a total of 27.9%, followed by Type-3 14.3% in female and 21.4 % in male and a total of 17.9%.Type-5 is found only in males with 1.4% and a total of 0.7%. The remaining type-4 and type-6 were not found.

In all the quadrants of the lip, type-1 is the most predominant one, except in the Right Upper quadrant. The second most common is type-2 and followed by type-3. Type-5 lip print pattern observed in all the quadrants except upper left quadrant. Type-6 found in only one subject in the upper right quadrant of the Lip. Type 4 pattern was not found in our study population.

Lip print pattern in relation to the blood groups were analyzed. The most common blood group is O+ve, found in 40.7% of study population. The next common is B +ve which is 28.6% and third common one is A +ve with 15.7% as observed in our study. The blood groups in relation to the lip print patterns in all the four quadrants were analyzed with chi square test and a p value less than 0.05 is considered as significant. In our study, none of the quadrants showed a statistical correlation, except for the Upper Left Quadrant which showed a near significant value. (p value is 0.055 in females and 0.064 in males).

Several Studies conducted in India by Shaini Basheer et al7 in Kerala, Hima B. Nalluri et al8 in Telangana, Simarpreet Sandhu et al9 in Punjab, Suraj Multani et al10 in Chhattisgarh and Aman Kumar et al11 of Bihar showed similar results that Type-1 pattern is the most common pattern.

In contrary to our results some of the studies conducted in Rajasthan12, Gujarat13, Maharashtra14 and Andhra Pradesh15, revealed Branched pattern is the predominant lip pattern. In another study conducted by Devaraj et al at Karnataka16 showed Reticular Pattern is the common type. Saraswathi T R et al of Tamil Nadu1 shows Intersecting pattern is most predominant.

In relation to the blood group and lip print patterns, our study coincides with various other studies conducted by shaini basheer7 of Kerala, Rahul patel13 of Gujarat and pradhuman verma12 of Rajasthan, revealed no significant correlation.

Conclusion

A Study on lip print pattern conducted in the
Telangana population revealed that the commonest pattern is Type-1, followed by type 2 and Type 3. Several studies conducted in India also revealed similar results.

Overall, in our study, we observed that in each quadrant there was a mixture of the pattern. These patterns are unique for each individual. No particular pattern was specific to any gender and No similar lip print pattern was observed in any two subjects. Every individual has a unique lip print, thereby confirming the uniqueness of the lip print.

We did not find any significant relation between the blood groups and lip print pattern in our study, probably due to the small sample size.

Comparative Study to Assess the Knowledge on Worm Infestation among Urban and Rural Mothers of School Going Children (3-12 Yrs) at Karaikal District

Kalaivani E.¹, G. Ambujam²

¹Assistant Professor, Vinayaka Mission’s College of Nursing, Karaikal, Puducherry (UT), ²Dean & Professor of Surgery, Research Guide, Vinayaka Mission’s Medical College & Hospital, Karaikal, Puducherry (UT), Vinayaka Mission’s Research Foundation (Deemed to be University), Salem

Abstract

Background: Helminthes infections are more prevalent among school children aged 5-14 years. Hookworm burden is the major etiology for iron deficiency anemia in young children. One of the major health concerns especially among children is anemia and malnutrition. This risk has further complicated by lack of awareness on prevention of worm infestation among children and parents, care givers especially mothers. Increasing children’s and their Parents awareness of the problem can help to fight the disease.

Objectives: To assess the knowledge on worm infestation among urban and rural mothers of School going children.

Materials and Method: Non-experimental Comparative study was conducted to assess the knowledge among mothers in urban and rural area at Karaikal. Sample size comprised of 150 mothers of school going children were selected through non-probability or non-randomized convenience sampling. Out of 150 mothers 75 mothers from urban area and 75 mothers from rural area. The data was collected by using pretested structured knowledge questionnaire. Data was analyzed by both descriptive and inferential statistics.

Results: This study revealed that in urban area the majority of the mothers of school going children 37%(28) had adequate knowledge, 40%(30) had moderately adequate knowledge and 23%(17) had inadequate knowledge regarding worm infestation. Also revealed that in rural area the majority of the mothers of school going children 35%(26) had inadequate knowledge, 36%(27) had moderately adequate knowledge and 29%(22) had adequate knowledge regarding worm infestation. Mean and standard deviation (SD) of the urban and rural area mothers of school going children respectively 16.8±4.77, 15.01±5.16.

Conclusion: The researcher concluded that the need for more research to improve not only the knowledge also attitude and practices among mothers of school age children on worm infestations.

Keywords: Knowledge, worm infestations, Urban, Rural, Mothers of school going children.

Introduction

Children are nature’s gift and the fountain of life. They are our future and are a supremely important asset of the nation. They have to be protected and look after. By promoting their health, we will be strengthening the development of the family, Country, Nation and World.¹

Child development and wellbeing is influenced by many factors comprises the socio economic status of the family, educational level of the parents especially the mother, availability of safe drinking water and sanitary facilities and accessibility to health care services.
One of the silent and prevalent diseases in developing countries especially India is Worm infestation. It is more prevalent among school children. It can cause nutritional impairment and poor development of children. Knowledge of the worm infestation can assist in early detection of the diseases and reduce the incidence of complications.\textsuperscript{2,3,4}

In world’s population 24% or more than 1.5 billion people are infected with soil-transmitted helminth infections worldwide. Preschool-age children over 267 million and school-age children over 568 million live in areas where these parasites are intensively transmitted and are in need of interventions. Global wise over 600 million persons are estimated to be infected by 

S. stercoralis. Eggs that are attached to vegetables are ingested when the vegetables are not carefully cooked, peeled, washed in contaminated water and soil. Hookworm primarily can actively penetrate the skin when walking barefoot on the contaminated soil. Infestations causes’ loss of appetite leads to less nutritional intake affects the physical fitness, diarrea, loss of iron, protein and anemia. Health and hygiene education reduces transmission and re-infection by encouraging healthy behavior and provision of adequate sanitation. Because the main reason for infestations is poor personal and environmental sanitation. In 2018, over 676 million school-aged children were treated with anti helminthic medicines in endemic countries, corresponding to 53% of all children at risk.\textsuperscript{5}

In India, 225 million preschool(3-6yrs) and school-age (6-12 yrs) children are estimated to be at risk of worm infestations. India accounts for 65% of soil-transmitted helminth (parasitic worms) cases at South East Asia and 27% of cases world wide. In recent years, India has implemented national deworming programme, through which almost 250 million children are dewormed in February and August (twice a year).\textsuperscript{6,7}

The prevalence of anemia among the entire study population (350 children) and in those infected with worms was 56.6% and 56.9% respectively. With polyparasitism there was a relative increase in the frequency of anemia in females than males.\textsuperscript{8}

Worm infections and anemia are common in our children. Comprehensive control strategy involving good sanitation, supply of clean water and regular deworming (six month once) are recommended to prevent or reduce the prevalence.\textsuperscript{5} Multiple socio-economical, cultural, physiological and behavioral parameters along with illiteracy and poor sanitation influence intestinal parasitic infection. Awareness on infectious diseases, improving hygiene and application of supportive programs for parents to elevate socioeconomic conditions may reduce the burden of infection.

Materials and Method

The research approach adopted for the present study was Non Experimental Comparative research approach. Participants were selected by using non-probability or non randomozied convenience sampling technique. The total number of mothers of school going children included was 150(75 from urban and 75 from rural area). The study was conducted at Karaikal, Puducherry (U.T). The tools used for this study were demographic proforma and structured knowledge questionnaire. The structured knowledge questionnaire consisted of 25 items comprised of general aspects of worm infestations, types and mode of transmission, signs, symptoms, diagnosis, Treatment, prevention and complication of worm infestations.

The tool was pre-tested by administering it to sixteen mothers of school going children (8 from urban and 8 from rural area). The Participants found that the instructions and the language of the tool were simple, clear and understandable and the time taken to complete the tool was 30 minutes. The reliability of the tool was tested by split half method. A pilot study was conducted to find out the feasibility of the study. Data analysis was done by using both descriptive and inferential statistics.

Results

The study Total participants consisted of 150(75+75) mothers of school going children. Among 75 mothers from urban area about 45%(34)of mothers of school going children belonged to the age group of 31-40 years and majority 40% (30)of mothers belonged to Hindu. Maximum percentage 55% (41) of mothers had completed her degree. Most of the mothers 45% (34) were home maker. Nearly 32% (24) of the mothers had family monthly income Rs. 10001 to 20,000. Most of the mothers 36% (27) had information about worm infestations from mass media.

Among 75 mothers from rural area about 45% (34) of mothers of school going children belonged to the age group of 31-40 years and majority 48% (36) of mothers belonged to Hindu. Maximum percentage 51% (38) of
mothers had completed her degree. Most of the mothers 52% (39) were home maker. Nearly 39% (29) of the mothers had family monthly income Rs. 5000 to 10,000. Most of the mothers 48% (36) had information about worm infestations from mass media.

The chi-square values of demographic variables such as age of the mother, religion, education, occupation, monthly family income and source of information, regarding worm infestation among mothers of school going children from urban area were not significant at P≤0.05. Thus, it is concluded that there was no association between knowledge score and selected demographic variable.

The chi-square values of demographic variables such as age of the mother, occupation, regarding worm infestation among mothers of school going children from rural area were significant at P≤0.05. Mean while there was no association with demographic variables such as religion, education, monthly family income and source of information at P≤0.05.

### Discussion

The high prevalence of parasitic infestation seems directly related to the unhygienic living conditions associated with lack of knowledge about the communicable disease and variety of allied factors, which need to be studied. Socioeconomic status and occupation of parents, the age of children and ethnicity are significantly associated with parasitic infections. Intervention measures are important to take up sustained health education, provision of safe drinking water and improvement in environmental sanitation. During the school health checkups, periodic screening for intestinal parasites and blood indices can be evaluated.

Present study revealed that in urban area the majority of the mothers of school going children 37% (28) had adequate knowledge, 40% (30) had moderately adequate knowledge and 23% (17) had inadequate knowledge regarding worm infestation. Also revealed that in rural area the majority of the mothers of school going children 35% (26) had inadequate knowledge, 36% (27) had moderately adequate knowledge and 29% (22) had adequate knowledge regarding worm infestation.

Sadhna Shinde et al conducted a community based, cross-sectional survey of 100 mothers to assessing the knowledge regarding worm infestations in selected slums in Pune and revealed that 75% of the mothers were having average knowledge, 22% of mothers had poor knowledge & only 3% of mothers were having good knowledge regarding worm infestation.

Another one study conducted by Suganya et al to evaluated the Knowledge regarding prevention of worm infestations among mothers of under five children. The result showed that among 60 samples 60 (98.4%) of mothers have inadequate knowledge and 1 (1.6%) of mothers have adequate knowledge regarding prevention of worm infestation.
One more study was conducted by Madan Mohan Gupta et al to assess the knowledge regarding worm infestation among mothers of pre-school children. The study result showed that, 48 (48%) mothers of pre-school children had moderately adequate knowledge, 42 (42%) had inadequate knowledge and 10 (10%) had adequate knowledge regarding worm infestation.13

Descriptive study had been conducted by Sharma Ankit et al on Awareness of Worm Infestation among Mothers and its Prevalence in their Preschool Children. The study results showed that 55% mothers of preschool children had average knowledge regarding worm infestation followed by 24% had good and 21% mothers had poor knowledge.14

Another one study conducted by M. Hemamalini et al regarding Knowledge on Worm Infestation among Mothers with Under Five Children 50 mothers, 18 (36%) mothers have in adequate knowledge; 20 (40%) mothers have moderately adequate knowledge and 12 (24%) mothers have adequate knowledge.15

The findings of the present study revealed that mean and standard deviation (SD) of the urban and rural mothers of school going children respectively 16.8±4.77, 15.01±5.16. Also present study concluded that there was no association between knowledge score and selected demographic variable among urban mothers of school going children. Similar study had been conducted by Rimple Sharma et al and revealed that mean knowledge score of urban mothers was higher (18.86) as compared to rural mothers (16.96) regarding worm infestation in children. It was found that there was no impact of demographic variables on knowledge score of urban mothers.16

Jebasubitha conducted study on to assess the effectiveness of structured teaching programme on knowledge regarding prevention of worm infestation among mothers of under five children. The result shows that, there is no significant association between the mean pre-test knowledge scores and the selected demographic variables such as age of the mother, education, type of family, age of the child, family income.17

Another one study provides information that most of the caregivers had a good knowledge regarding deworming but failed in practicing necessary measures to control and prevent it. Worm infestation is one of the easily preventable disease.18 Health awareness, frequent monitoring, behavior change programme and implementing interventional programs among parents and caregivers particularly among the rural population would be vital. So that the prevalence of the worm infestations can be prevented or minimized19, 20, 21

**Conclusion**

The present study concluded that most of the urban and rural mothers had moderately adequate and inadequate knowledge on worm infestations. Hence the knowledge, attitude and practice of the mothers can be enhanced through mass health education program on prevention of worm infestation which in turn promotes the growth and development of the school going children.

Abstract

It is estimated that about 25% of humanity is infected with the bacterium Mycobacterium tuberculosis. That is about 2 billion people. Several new vaccines will pass Phase I clinical trials in the next few years. This paper briefly summarizes past and present challenges to developing a vaccine against tuberculosis as well as treating tuberculosis. TB is a pathogen that infects more individuals globally than any other communicable disease. TB is particularly devastating in poor developing countries, notably in Africa and Southeast Asia. Despite the WHO’s efforts to overcome TB, Multi Drug Resistant (MDR) TB and Extremely Drug Resistant (XDR) TB are huge challenges.

Keywords: TB, MDR TB, XDR TB, Tuberculosis, Multidrug Resistant Tuberculosis, Extremely Drug resistant tuberculosis, TB vaccine, TB eradication, Millennium Development Goals, MDGs.

Introduction

Global efforts are being made to eradicate tuberculosis (TB) as a public health problem by 2030. TB treatment can cause psychiatric disorders. The occurrence, prevalence and mortality rate of TB varies between countries and the paucity of accurate data makes an accurate assessment even more challenging. The psychological interactions are most common in the advanced stages of disease management and in patients with BMI ≤ 18. This necessitates continuous monitoring throughout the management.¹ Antimicrobial resistance (AMR) is a leading cause of mortality worldwide.

Bacteria mutate faster than we can develop new antibiotics. Vaccination with BCG reduces mortality rates.² BCG co-administered with DPT also reduces mortality rates.³ The evidence is overwhelming that BCG vaccines are cost compatible one and help in reducing mortality.⁴ These vaccines act as immunity enhancers and appropriate selection of drug transporters may produce a better result. Macrophages play a vital role in the development of TB granulomas and the infection process. Cell-mediated immunity acts against Mycobacterium. Macrophages are immune cells that act as a first-line defence against Mycobacterium infection.⁵,⁶

Post graduate scholar – MHA program, Prasanna School of Public Health, Manipal Academy of Higher Education, Karnataka, India –576104
Mycobacterium tuberculosis is capable of producing disease in any part of the human body including lungs and bone. TB acts differently on different organs, e.g., spine and lungs. Therefore, the management also varies. The need of the hour is for personalized TB management.7,8 When certain cautiously and carefully chosen medicines are given together in the right proportions, we might get synergistic bactericidal actions that kill the extremely resistant bacteria. Combination therapy is used to treat tuberculosis. Research reveals that poverty and co-infection with human immunodeficiency virus and non-communicable diseases such as cancer and candidiasis are challenges to overcome the disease.9,10 Synergistic combination treatments can be developed cheaply, used in patients safely since the constituent drugs are well known and thus could potentially be widely distributed.

WHO global TB statistics: The Millennium Development Goals (MDGs) aim for a TB free world by 2050. The WHO report on global TB 2019 says around 3.4% TB cases were MDR TB or Rifampin resistance (RR) TB. This was for the year 2018. 3 countries account for half of the world’s MDR burden. India accounts for 27% of the burden. China accounts for 14% and the Russia Federation for 9%.11 Various factors influence human health: human behavior, lifestyle modification, socioeconomic factors, political scenario, transcultural issues, and genetic factors. All of them have varying levels of significance.12 In the eradication of TB, the government must take the help of private clinicians and NGOs. Effective cooperation between the public and private sectors can drive synergies in the TB control program.

Oto toxicity, renal toxicity and hepatotoxicity can be caused by a lengthy duration of intake of medication. Toxicity and unaffordability have been identified as causes of poor outcomes.13 In the early twentieth century, socio economic changes led to a decline in TB morbidity and mortality in Western Europe and Northern America.14,15

Discussion

Current advances in Nano medicine have seen significant strategic developments in both experimental and clinical research. These successes have been made possible because of the continuous synchronization and collaboration of different disciplines: inter-professional practice (IPP). The current focus is on reducing the rate of occurrence of TB through increasing education and awareness efforts. One approach that has not been tested is the benefits of the use of more nutritious antioxidant food in the diets of TB patients. Extensive clinical trials in animals are required. Priya Rathie et al. in their research on “Patient treatment pathways of multi drug-resistant tuberculosis cases in coastal South India: Road to a drug-resistant tuberculosis center” stress that the health-seeking activities of a patient are totally influenced by the awareness of the infection, the severity of symptoms or stage of the diseases and availability of social support, especially in the form of rehabilitation. As famous futurist Michio Kaku, quantum physicist Dr. Amit Goswami and the Mahe former Vice-chancellor BM Hegde say: Precision in global health can be brought about by improved artificial intelligence and an incorporation of the concepts of quantum physics through holistic or integrated approaches which combine Genetics, Medical sociology and data sciences.

Conclusion

TB remains a major challenge in global health, despite the emergence of new infectious diseases like Nipah, H1N1, Corona etc. It means significantly effective as well as safer vaccines are required to rein in this epidemic. Effective interventions on a significant scale are especially required in TB-HIV and TB–Candidiasis co-infections. Even though the 2014 WHO report says that the mortality rate due to communicable diseases has decreased significantly, research on anti TB treatment must not cease. This, in spite of unsatisfactory, substandard, poor outcomes from various experimental and clinical trials. It is imperative on the global medical research community to find a safe and efficacious vaccine.

Occupational Stress among Radiographers Working in Tertiary Care Hospital in Udupi and Mangalore

Kaushik Nayak¹, Navish Kumar¹, Nitika C. Panakkal³

¹MSc Medical Imaging Technology, Department of Medical Imaging Technology, ³MSc Medical Imaging Technology, Assistant Professor (Sr. Scale), Department of Medical Imaging Technology, Manipal College of Health Professions, Manipal Academy of Higher Education, Manipal, Karnataka, India

Abstract

Introduction: Occupational stress can negatively impact an individual and is associated with a wide range of physical and mental effects resulting in psychosocial and biomechanical stress. Moreover, health care workers have been reported to have a great deal of stress mainly due to the shift duties and increased workload.

Objectives: Therefore the study aimed to determine the psychosocial predictors of stress among radiographers in tertiary care hospitals of Udupi and Mangalore. Data was collected from 55 radiographers from three tertiary care hospitals using a standard questionnaire published by the UK health and safety (HSE). A score and an aggregate score was generated for each item as well as each of seven sets of working condition like “job demands, control, support from managers, support from peers, role, change and relationships”. The analysis tool published by the HSE was used to analyze data.

Results: The indicator analysis tool recommended 11 “psychosocial work conditions” that required improvement. On an aggregate level from the seven psychosocial working conditions ‘relationship’ and ‘Demand’ category warranted improvement.

Conclusion: The study showed majority categories being identified as “good and need to maintain performance”. However that main predictors of occupational stress was found to be excess workload followed by relationship conflicts among co-workers.

Keywords: Occupational stress, Radiographers, Psychosocial stress, stressors, management standards.

Introduction

Occupational stress has been recognized as an important health problem for employees worldwide. The “health and safety executive “defines occupational stress as the “adverse reaction people have to excessive pressures or other demands placed upon them”(1). The combination of high demands over the job and a low amount of control over the situation can lead to stress. Occupational stress is considered as an issue of concern as it is been associated to a variety of adverse physical and mental effects resulting in biomechanical as well psychosocial stress(2,3). Physical effects include Physical fatigue, respiratory problems, headaches, low back pain and muscular tension and impaired immune functioning(4). Mental effects include mood swings, anxiety and also socially withdrawn which results in lowered performance and productivity, obesity or weight loss and increased intake of alcohol(4). Sometimes a more severe consequence is “burnout”. Burnout is
considered a form of emotional and mental exhaustion, depersonalization and reduced sense of personal accomplishment\(^5\). Stress in workplace can have many different sources that can effect both the employer and employees involved. The factors that causes stress is called stressors. According to Health and safety executive management standards there are 6 work design stressors that if not managed well can result in a decreased productivity, poor health and wellbeing. These stressors are Demand, control, support, role, relationships and change\(^6\). Among the various health care professionals, radiographers in general are exposed to a great deal of stress where work problems, role ambiguity, role conflict and social support problems is considered the highest predictors of stress\(^6\). Occupational stress if present in the workplace should be managed for improving individual mental and physical health thus improving work efficiency and productivity for better patient care. Although numerous studies have explored work stress among health care professionals in many countries, there are few in the country that is been done on radiographers. To the best of our knowledge there is no published data on the psychosocial predictors of stress among radiographers in tertiary care hospitals. Therefore the aim of the study was to determine the psychosocial predictors of stress among radiographers in tertiary care hospitals of Udupi and Mangalore.

**Material and Method**

The study approval was acquired from Institution Research Committee and ethics committee. The sample size included 55 radiographers from 3 tertiary care hospitals of Udupi and Mangalore regions. Data was collected using a self-administered questionnaire published by health and safety executive UK\(^7\). A pre-test was conducted among 3 radiographers to know whether they were able to understand the questions. The questionnaire included thirty five questions with a 5 point Likert scale (never, seldom, sometimes, often and always). Each item was represented by an individual score with a value ranging from 1-5 with 1 being the least desirable and 5 is the most desirable. The scoring was reversed for negatively phrased question. The questionnaire included two sections. The first focused on the individual’s personal profile like subjects name, gender, years of experience and section two measured the psychosocial work conditions. The minimum and maximum score obtained on the questionnaire was considered 35 and 175 respectively. The data obtained from the questionnaire were analyzed using SPSS version 22.0. To analyze the data for possible stressors, the questionnaire responses were entered into an excel sheet analysis tool published by HSE management standards. Individual score and an aggregate score was generated for each item as well as for each of 7 sets of psychosocial working condition like “job demands, control, Manager Support, peer support, role, change and relationships”. The analysis tool also presents recommendation for action in relation to benchmark data by assigning color code. The four categories of recommendation include “red: urgent action needed”, “yellow: clear need for improvement”, “blue: good, but need for improvement” and “green: doing very well, need to maintain performance”. Descriptive analysis was done to summarize the average levels of job stress. Independent t test was used to find out any differences in stress levels between various stressors among Gender, age groups (<40 years and >40 years), work experience (<2 years and >2 years) and marital status (married and unmarried). A p value < 0.05 was considered significant when comparing the means between various groups.

**Results**

The study included 55 radiographers from 3 different tertiary care hospitals. In our study 20% of radiographers were above 40 years of age. Majority of them were males (55%), with females comprising of 45 %. Out of the 55 radiographers, 51 % of them were married. 22 out of 55 radiographers had less than 10 years of experience and 25% of them had less than 2 years of experience. The mean score for job stress among 55 radiographer was found to be 133 ranging from 105 to 163 [table 1]. The mean score of indicator items for the seven stressors is depicted in figure 1. The mean score identified below the 20\(^{th}\) percentile in comparison to the benchmark data gathered by HSE from 136 organizations was “red lighted” ‘by the analysis tool indicating “urgent action required”. None of the 7 management standards categories was found to be below the 20\(^{th}\) percentile at an aggregate level. However, scores of 3 individual items dispersed across 2 stressor category were below the 20\(^{th}\) percentile indicating urgent need of action. Scores on 3 items were yellow lighted as they were found to be between the 24\(^{th}\) and 49\(^{th}\) percentile indicating “clear need for improvement”. These items were scattered across 2 of the analysis categories. At the aggregate level, one among the seven categories (relationships) were “yellow lighted”. Scores on 5 items were found to be between the 50\(^{th}\) and the 79\(^{th}\) percentile. These items were highlighted blue with the recommendation
“good, but need for improvement” and were distributed across the ‘Demand and Control’ category. At the aggregate level, one among seven categories (demands) was observed as being in this group. Majority of the items (24) were identified as being greater than the 80th percentile and were green lighted indicating ‘doing very well, need to maintain performance’. In sum, out of 35 psychosocial working conditions examined through the indicator tool, 11 of them indicated requiring improvement when compared to benchmark data gathered from organizations in Britain.

Independent t test showed no significant difference in mean scores for all seven analysis categories between males and females. “(p = 0.38; p = 0.49; p = 0.60; p = 0.87; p = 0.12; 0.77; 0.87)”. Similarly there was no significant difference in mean score of stress levels among age groups “(p = 0.47; p = 0.91; p = 0.50; p = 0.75; p = 0.64; 0.50; 0.53)”, years of experience “(p = 0.14; p = 0.99; p = 0.38; p = 0.82; p = 0.35; p = 0.75; p = 0.23)” and marital status “(p = 0.36; p = 0.05; p = 0.24; p = 0.911; p = 0.64; p = 0.98; p = 0.78)” for all seven analysis categories.

Figure 1. Bar diagram showing the mean score of indicator items for seven stressor categories

Discussion

The results of the study showed that 24 out of 35 items were recognized as being greater than 80th percentile indicating ‘doing very well and need to maintain performance and the rest of 11 evaluated through indicator tool were indicated as requiring improvement when compared with “HSE s current benchmark data”. A lot of studies report excess demand, lack of social support, role conflict and managerial support as the main sources of occupational stress among radiographers(3,6,8,9). Although the present study shows that majority of the categories of psychosocial work environment is good and need to be maintained, there is a need for improvement for the demand and relationship category. Demand can be explained as those aspects of the job in a working environment that is difficult for the employee to achieve(4). These include workload, work pattern and working environment. A study conducted by Natal et al reported that accelerated work load and faulty equipment was the major cause of occupational stress. The high workload was due to high patient to staff ratio requiring more effort from radiographers to work more hard and intensively to meet the demands of staff shortage and high workload(4). The present study showed that majority (70%) of the respondents agreed that they had to work very intensively and very fast more often to
compensate for staff shortage and high workload. The relationship stressor is due to dealing with unacceptable behavior and is caused when a person is subjected to “personal harassment in the form of unkind words or behavior”. Conflict in the workplace has been recognized as a significant cause of stress for some workers\(^\text{10}\). In a survey conducted by Guest et al in 2004, 13% of participants had experienced bullying or harassment by co-workers\(^\text{11}\). The present study reported that around 44% of staff responded that they are always, often and sometimes bullied and 24% staff reported that they are always, often or sometimes subjected to “personal harassment in form of unkind words or behavior”. These recommendations provided by the indicator analysis tool are made based on benchmark data obtained from a representative number of professional groups and are not organization or sector specific. Therefore further studies can be done to develop a standardized questionnaire to evaluate the occupational stress among health care professionals. Interventions can be done for staff members to attend workshops that would help develop their skills and attitude and the effectiveness of these interventions should be assessed in response to the analysis tool recommendation. One of the limitations of the study was that there was a low response rate, as a result only few radiographers enrolled for the study. Therefore future studies can be done in a large scale to include more number of hospitals locally or regionally. Also the biomechanical stress was not evaluated in the present due to time constraints. Musculoskeletal stress is often related to excess workload which can result in psychosocial stress\(^\text{3}\). Therefore further research can be done to evaluate the biomechanical stress among radiographers. Managing occupational stress will not only improve the work efficiency but also increase the productivity which in turn will result in a better quality of care in healthcare.

**Conclusion**

The study has shown the main source of stress being excess demand followed by relationship conflicts among co-workers. Therefore it is recommended to develop interventions needed to manage psychosocial stress that may result in an improved work efficiency.

**Acknowledgement:** The authors would like to acknowledge the Institute research committee and ethics committee, Kasturba hospital for their support to undertake this study. We also extend our heartfelt gratitude to all the participating organizations for their support in data collection. We are also extremely thankful to Health and safety executive UK for providing us with the data collection tool.

**Conflict of Interest:** None

**Funding:** There no external funding for this research project as this project was conducted within the institute itself that provided us with all facilities required to conduct the project.

**Ethical Clearance:** Yes

Impact of COVID-19 on Stress in Collegiate Student

Kumari Mangalam¹, Singh Adarsh², Anand Akshay², Arora Sakshi³, Sharma Yamini³, Sharma Jyoti⁴, Yadav Megha⁴

¹Assistant Professor, Galgotias University, Greater Noida, ²Student, Galgotias University, ³Assistant professor, Manav Rachna International Institute of Research and Studies, ⁴Assistant Professor, Galgotias University Greater Noida

Abstract

Background: A sudden invasion of COVID-19 globally has not only creating fatality but also leading to intolerable psychological pressure in the students as well as other groups. To cope up with this deadly situation many countries declare to be in quarantine and lockdown targeting to limit the transmission. All these situations were creating a lot of curiosity and concern in every individual. This pandemic has increased the level of anxiety and stress in the students.

Objectives: This study was aimed to assess the level of stress in students among the Indian population.

Method and Materials: For this an online survey was done using the perceived stress scale (PSS) questionnaire. A total of 475 responses were received from different universities through Google forms which were distributed to them by the various social media platforms.

Results: Out of 475 responses 58.6% were male and 41.4% were female. The stress levels identified in students were mostly moderate and high stress with 53.6% and 35.4%.

Conclusion: The students were preoccupied with the feelings of COVID-19. COVID-19 is creating various types of mental health problems initialing with stress, anxiety, distress insomnia, etc. The thoughts have become so intense that there is a need to intensify the situation. Students as well as people are in need to deal with their stress. This is a need of an hour.

Keywords: Stress, COVID-19, Corona virus, mental health, impact.

Introduction

Today the pronounced concern and threat in the universe is an invasion of Corona virus aka COVID-19. In December 2019, a public health emergency of global concern an out broke in Wuhan, China which gradually spread to many countries affecting the Mass population of the world¹.

These viruses generally transmit through human to human transmission and present with clinical manifestation of respiratory and few presents with severe cardiovascular symptoms².

This sudden widespread outbreak is connected with various psychological distresses and presents the features of mental illness³. As a result of this life-threatening condition, targets were made to restrict the transmission, early identification, spreading key information regarding awareness of the disease, preventing infection etc⁴.

To achieve the above-mentioned goals many countries implemented the state of lockdown. Although it is contributing to the global economic recession, pause in the production and services and daily routines⁵.

As COVID-19, a new contiguous disease is at its emergence and the way of spreading further creating fear, confusion, anxiety, psychological distress among the public. Lockdown situations have created unnecessary psychological pressure on the students specifically due to the unavailability of medicine and vaccine.

Since mid of March 2020, schools and colleges
were suspended nationwide. For students, such cessation means a deficit in the exploration of resources, lack of physical activity and their comfort zone. Going to school and colleges acts as a coping system with mental health issues for students. Students are getting irritated, frustrated and short-tempered on the disruption of their daily habits and routines.

Lockdown condition is creating a hostage like condition for everyone. Many students are struggling with their online classes and exams. Exams are getting cancelled and postponed in various countries. Particularly final year students are stressed about their degrees, evacuation of the dormitory, exams, job conditions in the market. The present study was aimed to assess the stress in collegiate students.

Material and Method

The present study was a cross-sectional, observational study conducted in the students from different Universities of Greater Noida, India. This was an online and self-reported study. An online Perceived Stress Scale questionnaire was developed by using Google forms. Before the questionnaire, a consent form was taken through e-mails and other social media platforms from the subject. The subjects were encouraged and demonstrated about the study after that link was sent to them. That link was auto directed to the information about the study and consent form. After accepting the survey they need to fill their demographic data and then the set of several questions appeared which was to be filled by the participants.

Perceived stress scale is a stress assessment scale which came into existence in 1983. There were 10 questions in the questionnaire. The questions were supposed to be rated on a 5 point scale ranging from never, rarely, sometimes, fairly often, very often. Score range between 0-13 is considered as low stress, 14-26 are grouped under moderate stress and 27-40 are grouped under high stress.

Descriptive statistics have been used in the study to analyze the findings. Mean, standard deviation and proportions have been used to estimate the result.

Result

The online self-reported survey was conducted in the students of different universities of Greater Noida, India. A total of 475 responses were recorded. All students were between 18-24 years of age and Indian origin. The study was limited for the student who had any type of psychological and mental disorder. The students who know the English language were included in the study.

The mean age was 22.45 ± 3.95 Years. Among the total subjects 58.6% were male and 41.4% were female. Out of total strength, (fig. 1) 53.6% (19.26±3.19) participants were moderately stressed, 10.7%(10.33±2.45) were having a low stress and rest 35.57 (33.72±3.04) were highly stressed.

Fig 1. Showing overall stress in the students due to Covid-19
Discussion

COVID-19 is considered pandemic globally and the most stressful situation for the whole human race. People of any caste, race, religion and community are facing a spectrum of challenges during this phase. Many times Lack of acknowledgment generally leads to an intolerable reaction, which may further adversely affect mental conditions. Impacts are so intensified, that they may severely affect the mental, physical and social well-being of any community. The mental state initially comes in terms of fear, anxiety, behaviour change and ultimately leads to stress.

Hence this study was attempted to assess stress in collegiate students. COVID-19 infection is a highly contagious disease and simultaneously affects a large population.

Every pandemic disease has its specific characteristics concerning causality, advancement and to control the measures. It is important to provide instruction, education and acknowledgment regarding the prevention and spreading of disease. Responses to epidemic partly depend on the mortality rate. Various studies have shown that the outbreak of many infectious diseases including severe acute respiratory syndrome (SARS) 2003 epidemic and pandemic novel influenza A (H1N1) 2009 has adversely affect mental health. Several post-traumatic stress disorder (PTSD), Psychological suffering along with anxiety and depression have been reported among populations that were exposed to mass conflict and displacement. Similar findings of high levels of psychological distress were recorded during the outbreak of the Ebola virus in Guinea and Sierra Leone in all Dominance countries.

Ginger reported that 88% of the workers are moderate to severe stress for the last 4-6 weeks. Quarantine, social distancing and separation may be leading to psychologically distressing for many people.

Our participants have not infected with COVID-19 still more students were highly and moderately stressed and they need to cope up with their stress otherwise it will further lead to many cardiovascular problems. It can be assumed that, people who are infected with COVID-19 suspected to have highly stressed and compromised mental health.

In this time of crisis it is crucial to cope with stress, anxiety, depression and other psychological disorder otherwise it may transform into severe distress leading to denial thoughts like hopelessness, dullness, failing and suicidal feelings.

Limitations this study is limited for the student who had Smartphone, e-mail IDs, internet issue and the ability to English. This study represents the data of only the educated population so it should not be generalized to the whole population.

Conclusion

COVID-19 is creating fatality, economic defoliation, psychological trauma, etc. It is clear that this pandemic has led to a vigorous and multifaceted response from students, psychiatrists and allied professionals and for that mental health issues should be taken into consideration at multiple domains and in every age group and populations. During the COVID-19 pandemic situation, students as well as people are in need to deal with their stress.

Abstract

This work developed a gene appearance scheme such as pathway or protein-protein interaction details to provide improved result in forecast of melanoma sufferers. Techniques utilizing this strategy usually aggregate the appearance of genetics into new blend functions, while the additional details guide this gathering or amassing. Previous researches were limited to few details’ places with some sufferers. Moreover, each study used different details and assessment procedures. Thus, it finds to be difficult to evaluate the performance. To overcome this difficulty, introduced Mutual Information (MI). The category evaluates using the common details in a python package. The feature selection method contains a pool of normalized Affymetrix microarrays. With the advent of existing techniques, we included two efficient prognostic gene signature selection schemes for predicting the breast cancer. The performance results were proved the better results in breast density classification.

Keywords: Mammogram, Mutual Information (MI), PPI Networks, Gene Ranking, Medical images.

Introduction

Breast cancer impacts in large amount of women population and its relevant facts are referred from[1]-[34]. In early days, factors which cause breast cancer can be seen through X-Ray[8]. In Jordan, within a decade the breast cancer become the most typical melanoma. Due to this increase many females have got awareness. Between the period of 1996 to 2007, this situation has been increased from 448 to 817 situations, so 369 new situations have been recorded [2]. However, in spite of the ever-increasing cases of breast cancer over the past years, breast cancer fatal rate has decreased amongst females of every age groups[5]. Using self-check, a woman can do regular checkup in routine basis and their outcome can be considered as early invention of the illness[11].

Mammogram is found in mammography test which helps in earlier detection and analysis of breast illness[2]. In earlier days X-rays are considered as the most regularly used way of medical imaging [3]. Electronic Mammography, Computer-aided recognition and Breasts tom synthesis are the latest development in mammography[4].

Literature Survey: In malignant cases, the clinical diagnosis is best suited for treating the breast cancer. The tumor size and its patterns found in the lump are used for detecting the breast cancer. Sarvestani et al, 2010 proposed the neural systems frameworks to discover the breast Malignancy diagnosis. They examined on different neural systems techniques such as Multilayer Perceptron (MLP), Self Organizing Map (SOM), Radial Basis Function (RBF) and Probabilistic Neural Network (PNN)[23].

Abdelaal et al, 2010 studied on the Support Vector Machines (SVM)[24]. Especially, they focused on the Tree Boost and Tree Forest classifier to extract
the mammographic features based on the ages. They proved good comparable results in terms of accuracy of predicting breast cancer.

Padmavathi, 2011 performed on the comparative study on RBF and MLP using WBC dataset. The logistic regression method were used to find the rate of tumor growth. When looking at MLP and RBF neural system models, it was discovered that RBF had great prescient abilities and furthermore time taken by RBF was not as much as MLP\cite{Padmavathi}.

H. Yusuff et al, 2012 studied on analyzing the breast cancer prediction using logistic regression. The data are generated by the interviews and questionnaires. The significant values were used for the prediction of breast cancer\cite{H. Yusuff et al}. The results were obtained as 91.5% from mammograms and 67.4% of correct classification. A . Priyanga et al, 2013 has delivered a great source which is used in the early recognition of breast cancer\cite{Priyanga et al}.

Vikas Chaurasia et al, 2014 suggested data mining techniques named logistic regression systems \cite{Vikas Chaurasia et al}. They presented by RepTree, RBF network and logistic regression. A 10-fold cross validation method was used to predict the breast cancer detection at an earlier stage. The result obtained to be 74.5%.

The reviews depicted that there are many researchers studied on the breast cancer diagnosis but still there is a lack of accurate algorithms to find more accuracy to detect breast cancer.

**Research Methodology**

In the era of Medical Image Processing Segmentation has given its eternity to give fruitful results. The pictures are fragmented into a few sections in view of their Region of Interests (ROI). The part of division is to play out the assignment, for example, feature extraction and classification. This procedure is connected in breast cancer result to extract the data, for example, confining suspicious regions, producing measurable values and following of the onset and improvement of breast disease and in addition assessment of physiological structures.

**Near-skin tissues** which contains uncompressed greasy structure, situated at the edge of the breast, close to the skin-air interface where the breast is inadequately pressed.

**Fatty region** which contain oily structure that is arranged close by the uncompressed oily tissues encompassing the denser region of fibro-glandular tissue.

**Glandular regions**, which involve non-uniform breast thickness tissue with heterogeneous surface that wraps the hyper-thick area of the fibro-glandular tissue.

**Hyper-thick district**, which is symbolized by high thickness segments of the fibro-glandular tissue, which is by all accounts white tissue can be a disease.

The breast edge can be gotten by isolating the mammogram into breast and foundation areas. The extricated bosoms limit ought to successfully outlined the skin-air interface and ensure the breast area in picture. Then again, skin-line area in mammograms where the breast decreases is regularly low in dark level differentiation. It is caused by the absence of standard pressure of the breast, close to the breast limit area. This effect decreases the deceivability along the fringe district of the mammogram and makes it hard to protect the breast skin-line and to recognize the breast range position.

Breast thickness is an estimation of the thick structure of fibro-glandular tissue, which is by all accounts white on a mammogram. Fibro-glandular tissues seem to have circle or cone designs and extend through the interior of the breast. In light of the thickness level, the breast tissue is ordered.

**Experimental Study:** To present an existing work in a efficient manner large number of images and their detailed descriptions are needed. Datasets such as MIAS (Mammographic Image Analysis Society Digital Mammogram Database) and DDSM (Digital Database for Screening Mammography) are the well-known datasets which are used in mammography to find out the existence of the breast cancer. These data sets were extracted from freely available repositories. Information’s contained here are focuses on superior of images and on wide range of cases. To find out the exactness of images concepts of edge detection algorithms were used. After finding exactness of disease classification algorithms were applied. Implementation is done using MATLAB code. The graphical user interface was designed to provide the outmost user ambiance and ease of use. In GUI, the image is chosen and the intrinsic properties of the image such as running aspect, bandwidth threshold, initial index and the initial row of the image is assisted to predict the breast cancer. The steps involved in mammogram is depicted in Fig. 1.
MRI of the breast: Magnetic Resonance Imaging is the most appealing contrasting option to Mammography. MRI is sensitive for identifying a few growths which could be missed by mammography. To be effective, contrast upgraded breast MRI is done by infusing in the patient’s body of a paramagnetic complexity specialist.

This strategy depends on the speculation that, after the infusion of the operator, variations from the norm upgrade more than ordinary tissues because of their expanded vascularity, vascular piousness’ and interstitial spaces MRI shapes 3D uncompressed picture. It can perform with all ladies including who are not reasonable for mammography, for example, young ladies with thick breast and ladies with silicone-filled breast implants. Since it utilizes magnetic fields, MRI has no destructive consequences for human bodies. Be that as it may, MRI sets aside rather long opportunity to perform and has high cost which is more than ten times more noteworthy than mammography.

Support vector machine: Support vector machines (SVMs) are an arrangement of Supervised learning techniques that examine information and perceive designs, utilized for characterization and regression investigation. All the more formally, SVM builds a hyper plane or set of hyper planes in a high or unbounded dimensional space, which can be utilized for classification, regression or different errands. Instinctively, a great detachment is accomplished by the hyper plane that has the biggest separation to the closest preparing information purposes of any class, since by and large the bigger the edge the lower the speculation error of the classifier.

The fundamental thought of SVM is that it anticipates information focuses from a given two-class preparing set in a higher dimensional space and finds an ideal hyper plane. The optimal one is the one that isolates the information with the maximal edge. SVMs recognize the information focuses close to the ideal isolating hyper plane which is called support vectors. The distance between the isolating hyper plane and the closest of the positive and negative information focuses is known as the margin of the SVM classifier.

4.3 Database

Total quantities of 412 examples are acquired from mammograms containing small scale calcifications from MIAS. From the collected data based on the principle of classification concepts, partitioned the 80% samples into training data set and 20% of the samples are described as testing set. The training set contains 340 specimens, of which, 3155 normal, benign and malignant cases. Remaining 70 tests are utilized for testing SVM classifier. Testing set contains 15 instances of normal and 15 instances of abnormal respectively and results are displayed in Fig.2-4.
In pattern recognition systems, Fuzzy C-means algorithm is the most often used techniques. Fuzzy C-mean is also known as Fuzzy ISODATA. A group of data may be belonging to one or more cluster is known as Fuzzy C-Means (FCM) which is described to lessen the minimization problem to accomplish a well-known classification system.
The working of Fuzzy C-means is given as:

(a) Determine the matrix as \( U = [u_{ij}] \) and \( U^{(0)} \).

(b) Estimating the cluster centers in vector format as \( C^{(k)} = [C_j] \) with \( U^{(k)} \).

(c) Updating the \( U^{(k)} \) and \( U^{(k+1)} \) as

\[
U_j = \frac{1}{\sum_{i=1}^{c} \frac{\| x_i - c_j \|}{\| x_i - c_j \|}}
\]

If \( \| U_j^{k+1} - U_j^k \| <|\epsilon| \) is met, then the function is terminated or else follows the step (b).

### Parameter Selection and Training:

Since this work has been concentrate more on classification of miniaturized scale calcification into benign or malignant, the ordinary case won’t be utilized. Each of benign and malignant cases has a metadata that demonstrated the area and size of the small-scale calcification. This work proposed the classification of computerized mammogram utilizing Fuzzy and SVM classifier. The quantities of training and testing sets are appeared in “Table 1”. “Table 2” demonstrates the classification rate for normal and abnormal categories and the simulation results for tumor severities of small-scale calcification (benign and malign).

<table>
<thead>
<tr>
<th>Table 1. Number of Training and Testing Sets</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Category</strong></td>
</tr>

</tr>
<tr>
<td>Normal</td>
</tr>
<tr>
<td>Abnormal</td>
</tr>
<tr>
<td>Benign</td>
</tr>
<tr>
<td>Malignant</td>
</tr>
</tbody>
</table>

Table 1 lists the number of training and testing data sets taken with basic classification concepts for the stages such as Normal, Abnormal, Benign, Malignant. Table 2 shows the classification. Table 2 shows the Classification rate of Proposed technique with the existing techniques such as Support Vector Machine and FCM. From the results it is clearly understood that Proposed technique has shown better performance comparing with existing technique like Support Vector Machine and Fuzzy C Means Clustering Algorithms.

### Conclusion

The glandular tissue is the most recommended part for estimating the density of the breast tissue. The classification is based on the density level to suspect the breast cancer. The glandular tissue visualized the affected region. The anatomical regions are segmented and classified which exposed the affected part to the radiologist to interpret the results. The breast density estimation is classified accurately in order to predict the breast cancer at an earlier stage. The performance results proved that the breast density classification yields better results. It is clearly seen that proposed work has given better performance. As a future work, the segmentation is merged with the glandular tissue in screening mammography.

Pattern of Poisoning Cases at Tertiary Care Center at Geetanjali Medical College & Hospital, Udaipur

Lovekumar R. Bhagora\textsuperscript{1}, Sanjeev Kumar\textsuperscript{2}

\textsuperscript{1}Assistant Professor, Dept. of Forensic Medicine, Geetanjali Medical College, Udaipur, \textsuperscript{2}Professor & Head, Dept. of Forensic Medicine, Geetanjali Medical College, Udaipur, Rajasthan

Abstract

\textbf{Introduction}: Poisoning is a global public health problem causing significant morbidity and mortality. It is important to know the pattern and outcome of acute poisoning cases for proper planning, prevention and management of these cases.

\textbf{Aims and Objective}: To find out the pattern of poisoning reported in Geetanjali Medical College, Udaipur.

\textbf{Material and Methodology}: The present prospective study had been conducted in the Department of Forensic Medicine, Geetanjali Medical College & Hospital, Udaipur, Rajasthan during the period of Two year from 1\textsuperscript{st} Jan 2017 to 31\textsuperscript{th} Dec 2018.

\textbf{Result and Observation}: In our study majority of poisoning case [101 cases (35.69%)] were observed in the age group of 21-30 years followed by the age group of 11-20 years. Male person [153 cases (54.06%)] most commonly affected by poison and majority of patients [184 cases (65.02%)] belongs to Rural area. In our study majority numbers of cases [128 cases (43.82%)] found in rainy season. In our study higher number of poisoning cases were due to Aluminium phosphide poisoning [106 cases (37.47%)] followed by snakebite poisoning [62 cases (21.91 %)]. Among insecticides, maximum 40 cases (14.13 %) were due to Organophosphorus compounds. \textbf{Conclusion}: Awareness and education about the potential toxicity of commonly used pesticides and drugs may help in reducing the burden of poisoning.

\textbf{Keyword}: Prospective study, Poison, Aluminium Phosphide, Snake bite, Organophosphorus, Udaipur.

Introduction

Poisoning is a global public health problem causing significant morbidity and mortality. It is important to know the pattern and outcome of acute poisoning cases for proper planning, prevention and management of these cases.

Mortality and morbidity of poisoning cases varies from country to country depending on the nature of poison and availability of facilities and treatment by qualified doctors\textsuperscript{1}.

Poisoning is a medical emergency and a patient is always invariably rushed to the hospital at the earliest possible moment, irrespective of the amount and nature of poison ingested\textsuperscript{2}.

Poisoning is one of the major causes of hospitalization through emergency and is a major public health problem\textsuperscript{3}. Pattern of poisoning in a region depends on variety of factors, such as availability of the poisons, socio-economic status of the population, religious and cultural influences and availability of drugs.

Considering the cost and outcomes of the poison cases reported to the hospitals, it is found necessary
to establish a Poison Information Centre (PIC) which should be networked with other poison information centres in India and with other countries, by which identifying the poisons and managing the cases will become more efficient.

**Aims and Objective:**

To find out the pattern of poisoning reported to the hospital.

To determine the age and sex wise distribution of poisoning cases.

To find out the duration of hospital stay.

To find out nature and type of Poison.

**Material and Methodology**

The present prospective study had been conducted in the Department of Forensic Medicine & Toxicology at Geetanjali Medical College & Hospital, Udaipur, Rajasthan during the period from 1st Jan 2017 to 31st Dec 2018.

The diagnosis of poisoning was based on history given by clinical examination, police officer, patient relatives and medical case papers. Necessary laboratory tests were also performed to confirm the diagnosis of poisoning (if available). All cases of poisoning admitted to the hospital were included in this study. The data including demographic profile of patients, duration of hospital stay, nature and class of poison, outcome and circumstances of poisoning were obtained from medical records and were documented on a pre-structured proforma.

**Result and Observation**

In our study majority of case [101 cases (35.69%)] were observed in the age group of 21-30 years followed by the age group of 11-20 years [65 cases (22.26%)] followed by 31-40 years[46 cases (16.25%)]. While only 5 case (01.77%) was observed in between 61-70 years age group. [Table 1].

Majority [153 cases (54.06%)] of cases of Poison were Male person while [130 cases (45.94%)] were female. [Table 2]

In our study majority of cases [184 cases (65.02%)] belongs to Rural area, while 99 cases (34.98%) belongs to Urban area. [Table 3]

In our study majority numbers cases [128 cases (43.82%)] of Poison found in rainy season [Table 4].

The hospitalization time for the poisoning cases in our study, varied between 1-37 days with a mean duration of hospitalization of 4 -7 days. [Table 5].

In our study Out of total 283 poison cases, Aluminium phosphide poisoning were found in 106 cases (37.47%) followed by snakebite poisoning was there in 62 cases (21.91 %) and acid poisoning - 3 cases (1.06 %).Among insecticides, maximum - 40 cases (14.13 %) were due to the organophosphorus compounds. [Table 6].

**Discussion**

In the present study, majority of Poisoning cases (21.30%) were observed in the age group of 21-30 years. which was also similar with various studies, like Gupta P et al5, Bari M S Vet al6. This shows that young adults are more vulnerable to this health problem which might be due to emotional and social disharmony, occupational problems and risk taking behaviors at these ages.

The pattern of poisoning with respect to gender in our study indicates that there were more cases of poisoning among the male patients(54.06%) compared to female patients(45.94%).This type of similar finding are observed by Gupta Pet al5, Bari M S V et al6. High proportion of poisoning among males might be due to change in the lifestyle and cultural patterns, reactive depression and high degree of stress in academic, financial and social sectors.

In the present study, majority of victims (65.02%) were belongs to rural area, while 34.98 % victims were belongs to urban area. Nearly similar finding are seen in the study done by Sharma BR et al7. This maybe because widespread use of pesticide in agriculture sector in rural area. Poverty, failure of crops, family problems and easy availability of the poison in their household made people of rural area more prone for poisoning. However, study done by Abubakar S etal8 from state of Karnataka, the incidence was more in those who were from urban background.

A season-wise variation was seen in the poisoning incidence in the present study. Maximum numbers of poisoning cases [128 cases (43.82%)] were seen in the rainy season . This may be due to increased work and labour pressure, financial crisis and increased use and availability of pesticides, Insecticide during that season. Also snake bite cases more seen in this season.
The hospitalization time for the poisoning cases in our study, varied between 1-37 days with 30.74% showing a mean duration of hospitalization of 4-7 days. A similar result was found in the study conducted by Abubakar S et al\(^8\) in southern India, which indicated that the average number of days of hospitalization was 4-7 days (33.3%).

The Southern parts of Rajasthan, mostly comprising of agricultural land, the geographic distribution of the Victims chiefly being from rural areas and comprising of 184 cases. In our study most of cases of poisoning were due to Aluminium phosphide, Snake bite and Organophosphate poison. Because of abundant use of pesticides, Insecticides in agricultural fields of rural areas and inhabitation of poisonous reptiles (snakebite) in unhealthy and hilly rural areas, Organophosphate and aluminium phosphide are common agents used for poisoning because of low cost and easy availability and since majority of patients in our study were from rural background and were farmers, they used these pesticides instead of other poisons. Snake bite is also common in our study because of predominance of people of rural area.

Conclusion

Most common type of poisoning cases reported overall was aluminium phosphide followed by snake bite followed by organophosphate. Proportion of mortality and requirement of ventilator was higher in case of aluminium phosphide poisoning. We suggest the government should regulate the import, manufacture, sale, transport, distribution and use of insecticides and pesticides. Upgrading the peripheral health centres to manage cases of poisoning in emergency including training of staff to give first aid treatment of poisoning (including timely intubation and respiratory support on AMBU bag) and availability of antidote and anti-snake venoms and increase in public awareness about the seriousness of problem through health education.

Awareness and education about the potential toxicity of commonly used pesticides and drugs may help in reducing the burden of poisoning. We should have to establish a poison information centre (PIC) which should be networked with other poison information centre in India and with developed countries which can help in identifying the poison and managing the cases.

Integration and Synchronization of Population Policies Through Grand Design Population Development in Indonesia

Lutfi Agus Salim

Associate Professor in Department Biostatistic and Demography, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia

Abstract

The problem of population in Indonesia is complex. Population policy in the era of decentralization is still not integrated and sustainable. Grand Design of Population Development is a guideline for population-oriented policies, strategies and development programs, which contains important current population issues, desired population conditions, population development programs, population development roadmaps covering population quantity control, quality development population, family development, spatial planning and population regulation and population administration development. Approach Grand Design of Population Development can influencing policy and responsive policy towards population dynamics. With the Grand Design of Population Development, a region can prepare itself to welcome the demographic bonus that can be done through improving human quality. Human development as an effort to develop capability the ability of human self, which contains four elements, namely productivity, equity, sustainability and empowerment. The roadmap set out in Grand Design of Population Development will be implemented on an ongoing basis to improve human quality, reflected in the increasing Human Development Index.

Keywords: Population policies, grand design population development.

Introduction

People is the object and subject of development (people centered development). To reach a development goal is determined by the human development, economy, culture and national character. Development oriented to the potential and needs of social, economic, cultural, physical and spiritual tranquility of the people. A large population will become a force for national development if it is accompanied by a qualified and competitive population, because a high-quality population will accelerate the achievement of economic and social growth(1).

Some of the regulations that form the basis of the drafting of a Grand Design for Population Development (GDPD) are as follows: 1.) Indonesian’s Law Constitution of 1945 (Preamble, Article 28B, article 33 and article 34); 2.) Law Number 24 of 2013 concerning Population Administration; 3.) Law No. 39 of 1999 concerning Human Rights; 4.) Government Regulation Number 87 of 2014 concerning Development of Population and Family Development, Family Planning and Family Information Systems; 5.) Presidential Regulation 153 of 2014 concerning GDPD(2).

The population in an area in a particular year is influenced by birth, death and migration (3). Births that occur will be incremental while deaths will be a deduction from the population. Likewise with migration, the number of people come is supplementary and the people left is reduced(4).

In line with regional autonomy, a population development effort that is consistent and sustainable is the most appropriate choice amid complex population

Based on these problems, the researcher raised the research topic with the title “Grand Design of Population Development in improving the quality of human development in Indonesia”

**Problem Formulation:** The total population in the world reached seven billion and is expected to nine billion by 2035. More than three-quarters of the world’s population live in developing countries, one of which is Indonesia with a population of more than 237 million people in the year 2010 with a population growth rate of 1.3% per year (3).

Projection shows that population of Indonesia will keep increasing in the next twenty five years from, 238.5 million in 2010 to 305.6 million in 2035. However, In the period of 2010-2015 and 2030-2035 the population growth rate will decrease from 1.38 percent to 0.62 percent per year. This decrease is determined by a decrease of the birth and death rates. The decrease rate caused by birth is faster than that caused by death. The Crude Birth Rate (CBR) will decrease from approximately 21.0 for 1000 population in the beginning of the projection to 14.0 per 1000 population in the end of the projection period. Meanwhile the Crude Dead Rate (CDR) will increase from 6.4 per 1000 population to 8.8 per 1000 population in the same period of time (6).

In the same period of time, the productive ages, 15-64 years, increase from 66.5 percent to 67.9 percent and those of 65 years and above increase from 5.0 percent to 10.6 percent. This change in age composition decreased the dependency ratio from 50.5 percent in 2010 to 47.3 percent in 2035. Then the decrease in the dependency ratio means a decrease of economic burden to the population in productive ages which has always been supporting the unproductive age population (6).

Indonesia Gold in 2045 is a condition in Indonesia is superior, advanced to compete with other nations in the world in 2045 (7). In that year Indonesia also must be moved out of the zone Middle Income Trap which can be achieved if carried out policy reforms focused on increasing the significant economic growth and strengthening of human resource capacity (1).

**Literatures:**

**People Centered Development:** Malthus says “If there are no restrictions on population will multiply very quickly and fulfill some parts of the earth’s quickly. Humans need food for life but rate of growth of food is much slower” (8). Population projection is a scientific calculation based on assumptions of the components of the population growth rate, namely birth, death and movement (12).

Development as a effort or a series for growth and change that are planned and carried out consciously by a nation, state and government, towards modernity in the context of nation building (13). Development is a process of change all social systems, such as politics, economy, infrastructure, defense, education and technology, institutions and culture (14). Development as an economic, social and cultural transformation (15).

Development in this article is defined as a form of change that is planned; each person or group of people certainly hope have a better shape or even perfect than the previous situation; to realize this hope certainly require a plan. Development planning is felt more as a more rational and orderly effort for the development of undeveloped or newly developing societies (16).

According to Heran is a useful change towards sustainable social and economic systems which are decided as the will of a nation (17). Development is a process that moves in a straight line, namely from backward society to developed country society. Development was first used in the sense of economic growth. A community is considered successful in carrying out development, if the economic growth of the community is quite high (18).

**Problem Solution:** Development is a process of transformation of the community from a situation to another situation that is closer to the ideals of the community, though two things to consider, continuity and change. Development is a process of change that occurs naturally as a result of development (14). Thus, the development process occurs in all aspects of community life, economic, social, cultural, political, which takes place at the macro (national) and micro (community/group) level (3).

This paradigm gives the role of the individual as a subject, the actor who sets goals, controls resources and directs the processes that affect his life. According to this paradigm, the main goal of development is to create an environment that allows its people to enjoy a creative, healthy and long-life. All development policies must be carried out based on the principle of people centered development in order to achieve population-oriented development.
Quality of the population is the condition of the population in physical and non-physical aspects which include the degree of health, education, employment, productivity, social level, resilience, independence, intelligence, as a basic measure to develop abilities and enjoy life as human beings who are pious, cultured, have personality, nationally and live well.

**Funding:**

**Grand Design of Population Development (GDPD):** Regional development is carried out through the development of regional autonomy and the regulation of resources that provide opportunities for the realization of good governance. Mandated by Law 23 of 2014, one of the affairs of population control is to guide and synchronize population control policies. One product of the integration and synchronization of population policy is the GDPD document which can be used as guidance on population-oriented policies, strategies and development programs. According to Presidential Regulation 153 of 2014 concerning the GDPD, it is stated that GDPD is a formulation of population development planning for the next 25 years and is elaborated every five years which contains important issues of current population, population conditions desirable, population development program, population development roadmap which includes population quantity control, population quality development, family development, spatial distribution and population regulation and population administration development.

Grand Design of Population Development can be used as a guide for stakeholders in local governments in integrating population policies, targets and programs into Regional Mid-Term Development Plan (RPJMD) document, both influencing policies and responsive policies on population dynamics in the regions. Especially, GDPD can accelerate development and can integrate the population development program.

**Discussion**

**Policy And Strategy Fill In Demographic Deviden By GDPD:** In 2020 and 2030 Indonesia will receive Demographic Deviden. the success in exploiting the demographic bonus is affected by the government’s readiness to prepare a qualified workforce. Furthermore, the government has a very important role to manage the resource potential of Indonesia.

A country have a demographic deviden if the population of productive age (15-64 years) more than the not-productive age (0-14 years and 65 years and above). The comparison between the two population groups is called the Dependency Ratio. The economic benefit due to the decrease in the Dependency Ratio is called the Demographic Deviden. The decline in the dependency ratio at some point will reach its lowest point and turn back up again, when it shows the lowest number which is usually under 50%, called The Window of Opportunity where the opportunity is very short only occurs once in a decade of the entire life journey population.

A country or region is said to have a demographic bonus if the dependency ratio is below 50.0 percent. A demographic deviden is an opportunity for a country’s economic prosperity because of the large proportion of the productive population. If this opportunity is not utilized to its full potential, it will be an anti demographic (bomb disaster) bonus.

With the GDPD, an area can prepare itself to welcome demographic deviden that can be done through improving the quality of public health, especially the health of the productive age population so that during the elderly boom, the aging population will not be a problem (especially the problem of funds swelling health insurance), improving the quality of education and developing skills, controlling population growth rates and supporting economic policies.

**Strategies that can be taken by the government in picking demographic deviden include:**

**Improving the quality of adolescent:** The development of a prosperous family will provide educational platforms for future generations, especially adolescents who will soon enter the productive age. Encourage the creation of quality families so that it is expected to produce a quality generation, especially for adolescents in the family, restore family functions so that they can help the development process of adolescents who are full of dynamics, provide a forum or event that provides opportunities for adolescents to appreciate their talents and abilities, incorporate life learning skills into the school curriculum so that graduates can be ready to use, maximizing the GenRe Program in schools, colleges and the surrounding environment through advocacy and IEC, increasing awareness and participation of governments and stakeholders in making pro-youth policies.

**Improving the quality of education:** Decreasing
the number of children born gives flexibility to improve family quality. All expenditures can be more focused on education and health to improve the quality of competitive human resources. Improving the quality of the population of productive age can be done by providing skills that are in accordance with the needs of the labor market with competitive quality. Preparation and utilization of demographic deviden one of which includes the expansion of universal secondary education and strengthening the linkages of vocational and industrial education and training.

**Placing elderly people as a asset, not a burden:**
Being in the era of demographic deviden and their continuation in the future, the increase in the elderly population in the future can be used as a potential rather than a burden. Older people with health problems and declining productivity can be a burden. But with the improvement of the quality of existing health, the elderly population is expected to continue to be able to produce. To get a productive elderly population, population-based development programs are needed and the programs are long-term.

**Improving a Health Program:** Development programs in health sector that prepare a healthy population, not easily sick, so that those who later enter old age will still be healthy. With good health, they can still be productive in economic activities. While preparing healthy people, but the state must also protect them with health insurance. In addition, from the community’s point of view, there must be a continuing awareness program to save money or participate in a pension fund program that can be relied upon when retirement has arrived.

The strategies are as follows: Increasing access and quality of primary level health services, Improving Access and Quality of Referral Health Services, Healthy Living Community Movement Program and Family Approach

**Economic Empowerment:** With the Demographic Bonus a Window of Opportunity through birth is prevented. This fact will increase significantly towards increasing family opportunities for productive activities. Productive activities will lead to an increase in community welfare, namely: 1) increasing women’s motivation to enter the labor market, 2) increasing women’s participation, 3) saving society and 4) human capital (human capital) available.

**Importance of GDPD on Human Quality Development:** Human development as an effort to develop the ability of human self, which contains four elements, namely productivity, equity, sustainability and empowerment. Quality human development that has been achieved by an area can be done by measuring the quality of development using Human Development Index (HDI) which include 3 parameters: 1) Success in health, by looking at life expectancy, 2) The ability to reflect on the success of educational development by looking at old expectations school and length of school, 3) The amount of goods and services that can be provided by the community to its citizens is by looking at the purchasing power parity of the community.

![Figure 1. Contribution of GDPD in HDI](image)
Meanwhile GDPD is a formulation of population development planning which includes five aspects, namely population quantity control, population quality development, family development, spatial planning and population regulation and population administration development. The five aspects of GDPD are very closely related to efforts to develop human quality through its deciding components. If a regency/municipality has compiled GDPD properly according to the stipulated provisions, then in fact the efforts of the regency/city in the development of human quality are already on the correct roadmap. The direction of development policies and programs in GDPD has been made, medium term and long term. The flow of importance of GDPD in Human Quality Development can be described as follows:

**Conclusion**

Some recommendations from the grand design of population:

Utilization of GDPD in the roadmap for the development of human quality and sustainable development, because most of the population programs contained in GDPD are promoting human development and sustainability.

Integration, Synchronization and Synergy of GDPD programs and roadmaps relating to human quality development and sustainable development.

Strengthened networking of policies and programs among stakeholders in building population governance to support the creation of sustainable development.

It must be realized from the start that population development through quantity control efforts is a long-term investment and the results will be felt in the future.

Facial Reconstruction: Solving Mysteries and Rewriting Histories

M.K. Sunil\textsuperscript{1}, Roopika Handa\textsuperscript{2}, Anudeep Raina\textsuperscript{3}, Suranagama Lehri\textsuperscript{4}, Vasundhara\textsuperscript{4}, Aiman Mahfooz\textsuperscript{4}

\textsuperscript{1}Professor and Head, \textsuperscript{2}Professor, \textsuperscript{3}Reader, \textsuperscript{4}PG Student, Dept. of Oral medicine and Radiology

Abstract

Facial reconstruction is a multidisciplinary field that holds the ability to identify a missing person from the scratch. It comes into play when all other techniques fail. Over the years, the journey of facial reconstruction has taken many noteworthy turns and has emerged as a triumph. There have been several attempts from two dimensional techniques which utilize the soft tissue depth to the more recent three dimensional technology in reconstructing the facial features on the skull. From crime cases to the distress caused by natural disasters, facial reconstruction solves it all.

Keywords: Facial Reconstruction, Manual Processing, Three dimensional printing.

Introduction

“The real face is not behind the mask, it is actually with the mask”; and facial reconstruction is the science as well as art that fabricates the veil which beholds the identity of a person. Faces are fascinating with intriguing histories and with the help of forensic advancements, these can be unraveled to crack crimes and help find families their loved ones.

Facial reconstruction is mainly used in two principal branches of science: forensic science and archaeology. Skulls are indestructible for centuries and thus are being utilized for years to teach anatomy lessons and more recently have been identified as a major means to discover a person’s identity.\textsuperscript{2}

The face of an individual has several different types of exclusive features and thus, is of great importance in identification and recognition of a person. Forensic facial reconstruction is an alternative method in the identification process where there is little or no other evidence available.\textsuperscript{3}

Hence, in this collaborative review of literature, we have outlined the history, the process, the manual and advanced methodologies and number of commercially available soft wares for facial reconstruction.

The Historical Outline: The history has witnessed, a multitude of different traditions to deal with the dead. Among the various rituals, the first evidence that the skull was used for remembering the dead dates from the Neolithic Age \textsuperscript{4}. Similarly, there are multiple examples from the past depicting how special consideration was given to the head or skull.

Few years later, death masks came into existence and in the Italian Renaissance period, death-mask art was most appreciated. Artists from northern Italy were the first to provide wax models for doctors and surgeons.

Nineteenth century marked the beginning of crime detection and in 1895, a German anatomist, Wilhelm His did the first facial reconstruction. He reconstructed the face of German composer Johann Sebastian Bach. Another breakthrough came with the advent of “Welcker Facial Reconstruction Technique” by a Welcker, a Germanphysiologist and anatomist. He utilized the average soft tissue depths to construct the mask over the dried skull.\textsuperscript{1}
In 1946, Wilton Maria Krogmann, brought modifications in the existing method by documenting five basic principles of reconstruction of soft tissues of the face i.e. the relation of eyeball to orbit, the shape of nose tip, the ear location, the mouth width and the ear length.

Forensic facial reconstruction took a quantum leap in the 1980s, when Computerized reconstruction was first studied at London College University. Here, at the university, the pioneers carried out a cranial reconstruction procedure using a laser like scanner and video camera.

**The Process:** The main focus of facial reconstruction is to reinstate the characteristics and features to the details of the dried skull. The creation of the face from the skull is a procedure of approximation.

The traditional facial reconstruction method are based on manual procedures, producing 2D portraits or 3D sculptures.

**These method basically consists of three steps:**

- Creating a replica of the raw skull with a sparse set of anatomical landmarks
- apply an average soft tissue thickness to each skull landmark in order to estimate a corresponding landmark on the face
- draw up or sculpt a face fitting the estimated landmarks.

The process of facial reconstruction demands a multidisciplinary approach, where forensic artists, archaeologists, medical team, all team up to reconstruct a person’s identity. Finally a qualitative comparison is made between facial reconstructions of a real-case skull, based on two typical static face models.

However, one reconstruction might take several days to months. In order to alleviate these difficulties, several computer graphic software packages have been developed. These advancements utilize the same basic procedure of manual processing, which permits to take advantage of both human expertise and the precision of softwares. The main aim of forensic facial approximations is to promote recognition of a deceased person and all the processes and methodologies are designed to achieve an accurate forensic facial approximation (FFA).

**The Methodologies**

Methodologies of facial reconstruction involves:

- Two Dimensional Reconstruction
- 3D Manual Reconstruction
- Three dimensional printing for facial reconstruction

**Two-dimensional reconstruction:** In 1980s, Karen Taylor in Austin, Texas developed the construction of face engaging the soft tissue depth estimates. Two dimensional reconstruction focuses on this principle and brings into role the antemortem photographs of an individual.

Moreover, these days certain software programmes like CARESTM or CARES (Computer Assisted Recovery Enhancement System) and FACES (Forensic Anthropology Computer Enhancement System) etc quickly produce 2D reconstruction which can be edited and manipulated. These softwares work by digitization radiographs, photographs which will replicate an electronically altered version of the image.

**3D Manual Reconstruction:** This method also needs both an artist and a forensic anthropologist. This method is similar to two dimensional method as it also requires the use of tissue depth markers of specified lengths to represent different soft tissue depths. The markers are inserted into small holes on the skull cast at specific strategic points or landmarks. In the computerized method, computer software produces reconstruction by using scanned and stock photographs.

**Legends:** Here is a diagramatic presentation of the model generation using three dimensional and CT scans and processing them in the software: (diagram 1).
Three dimensional printing for facial reconstruction: This method of facial reconstruction is efficient, accurate and noninvasive to the remains, whether it is used for forensics or archaeological purposes. Reconstruction can be processed through Abode Photoshop for final rendering.

Conclusion

Forensic facial reconstruction provides a noninvasive and relatively simple approach to identify a missing person. This is one of the most crucial gateways to solve crime scenes as well as help families find their lost ones. This technique is not only used for identification of individuals from skeletal remains but is also used for archaeological research purposes. Moreover, with the advent of three-dimensional technologies, the whole process has become relatively quick and simpler, opening new gates to this amazing field.

Cheiloscopy–An Efficient Method for Gender Dimorphism

Mahesh Jambure¹, Ashlesha Jambure²

¹Associate Professor, Dept. of Forensic Medicine, ²Assistant Professor, Dept. of Biochemistry, MGM’s Medical College, N-6, CIDCO, Aurangabad-431005 Maharashtra

Abstract

Lip print is an anatomical character of the human lips. In forensic identification, lip print patterns can lead us to important information and helps in person’s identification. The grooves present on human lips (Sulci labiorum) are unique to each person and can be used to determine identity. Fingerprints, post-mortem reports and of late, DNA fingerprinting, have been successful in person identification in the field of forensic science. Just as in these method, lip prints can be instrumental in identifying a person positively and can be used to verify the presence or absence of a person at the scene of crime. Cheiloscopic techniques have an equal value in relation to other types of forensic evidences for personal identification.

Material and Method: The study was conducted on 100 students of age group 18-25 yrs. Lip stick was applied on each individual and the lip-print was obtained on a paper. The lip impression patterns were studied, classified and recorded using magnifying lens with light.

Result: Lip patterns are unique for the individual and no two patterns are identical to each other. In study population, Type III pattern was most common in male while In females predominant pattern was type I. Thus in medico legal case, due to clear differentiation in sexes it is easy to identify person and gender.

Conclusion: Cheiloscopy can be reliable method for personal identification and gender dimorphism.

Keywords: Lip prints, cheiloscopy, personal identification, sex determination

Introduction

In the field of forensic science, it is important to verify the presence or absence of a person at the scene of crime and to establish person’s individuality for legally as well as humanitarian purpose. For identifying it is also essential to determine the gender of an individual¹.

Various well known implanted method of person identification like fingerprints, anthropology, odontology, DNA analysis, iris scan, post mortem findings and other techniques that determine gender, approximate age, height, etc., have been successfully used. Just as in these method, lip prints can be instrumental in identifying a person positively. It is least invasive and cost effective procedure among all²³⁴.

Lip print is an anatomical character of the human lips. “It is defined as the normal lines and fissures present in the form of wrinkles and grooves that are located in the transition zone of the human lip, between the inner labial mucosa and the outer skin, the examination of which is referred as cheiloscopy⁵⁶.

Lip prints are not affected by injuries, environmental changes and diseases. The grooves present on human lips (Sulci Labiorum) are unique to each person. As lip prints remain unchanged throughout the life, based on their characteristic arrangements cheiloscopic techniques have an equal value in relation to other types of forensic evidences for personal identification⁷⁸.

For identification purpose, lip print left in crime scene can be used as the evidence to compare with that of the suspect. Cheiloscopy as a tool for identification was

Assistant Professor, Dept. Of Biochemistry, MGM’s Medical College,N-6, CIDCO, Aurangabad 431005-Maharashtra
e-mail: draashlesha@gmail.com
first recommended as early as 1932 by Edmond Locard (1877-1966), one of France’s greatest criminologists\(^9\).

By 1950, in textbook on homicide cheiloscopy was described as a method of identification\(^10\). In 1967, Santos classified and divided lip groove into four types for the first time namely\(^11,12\).

1. Straight line
2. Curved line
3. Angled line
4. Sine-shaped curve

Suzuki and Tsuchihashi, in 1970, devised a classification method of lip prints, which follows\(^13,14\). (Figure 1, 2).

1. Type I: A clear-cut groove running vertically across the lip.
2. Type I’: Partial-length groove of Type I.
3. Type II: A Branched groove.
4. Type III: An intersected groove.
5. Type IV: A Reticular pattern
6. Type V: Other patterns.

**Figure 1: Various lip print patterns**

In literature, these are most widely used classifications. For discrimination of the sex of an individual, Vahanwahal and Parekh (2000); Sivpathasundaram, et al. (2001) gave coding as Type I, I’, II patterns are dominant in females and Type III, IV, V are dominant in males\(^15,16\).

Researchers suggested that lip prints are suitable for comparison, analysis and identification of a person\(^17,18\). The present study is undertaken with aim to study the predominant type of lip patterns in study population and to correlate it for identification of gender.

**Material and Method**

A cross sectional descriptive study was conducted in department of Forensic medicine after approval of institutional ethical committee.

The purpose of the study was briefed to all the
participants and written informed consent was obtained from each of the participants.

The study was conducted on 100 students from 2nd MBBS at MGM’s Medical College Aurangabad. Male and female students of age group 18-25 who were willing to participate, whose lips were free from any pathology, had normal transition zone between the mucosa and skin included in study group. Those having gross deformities of lip (cleft lip, ulcers, scar, trauma, inflammation, lesions) heavy smokers, allergy to lipstick were excluded from study.

A dark colored frosted lipstick, thin bond paper, a magnifying lens, cellophane tape, pen/pencil were required as a study material.

The lips were cleaned and a thin layer of red/brown colored lipstick was applied on the lips. he person was asked to rub both the lips to spread the applied lipstick evenly A sheet of bond paper was folded and the “hinged” portion of the paper was inserted in between the lips and subjects were asked to press their lips onto it. It was then “unfolded” again. The cellophane tape was pasted on bond paper to preserve the record. The lip prints were coded according to name and sex of an individual.

A horizontal line dividing upper lip from lower lip and a median vertical line dividing lips into two halves was drawn. Thus, lip prints were divided in first right upper, second left upper, third left lower and fourth right lower quadrants for identification of a person. The number of lines and furrows, their length, branching and combinations in each quadrant were noted using magnifying lens in light. Analysis of lip patterns was done based on the classification system given by Suzuki and Tsuchihashi in 1970\textsuperscript{13}.

For determination of sex middle 10 mm of lower lip was selected due to numerically supremacy and clear visibility of the lines\textsuperscript{15,19}. Most common pattern of lip prints in male and female was determined, also similarity of lip prints between two impressions was studied.

Statistical analysis was done using statistical package for social science (SPSS). Ver16. The frequency of each type of lip print was tabulated and the percentage of each type was calculated. For gender identification the data was analyzed with Chi-square test using Yate’s correction and a $P$-value less than 0.05 was considered as significant. Analysis of all the lip prints was done by two observers independently and evaluation of data was done to eliminate any subjective bias.

**Findings:** The study was conducted on 100 subjects including 50 males and 50 females. In each subject, lip print pattern was different in all four quadrants also multiple patterns were observed in each single quadrant. Hence we can conclude that no two lip prints are identical to each other and are unique for the individual. This can help in identification of an individuals as well as the gender.

Most common lip patterns in total study population, in males and females were determined, presented in Table 1 and graphically represented in Figure 3,4. In males predominant pattern was Type III, followed by type IV. Type I’, V, II, I followed next. In females predominant pattern was type I, followed by type I’ and type II. Type III, IV, V followed next.

Identification of sex was correctly possible in 43 males and 45 females, while there was error in correct reporting of gender in 07 males and 05 females. Thus in medico legal case, due to clear differentiation in sexes it is easy to identify person and gender. (Table-2).

Discussion

“Identity” is a set of physical characteristics, functional or psychic, normal or pathological- that define an individual.
Identification of individuality of a human is a prerequisite for personal, social and legal reasons and to certify death. Classification of unidentified body or a trace into groups of age, sex, race, height narrows the possibilities for identification. More the unique characteristics, smaller is the group of comparison.

Lip prints are recognizable from the 6th week of fetal life. They are not affected by environmental changes, pathologies, minor trauma and inflammation. When lips are impressed onto variety of surfaces (like photographs, glass, papers, windows cutlery, cigarette) the visible morphology and patterns produced by them are important tool for identification of a person. Due to the specific pattern of grooves and wrinkles in lips, cheiloscopy has become an important antemortem identification procedure and a source of circumstantial evidence. It can conclude the character of the event, number and sex of person involved, cosmetics used, habits, occupational trails and pathology present in lip itself.

This study was carried out to study the predominant type of lip patterns in study population and for identification of gender from it. In all subjects no two patterns were identical, this finding correlate with the study of Tsuchihashi and Suzuki et al. This proves the uniqueness of lip patterns. We have excluded subjects having cleft lip, ulcers, scar, trauma, inflammation, lesions as these can be the identification mark themselves. In our study, we found Type III and Type IV lip prints commonly seen in males and Type I, I’ and II commonly seen among females. This is in agreement with study by Sharma BS et al. from this it can be concluded that cheiloscopy can be a mean for identification and gender estimation with good accuracy and reproducibility. Post mortem changes in lip pattern from cadaver should also be taken into consideration as studied by Utsuno et al.

Conclusion

Cheiloscopy plays important role in establishing identity of an individual. Among various methods such as finger prints, DNA analysis, Iris scan, anthropology, dental records, cheiloscopy is cost effective, non invasive and reliable method of personal identification. From our study and available literature we can conclude that cheiloscopy can be reliable method for identification.

Lip prints are accepted as identification mark in some places, it needs further studies with advanced procedures in large population of different races, family members, twins and siblings. There is need of development of standard procedure for collection, development, study, documentation and comparison of individual detail of lip prints so that data base of lip prints of individuals located in geographical area can be created.

The Role of Peer Support in HIV Testing among Risk Groups with Social Influence and Communication Competency Approaches (Study in Tulungagung Regency, Indonesia)

Mamik Hidayah¹, Ratna Dwi Wulandari², Agung Dwi Laksono³

¹Master Program in Health Policy and Administration, ²Researcher, Department of Health Policy and Administration, Faculty of Public Health, Universitas Airlangga, Indonesia, ³Researcher, National Institute of Health Research and Development, Indonesian Ministry of Health

Abstract

Patients with HIV/AIDS in Indonesia are increasing rapidly, especially in Tulungagung Regency, this requires serious treatment to prevent an epidemic that continues to spread. The research was aimed at optimizing the role of peer support in HIV testing in at-risk groups. The study was conducted descriptively observational. The sample was a risk group consisting of FSW and MSM as many as 72 people. The results of the study showed that 73% of the risk groups that had the effect of peer support had already taken an HIV test. The most influential form of social influence on risk groups of 44.44% was conformity, which is the behavior of the following habits in groups. In addition to the influence of peer support the communication competencies of peer support also affect risk groups. 69.7% of the risk groups that received peer support motivation had tested for HIV. A good level of peer support knowledge could affect 86.4% of the risk groups for testing. Good peer support skills could influence 85.7% of risk groups to take an HIV test. It could be concluded that knowledge from risk groups is related to attitudes and intentions to carry out HIV testing. Risk groups that have good intentions, carry out HIV testing. Communication competency consists of motivation, knowledge and skills related to HIV testing. Social influence was related to HIV testing. The form of social influence most felt by risk groups was conformity, then compliance and the least perceived is obedience.

Keywords: Peer support, risk groups, social influence, communication competency.

Introduction

The case of HIV-AIDS is a health problem that is a serious problem for the community. This case is growing rapidly in the world and the rapid spread of HIV in various countries is becoming a big problem. The UN through the Millennium Development Goals program includes HIV-AIDS as a focus for countries to be taken seriously. The spread of HIV-AIDS is not merely a health problem but has political, economic, social, ethical, religious and legal implications and even has a real, immediate, or slow impact, touching almost all aspects of human life ¹. This threatens the nation’s efforts to improve the quality of human resources. In the UNAIDS declaration, the goal of controlling HIV AIDS is Getting Three Zeroes (Zero New Infection, Zero AIDS-related death, Zero Stigma and Discrimination)²–⁴.

In general, counseling and testing are the main strategies in the prevention and management of HIV cases. Until 2006, global policies undertaken for HIV surveillance were with Client-Initiated Voluntary Counseling and Testing (VCT) carried out inside and outside the Health Services Unit. According to WHO, HIV testing services have the principle of “5C” namely informed consent, counseling, confidentiality, correct

test results and connection to care treatment and prevention services.\textsuperscript{5–7}

East Java is one of the provinces which has quite a high number of HIV-ADS sufferers and occupies the top position in Indonesia. The number of HIV cases in East Java in 2019 was 8,934. In Tulungagung District the number of HIV-AIDS cases from year to year showed an increase. As is the case with the iceberg, there are likely to be many unsolved cases. This is the duty of all parties to be able to find cases as early as possible to prevent further spread.

In 2019 in Tulungagung Regency the population groups at risk were 19,093 people who were willing to take an HIV test of 12,758 people. National targets 90\% of risk groups know their status. Risk groups are groups that are at risk for HIV-AIDS and have the potential to transmit HIV-AIDS.\textsuperscript{8} Included in this risk group are pregnant women, TB patients, female sex workers (FSW), MSM, transsexuals, IDUs and inmates.

In Tulungagung Regency, to invite at-risk populations to want to conduct an examination carried out in collaboration with various parties both from the Health Office, AIDS Eradication Commission and also the role of peer support. Peer support is a group of people infected with HIV to get together and support each other because they have the same fate. Peer support began to be formed in 2006. The formation of peer support in the Tulungagung Regency aims to encourage at-risk populations to want to check HIV so that they know their status while helping people living with HIV to live better quality. This peer support consists of people who care about the spread of HIV-AIDS cases who then join to form a group known as peer support groups. The members of this peer group consisting of people living with HIV-AIDS (PLWHA) who have the determination to overcome the spread of HIV-AIDS. They consist of MSM (Gay), transsexuals and FSW groups.

The number of peer support members in Tulungagung is around 30 people consisting of 19 women and 11 men. The existence of peer support is very helpful in inviting risk groups to conduct examinations because they have access and high emotional closeness with risk groups. Included in this risk group are pregnant women, FSW, TB patients, MSM, transsexuals people, IDUs and prison prisoners. Peer support groups (PSG) in Tulungagung reach MSM, transsexuals people and FSW by\textsuperscript{9,10}. While other risk groups, already under the Health Center target. The health center also reaches MSM, transsexuals people and FSW, but they still need the existence of peer support because they are the link. Without peer support, it will be difficult to reach this community. This is where the importance of the role of PSG.

The results of previous research on the role of PSG stated that several factors influence peer support in the HIV-AIDS response system at both the provincial and district levels.\textsuperscript{11} The study mentioned that the factors that influence peer support are divided into 2 namely internal and external factors. As for what is included in internal factors are group motivation, leadership, independence and management and group accountability. Whereas included in the external group are involved in the HIV-AIDS control system, access to resources and entry into the referral system.

Other research also states that with the support of peer support, the quality of life of PLWHA is increasing (Pebrianti, 2018). With this support, PLWHA can live, as usual, be able to socialize, be independent, be productive and have a quality of life. Therefore the role of peer support is very important in the HIV-AIDS response system both in early discovery and in providing support to PLWHA.

In addition to the two studies above, there is also research that states that PSG is the right place for PLWHA to share information, support and motivate each other.\textsuperscript{13,14} Because PSG is formed from the ODHA element itself, the existence of PSG is easily accepted. In some areas there is still no access to health services and information about HIV-AIDS, so this is an important role for peer support.

To enhance the role of peer support in engaging these risk groups, it can be learned using communication competency theory and social influence. This theory states that in motivating people to want to change attitudes, beliefs, perceptions and behavior, efforts need to influence and communicate well. Research is aimed at optimizing the role of peer support in HIV testing in at-risk groups.

**Materials and Method**

The study was conducted with an observational descriptive approach with cross sectional research design. The study was conducted in Tulungagung Regency, Indonesia in February-March 2020. The sample in this study was a risk group consisting of 72 FSW and MSM.
**Findings:** Communication competence which includes motivation, knowledge and skills, all three have a significant relationship with HIV testing in risk groups. The results of the analysis can be seen in the following Table 1.

**Table 1. Relationship of Peer Support Motivation and HIV Testing in Tulungagung Regency, Indonesia, 2020**

<table>
<thead>
<tr>
<th>No.</th>
<th>Peer Support Motivation</th>

<td>Good</td>
<td>10</td>
<td>30.3</td>
</tr>
<tr>
<td>Total</td>
<td></td>
<td>36</td>
<td>50</td>
</tr>
</tbody>
</table>

Based on the Spearman correlation test it is known that sig (2-tailed) is 0.001 and the Correlation Coefficient is 0.425. It can be concluded that there is a relationship between motivation from peer support and HIV testing in risk groups. Based on Table 1 it can be seen that the motivation of the lack of peer support, 91.7% of risk groups have not tested for HIV. While good peer support motivation, 69.7% of risk groups have tested for HIV. The better the motivation of the risk groups, the more risk groups will get HIV testing.

These results are consistent with research from Anggipita which states that there is a significant relationship between motivation from peer support and PLWHA compliance to take ARVs. Research from Handayani and Mardiati\textsuperscript{11} also states that motivation from peer support can influence members to support each other and carry out positive activities.

**Table 2. Relationship of Peer Support Knowledge with HIV Testing in Tulungagung Regency, Indonesia, 2020**

<table>
<thead>
<tr>
<th>No</th>
<th>Peer Support Knowledge</th>
<th>HIV testing</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>

<td>3</td>
<td>Good</td>
<td>3</td>
<td>13.6</td>
</tr>
<tr>
<td>Total</td>
<td></td>
<td>36</td>
<td>50</td>
</tr>
</tbody>
</table>

Based on the Spearman correlation test it is known that sig (2-tailed) is 0.001 and the Correlation Coefficient is 0.546. This shows that there is a relationship between the level of peer support knowledge and HIV testing in risk groups. Based on Table 2 it can be seen that with a good level of peer support knowledge, 86.4% of the risk groups have tested. While with a lack of peer support knowledge, 85% of the risk groups have not tested for HIV.

This is in line with research conducted by Pratiwi and Rosida\textsuperscript{15} which states that good knowledge about HIV/AIDS and there is support and care if the results are positive will cause a person to seek VCT service facilities. Respondents who know about HIV and VCT will influence the person to find out their HIV status so he uses the available VCT service facilities.

Based on the Spearman correlation test it is
known that \( \text{sig (2-tailed)} = 0.005 \) and the Correlation Coefficient is 0.342. This can be interpreted that there is a relationship between peer support skills and HIV testing in risk groups. From Table 3 above it can be seen that with good peer support skills, 85.7% of the risk groups have tested for HIV. While the lack of peer support skills, as many as 65.2% of risk groups have not tested for HIV.

<table>
<thead>
<tr>
<th>No</th>

<td>Total</td>
<td>36</td>
<td>50</td>
</tr>
</tbody>
</table>

Table 3. Relationship of Peer Support Skills and HIV Testing in Tulungagung Regency, Indonesia, 2020

Based on the analysis of each component of communication competency with HIV testing in the above risk groups, there was a significant correlation. So communication competency from peer support can influence risk groups to carry out HIV testing. Social influence is an effort made by peer support to change the attitudes, beliefs, perceptions, or behavior of risk groups. There are 3 forms of social influence, namely conformity, compliance, and obedience. The results of the study note that there is a strong relationship between social influence with HIV testing as shown in Table 4.

<table>
<thead>
<tr>
<th>No</th>
<th>Social Influence</th>
<th>HIV testing</th>
<th>Total</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>

<td>74.3</td>
</tr>
<tr>
<td>2</td>
<td>Yes</td>
<td>10</td>
<td>27</td>
</tr>
<tr>
<td></td>
<td>Total</td>
<td>36</td>
<td>50</td>
</tr>
</tbody>
</table>

Table 4. Relationship between Social Influence and HIV Testing in Tulungagung Regency, Indonesia, 2020

Based on statistical tests it is known that asymptomatic \( \text{sig (2-sided)} = 0.001 \) and Contingency Coefficient is 0.427. This can be interpreted that there is a relationship between social influence with HIV testing in risk groups.

Risk groups that were influenced by peer support as much as 73% had already tested for HIV. Whereas the risk group that did not get the influence from peer support, amounted to 74.3% had not tested for HIV and only 25.7% had tested for HIV. Risk groups that are influenced by peer support are 7.8 times more likely to take an HIV test. The results of the study also state that the form of social influence most felt by risk groups is conformity, as shown in the following table.

<table>
<thead>
<tr>
<th>No.</th>
<th>Social Influence Form</th>
<th>Total</th>
<th>%</th>
<th>% cumulative</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>

<td>9</td>
<td>12.5</td>
<td>100</td>
</tr>
<tr>
<td></td>
<td>Total</td>
<td>72</td>
<td>100</td>
<td></td>
</tr>
</tbody>
</table>

Table 5. Identification of the Social Influence Form in Tulungagung Regency, Indonesia, 2020
Based on Table 5 it can be seen that the form of social influence that is felt by the most risk groups is conformity at 44.44% then compliance at 43.06%. The form of obedience is only 12.5% of risk groups who feel it. This is in line with research by Hanindya Sucita Putri\textsuperscript{16} which states that there is a positive and significant relationship between conformity with peers and consumptive behavior in class X (ten) and XI (eleven) students. Research from Ayu Rahmadhita Apsari\textsuperscript{17} states that there is a positive relationship between conformity and premarital sexual behavior in adolescents. Another study conducted by Slamet Andi Priyatmoko\textsuperscript{18} also mentioned that there was a significant relationship between social influence and the decision to buy something.

**Conclusions**

Based on the results of the study it can be concluded that: Communication Competency which consists of 3 components namely motivation, knowledge and skills have a positive relationship with HIV testing. The better the motivation of the risk groups, the more risk groups will get HIV testing. The better the level of peer support knowledge, the easier it will be to provide information to at-risk groups so that they can influence them to test for HIV. With good skills, peer support can set an example and can be trusted by risk groups.

Social Influence carried out by peer support in at-risk groups was very influential in that more people had tested for HIV. The form of social influence that is given peer support and is felt by many at-risk groups is conformity, which is behavior following the habits that exist in the community. A persuasive approach by peer support has proven to be able to invite risk groups to take an HIV test.

Ten Year Autopsy Study of Differentiating Features Between Hanging and Strangulation

Manoj Kumar Sharma¹, Jaspinder Pratap Singh¹, Kuldip Kumar², Ashok Chanana³

Junior Resident¹, Associate Professor², Professor and Head³,
Department of Forensic Medicine and Toxicology, Government Medical College, Amritsar

Abstract

Introduction: Hanging is that form of asphyxia which is caused by the suspension of the body by a ligature which encircles the neck, the constricting force being the weight of the body, or part of body weight. Strangulation is a form of death caused by constricting the neck by some means other than body weight. The means used may be ligature (ligature strangulation), human hand (throttling or manual strangulation), elbow (mugging), or some hard subject such as stick (bansdola).

Aims and Objectives: To study the differentiating aspect between Hanging and Strangulation, with respect to type of ligature material and its position, external and internal finding of neck and changes in the subcutaneous tissue of neck.

Results: Hanging amounted for 50.37% cases while strangulation was 17.20% cases among the violent asphyxial deaths. Clothes (65.45%) were most common ligature material both in hanging and strangulation as well. Position of ligature was above the level of thyroid in 95.12% cases while in strangulation the position of ligature was at level of thyroid in most of the cases (45.71%). Associated injuries are present in 51.43% cases of strangulation. Subcutaneous tissue is white glistening in most of hanging cases (76.58%) while contused in most of strangulation (82.86%) cases.

Conclusion and Suggestions: It is suggested that in the interest of justice to avoid confusion, in all cases of violent asphyxial deaths, the post-mortem examination should be conducted by the Forensic experts only. Police personal should also be given training that they should not cut the ligature material and remove ligature material before post-mortem examination so that easy differentiation of hanging and strangulation can be made.

Keywords: Hanging, Strangulation, ligature material, violent asphyxial deaths, internal neck findings.

Introduction

Hanging is that form of asphyxia which is caused by the suspension of the body by a ligature which encircles the neck, the constricting force being the weight of the body, or part of body weight.

Hanging is classified on the basis of:

(A) Degree of suspension, 1. Complete hanging: The body is completely suspended without any part of the body touching the ground. 2. Partial hanging: The body is partially suspended, the toes or feet touching the ground, or in sitting, kneeling, lying down, prone, or any posture with only head and chest off the ground.

(B) Position of the knot 1. Typical hanging: Knot is present over the central part over the back of the neck. 2. Atypical hanging: The knot is anywhere other than on the occiput, i.e., on the right or left side or front of the neck.

The “mark of hanging” on the victim depends upon various factors like height of suspension point, nature and composition of the ligature material used, the weight of the body, duration of the suspension, things which intervene between the ligature material and skin of the neck. It requires an expert’s skill and care for the determination of cause and manner of death. Multiple rounds of ligature around the neck with two or more fixed knots calls special care in interpretation to decide the cause and manner of death, other injuries over the neck and bodily injuries could complicate the matter.2

The level at which the ligature mark lies is also of importance in making the distinction between hanging and strangulation by a ligature. Strangulation is a form of death caused by constricting the neck by some means other than body weight. The cause of death in hanging and strangulation is mainly due to asphyxia. Still, it may be due to venous congestion, cerebral ischemia, shock, or a combination of more than two causes. Fracture-dislocation of cervical vertebrae occurs in judicial hanging. Postmortem appearances vary according to mode of death. There are external and internal appearances. External appearances are due to ligature on the neck and those peculiar to the mode of death. The ligature mark on the neck varies according to the nature of the material used as a ligature, which requires a detail inspection. In complete hanging, the ligature mark is usually situated above thyroid cartilage between larynx and chin. It is directed obliquely upward along the line of the mandible (lower jaw) and reaches the mastoid process behind the ear. It is sometimes absent at the back where two limbs of noose stretch upward toward the knot. The mark may be found on or below the thyroid cartilage, especially in case of partial suspension. It may also be circular. In the case of strangulation by ligature, the mark is well defined and usually situated low down in the neck below the thyroid cartilages and encircling the neck horizontally and completely. The marks are multiple if ligature is twisted several times around the neck. It may be oblique as in hanging if the victim has been dragged by ligature or strangled in recumbent position.3

**Aims and Objectives:** The present study was carried out with a view to study the incidence and to study the differentiating aspect between Hanging and Strangulation, with respect to type of ligature material and its position, external and internal finding of neck and changes in the subcutaneous tissue of neck.

**Material and Method**

Data has been collected from autopsies conducted on dead bodies of cases of violent asphyxial deaths at the mortuary of department of Forensic Medicine and Toxicology, Govt. Medical College, Amritsar, during period of last 10 years from 1st January 2006 to 31st December 2015.

407 cases of violent asphyxial deaths has been studied using pre-tested structured schedule, all cases of violent asphyxial deaths brought to department of Forensic Medicine and Toxicology, Government Medical College, Amritsar, mortuary for autopsy and those who fulfill the inclusion and exclusion criteria had been selected on a purposive sampling basis.

**Inclusion Criteria:** Autopsy on all cases of violent asphyxial deaths conducted at mortuary of department of Forensic Medicine and Toxicology, Govt. Medical College, Amritsar during a period of ten years.

**Exclusion Criteria:**
1. All deaths due to violence other than asphyxial death.
2. Deaths due to chemical asphyxiants.
3. Deaths due to poisoning.
4. Sudden natural deaths.
5. Deaths due to cold, starvation, heat and anaphylaxis.

**Observations:**

| Table 1: Incidence of violent asphyxial deaths based on method of asphyxiation |
|---------------------------------|----------|------|
| Type of Asphyxial death         | No. of cases | %    |
| Hanging                         | 205       | 50.37|
| Strangulation                   | 70        | 17.20|
| Throttling                      | 5         | 1.23 |
| Traumatic asphyxia              | 3         | 0.74 |
| Suffocation                     | 4         | 0.98 |
| Drowning                        | 120       | 29.48|
| **Total**                       | **407**   | **100.0**|

Discussion

In the total number of cases of hanging and strangulation, the offending weapons were found to be various types of ligature materials. 37.82% of the males and 27.63% of females preferred soft materials (saree, veil, towel, etc.) whereas 23.27% of men and 11.27% women used hard ligature material (wire, rope, string, etc.). These findings correlate with the study of Patel et al where they found in hanging 80% of the victims used soft materials and 20% victims used hard materials. In strangulation cases, they found that 66.67% victims were strangulated by using soft material and 33.33% victims were strangulated by using hard materials. In a study conducted only on type of ligature material used for hanging by Sharma et al they found that soft material was used in 56.36% and hard material in 43.64% cases. In another study conducted only on type of ligature material used for hanging by Naik et al they found that soft material was used in 53.97% and hard material in 46.03%. Lastly, in a study by Vijaynath et al on type of ligature material used for hanging, they found that soft material was used in 70% cases and hard material was used in 30%.

In 97.82% cases of hanging and strangulation, the ligature mark was single in number while only in 2.18% cases it was multiple. In only 7.14% cases of strangulation, the ligature mark was multiple in number.

In 95.12% cases of hanging the ligature mark was situated above the level of thyroid cartilage followed by 4.39 % of the cases showing the ligature mark below the level of thyroid cartilage, the least was a single case (0.49%) showing the ligature mark at the level of thyroid cartilage. In hanging, the ligature mark is usually situated above the level of thyroid cartilage due to the fact that during the suspension of the body there is slippage of ligature material over the upper part of the neck and the constriction force being the weight of the body. While in strangulation in 15.71% cases the ligature mark was situated above the level of thyroid cartilage in 45.71% of the cases showing the mark below the level of thyroid cartilage and in 38.57% cases showing the ligature mark at the level of thyroid cartilage which is reverse trend as compared to hanging.

In 98.54 % of the cases of hanging the ligature mark was obliquely placed over the front of neck and in only 0.49 % of the cases it was horizontal. While this trend was reverse in strangulation in which in 87.14 % of the cases the ligature mark was horizontally placed over the front of neck and in 12.86 % of the cases it was oblique.

In 99.51% cases of hanging the ligature mark was partial and in only 0.49 % of the cases showing the complete ligature mark. While in strangulation in 72.86% cases it was partial and in 27.14% cases the ligature mark was complete. These results correlate with the study by Patel et al who observed the following, among the hanging cases 100% victims had oblique ligature mark on the neck and 100 % transverse ligature mark on the neck in strangulations. In 93.75% cases the ligature mark was above the level of thyroid cartilage while in 6.25% cases the ligature mark was at the level of thyroid cartilage in hanging deaths.
The classical external asphyxial findings such as cyanosis in hanging was found in 97.07% cases, dribbling of saliva in 28.29% cases, protrusion of tongue in 31.71% of cases and it was clenched between teeth in 19.02% cases, seminal fluid discharge in 12.20% cases, external injury marks in 10.24% cases, froth from nostrils in 16.09% cases and rigor mortis in 96.10% cases. These results closely correlate with study made by Patel et al who observed the following: congestion of face 77.5%, dribbling of saliva 71.25%, discharge of semen 17.5%, discharge of feces 13.75%, struggle marks nil cases.

Internal findings in cases of hanging were found as, torn intima of common carotid artery in 52.20% cases, fracture of thyroid cartilage in 0.98%, fracture of hyoid bone in 2.44% cases, tear of neck muscles in 91.22% cases and infiltration of blood in the soft tissues of neck in 99.51% cases and subcutaneous tissue was found contused in 22.44% cases and white glistening in 76.58% which differs from the study by Patel et al who found contusions in strap muscles of neck in 6.25% cases of hanging but no carotid artery tears or fractures of hyoid bone and thyroid cartilage. This study is partly consistent with the study by Patil et al where he found no victims of hyoid bone fracture. The results however varied from the studies of Sharma et al and Clement et al.

In strangulation cases encountered cyanosis was found in 92.86% cases, discharge of semen was found in 2.86% cases, external injuries were found in 52.86% cases and froth from nostrils in 37.14% cases, tongue was protruded in 38.57% cases and it was clenched in between teeth in 21.43% cases. Rigor mortis present in 77.14% cases. These results closely correlate with the study made by Patel et al who observed the following; congestion in 100% cases, discharge of semen, urine and stools in zero percent cases, struggle marks in 100% cases.

Internal findings in strangulation cases observed were as follows- Contusions of strap muscles in 82.86% cases, fracture of thyroid cartilage in 11.43% cases, fracture of hyoid bone in 10% cases were observed. Intima of carotid artery was found torn in 60% cases while neck muscles were torn in 94.29% cases and infiltration of blood in the soft tissues was present in 100% cases. These results partially correlate with the study of Patel et al who observed strap muscle contusions in 100% cases and 66% cases having hyoid bone fracture with nil per fracture of thyroid cartilage. The results once again vary from the studies of Sharma et al, in which they found hyoid bone fracture in 21% cases, thyroid cartilage fracture in 17% cases and neck muscles were found torn in 54% cases and Clement et al, Patil et al in which they found hyoid bone fracture in 42% cases.

**Conclusion and Suggestions**

Ligature mark was situated above the level of the thyroid cartilage in most of the cases in hanging while it was either below or at the level of thyroid cartilage in strangulation. The preferred ligature material used in both hanging and strangulation cases was soft in most of the cases. As most of the postmortem cases of violent asphyxial deaths are being conducted by the doctors who are not Forensic experts and they found difficulty in concluding whether it is a case of hanging or strangulation. It is suggested that in the interest of justice to avoid confusion, in all cases of violent asphyxial deaths, the postmortem examination should be conducted by the Forensic experts only. Police personals should also be given training that they should not cut the ligature material and remove ligature material before postmortem examination so that easy differentiation of hanging and strangulation can be made. They should also routinely take the help of technology by video recording and photography of the scene of crime.

Assessment of Violence Among Late Adolescence

Mansour Abdullah Falah Al-Zorfi¹, Hussein Jassim Muhammad Al-Ibrahimi²

¹Assis. Prof., University of Kufa-College of Nursing-Family and Community Health Nursing, ²Assis. Prof., University of Babylon-College of Nursing-Family and Community Health Nursing

Abstract

Background: In today’s society, adolescents have seen an increase in violence. Teenagers face many situations that cause these problems. There are several factors: the mass media, peer pressure and society’s view of the “ideal” person. Television, radio and newspapers are all ways to get messages to people. One might watch a violent movie and decide to reactivate the scenes, causing harm to themselves or others. The hidden meanings of racism and hatred are put into music. Teenagers hear the words of their supposed role models and think it’s good to follow in their footsteps.

Objectives: Assessment of violence among Late Adolescence.

Methodology: A descriptive cross-sectional study was carried out in order to achieve the stated objectives. The study has begun from 1st September 2018. Settings of the Study: The settings of the study include (41) High secondary schools which are distributed in (3) Districts of Al-Najaf Governorate, urban (23) schools and rural (18) schools, these schools are systematic randomly selected.

Result: Showed that the most majority is low violence 51.2%.

Conclusions: The majority of the sub-domain of violence was the trend towards violence and Most of the study sample had low violence.

Recommendations: Supporting educational method by the Educational Committee that limits violent behavior of adolescents in schools, such as (moving away from scenes of an aggressive nature, beating, violence, fighting, quarrels and blood scenes) and the teacher devotes part of the lesson time to clarifying issues and harms of violence and to show the benefits of tolerance and contentment. And The school administration cooperated with the teenager’s family to identify the causes of his violence. Finally, The Ministry of Education is working to create posters that reject violence and suspend it throughout the school.

Keyword: Assessment. Violence. Late adolescence.

Introduction

Despite a widespread belief that violence begets violence, methodological problems substantially restrict knowledge of the long-term consequences of childhood victimization. Empirical evidence for this cycle of violence has been examined. Findings from a cohort study show that being abused or neglected as a child increases one’s risk for delinquency, adult criminal behavior and violent criminal behavior. However, the majority of abused and neglected Adolescence do not become delinquent, criminal, or violent.

Methodology

Design of the Study: A descriptive cross-sectional study was carried out in order to achieve the stated objectives. The study has begun from 1st September 2018.

Settings of the Study: The settings of the study include (41) High secondary schools which are distributed in (3) Districts of Al-Najaf Governorate, urban (23) schools and rural (18) schools, these schools are systematic randomly selected.

This table showed that the most majority is low violence 51.2%.

Figure (1) Overall assessment for Violence in the study sample.

Discussion of the Results

The phenomenon of violence among adolescents has spread widely and its consequences have become serious for society. If we search for the causes of this phenomenon, we will discover that the family, the school, the media, communication and the Internet have a great role in deepening violence and its spread among youth and adolescents in a severe way that may eventually lead to destruction or imprisonment.

Table (1), which includes the sub-domain of violence, which contains four axes, where the majority of the axis (trend towards violence) was compared to the other axes.

A study by (Puigvert and et.al., 2019), in Spain, revealed that in addition to this sub-domain (the trend towards violence), which was more responsive, it found (Violence in Self-Defense) the same as the previous response.1

And another study in New Delhi conducted by (McMahon, 2011), on secondary schools, where a sample of 1520 boys and girls were collected and the study found that the vast majority of the sub-domain (violence in self-defense) From the other subdomain.2

In Nigeria, a number of researchers participated in conducting a field survey of secondary school students for a sample of 2150 students through a questionnaire distributed to them and the majority of the sub-domains results (physical violence toward others) from the rest of the other sub-domains.3
Likewise, in Turkey, a group of researchers undertook a research concerned with violence in schools among adolescents through a questionnaire that students filled in and the results showed that most of the two sub-domains (verbal violence toward other) and (violence in self-defense).  

Table 2, which included an overall assessment of violence, where the study showed that the most majority is low violence.

A study conducted by (Paterson, R. and et.al., 2012), in Melbourne, revealed that the reason for the decrease in violence is due to the good interaction of the family with the teenager and the creation of a valid environment away from conflicts and disputes, while the Arab countries and in Iraq the decrease in violence is due to the Islamic rules that reject violence and what follows of problems in society, as well as the severity of tribal judgments and not to attack others.

Also, a study conducted in Sweden (Speere, 2012), conducted on a number of secondary schools showed that students are teenagers, where they found that there is a decrease in violence for them and this is due to the environment Sound and proper education and also the appropriate way to deal with adolescents at this stage.

We also add a study in Norway on teen violence. The results showed that there is a moderate level of violence, because the poor environment and lack of interaction by the family with the teenager will give birth to a teenager with all forms of violence.

The Najaf community is considered almost one of the quietest societies in the Middle Euphrates, as is the case in disagreements, conflicts and disputes, because the province has a great sanctity in the hearts of people, as it contains many holy shrines and the most important of the shrine of Imam Ali (the best of prayers and peace) and also the presence The most important religious references that always seek calm, advice and guidance and also rejects all forms and types of violence and aggression and this in turn is reflected in the behavior of this society in teaching, education, dealing and resolving all disputes by peaceful means without resorting to fighting and conflicts (researcher).

Conclusions

The majority of the sub-domain of violence was the trend towards violence and Most of the study sample had low violence.

Recommendations: Supporting educational method by the Educational Committee that limits violent behavior of adolescents in schools, such as (moving away from scenes of an aggressive nature, beating, violence, fighting, quarrels and blood scenes).

The teacher devotes part of the lesson time to clarifying issues and harms of violence and to show the benefits of tolerance and contentment.

The school administration cooperated with the teenager’s family to identify the causes of his violence.

The Ministry of Education is working to create posters that reject violence and suspend it throughout the school.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the College of Nursing, University of Kufa, Iraq and all experiments were carried out in accordance with approved guidelines.

A 10 Year Autopsy Study of Hospital Deaths Brought to the Mortuary of a Tertiary Care Hospital in North East India

Memchoubi Phanjoubam¹, Th. Meera Devi², Seram Elizabeth Devi³, Lynda B. Zohlupuii³

1Associate Professor, 2Professor and Head, 3Post Graduate Trainee,
Department of Forensic Medicine and Toxicology, Regional Institute of Medical Sciences, Imphal

Abstract

Without autopsies, hospitals bury their mistakes. However, not every hospital death is autopsied. As a result, experts say, diagnostic errors are missed, opportunities to improve medical treatment are lost and health-care statistics are skewed. In this 10 year retrospective study, hospital death cases which were brought for autopsy were analyzed with respect to year wise incidence, sex and age wise incidence, reasons for hospitalization and cause of death to ascertain whether the deaths were due to medical negligence or due to natural course of events of the disease. The findings reveal that 40% of the cases were due to negligence. This substantial loss could have been prevented if timely intervention was done. The study aims to highlight this important aspect of medical practice.

Keywords: Hospital deaths, autopsies, medical negligence.

Introduction

Without autopsies, hospitals bury their mistakes. Hospital autopsies have become a rarity. As a result, experts say, diagnostic errors are missed, opportunities to improve medical treatment are lost and health-care statistics are skewed. Studies have placed the number of deaths as high as 250,000 deaths per year, which would make medical error the third leading cause of death, behind cancer and cardiovascular disease. It is also shown that the number of previously healthy people who die every year from hospital error is about 7,150. The remainder of preventable deaths occurred in patients with less than a three-month life expectancy. Most of the hospital errors involved poor monitoring or management of medical conditions, diagnostic errors and errors related to surgery and procedures, the study shows.

Material and Method: After obtaining ethical clearance from the institute’s Research Ethics Board, a retrospective analysis of post mortem records of hospital death cases brought for autopsy to the morgue of a tertiary care hospital in North East India was done. The period was from 2010 to 2019. Cases were analyzed with respect to year wise incidence, sex and age wise incidence, reasons for hospitalization and cause of death to ascertain whether the deaths were due to medical negligence or due to natural course of the disease. Findings are the compared with prevailing trends elsewhere in the world.

Results and Observations: Fig. 1 shows the year wise incidence. Cases were maximum in 2016 and show a gradual increasing trend towards the later part of the study period as shown in Fig. 1.

Male and female cases were equal in number i.e., 50% each (Fig. 2).

As shown in Fig. 3, regarding the age wise incidence, cases were maximum in the 31-40 yr (31.8%) followed by 51-60 yr(22.7%) and least in the lower age groups.

Fig. 4 shows the reasons for hospitalization. Heart disease was the main reason for hospitalization followed by delivery.

Fig. 5 shows that 40.9% of the deaths were due to medical negligence or gross medical error.

The various causes of death are shown in Table 1. Myocardial infarction was the commonest cause of death followed by followed by bronchopneumonia and coronary artery disease. Out of the 6 cases which were brought for delivery, 5 parturients and 1 newborn died during or after delivery. Cervical haematoma and post partum haemorrhage (PPH) following Normal Vaginal Delivery (NVD), Post Caesarian Section(CS) amniotic fluid embolism, Intrapartum haemorrhage and Post-partum haemorrhage following Normal Vaginal Delivery, Uterine rupture during Caesarian Section, Post-partum haemorrhage following Caesarian Section and Suffocation of newborn with mucoid substance due to non-suction following Normal Vaginal Delivery were the various causes of mortality.

In one case, Lung injury following intercostal tube insertion was the cause of death.

The remaining included deaths due to cirrhosis (2 cases) and cysticercosis (1 case).

**Fig. 5: Manner of death**

**Discussion**

In a review of the patient records of 100 adults who died in 10 hospitals across England in 2009, it was observed that one death in 20 had a greater than 50% chance of being preventable. In the present study, it is evident from the findings that 40.9% of the cases could be due to medical negligence or gross medical error.

In the present study, delivery related deaths were maximum among the deaths due to medical negligence. Post partum haemorrhage, uterine rupture and amniotic fluid embolism were the prominent causes of death. In one case, the newborn died due to suffocation of the mucus which is quite different from other studies. In a study on The Maternal Mortality Rate (MMR) over a nine-year period (1998-2006), the MMR was 827/100000 live births (471 maternal deaths against 56944 live births). An autopsy was performed in 277 cases (58.8%). In the autopsy group, the most common causes of maternal mortality were pre-eclampsia (14.44%) and hemorrhage (11.55%). However, indirect causes like infectious diseases (9.75%) and cardiac (9.75%) diseases also contributed to maternal deaths.

A total of 13,074 autopsy records of fatal pulmonary
embolism were analyzed using univariate and multivariate conditional logistic regression. Pulmonary embolism was considered fatal in 328 (2.5%) patients. In the multivariate analysis, conditions that were more common in patients who died of pulmonary embolism were atherosclerosis, congestive heart failure and neurological surgery. Some conditions were negatively associated with fatal pulmonary embolism, including hemorrhagic stroke, aortic aneurism, cirrhosis, acquired immune deficiency syndrome and pneumonia. Interestingly, in the control group, patients with hemorrhagic stroke and aortic aneurism had short hospital stays (8.5 and 8.8 days, respectively) and the hemorrhage itself was the main cause of death in most of them (90.6% and 68.4%, respectively), which may have prevented the development of pulmonary embolism. Cirrhotic patients in the control group also had short hospital stays (7 days) and 50% died from bleeding complications. In our study, one case died due to amniotic fluid embolism following Caesarian section, which was diagnosed after an autopsy examination.

One neonate in our study died of suffocation with mucus due to lack of suction by the attending doctor. According to a study, the factors associated with neonatal deaths were fetal congenital anomaly, low birth weight, first minute Apgar score under 7; zero to 3 prenatals appointments and prematurity, none of which played any role in our case which indirectly indicates that the death was due to gross medical negligence.

A 10 Year Post Mortem Study of Choking Cases Brought to the Mortuary of a Tertiary Care Hospital in Imphal

Memchoubi Phanjoubam1, Supriya Keisham2, Th. Meera Devi3, Seram Elizabeth Devi4, Soibam Neha4

1Associate Professor, 2Assistant Professor, 3Professor and Head, 4Post Graduate Trainee, Department of Forensic Medicine and Toxicology, Regional Institute of Medical Sciences, Imphal

Abstract

Choking is the obstruction of air flow into the lungs and is almost always accidental. In this paper, cases of choking mistaken to be deaths due to foul play are studied. Any complaint is not true unless it is proved so. In all these cases, family members blamed the deaths on some parties who were in fact completely innocent. Meticulous autopsy helped in establishing the exact cause of death in these cases by disproving the false charge of assault. From the legal standpoint, the importance of establishing an exact diagnosis is obvious.

Keywords: Allegations, foul play, choking.

Introduction

Choking is the mechanical obstruction of the flow of air from the environment into the lungs. Choking prevents breathing and can be partial or complete, with partial choking allowing some, although inadequate flow of air into the lungs. Prolonged or complete choking results in asphyxia which leads to anoxia and is potentially fatal. Choking can be caused by (i) physical obstruction of the airway by a foreign body, (ii) respiratory diseases that involve obstruction of the airway and (iii) compression of the laryngopharynx, larynx, or trachea in strangulation and intravenous larygospasm. Obstruction of the airway can occur at the level of the pharynx or trachea. Food that can adapt their shape to that of the pharynx (such as bananas and gelatinous candies) can be a danger not just for children but for persons of any age. Among some of the most notable cases of choking deaths, mention may be made of Air Marshal Subroto Mukherjee, the first Chief of the Air Staff of the Indian Air Force who died on November 8, 1960 at Tokyo, by choking on a piece of food lodged in his windpipe.

On the other hand, allegations of excessive use of force and extrajudicial killings by police or armed forces are common in the north-eastern state of Manipur. A petition filed by two non Governmental organizations with the Supreme Court of India claimed that at least 1528 extrajudicial killings were carried out by the police or security forces in Manipur during 1979-2012 (supreme Court of India Writ Petition [Criminal] No. 129 of 2012. Interestingly, one of the present cases was also brought as a case of death due to police atrocity which was disproved by autopsy as it turned out to be due to choking and a case of natural death.

Material and Method

A retrospective analysis of all the deaths due to choking was done in the Department of Forensic Medicine and Toxicology of a tertiary care teaching hospital in Imphal. After obtaining Institutional Ethics Committee clearance, the cases were studied with regard to the sex and age wise distribution, type of food present, site of obstruction, association with alcohol and activity before choking.

Results and Observations

A total of eight cases were brought for autopsy in the 10-year period. All the cases were males and all
these cases were associated with allegations of foul play. Maximum incidence was seen in the 21-30 yr age group followed by 0-10 and 11-20 yr age groups as shown in Fig. 1. Presence of food particles in the respiratory tract beyond the trachea was seen in seven cases and alcohol was associated in six cases as shown in Figs. 2 & 3. Table 1 shows the activity before death. In one case, a three-year old boy was fed a piece of bread and he choked on it and died the next day due to aspiration bronchopneumonia. In four cases, the victims were found dead and on autopsy food particles were seen in the respiratory tract beyond the bronchi. In one case, the victim played football just after food and started choking and died. In another case, the victim slept just after dinner and got up choking and died. There was also a case where the victim took a walk after dinner and started choking and died. Regarding the site of obstruction, food particles reached the bronchioles in 1 case, trachea in one case and bronchi in five cases and in the case of the child no food particles could be seen as the child had consumed only a small piece of bread (Table 2). Regarding stomach contents, five cases had semi-digested food particles, one case had rice particles, another case had vegetable particles and in the case of the three-yr old child, only some mucoid substance was present (Table 3). Similar substances were present in the respiratory tracts of the victims.

Discussion

Airway obstruction can be of anatomical or mechanical origin. Anatomical obstruction may be produced by anatomical structures such as tongue, swollen tissues of mouth and throat like inflamed epiglottis. In these natural deaths, there is obstruction of the airway by the inflamed epiglottis and adjacent soft tissue and are of anatomical origin as said above.

Mechanical obstruction occurs due to foreign body. Physical findings of wheeze, rhonchi, stridor, or retractions were associated significantly with a diagnosis of an unwitnessed foreign body. Death due to choking is due to unintentional ingestion or inhalation of food or other objects resulting in the obstruction of respiration.

Choking is almost always accidental. In the above cases, the deaths which were suspected to be due to foul play, turned out to be accidental deaths due to mechanical airway obstruction by food particles. Some of the common risk factors of choking are old age, poor dentition and alcohol consumption. Other risk factors include chronic disease, sedation, eating risky food and senility, although choking is reported to be higher in the age above 65 yrs, we saw no case in this age group. In the present cases, there was history of consumption of alcohol in one case. Some of the other common causes of choking include swallowing large pieces of poorly chewed food, eating while talking excitedly or laughing, or eating too fast and walking, playing, or running with food or object in the mouth. In one case the person was playing football just after eating. In another case, the person went for a walk after dinner and died due to choking.

On the other hand, gastric contents are aspirated in the windpipe due to the handling of the body, or as a terminal event in natural death (agonal artefact) or due to resuscitation. Hence, agonal artefact may look like a case of choking and vice versa. However, the difference lies in the extent up to which food particles enter the lungs. In choking, the bronchioles are filled with food particles whereas in agonal artefact, food particles may reach only up to the larynx. In all these cases the food particles were found beyond the bronchi which ruled out agonal artefact.

Even though the allegation was that of foul play, the points in favor of choking in these cases were the absence of signs of external or internal physical injury (except minor abrasions in two of the cases), the presence of food particles in the respiratory tract reaching up to the bronchioles (which ruled out agonal artefact) and the presence of signs of asphyxia.

Conclusion

Any complaint is not true unless it is proved so. Meticulous autopsy helped in establishing the exact cause of death in these cases by disproving the false charge of assault thereby avoiding public outrage. From the legal standpoint, the importance of establishing an exact diagnosis is obvious. Whenever death is attributed to heart disease, the beneficiary of the estate is denied the double indemnity insurance benefits that are allotted when death can be proved to have occurred as the result of accidental inhalation of food. Therefore, establishing choking as the real cause of death gives two benefits, i.e., allegations are allayed and indemnity benefits are doubled if the life of the deceased has been insured.

The Effects of Deep Breathing on Blood Pressure Reduction in Elderly Hypertensive Patients at a Retirement Home in Surabaya

Moch. Chaerudin¹, Elida Ulfiana², Erna Dwi Wahyuni²

¹Student in Faculty of Nursing, Universitas Airlangga Surabaya, 60115, Indonesia,
²Lecturer Faculty of Nursing, Universitas Airlangga Surabaya, 60115, Indonesia

Abstract

Introduction: The hypertension incidences in the elderly does not only cause stroke but also an increase in the mortality rate. The elderly who suffer from hypertension require further therapy to lower their blood pressure levels. One of the self-therapies that nurses can provide to hypertensive patients is deep breathing therapy. This study aims to determine the effects of deep breathing therapy in the elderly with hypertension.

Method: This study employed a quasi-experimental research design with two groups of pretest-posttest design. A total of 12 research samples were divided into two groups: the treatment group and the control group, each group consisted of six respondents. The research instruments utilized were a questionnaire, SOP (Standard Operating Procedure) of breathing techniques, blood pressure measurement tools (sphygmomanometer and stethoscope) and observation sheets on blood pressure measurement. The data were analyzed using paired t-test and independent t-test.

Results: All of the respondents in the study were women aged 55 years old or older. The mean value of systolic blood pressure before being given the intervention was 158.33 mmHg in the treatment group and 157.69 mmHg in the control group. The analysis with an Independent t-test between the control group and the treatment group indicated \( p = 0.002 \) (\( \alpha<0.05 \)) as the difference in systolic blood pressure between the two groups. The treatment group experienced a drop in blood pressure by 10-30 mmHg.

Conclusion: Deep breathing therapy effectively reduces blood pressure in the elderly with hypertension by consistent interventions for seven consecutive days.

Keywords: Deep breathing intervention, elderly, isolated hypertension.

Introduction

The elderly experience the aging process that affects their physical and mental changes. Therefore, they have a higher risk of hypertension with the prognosis for stroke by 36% and an increase in the number of deaths by 14%.

Hypertension is a significant risk factor of cardiovascular morbidity and mortality, especially in the elderly. Such chronic disease frequently occurs without symptoms, thus requiring optimal control. Hypertension in the elderly can occur due to increased sodium sensitivity, isolated systolic hypertension with arterial stiffness and endothelial dysfunction that increase with age.

Men and women older than 55 years old highly at risk of suffering from hypertension, with a prevalence of 93% at approximately 80 years old. The hypertension incidences in the elderly living in rural areas are very high, with a prevalence of 40.5%, where 39.2% occur...
in men and 40.8% in women. The Agency of Health Research and Development report in 2011 confirmed that the cause of death in 15 districts/cities in the elderly group was hypertension, with 4.4% of deaths at <65 years old and 4.6% at >65 years old.

The preliminary studies conducted at Hargodedali Retirement Home, Indonesia, reported that 20 out of 51 elderly patients (39.2%) suffered from hypertension. Hypertension incidences in Hargodedali Retirement Home were recorded as the highest compared to other places. The attempts made to lower blood pressure, including pharmacological therapy, green banana and green tea consumption, as well as exercise, for the elderly every Monday, were still not optimal.

Hypertension that generally occurs in the elderly requires further therapy, which is a treatment that not only decreases the mortality rate but also reduces stroke incidences. The purpose of treating patients with isolated hypertension is to lower their blood pressure to the normal level while hypertension management in the elderly can be performed by pharmacological and nonpharmacological techniques.

Deep breathing techniques are part of nursing interventions that aim to provide various benefits. The effects of deep breathing techniques include pulse decrease, muscle tension decrease and metabolic rate decrease. Meanwhile, the techniques increase global awareness, peace and wellness feelings and relaxed alertness period. The advantage of deep breathing exercises is that it can be performed at anytime and anywhere. Furthermore, the techniques are very easy to perform independently by the patient without a medium to relax tense muscles.

The functional consequences theory elaborates that age is related to changes and risk factors. Without the intervention, the functional consequences will be negative. Otherwise, with the intervention, the functional consequences will be positive. The role of gerontological nursing is to identify factors that cause negative functional consequences and initiate interventions to foster positive functional consequences. In accordance with this theory, the elderly hypertensive patients who perform deep breathing techniques can change negative consequences in the form of blood pressure increase into the positive consequences in the form of blood pressure decrease. This study aims to determine the effect of deep breathing on reducing blood pressure in the elderly with hypertension.

**Method**

This study employed a quasi-experimental research design with two groups of pretest-posttest design. The research site was at Hargodedali Retirement Home, Surabaya, Indonesia. In this design, groups that fulfilled the inclusion criteria were observed for their blood pressure. There were inclusion criteria set by the researchers, i.e., the elderly with normal hearing, a patient who received hypertension treatment and were willing to be the respondents. Furthermore, the elderly would be intervened using deep breathing techniques. The intervention was performed for seven days, while the respondents’ blood pressure was observed before and after the treatment.

The sampling techniques employed in this study were non-probability sampling with a purposive sampling type. The samples in the control group consisted of 6 respondents, while the treatment group, which performed deep breathing techniques, were six respondents. The total samples in this study were 12 respondents.

The determination of the selected samples consisted of isolated hypertensive patients who fulfilled the established inclusion and exclusion criteria. After specifying the sample size of the study (12 elderly), then the data collection and matching were carried out, i.e., the process of adjusting confounding variables between 2 groups (6 elderly in each group), thus the confounding variables were divided equally.

The instrument utilized in this study was questionnaires related to demographic data, SOP (Standard Operating Procedures) for deep breathing techniques and observation sheets for blood pressure measurement, sphygmomanometer and stethoscope. The observation sheet in this study contained a format consisting of respondents codes, age, sex and blood pressure before and after deep breathing exercises in the treatment and control groups designed by the researcher.

The data analysis was processed based on existing data by using tables and statistical tests. The variables tested were the pretest and posttest of systolic blood pressure as well as the comparison results between the treatment group and the control group. The interval data for blood pressure measurement using paired t-test were used to compare the interval data of pre and post-treatment tests. Meanwhile, the independent t-test was employed to compare the interval data of the treatment group and the control group.
Results

The first research results were related to the demographic data of the elderly respondents involved. Twelve respondents who were divided into two groups were recorded for their general information, including age, sex, smoking history, family history of hypertension, their savoury tooth and regular exercise.

</table>

Systolic Blood Pressure Before and After the Intervention: The respondents’ characteristics based on age suggested that most of the respondents in each group were 70-85 years old, i.e., 4 people in the intervention group (66.7%) and 4 people in the control group (66.7%). The respondents’ characteristics by gender indicated that all respondents in each group were women. The respondents’ characteristics based on smoking status denoted that all respondents in each group had never smoked.

In addition, the respondents’ characteristics based on a family history of hypertension suggested that most of the respondents in each group had a family member with hypertension, i.e., there were 2 people in the intervention group (33.3%) and 2 people in control group (33.3%). Regarding the respondents’ characteristics based on savoury tooth, all of the respondents in each group did not like the salty taste. This data was obtained from interviews related to demographic data. Furthermore, the nutrition fulfillment at the elderly nursing home was adjusted to the type of illness that the respondent suffered. Thus, the nutrients fulfillment was homogeneous.
Systolic Blood Pressure Before and After the Intervention: The mean in systolic blood pressure is different before and after intervention in each group. It was observed that the mean value of systolic blood pressure before intervention in the treatment group was 158.33 mmHg and in the control group was 157.69 mmHg. After the intervention was performed with 21 times of deep breathing exercises for one week, the mean value of systolic blood pressure in the treatment group reached 140.00 mmHg.

The results of the advanced statistical analysis utilizing the Independent t-test between the control group and the treatment group obtained \( p=0.002 (\alpha <0.05) \). Therefore, it is concluded that there were differences in systolic blood pressure between the two groups. The preliminary data measurement (pretest) of blood pressure in the intervention group, with 6 hypertensive respondents indicated 2 people in stage 1 hypertension and 4 people in stage 2 hypertension. In the control group, it is observed that there were 3 people in stage 1 hypertension and 3 people in stage hypertension 2.

The blood pressure results in the treatment group after provided with deep breathing exercises (posttest) also suggested that all respondents (6 people) tended to experience a decrease which changed the hypertension category, i.e., 1 respondent reached the prehypertension category (120-139 mmHg) and 5 respondents reached the stage 1 hypertension category (140-159 mmHg). On the other and, in the control group, there were 2 respondents reached stage 1 hypertension category and 4 respondents with stage 2 hypertension category (\( \geq160 \text{ mmHg} \)).

Discussion

The critical factor causing hypertension is age. The older a person, the higher a person’s blood pressure. That condition is related to changes in anatomical and physiological structures, especially of the cardiovascular system changes due to the aging process. It occurs because of a decrease in blood vessel elasticity, blood vessel stretching power and smooth muscle relaxation. The factors contributing to the thickening and stiffening of the endothelial blood vessels in the aging process include an increase in collagen and calcium and a decrease in elastin, calcification and fat deposits.

All respondents in this study were female, so the case was similar to prior studies. In the prior study results, it was suggested that hypertension tended to occurred higher to women (58.3%) than to men (41.7%) after menopause. It occurred higher to women because of the production of their sexual hormones changes during menopause, which cause an increase in blood pressure. Women are greatly affected by several hormones that function to protect women from hypertension and its complications, including the thickening of blood vessels or atherosclerosis walls.

Thenext factor causing hypertension is due to diet food consumption, for example, unable to undertake a
low-salt diet. The respondents consumed food according to the food served based on the nursing policy. There was a special diet menu as the treatment, so there were limits as a benchmark to monitor whether the respondents had performed a low salt diet appropriately and consistently. Sodium consumption can be a significant factor causing hypertension. The compliance of low calcium, potassium and magnesium diet contributed to lowering blood pressure.

The treatment group had performed deep breathing techniques three times in one week for 7 days. In every 15 minutes of exercise, there was a decrease in systolic blood pressure by 140.00 mmHg. Therefore, there was a change regarding the hypertension category, which declined to stage 1 hypertension. Slow breathing frequency increases vascular vasodilation, which activates the Hering-Breuer reflex and then reduce the chemoreflex sensitivity and increase baroreflex. The deep breath therapy is beneficial as tense muscles relaxation, metabolic rate decrease, feelings of peace and alertness improvement and lowering blood pressure.

After 7 days of intervention, the mean of systolic blood pressure was the lowest in the deep breathing treatment group, which was 140 mmHg. Meanwhile, the control group reached 160 mmHg. The further analysis stated that the results obtained in both groups signifying systolic blood pressure decrease, which attributed to deep breathing exercises in the elderly with isolated hypertension. Deep breathing exercises in the form of slow breathing led to changes in breathing pattern intervals, which resulted in baroreflex efficiency increase. Eventually, the blood pressure can be lowered.

The role of gerontological nursing was to identify the factors causing negative functional consequences after initial deep breathing intervention that would produce positive functional consequences. Gerontological nursing aims to make the elderly relaxed and comfortable. The slowed breathing frequency triggers a decrease in the impulse of the respiratory and cardiovascular system. The respiratory and cardiovascular systems have the same regulatory mechanism. A change to one system will affect the other system functions. The deep breathing maximizes lung expansion during breathing. In addition, the breath-holding phase aims to maximize the oxygen diffusion in the lungs to acquire the oxygen better fulfillment for cellular metabolism in the elderly. Slow breathing can reduce sympathetic nerve activity by increasing central inhibitory rhythm. Hence, it created comfort and relaxation.

Conclusion

Deep breathing exercises and techniques effectively reduce blood pressure in the elderly with hypertension. It is corroborated by the difference in systolic blood pressure before and after the intervention in the elderly with isolated hypertension. Besides, it is also proved by a mean difference between the treatment and control groups. Breath control can reduce systolic blood pressure in the elderly with isolated hypertension by 3 times exercises a day and each exercise is performed in 15 minutes for 7 days.

Abstract

This study aimed for molecular characterization of local isolates of \textit{L. tropica} and \textit{L. major} and their relatedness to reference isolated from neighboring countries. Exudates and dermal tissues were collected from the cutaneous lesions of 50 newly diagnosed patients with CL. Leishmania DNA was extracted from lesion exudate and 5.8S rRNA gene was amplified using two sets of specific primers through nested PCR. A total of 12 PCR products were directly sequenced and the resultant sequences were aligned with reference sequences in National Center for Biotechnology Information (NCBI). A phylogenetic tree was constructed for local \textit{Leishmania} isolates with the reference isolates using Mega 6 software. According to alignment results out of 12 sequences, 9 sequences were belonging to \textit{L. major}, while 3 sequences were belonging to \textit{L. tropica}. All local \textit{L. major} isolates were very close to reference isolate KP773404.1 (an Iranian isolate), while all local \textit{L. tropica} isolates were very close to reference isolate KY612611.1 (an Iranian isolate) with an identity of 98%. Phylogenetic trees confirmed that closest isolates for local Leishmania (whether \textit{L. tropica} or \textit{L. major}) was the Iranian isolate. These data indicate that local isolates of \textit{L. tropica} and \textit{L. major} are closely related to Iranian isolates.

Keywords: Cutaneous leishmaniasis, phylogenetic analysis.

Introduction

Leishmaniasis, a disease caused by different species of Leishmania, is the third most significant arthropod-borne disease for the global burden of diseases[1]. Among the three types of the disease (cutaneous, visceral and mucocutaneous), the cutaneous leishmaniasis (CL) is the most common form of the disease which encompasses about three-fourths of the total cases. This disease is one of the few infectious diseases recently rising in incidence globally[2,3].

Molecular characterization of the causative agent of CL may facilitate the determining molecular epidemiology and hence can help in introducing effective control programs. Polymerase chain reaction (PCR) brought about the infusion of techniques for identification and genetic characterization of \textit{Leishmania}[4]. Different genes such as 5.8S rRNA and internal transcribed spacer-1 gene have been used successfully for both diagnosis and molecular characterization of CL[5]. Studies concerning phylogenetic analysis and molecular characterization of \textit{L. tropica} and \textit{L. major} are scarce in Iraq despite the endemicity of the disease.

Therefore, this study aimed to molecular characterization of local isolates of \textit{L. tropica} and \textit{L. major} and their relatedness to reference isolated from neighboring countries.

Subjects and Method

The study Population: This study was performed in the dermatology clinic of Baquba Teaching Hospital in Diyala city/Iraq, from November 2018 to the end of August 2019. A total 30 newly diagnosed patients...
with confirmed CL were included. The diagnosis of CL was based on clinical signs and detection of Leishman Donovan bodies with direct microscopic examination after staining of lesion exudate with Geimsa stain.

**Dermal scraping:** A deep disinfecting of the indurated active margin of the lesion with 70% ethanol was performed. Samples were taken by using disposable sterile surgical blade to make an incision in the border of the lesion. Exudates and dermal tissues from the wall of the slit were scraped and smeared on two glass slides. The touch impression smears were air dried, methanol-fixed, stained with Giemsa and finally examined for amastigotes by microscopy.

**Leishmania gene amplification:** Leishmania DNA was extracted from lesion exudate using a ready commercial kit (Analytikjena/Germany). Nested PCR technique was used for amplification of 18.5S rRNA *Leishmania* gene. The primers of the first round were forward: 5′- CTGTAGGTGACCTGCAGCAGCTGGATCATT-3′ and reverse: 5′-GCGGGTAGTCCTGCACACTCAGGTCTG-3′ with an expected fragment length of 110 bp. The primers of the second round were forward: 5′-CTGGATCATTTCGAGATGCATT-3′ and reverse: 5′-TGATACCATTATCGACATT-3′ with an expected fragment length of 350 bp. The PCR conditions in the first and second round were as previously mentioned[6].

**DNA Sequencing and Sequence Alignment:** Twelve PCR products form the second round nested-PCR were sent abroad (Macrogen/Korea) for direct sequencing. The resultant sequences were aligned with 24 references sequences in the National Center for Biotechnology Information (NCBI) using Basic local alignment search tool (BLAST). The identity between the local and reference sequences was calculated. Mega 6 software was used to construct the phylogenetic tree for *L. torpica* and *L. major* local isolates.

**Results**

**Gel Electrophoresis:** The nested PCR products of the first and second round were subjected to a 2% agarose gel electrophoresis and examined by exposure to ultra violet light after Red Stain staining (Figure 1).

![Gel electrophoresis on 2% agarose at 5 volt/cm² of first (upper) and second (lower) nested PCR products. M: DNA ladder, lanes 1-15: PCR products from CL patients](image_url)
Sequencing and Sequence Alignment: The PCR products of 12 samples were sent abroad to Macrogen Company (Korea) for direct sequencing. The resultant sequences were compared with reference sequences using Basic Local Alignment Search Tool (BLAST) program at the National Center Biotechnology Information (NCBI) which is available online at (http://www.ncbi.nlm.nih.gov).

According to alignment results out of 12 sequences, 9 sequences were belonging to *L. major*, while 3 sequences were belonging to *L. tropica*. All local *L. major* isolates were very close to reference isolate KP773404.1 (Iranian isolate), while all local *L. tropica* isolates were very close to reference isolate KY612611.1 with an identity of 98%.

The base substitution, location of this substitution, nucleotide change each isolates in relation to reference isolates are presented in Table 1. The base substitution ranged from 2-6 bases at different sites of the gene with identities ranging from 97-99%.

**Table 1: The base substitution, location of this substitution, nucleotide change for each isolate in relation to reference isolates**

**Phylogenetic Tree:** Mega 6 software was used to construct the phylogenetic tree of the local isolate of *L. tropica* in relation with 14 most closest reference isolates (Figure 2). The tree showed two main clades: on containing three reference isolates (from USA, Libya and Tunisia) and the other clade involving the local isolate and all the other reference isolates. The closest isolates for local Leishmania was the Iranian isolate.
Figure 2: Phylogenetic trees for 5.8S rRNA gene constructed by the maximum likelihood method for local *L. tropica* isolate and 14 reference isolates. Phylogenetic distance was estimated using the Kimura two-parameter model. The tree was supported by bootstrapping with 1000 replicates\[7\].

Similarly, a phylogenetic tree was constructed between the local isolate of *L. major* with 14 closest reference isolates. The tree (Figure 3) had two main clades: one contains only a Turkish isolate while the other involving the local isolate with all other reference isolates. The local isolate had a 98% identity to all reference isolates except the Turkish isolate (identity 97%).

Figure 3: Phylogenetic trees for 5.8S rRNA gene constructed by the maximum likelihood method for local *L. major* isolate and 14 reference isolates. Phylogenetic distance was estimated using the Kimura two-parameter model. The tree was supported by bootstrapping with 1000 replicates\[7\].
Discussion

To evaluate genetic diversity of *Leishmania*, authors have employed several DNA markers whether nuclear or extranuclear. The most commonly used markers were 18S-rRNA, mini-exon, gp63 gene locus, HSP-70, microsatellites, minicircles of kinetoplast DNA (kDNA), ribosomal internal transcribed spacer regions (ITS-rDNA) and cytochrome b (Cyt b) (kDNA maxicircle) [8,9]. The ITS-rDNA marker, for example, was utilized to deduce the evolutionary relationships in genus *Leishmania* because of its conserved region with relatively low intracellular polymorphisms [10].

The most interesting finding in the current study was that the limited variation among the investigated isolates compared with the other international studies. For example, in Iran, Mohammadihaet al. [11] amplifies the ITS-rDNA gene for 25 isolates and used RFLP for genotyping of PCR products. The authors reported high diversity among isolates whether they belong to *L. tropica* or *L. major*. In another study, Azmi et al. [12] reported that *L. tropica* is a very heterogenous species and this was evidenced by low bootstrap values obtained on the phylogenetic tree. The low diversity in the current study may be attributed mainly to a geographical reason, because almost all samples were collected from a small geographical location.

The other most interesting finding was that local isolates had a relatively high compatibility to isolates from different countries. In fact, this does not reflect a reciprocal transmission from these countries to Iraq and vice versa. Rather, in such countries, different isolates have been recorded in NCBI, among which there are some isolates which resemble other international isolates including Iraqi isolates.

Collectively, these data indicate that local isolates of CL (whether *L. major* of *L. tropica*) have less genetic variability compared with internal isolates and they are very close to their counterpart Iranian isolates. As such, it is of paramount importance to restrict the individual travelling between the two countries for effective control of the diseases especially for anthropotic CL.

Acknowledgement: The authors highly appreciate the great help from Dr. Mohammed Ali during the blood sample collection

Conflicts of Interest: The authors declare that they have no conflict of interest.

Ethical Clearance: This study was approved by the Institutional Review Board/College of Medicine/Diyala University. A consent from each patient was obtained prior to data collection after explaining the aim of study. The confidentiality of data throughout the study was guaranteed and the included patients were assured that data will be used for research purpose only.

Abstract

Background: Endoscopic ultrasonography guided-fine needle aspiration offers through linear endoscopy an opportunity for sampling mediastinal, intra-abdominal, pancreatic and pelvic lesions under direct visualization.

Aim of Study: To assess the validity of endoscopic ultrasonography guided-fine needle aspiration from patients with gastrointestinal tract disorder discovered by endoscopy or other imaging modalities in comparison to histopathology.

Patients and Method: A retrospective data review study conducted in Kurdistan Center for Gastroenterology & Hepatology in Sulaimani through the period from 1st of January 2016 to 31st of December 2016 on sample of 102 suspected gastrointestinal tumors patients. Endoscopic ultrasonography data base at Kurdistan Center during 4 years period (January 2013- December 2016) is searched for all patients referred for Endoscopic ultrasonography-fine needle aspiration.

Results: Endoscopic ultrasonography showed that 51% of suspected gastrointestinal tumor patients had malignancy while histopathology showed that 45.1% of suspected patients had malignancy. The validity results of endoscopic ultrasonography-fine needle aspiration in comparison to histopathology findings were sensitivity (87%), specificity (78.6%), +ve predictive value (76.9%), -ve predictive value (88%) and accuracy (82.3%).

Conclusions: Endoscopic Ultrasonography-Fine Needle Aspiration is an appropriate diagnostic choice for suspected gastrointestinal tumors.

Keywords: Endoscopic ultrasonography guided-fine needle aspiration, Histopathology, Gastrointestinal tumors.

Introduction

The endoscopic ultrasonography-guided fine needle aspiration (EUS-FNA) facilitates the chance for acquiring samples for mediastinal, intra-abdominal and pancreatic lesions through direct vision¹². The EUS-FNA is beneficial for collecting cytological materials, so had an accurate diagnosis for many suspected clinical lesions ranging from 52-94% ³⁴. However, the histopathology examination has an important role in improving the diagnostic yield⁵.

Many clinical roles are reported for EUS-FNA which daily increased with advancement of oncology.
and molecular genetics. The EUS-FNA is useful in gastrointestinal (GIT) tumors staging, treatment and prognosis. The first clinical indications of EUS-FNA are sampling of nodes in different GIT tumors like esophageal carcinoma, mediastinal lymphnodes and tumors, pancreatic masses, etc. The EUS-FNA has a significant role in the differential diagnosis of solid pancreatic tumors. The EUS-FNA is contraindicated in cases when there is a suspicion of affecting cancer treatment. Additional contraindications of EUS-FNA are like other endoscopic procedures which are severe hemorrhage and thrombocytopenia, or risk of tumor seeding and blood vessels in way of endoscopy.

The main complication of EUS-FNA as recorded by the European Society of Gastrointestinal Endoscopy (ESGE) guidelines was acute pancreatitis with incidence range of 0.26-2%. However, the ESGE guidelines stated that EUS-FNA is a safe procedure with a low rate of general complications (incidence rate 1%) that increased in cystic lesions as compared to solid lesions. Many authors reported lower rates of EUS-FNA severe complications like bleeding, perforation and death. Seeding of tumors related to EUS-FNA for pancreatic adenocarcinoma is rare. The EUS-FNA in comparison to percutaneous route, has a great advantage of lower risk of peritoneal seeding.

The increase in GIT cancer rates globally and nationally in last decades which was related to dietary and lifestyle changes in addition to medical advances in diagnosis, staging, treatment and prognosis of GIT cancers in Iraq are the main rationale for present study. The objective of this study was to assess the validity of EUS-FNA from patients with gastrointestinal tract disorder discovered by endoscopy or other imaging modalities in comparison to histopathology examination.

**Methodology**

The design of current study was retrospective data review study conducted in Kurdistan Center for Gastroenterology & Hepatology (KCGH) in Sulaimani city-Iraq through the period from 1st of January 2016 to 31st of December 2016. Study population was patients with suspected gastrointestinal tract lesion by endoscopy or imaging study referred to KCGH center for EUS-FNA for further evaluation of the lesion. Patients with suspected gastrointestinal tract lesion by endoscopy or imaging study with adulthood age group (≥28 years) and completed data specifically the EUS-FNA and histopathology were the inclusion criteria. The exclusion criteria were known cases of other tumors, incomplete data and younger age patients. A sample of 102 suspected gastrointestinal (GIT) tumor patients referred to KCGH in Sulaimani criteria was taken. The ethical considerations were obtained from Helsinki Declaration by respecting confidentiality of patients, approval on study was acquired from KCGH authority and the researcher was responsible about the saved data.

The data were collected by the researcher through review of patients’ files and fulfilling a prepared questionnaire. Diagnosis was made on the basis of history, examination, investigations, imaging and histopathology. Investigations (like complete blood picture, liver function tests, CA19-9, HbA1c, renal function tests, Virology, etc.) imaging (like transabdominal ultrasonography, magnetic resonance imaging, computerized tomography scan and magnetic resonance cholangiopancreatography) and histopathology were carried out in KCGH. Interpretation of these investigations was done by Gastroenterologist and Radiologist. The questionnaire included the followings: demographic characteristics (age and gender), EUS-FNA characteristics (needle size, number of passes and technique of sampling, EUS findings and histopathology findings.

The EUS data base at KCGH center during 4 years period (January 2013- December 2016) is searched for all patients referred for EUS-FNA. The model is Pentax Videoscope EG3870UTK and Hitashi Avius Doppler Ultrasound (done by 3 gastroenterologists). Cytology was done in Kurdistan center of gastroenterology and hepatology (GIT expert pathologist). The needles used for EUS-FNA had size ranged between 19-25 G. The passes numbers of EUS-FNA were ranging between 1-4 passes. All the biopsies and surgical specimens were fixed with Formalin and alcohol to be prepared for examination. The slides were stained with eosin, hematoxlin and immunohistochemical substances.

The data collected were analyzed statistically by Statistical Package of Social Sciences software version 22. Chi-square test and Fischer’s exact test were applied for analyzing the data as suitable. Two by two table was applied for calculation of validity findings of EUS-FNA in comparison to Histopathology. Level of significance (p value) was regarded statistically significant if it was 0.05 or less.
Results

Most (94.1%) of EUS-FNA needles had size of 22G and more than two thirds (78.4%) of patients had two needle passes. All these findings were shown in table 1.

The common EUS findings were unresectable pancreatic head tumor (8.8%), neuro-endocrine tumors (6.9%), pancreatic genu mass (4.9%), Portahepatis (4.9%), mediastinal LAP (4.9%), etc. All these findings were shown in table 2.

EUS showed that 51% of suspected GIT tumor patients had malignancy while histopathology showed that 45.1% of suspected GIT patients had malignancy. All these findings were shown in figures 1 and 2.

**Discussion**

Early detection of gastrointestinal tumors is important in lives saving as dangerous GIT tumors are asymptomatic. For that, many imaging modalities were developed for screening and early diagnosis with best localization of GIT lesions

Present study showed that the validity results of EUS-FNA in diagnosing malignancy of GIT are sensitivity (87%), specificity (78.6%), positive predictive value (76.9%), negative predictive value (88%) and accuracy (82.3%). These findings are close to results of previous Iraqi study included 40 patients with pancreatic
mass and reported EUS-FNA sensitivity is 80.9% in diagnosing malignancy of pancreas. Validity results of EUS-FNA by our study were higher than results of Baek et al study in South Korea which was a retrospective review of 191 cases of pancreatic lesions initially diagnosed by EUS-FNA and reported that EUS-FNA diagnostic accuracy was 78.4%, sensitivity was 79.2% and specificity was 75.7%. The positive predictive value was 92.0% and negative predictive value was 50.9%. However, our EUS-FNA validity results were lower than results of Baghbanian et al study in Iran which stated that EUS-FNA sensitivity, specificity, positive predictive value, negative predictive value and accuracy of this procedure concerning malignancy of GIT were 88%, 100%, 100%, 70% and 90%, respectively. These differences in EUS-FNA validity results between studies might be attributed to difference in sample size and study designs in addition to different inclusion criteria. In spite these differences, all studies pointed to good accuracy of EUS-FNA for diagnosing malignant GIT tumor.

Despite of this acceptable accuracy for EUS-FNA, there is a debate on importance of sampling for pancreatic lesions, specifically for those who are with surgically resectable lesion. The reason was that EUS-FNA could be restrained by the stenosis or other anatomical factors and EUS validity decreased with chronic pancreatitis in addition to complications of needle tract seeding. However, the EUS-FNA helps in excluding other types of tumors, helpful in surgical planning and in diagnosis confirmation. EUS-FNA sensitivity and specificity is directly related to pathologist’s experience and endosonographist’s skills.

In our study, there was a significant association between increased age of suspected GIT tumor patients and malignancy (p=0.002). This is similar to results of McCleary et al study in USA which showed that GIT malignant tumors were more prevalent among elderly population (>70 years age). Present study showed that male gender was significantly associated with malignant GIT tumors (p=0.04). This finding coincides with results of Thakur et al study in India which showed a male preponderance for all sites in the gastrointestinal tract with 34 (64.0%) male patients and 19 (36.0%) female patients.

In conclusion, Endoscopic Ultrasonography-Fine Needle Aspiration is an appropriate diagnostic choice for suspected gastrointestinal tumors. Elderly age and male gender are more likely to predict malignancy of gastrointestinal tract. Encouraging Physicians and gastroenterologist to use the Endoscopic Ultrasonography-Fine Needle Aspiration as first choice in diagnosing gastrointestinal suspected lesions is the main recommendation.

Level of Knowledge and Awareness of Halitosis in the Dental Medicine Students

Muhammad Arya Rizkianto¹, Novita¹, Cindy Shavia¹, Gempita Anargia¹, Farah Maulidya Titani¹, Titian Fauzi Nurrahman¹, Regina Purnama Dewi Iskandar²

¹Undergraduate Student of Dental Medicine, Department Dental Public Health, Faculty of Dental Medicine, Universitas Airlangga Indonesia, ²Primary Health Care Research group, Faculty of Dental Medicine, Universitas Airlangga Indonesia

Abstract

Background: Halitosis is a general term that means bad odor in the oral cavity that is difficult to treat due to poor oral health and is a problem affecting 50% of the adult population. The impact of halitosis is closely related to the psychological and social effects of a person.

Purpose: To find out the level of knowledge and awareness of Dental Medicine Students of Universitas Airlangga about halitosis and the benefits of the perception and level of awareness of halitosis as a reference in carrying out health promotion.

Method: This research will use a cross-sectional random sampling study. The survey or questionnaire was distributed to 100 students from class of 2014 to 2019 Faculty of Dental Medicine, Universitas Airlangga, Surabaya, Indonesia.

Result: The results of this study show that the level of halitosis knowledge in pre-clinic students shows that 57% had proper knowledge and 43% had poor knowledge. While clinical students have a 46% poor knowledge result and 54% with proper knowledge. For the awareness of halitosis in pre-clinic students shows that 91% had a proper awareness and only 9% with poor awareness.

Conclusion: The average score of the respondents on poor knowledge of halitosis and poor awareness of halitosis, so health promotion that will be carried out can be emphasized on counseling about halitosis.

Keyword: Halitosis, Psychological and Social impacts, Knowledge about Halitosis.

Introduction

Halitosis is a general term that means bad odor in the oral cavity that is difficult to disappear due to poor oral health¹. Halitosis comes from the Latin word “halitus” meaning breath and the Greek word “osis” which means abnormal or disease. Halitosis is a term for defining bad odor from breathing. The unpleasant odor caused by the release of Volatile Sulfur Compounds (VSCs) caused by the decay activity of gram-negative microorganisms². Halitosis can be divided into 3 types, namely true halitosis, pseudohalitosis and halitophobia³.

The cause of halitosis is still unknown, but most of the causes are food scraps left in the oral cavity which are then processed by the oral flora⁴. Of particular concern are saliva, tongue, interdental areas and teeth⁵,⁶. In addition, halitosis can also be caused by abnormalities in the oral cavity or systemic abnormalities or abnormalities in the extraoral⁷. Common causes of halitosis (more than 80%) are stomatological disorders such as calculus⁸, chronic...
gingivitis, periodontitis, poor oral hygiene, stomatitis caused by bacteria and fungi, inflammation of the mucous membranes and bones, tumors, etc. Other disorders that can also trigger halitosis are open pulp teeth, post extraction sores, dentures that are rarely removed and cleaned, cysts, oral cancer and food impaction.

The impact of halitosis is closely related to the psychological and social effects of a person. Unpleasant breath during communication can be an influence on a person’s social life and psychological health. Bad breath can also cause phobias, depression, excessive worries, behavior changes and can affect self-confidence. The social impact of halitosis has been studied in other studies where women tend to be ashamed of halitosis. More and more women feel that they cannot reach their academic goals because of bad breath. Women are more aware of their bad breath. The use of oral hygiene aids greatly influences individual social behavior and is very important for individuals who face insecurities about their bad breath in social interactions. In preventing halitosis, an individual’s knowledge and awareness of halitosis is needed.

Knowledge is the result of knowing obtained by humans by sensing an object. Knowledge becomes the main domain for the creation of human behavior. While awareness is a form of someone’s readiness to face all forms of surrounding events and cognitive events including memory, thoughts, feelings and physical. Both of these are interrelated and play an important role in preventing halitosis. Therefore, in this study the authors wanted to know the knowledge and awareness of halitosis in the community with samples taken from students of the Faculty of Dental Medicine, Universitas Airlangga. The data can then be used to develop a health promotion program on halitosis.

Material and Method

In this study a descriptive cross-sectional study method was used and the sample was taken randomly. This study was approved by the ethics commission of the Faculty of Dental Medicine, Universitas Airlangga. The subjects and locations used for this study were 100 Dental Medicine students at Universitas Airlangga in Surabaya from the class of 2014 to the class of 2019 (Preclinical and clinical students). The research instrument used to collect data in the form of questionnaires. Questionnaires are data collection techniques carried out by giving a set of questions or statements to other people who are subject to answer. The questions that will be used in this study are questions from a journal that had previously been made by Mubayrik and made several changes. Questions were shared using Google Form and filling was done in private and each sample filled in individually. The question format provided contains 3 pages consisting of identity data and informed consent, questions about self-awareness about halitosis and the last page contains questions about knowledge about halitosis. Total questions provided are 13 questions. The research variables seen in this study are knowledge about halitosis and awareness of halitosis.

In table 1, it can be seen the results of the questionnaire that has been summarized and analyzed. In the questionnaire, questions about self-evaluation of halitosis range or awareness of halitosis are represented by 4 questions which include how to evaluate halitosis in yourself, how to confirm the diagnosis of halitosis, how to cope with halitosis according to individual views and what action will be taken for acquaintances who experience halitosis. The questions are available in multiple choices from a through d and whoever answer a will be graded by 3 and whoever answer d will be scored 0. Individual scores of more than 7 will be rated proper and less than 7 will be judged poorly. After analyzing the data, the results of pre-clinical students who have proper awareness about halitosis by 91% and clinical students by 85% and overall respondents 90% have proper awareness of halitosis. Furthermore, for the variable knowledge about individual halitosis with scores 9 to 14 are considered proper and less than 8 means poor knowledge about halitosis. The results of pre-clinical students with proper knowledge by 57% and clinical students who have good knowledge by 54%. The presentation of the knowledge of Dental Medicine students of Universitas Airlangga to halitosis shows that 57% had a proper knowledge and the rest was poor or lack of knowledge. After testing the two variables, the authors also compared sex to awareness and knowledge of halitosis. The percentage of individual awareness of halitosis was higher in men at 92% while in women at 89%. This is contrary to students knowledge, women have better presentations of 64% and men by 38%.

Discussion

The results of the first part of the research about Halitosis Knowledge of Pre-Clinical and Clinical Students shows that the level of halitosis knowledge in pre-clinical students with poor knowledge is 43% and 57% had a proper knowledge. While clinical students have a 46% bad knowledge result and 54% proper knowledge. With the results of this study it was found that the level of knowledge of clinical students is lower than pre-clinic students. This means that it is not in accordance with the hypothesis that clinical students should have more and better knowledge about halitosis.

The results of this study are based on literature by Cassiano Kuchenbecker Rösing & Walter Loesche22, who stated that everyone in the field of dentistry should pay more particular attention to halitosis. However, the science behind understanding halitosis is still low. Some clinical approaches are based on opinion. As a dentist must have knowledge about current halitosis, diagnosis and treatment modalities to meet the needs of patients either consciously or knowledgeably with this problem. According to the results of Cameira N.J15’s research, students showed a lack of proper knowledge about halitosis and reported an inadequate level of education on the subject, which was inconsistent with the results of our study. In general, providing knowledge about halitosis is very important because it can be a manifestation of several diseases. Therefore early diagnosis seems to be a must. Conducting scientific publications and clinical guidance on this issue may be very helpful to health practitioners.

Knowing that majority of causes of halitosis are oral based, dentists must become primary health professionals in screening and managing halitosis in patients who complain about the disease. Poor education can lead to a lack of confidence by dental professionals and an unsatisfactory response to patient needs23. On the other hand, this problem is an obligation for a dentist to identify and develop knowledge in the field of dentistry.
to provide balanced scientific information to patients and to increase the knowledge of dentistry students. Halitosis is a recognizable disease that requires professional attention. To overcome this, dental schools must commit to give their students a strong emphasis on this condition. A self-evaluation check might be a starting point for a change. Furthermore, the results of the second part of research about Halitosis Awareness in Pre-Clinical and Clinical Students shows that 91% of the pre-clinical students had a proper awareness and only 9% had a poor awareness. While clinical students had a poor knowledge result of 15% and proper knowledge of 85%. With the results of this study it was found that the level of awareness of clinical students is lower than pre-clinical students. Based on Mubayrik A. study, found a relatively low level of self-reported halitosis awareness, but a much larger proportion indicates that bad breath is a problem for people around them. Most respondents indicated that they would overcome bad breath by covering up rather than treating the cause.

The results obtained are not in accordance with the hypothesis where it is expected that clinical students have a higher awareness than preclinical students. As in previous studies which showed that the first, second, third and fourth grade students experienced a significant increase in awareness of halitosis. This is comparable to the experience and education training of dental students who are getting more and more experienced on this field.

In the results of the third part of research about Halitosis Knowledge in Female and Male Students shows that the level of halitosis knowledge in female students with bad knowledge is 36% and proper knowledge is 64%. While male students have a poor knowledge result of 62% and poor knowledge of 38%. With the results of this study found that the level of knowledge of male students is lower than female students.

The results of the fourth part of the research about Halitosis Awareness in Female and Male Students showed that the level of halitosis awareness in female students had a result of 11% with poor awareness and 89% with proper awareness. While male students had 8% with poor awareness and 92% with proper awareness. With the results of this study it was found that the level of awareness of male students was lower than that of female students. The results of the above study in accordance with previous studies stated that female students had an awareness to maintain teeth and oral health better than male students. This could happen because women prefer to use dental floss and mouth wash than men. Some supporting factors include the fact that women take more care and attention of their body and appearance compared to men.

**Conclusion**

Our results show that the evaluation rate and awareness of the Unair Dental Medicine students about bad breath or halitosis is fairly good, with an average score of respondents towards poor knowledge of halitosis by 43% and proper knowledge by 57% and on the results for evaluating awareness of halitosis, the result of poor awareness of halitosis is 10% and those who have proper awareness are 90%. The evaluation obtained in this study where there is a large gap from the comparison of male and female students who are in the Faculty of Dental Medicine of Universitas Airlangga and there is an uneven distribution between pre-clinical and clinical students, causing a large enough comparation.

Awareness and Performance of Paramedics in Preventing toward Middle East Respiratory Syndrome Coronavirus Infection

Myeong- Jeong Chae¹, Jong-Geun Yun², Boyoung Kim³

¹Assistant Professor, Department of Nursing, Gwangju Women’s University, Gwang-ju, Korea, ²Assistant Professor, Department of Emergency Medical Services Honam University, Gwang-ju, Korea, ³Associate Professor, College of Nursing, Gyeongsang National University, South Korea

Abstract

The purpose of this study is to examine the knowledge of Middle East Respiratory Syndrome Coronavirus (MERS), wearing of protective equipment and the performance in preventing MERS infection among paramedics and analyze correlations. The survey was conducted on 96 active paramedics in K city, South Korea. The data were analyzed using the SPSS 21.0 program using descriptive statistics, t-test, one-way ANOVA, Scheffe test and Pearson’s correlation coefficient.

Through this analysis, it was found that higher knowledge of MERS resulted in higher scores in the actions to prevent infection. As such, it is necessary to raise the infection control performance of paramedics by reflecting strategies for ‘preparedness’ rather than ‘response’ in the training on MERS, which must focus on knowledge and infection prevention.

Keywords: Paramedics, MERS-coronavirus, knowledge, protective equipment, infection prevention.

Introduction

Middle East respiratory syndrome is a severe acute respiratory infection caused by the MERS⁰¹. Since the first confirmed case was reported in Saudi Arabia in 2012, cases have been reported around the world and the death toll has been steadily increasing⁰². In fact, it continues to occur in Korea, as there was a suspected case of MERS in September 2018⁰³. Similar to SARS, which hit Asia in 2003, there is still no cure or vaccine for the disease, which is accompanied by kidney failure along with symptoms of severe acute respiratory diseases such as high fever, coughing and difficulty in breathing⁰⁴.

Looking back at the outbreak of MERS in Korea in 2015, the system overseeing each component of the emergency medical system did not function properly during the outbreak and spread of MERS⁰⁴. This is because essential guidelines were missing and even the guidelines available were difficult to apply in the field⁰⁵. In addition, the infections were concentrated in medical environments and were highly prevalent among health and medical care workers⁰⁶. In particular, as paramedics have the most direct contact with active patients with infectious diseases before hospital treatment, they can be exposed to infectious diseases through contact with patients⁰⁷. For this reason, paramedics need to perform effective infection control actions to minimize their infections related to emergency medical care. In addition, they must conduct activities to prevent the spread of microorganisms in order to prevent exogenous healthcare-associated infections⁰⁸. Actions to prevent infection include hand hygiene, personal hygiene and
aseptic technique, invasive instrument management, wearing and removing protective equipment, disinfection and sterilization, quarantine and environmental management activities performed by paramedics.

Monitoring and reporting the outbreak of infections are the starting point and backbone of infection control projects and these projects can be properly carried out by accurately identifying infection control problems inherent to paramedics. In addition, effective infection control can be achieved by monitoring the measures taken to address the problems and the results of education through continuous infection monitoring activities. However, there is a lack of research and education on infection control for paramedics. Although the safety management SOP (Standard Operating Procedures) standard for paramedics has been prepared and enacted to protect paramedics from infections and the importance of paramedic safety is being emphasized, studies in Korea on infection control by paramedics before hospital treatment have only been performed by Yoon and Jung. As such, it is necessary to present the proper direction for infection control based on the reality of paramedics in Korea.

Therefore, the purpose of this study is to provide a basic data on infection control by examining the relationship between the knowledge of MERS, wearing protective equipment and the performance level of infection prevention for paramedics who are susceptible to infections at emergency sites.

Method

Study Participants and Data Collection: The participants in this study were selected from those who understood its purpose and objective and agreed to voluntarily participate in the study among active firefighting officers who entered the fire academy in K-area for retraining. To protect the participants, approval for this study was obtained from the university’s bioethics review committee. We explained to the participants that the data will be only used for research in addition to their contribution to the research and the details and method of research. We also informed them that they could withdraw from the study and explained the anonymity and confidentiality of the data and that all data will be destroyed after the study. We considered the ethical aspect for the participants by receiving written consent to participate in the study. We distributed 100 questionnaires considering the recovery rate and collected 96 questionnaires for the final analysis.

Research Variables: Korean tools to measure the performance of MERS knowledge and actions to prevent infection have not yet been developed and the infection control protocol in Korea clinically applies the protocol developed by the Centers for Disease Control and Prevention (CDC). Therefore, this study developed a questionnaire on MERS knowledge, wearing protective equipment and infection prevention performance after consulting with a licensed professor of emergency medicine based on the infection control guidelines for paramedics, materials presented by the Korea Centers for Disease Control and Prevention, training materials for Korean paramedics to prevent MERS infection and MERS response integrated administrative guidelines.

The questionnaire has a total of 30 yes/no questions, including 10 questions about knowledge, 5 questions for protective equipment and 15 questions for infection prevention performance.

Data analysis: The data collected in this study were analyzed using the SPSS 21.0 program descriptive statistics, t-test, one-way ANOVA, Scheffe test and Pearson’s correlation coefficient.

Result and Discussion

General Characteristics: The general characteristics of the paramedics are shown in Table 1 below. Out of 96 paramedics, 84 (87.5%) were male and 12 (12.5%) were female, so there about 3 times more male paramedics than female paramedics. In terms of age, 53 paramedics were under 29 (55.2%) and 43 were over 30 years old (44.8%). In terms of education, the paramedics consisted of 8 high-school graduates (8.3%), 36 university graduates (37.5%) and 52 college graduates (54.2%).

Performance of wearing protective equipment: The participants’ performance of wearing protective equipment against MERS is shown in Table 3. The items with the highest performance level were 95.8% for ‘wear N95 masks’ and ‘wear gloves,’ while the item with the lowest performance level was 91.7% for ‘wear gowns (protective coveralls) that cover the sleeves.’ The use of protective equipment is the last defense to prevent harmful factors from entering the human body and here the average performance rate was high, at 93.7%.

Knowledge of MERS, wearing protective equipment and preventing infection according to general characteristics: The differences in knowledge of MERS, wearing protective equipment and preventing
infection according to the general characteristics of the paramedics are shown in <Table 3>. There were no differences according to gender, age and educational background. There was a statistically significant difference in wearing protective equipment according to the position or rank ($F=3.621, \ p<.031$) and the post-analysis showed that fire captains scored higher than fire fighters.

**Relationship between Variables:** The correlations between the participants’ knowledge of MERS, wearing protective equipment and preventing infection are shown in <Table 4>. The higher the knowledge of MERS, the higher the score for actions to prevent infection ($r=.216, \ p<.034$).

The MERS outbreak is a historical event which brought about a paradigm shift in Korea’s national infectious disease prevention and response system$^9$. The outbreak of MERS was prevalent in medical institutions and between humans$^4$. In Korea, the spread of the MERS outbreak was attributed to a complex interplay of various individual factors including the lack of awareness by medical professionals, the culture of family nursing, the health care delivery system and the initial response system of the government. We will not be able to achieve the desired results when faced with a complicated crisis such as MERS with conventional medical knowledge alone. Therefore, the first step in building an effective infection prevention system against infectious diseases such as MERS is to enhance the awareness and related knowledge through education in infection control guidelines based on the requirements of occupational roles and responsibilities, such as paramedics who experience direct contact with patients$^{15}$.

In addition, in order to be able to operate an effective infection prevention system in the event of a pandemic, regardless of the prevalence of MERS epidemic, it is necessary to develop an effective educational program for specific guidelines in all areas regarding the prevention and management of radio waves and to introduce and apply it in paramedics practice$^{16}$. For example, measures should be developed to effectively train workers in MERS quarantine guidelines by implementing simulation-based training for MERS outbreak and regular training for wearing protective equipment, case management for MERS management according to MERS quarantine guidelines regularly updated by the Korea Centers for Disease Control$^{17}$. These changes are essential for the education of occupational groups in direct contact with patients by preparing strategies related to preparedness rather than response.

The limitations of this study include it having a design, possible reporting bias and being conducted in a single city in Korea with a small sample size limited to a single profession. Based on the results of this study, the following suggestions are made. Since the results of this study are limited to the paramedics in Korea, follow-up research should be conducted in other countries to allow for greater comparison.

Conclusion

Our study shows that as paramedics have more knowledge of MERS, they had higher scores for preventing infection. Therefore, it is necessary to build an effective infection prevention system for infectious diseases by reflecting our knowledge of MERS and specific details on preventing infection in the education for occupational groups in direct contact with patients.

Lemon Extract as an Alternative Etching Materials on Composite Resin Restoration Against Shear Strength

Nadia Putri Syawalia1, Endanus Harijanto2, R. Moh. Yogiartono2

1Undergraduate Student of Dental Medicine, Department of Dental Material Science and Technology, Faculty of Dental Medicine, Universitas Airlangga, 2Staff of Biomaterial Department, Faculty of Dental Medicine, Universitas Airlangga

Abstract

Background: Composite restoration is an adhesive (mechanical interlocking) restoration, which is from resin tags on micro porosity on the etched surface of the enamel. Etching is to clean the smear layer and forming porous on the enamel surface as to provide mechanical retention in the restoration. The acidic etching material that is often used is phosphoric acid with a concentration of 37%, but 37% phosphoric acid can cause inflammatory cell infiltration. Lemon contains citric acid, a weak acid that has the potential to be an alternative to acid etching.

Purpose: To find out the effect of lemon extract as an alternative etching material on the shear strength of composite resin.

Method: 14 samples of bovine teeth incisors were divided into two groups. Each group consisted of 7 samples, then cavity preparation. Group 1 with 37% phosphoric acid etching, group 2 with lemon extract. The samples were bonded, filled with composite resin and carried out shear strength tests.

Results: There was no significant difference in shear strength from the composite resin group with 37% phosphoric acid etching and composite resin group with lemon extract.

Conclusion: Lemon extract can be used as an alternative material for acid etching in composite resin.

Keywords: Shear strength, lemon extract, 37% phosphoric acid etching and composite resin.

Introduction

Recently, the field of dental medicine, composite resins have begun to be widely used as anterior and posterior restorative materials, due to the demand of patients who want tooth-colored restoration1. Composite resins are increasingly popular because they have good aesthetics and good mechanical strength, among others are not easily separated from the tooth surface, not easily cracked and broken, has a high visual opacity and low polymerization shrinkage.2

Composite resins are restorations whose basic principle of bonding with teeth is micromechanical (mechanical-interlocking)2, i.e. from resin tags on micro porosity on the enamel surface that has been etched3. Etching is performed to clean the smear layer and produce small pores on the enamel surface, so can provide mechanical retention in restoration4.

Acid etching material that is often used is phosphoric acid with concentrations ranging from 30-40%, but the most widely used concentration is 37%5. Phosphoric acid is a strong acid, 6 is able to release more hydrogen ions than weak acids, because it is able to completely mineralize6.
The strong acid can cause hydroxyapatite to dissolve so that the demineralization process occurs on the enamel surface\(^7\). When the composite resin is applied to the enamel surface that has been etched\(^8\), the resin will flow on the irregular surface and form a resin tag\(^9\), resulting in mechanical interlocking of the resin on the resin enamel\(^3\).

The use of phosphoric acid can be dangerous to the dental pulp\(^10\). Phosphoric acid can cause excessive demineralization so that it will increase the permeability of the dentin. Penetration of etching material will be more through the dentinal tubules into the pulp. The etching material of phosphoric acid with low pH causes the environment outside the cell to be hypertonic, so that the fluid inside the cytoplasm will be pulled out and the cell will contract. This can trigger permanent damage to odontoblast cells and cause an inflammatory reaction\(^11\).

The effects of using potentially harmful chemicals can be minimized by using alternative medicinal plants.

To overcome the shortcomings of etching that can irritate the dental pulp, natural materials that can replace etching, one of them with lemons. Lemon contains organic acids which are citric acid. Citric acid is a chelating solution that is able to remove the smear layer on the cavity so as to increase contact between the cavity surface and the restoration material\(^12\).

The shear strength test for tooth restoration is one way to measure the adhesion strength of the material\(^13\) to the restored tooth structure besides the tensile strength test\(^14,15\). In this research the magnitude of force acceptable for composite resin restorations was measured when the restorations were detached from the tooth surface. Shear strength can indicate how the adhesion occurs in vitro\(^16\).

The value obtained from the shear strength test is not absolute, but the value of the test results can be used to help compare an adhesive material. This research was conducted to find out more about the effect of lemon extract as an alternative etching material to the composite resin shear strength.

**Materials and Method**

The ingredients used were bovine teeth, 37% phosphoric acid, lemon extract, sterile aquadest, 96% ethanol, 0.9% PZ/NaCl solution, cotton pellet, composite resin bonding and composite resin.

The sample making of bovine teeth is as follows, each bovine teeth separated by the crown and roots, then planted on top of acrylic with the labial surface facing up. The sample was prepared in the labial section of a cylinder with a diameter of 4 mm and into 2 mm with contra angle low speed. Tooth cavity is checked using a sonde, to see the surface is smooth and then rinsed using distilled water and dried.

Making liquid lemon extract is as follows, as much as 1000 grams of lemon is prepared, washed clean, cut into small pieces and mashed with 96% ethanol as much as 2 liters using a blender. Lemon that has been smooth is transferred into a 2 liter volume jar for soaking (maceration) for 3 days. After 3 days soaking, then filtered with filter cloth separated the pulp with the filtrate. The ethanol filtrate was evaporated with a rotary evaporator with a temperature of 60 ° and ethanol pressure of 175 mbar until the solvent completely evaporated. The liquid yield of lemon extract was 165 ml, then the pH of the lemon extract is measured using litmus paper, around 2.5.

The next treatment procedure, bovine teeth were etched for 20 seconds, the samples were divided into 2 groups, namely group I: bovine teeth etched with 37% phosphoric acid, group II: bovine teeth) which was etched with liquid lemon extract. The etching material was rinsed with distilled water ± 1 cc until clean, then dry using blow dry for 10 seconds. Resin bonding was dropped on a microbrush as much as 1 drop (0.01 ml) and
applied to the surface of the cavity, irradiated with light
curing for 10 seconds (visible light with a wavelength of
400-800nm). Composite resin was applied using a plastic
filling instrument on the cavity layer by layer as many as
3 layers to meet the cavity, each layer was condensed
and shined by using light cure. Samples were stored in a
room temperature tool box for 24 hours. Shear strength
testing uses a Universal Testing Machine (Autograph).

Result

Average and standard deviation of composite resin
with phosphate and lemon extract can be seen on Table 1.

Information:

a. Group I: Bovine teeth etched with 37% phosphoric
acid
b. Group II: Bovine teeth etched with liquid lemon
extract

Normality test with the Kolmogorov-Smirnov Z
test in both groups obtained p value for composite resin
group with phosphoric acid etching p value = 0.200 (p> 0.05) and for composite resin group with lemon extract
obtained p value = 0.200 (p> 0, 05). This shows that
the data from the two groups are normally distributed.
After knowing the data the two groups were normally
distributed then Independent T-Test was conducted.

Levene test results obtained a significant level of
0.629 which indicates that the variance of homogeneity
of data is normal. The statistical test was continued
with the Independent T-Test by using the results in the
normal variant sequence. The results of the Independent
T-Test in the sample group A and sample B obtained
a significant level of p = 0.197 (p> 0.05). This shows
that there is no significant difference between the shear
strength of composite resins with acid etching and composite resins with lemon extract.

Discussion

This research uses incisive cow’s lower teeth. Lower
mandibular incisors are used because they are easier to
obtain and are easily standardized. The chemical and
micromorphological composition between bovine teeth
and human teeth also has similarities. The results showed
that the amount of inorganic pyrophosphate in enamel
and dentin bovine teeth and human teeth was almost
the same. The research was conducted to determine the
difference in shear strength of composite resins
using 37% phosphoric acid etching with composite
resins using lemon extract. The magnitude of the shear
strength (MPa) is assessed based on the shear force (kgf)
acceptable to composite resin restorations.

The results showed no significant difference in shear
strength between composite resin with 37% phosphoric
acid etching and composite resin with lemon extract
etching. Lemon extract contains weak acids namely,
citric acid. Citric acid in lemon extract plays a role in
the process of dissolution of tooth enamel, because at
acidic pH causes an increase in hydrogen ions, which
will damage hydroxyapatite. Lemon extract shows a pH
of 2.5. The degree of acidity affects the coefficient of the
reaction rate, that the lower the pH or the more acidic, the
higher the rate of reaction to release Ca-P ions in tooth
enamel. High concentrations of H+ ions can dissolve
Ca-P bonds in hydroxyapatite so that enamel loses the
inorganic minerals that make up hydroxyapatite. This
condition is known as the demineralization process.

Demineralization of tooth enamel occurs through a
diffusion process which is the process of transferring
molecules from the enamel to saliva due to acid. Demineralization occurs when hydroxyapatite (Ca10
(PO4) 6 (OH) 2) crystals in tooth enamel dissolve in
acidic conditions into Ca2+ , (PO4) 3- and OH-. This
reaction can be explained as follows: Ca10 (PO4) 6
(OH) 2 + 8H + ↔ 10Ca2 + + 6 (HPO4) 2- + 2H2O. The
CaHPO4 molecule is a neutral molecule that will diffuse
out of the enamel thus the email will lose the inorganic
minerals that make up hydroxyapatite, while the two OH
ions bind to the H + ion to form 2H2O in the email.

Demineralization that occurs in a long time will
cause the loss of hydroxyapatite crystals so that enamel
is more porous and increases the microporosity of tooth
enamel. The formed microporosity will be activated by
the bonding material and composite resin, resulting in a
shear strength that is not much different from the yield of
37% phosphoric acid.

The results of the SEM (Scanning Electron
Microscope) test after the application of lemon extract on
bovine teeth also showed the formation of microporosity.
Lemon extract is more beneficial in terms of tissue health, because the pH is not too low when compared to the pH of 37% phosphoric acid. Lemon extract also has the ability to remove the smear layer and form microporosity like 37% phosphoric acid etching. The results showed no significant difference, but taking into account the advantages of lemon extract, the lemon extract can still be used as an alternative to 37% phosphoric acid etching.

**Conclusions**

The conclusion of the research is that lemon extract can be used as an alternative etching material on composite resin spills with shear strength.

Triangular Interaction of Decision Making for Breastfeeding a New Infant-Centered Care Model

Nikmatur Rohmah1,2, Ah Yusuf3, Rachmat Hargono4, Saiful Walid5, Purgaryantyas Subyantoro6, Evi Triwahyuni7, Rahayu Sri Wahyuni8

1Doctoral Program, Faculty of Public Health, University of Airlangga Surabaya Indonesia, 2Faculty of Health Science, Muhammadiyah University of Jember East Java Indonesia, 3Faculty of Nursing, University of Airlangga Surabaya Indonesia, 4Faculty of Public Health, University of Airlangga Surabaya Indonesia, 5General Hospital Dr. H Koesnadi Bondowoso East Java Indonesia, 6Regional Hospital Dr. Soebandi Jember East Java Indonesia, 7Regional General Hospital Dr. Abdoer Rahem Situbondo East Java Indonesia, 8General Hospital Dr. H. Koesnadi Bondowoso East Java Indonesia

Abstract

To date, breastfeeding baby in hospitals is still a serious issue. The present study is aimed to investigate nurse-mother interaction in making decision on whether to breastfeed baby with low birth weight in a hospital. This qualitative study administered the grounded theory approach. For data collection, focus group discussion was implemented. Informants were selected with purposive sampling technique from three hospitals located in East Java Province, Indonesia. The validity test was satisfied with triangulation on sources, method and setting. New findings obtained from the study were classified into four categories, such as interaction, decision making, support and obstacles. The four categories form a triangle-shaped model of interaction. The first interaction is between nurse and spouse/family. The second one is between spouse/family with the mother. The third interaction is between mother and nurse. Support and obstacles may happen in every interaction. Decision making of breastfeeding mediated by the triangular interaction indicates that care is centered on infant. Nurses can improve the decision making quality of breastfeeding by minimizing obstacles and optimizing support in every flow of interaction.

Keywords: Breastfeeding, decision making, interaction, infant-centered care.

Introduction

Breast milk is the best food for infants. Breastfeeding infants with low birth weight (LBW) is a top priority because these infants commonly have poorer condition compared to infants with normal birth weight. However, when LBW infants are cared in a hospital, an undeniable problem happens, that is breastfeeding. Previous studies mention obstacles when breastfeeding infants during their stay in hospital, such as: 1) maternal and neonatal complication; 2) lack of quality and quantity in breastfeeding education; 3) hospital infrastructural obstacles for breastfeeding; 4) lack of privacy for breastfeeding mothers; and 5) lack of surveillance of baby care policy implementation in hospitals.(1)(2)(3)

Breastfeeding in hospitals is a challenge. Breast milk as an integral nutrition for babies is within mothers who stay apart from them. Separating mothers from their babies require therapeutic interaction mechanism enabling babies to receive breast milk continuously. The mother-nurse interaction is supposed to be not superficial interaction, but more on experience in developing relationship as a team who care for the babies. Goal achievement theory by King (1992) indicates that the
interaction process is influenced by perceptions of nurse and patient, goals, needs and values.\(^{(4),(5),(6)}\)

The mother-nurse interaction should start from the very first contact of baby caring. The interaction is principally aimed at fulfilling baby’s need, that is to improve its bio-psycho-spiritual health.\(^{(7)}\) However, the interaction commonly experiences problems, such as: 1) limited time for nurses to get to know patients and their families; 2) existence of opportunistic communication; 3) parents misunderstanding about nursing\(^{(8),(9)}\). Such problems result in delayed decision making for breastfeeding. Even worse, there will be an imbalance between breast milk supply and need; thus, low breastfeeding. The present study is aimed at discovering an appropriate model for nurse and mother interaction in making a decision of whether breastfeeding low birth weight infants in hospitals.

**Materials and Method**

This qualitative study administered grounded theory approach. This approach was considered appropriate because the study intended to investigate and understand the behavior in mother and nurse interaction in decision making. Field data becomes the grounded data to explain the real problem and to develop the theory.

**Participant:** 25 informants were selected purposively as samples consisted of three heads of perinatology room, five team chiefs of baby care, two implemented nurses and 15 mothers. The criteria determined for mothers as participants was to have a baby with low birth weight being nursed in baby care room starting from at least day two of care. An informant of the present study must be between 20 and 46 years old. The birth weight of born babies had to be between 1000 grams and 2400 grams. The nurse informants in the study aged between 28 to 47 years old, all nurse informants were female.

**Data Collections:** The data collection was performed in three hospitals located in East Java Province, Indonesia in August 2019. The main data collection technique administered was focus group discussion. FGD was done in every regency in three stages. The first FGD was done with the parents group, the second with the nurse group and the final stage was done with nurses and parents altogether. Other data were obtained from multiple sources, such as observation, field notes and literature review.

**Data analysis:** The data analysis of the present study was done in four stages. The first stage was coding to identify keywords. The following stage was concept building. The researchers gathered codes with similar data thus possible for categorization. Later the researchers created interrelated categories and built the concept. The third stage was categorization, that is to categorize interrelated concepts with the theory. The final stage was theorizing, in which the subject was explained by strengthening the existing theory.\(^{(10)}\)

**Findings:** The first stage of analysis successfully identified 70 keywords. These keywords were categorized following the content similarity thus forming a concept. The second stage of analysis resulted in 19 concepts. The interrelated concepts were arranged in a category. The following stage found four categorization, such as: interaction, decision making, support and obstacle. The concept of relationship, communication and information exchange formed the interaction category. Furthermore, the concept of choices, negotiation, distributed discussion, decision and commitment were wrapped up in the decision making category. The concept of being emotional, informational, instrumental and transporter formed the support category. Finally, the concept of complication, parent’s difficulties, breast milk production, infrastructure, distance, finance and lack of support were grouped in the obstacle category. Following these four categories, in the stage four of analysis a triangular interaction model was integrated involving reciprocal relationship of nurse, spouse/family and mother. Direct interaction is in making decision for breastfeeding. It can be seen that the reciprocal relationship of every subject involved is influenced by the support and obstacle factors (Fig 1.)

![Figure 1. Interaction Triangle in Decision Making](image)

Keterangan:
- **Obstacle**
- **Support**

Figure 1 describes the stages in the triangular interaction of decision making between nurse and mother/spouse/family. The first stage of interaction occurs between nurse and spouse/grandparents/family...
on day 1–2 of care. The second stage occurs between spouse/grandparents/family and mother on day 3–4. The third interaction is between mother and nurse on day 5 or longer. Support and obstacles may happen in every interaction.

Interactions consist of three concepts (1st-3rd concept), they are relationship, communication and information exchange. The first concept, the relationship, is the continuity of interaction between two or more people aimed at facilitating the process of getting to know each other. A positive relationship occurs when two parties involved in the interaction benefit from each other due to the harmonious reciprocity. This concept was formed in the first hand due to the interdependence in the nurse-parents interaction.

The second concept is communication. Communication and Interaction are two of the most frequently collocated words despite their differences. On the one hand, communication refers to the acts of sharing information, while on the other hand interaction is an extended term to which communication includes. A poor communication from a nurse will weaken the interaction impact. Actually, a quality communication tends to lead to individual communication, where communication in particular focuses on the patient/family condition. Being a nurse requires a well-trained communication skill so that the intended message can be successfully delivered. The whole process of nurse-parents interaction requires communication, begins with assessment, planning, implementing and evaluating.

The final concept is information or message exchange. Information exchange is a stage in analysis of decision making and an integral element in shared decision making. The present study empirically proves that there are three lanes of information exchange. The first one is information exchange between nurse and spouse/family, followed by that between spouse/family and mother and ended with information exchange between mother and nurses. In every information shared by nurses, the context must fit to knowledge, situation and awareness about information relevance with the situation faced. The information shared from mother/father/family must be in accordance with reality. Dishonesty may lead to misperception and decrease intervention. The three aforementioned contributed to the formation of interaction category. Interaction, communication, roles and decision making are essences in nursing.

The second category is decision making, comprised of five concepts (4-8th concept) such as choices, negotiation, distributed discussion, decision and commitment. Decision making is defined as taking one action among other alternatives. The fourth concept, choice, means that there is more than one available alternative action. The three alternatives in breastfeeding LBW are if baby is stable and has a good sucking reflex, direct breastfeeding is possible. If baby has poor sucking reflex, indirect breastfeeding (through feeding tube) is suggested. Finally, for unstable baby, breast milk needs to be stored in a reservoir. These alternatives are important when considering mother and baby’s condition.

The following concept is negotiation, that is the process of bargaining by reasoning together in order to achieve a mutual agreement. The data which supports this concept is the need of breast milk for LBW babies need mother’s presence, while they are separated. When mother does not breastfeed, the need for breast milk will not be fulfilled. The separation of mother and baby and inadequate breast milk are two situations which require negotiation. It plays a fundamental role in nursing and in making a decision. In this study, negotiation flows through three paths. The first one is when spouse/family negotiates with the nurse asking for postponement for the mother’s presence. Secondly, the negotiation takes place from mother to her spouse/family asking for some time to rest and recover before breastfeeding. The final negotiation is between mother-spouse-family to the nurse on duty to decide on the most applicable action for the condition.

The sixth concept is distributed discussion, that is when discussion is indirect between nurse and mother, mediated through spouse/family. Whereas distributed discussion means dispensed discussion, resulting in three paths of discussion. The paths occur because the spouse needs to speak with his wife beyond the time and place of discussion with the nurse. Mother only discusses with the nurse once she receives the key information from his spouse/family. The decision making becomes effective when the need to discuss with different people is reached. The core of the discussion is the need of breast milk for LBW. Any obstacles and available actions for breastfeeding are the topics of discussion.

The seventh concept is to decide or to ensure an option among others. Every activity in the process of decision making should eventually result in the best
choice. What it means by best is when the chosen action is a result of a thorough consideration expecting that the decision is approved by all parties involved. This chosen action is discussed after parents acknowledge the benefits and drawbacks of every available alternative. Breastfeeding for LBW includes several points to ponder, such as mother’s health, breast milk production, baby stability and sucking reflex. Whereas an appropriate consideration improves decision quality, the decision is collectively made, that mother’s decision is an agreement made with her family.

The eighth concept is commitment, that is an agreement to do something. Mother’s commitment to her decision indicates a quality decision. The quality decision must improve satisfaction and reduce regret. The keyword for commitment is mother’s presence to breastfeed or to deliver the pumped milk. Such commitment costs earnestness of all parties to take their roles. It is evident that different people involved in breastfeeding have different roles. These roles apply when making a decision through the interaction triangle. Whereas commitment makes baby as the center for care in making a decision for breastfeeding (Fig. 2).

Figure 2 shows that baby is the center of care which relies upon commitment of every party involved. The case of breastfeeding LBW has uniquely involved at least four major roles. Nurse plays the role as the leader and care designer, baby as the care receiver, mother as breast milk producer and spouse/grandparents/family take their role as transporter. Every involving party’s commitment towards each role indicates the attitude of acceptance and approval of decision.

The third category is support. Support consists of four concepts (9-12th concept) such as emotional, informational, instrumental and transporter support. To be precise, family support occurs through the three interaction paths. The ninth concept emotional support is given along with family acceptance of mother and baby’s condition, family’s willingness to help fulfill the mother and baby’s needs and family’s presence around.

The tenth concept is informational support, in which spouse/family delivers information to the mother. They receive information first from the nurse during the first interaction. Internal negotiation between mother, spouse and family needs information and knowledge about breast milk and needs to be aware of their roles in breastfeeding. Should any disharmony occur, negotiation will fail.

Furthermore, the eleventh concept is instrumental support, it is about family’s willingness to support financially for expenses incurred from the mother and baby care in the hospital. It is also about family’s readiness to take shifts in looking after the mother and baby in the hospital. On the other hand, the twelfth concept is the transporter support. It is spouse/family’s readiness and willingness to take mother or milk reservoir to the hospital where the baby is cared for. The fourth category is obstacle. This category consists of seven concepts (13-19th concept), such as baby’s complication (13th concept), parent’s difficulties (14th concept), breast milk production (15th concept), infrastructure (16th concept), distance (17th concept), finance (18th concept) and lack of support (19th concept). The obstacle category is found to occur in the three interaction paths.

Conclusions

Based on the descriptions of the four categories mentioned in the study, it can be concluded it is important to implement the triangular interaction model in decision making of whether to breastfeed LBW infants. Interaction, communication and information exchange are strategic ways to help parents decide. What is fundamental in the decision making is collaborated information, distributed discussion, decision and satisfying commitment.

Abstract

We live in a world where every day vast amounts of data flows in through various mediums. Data mining could be considered because of the natural growth of information technology. The concept of data mining is widely used all over as an instrument to mine hidden information from the database of companies that can be used by the respective companies to deal with their complicated business affairs and improve their services accordingly. Despite that the information revealed by data mining applications, people have shown their increasing concern about the other side of the coin, specifically the privacy threats posed by data mining. An individual’s privacy may be hampered or violated due to unauthorized access to their sensitive personal data, unwanted discovery of once embarrassing information etc. In this research paper the author desire to highlight the probable privacy issues that an individual must face due to data mining.

Keywords: Data mining, Information Technology, Individual’s Privacy, Sensitive Personal Data, Unauthorized Access.

Introduction

Since ancient times, the search for useful and important information has been carried on manually. With an expeditious growth in the volume of data, it is not possible to mine useful information manually. So, the miners have come up with more efficient and effective technologies or data mining techniques to handle such a search of useful patterns or knowledge. Data mining can be contemplated as an outcome of natural evolution of information technology. Data mining could be web data mining, social data mining, image data mining, healthcare data mining, financial data mining, e-book data mining, SQL data mining, mining data for fraud detection, stock market data mining, text or multimedia data mining, data mining for consumer segmentation, capturing, analysis and interpretation of data, new stories extraction, tracking and analyzing competitor’s growth, meta-data extrication from various websites and all. Since data mining deals with processing of “sensitive personal information”, data privacy and data security concerns are at its heights. With the advent of digital era and development of various technologies the data security, data protection and privacy preservation concern has just increased to another level.

Privacy, Security and Social Impact of Data Mining: Dr. B. Thuraisingham explained the main essence of Data mining by applying his own point of view and opinion. He stated, “Most of the time, data mining is part of our lives and we are often unaware of its presence. Data mining is present in many aspects of our lives and can influence our well-being of which we are unaware of such as ubiquitous and invisible data.
Invisible data mining can be in the form of smart software, such as search engines, customer adaptive web services, ‘intelligent’ database system, email managers, ticket masters and so on, incorporate data mining into its functional components”. [1]

However, it is important to know that many data mining application don’t even touch personal data, such as applications involving natural resources, the predictions of floods and drought, meteorology, astronomy, geography, geology, biology and other scientific and engineering data. Furthermore, most studies in data mining focus on the development of calculable algorithms and do not involve personal data. [2]

Dr. G. Piatetsky rightly stated “The focus of data mining technology is on the discovery of general or statistically significant patterns, not on specific information regarding individuals. For the data mining application that do involve personal data, in many cases, simple method such as removing sensitive IDs from data may protect the privacy of most individuals. Nevertheless, privacy concerns exist wherever personally identifiable information is collected and stored in digital form and data mining programs can access such data, even during data preparation”. [3]

Dr. Mark Todd stated, “Improper and nonexistent disclosure can be the root cause of privacy issues. To handle such concerns, numerous data security-enhancing techniques have been developed. There has been a great deal of recent effort on developing privacy preserving data mining method. Many data security-enhancing techniques have been developed to protect data. Database can employ a multilevel security model to classify and restrict data according to various security level, with users permitted access to only their authorized level”, where he explained the whole concept of Big data and how it is related to modern data science. Encryption is another technique in which individual data items may be encoded. This may include blind signatures (which build up on public key encryption), biometric encryption (where the image of the person’s iris or fingerprint is used to encode his/her information) and anonymous database (which permits the consolidation of various database but limit access to personal information to only those who need to know; personal information is encrypted and stored in different location. [4]

Intrusion detection is another active area of research that helps protect the privacy of personal data.

Privacy Issues and Data Mining when Violates Privacy of an Individual

As the definition goes ‘Data Mining’ is the mining of personal data stored in database for identifying potential knowledge, formerly unidentified, implicit information. [5] In an information era, preserving privacy refers to concealing personal information and having control over the use of such sensitive personal information. Before understanding how data mining has given rise to privacy issues, let us look at this example and get a hang of it. Example- There is a user who is capable enough to apply data mining software which is easily available online. This user can pose different queries and infer sensitive hypotheses. An inference problem occurs when a user who is engaged in data mining using various data mining techniques tries to withdraw inferences from the processed data. There are many data mining tools available online. [6]

The inference problem can be solved by building an inference controller which can detect the motives of the miner and prevent or stop the inference problem from occurring. Also, we can have different levels of privacy. For instance- Name, age, gender is comparatively less private than mobile phone numbers, salaries which are more private. Similarly, names and medical records collectively could be more private. [7]

With the origin of World Wide Web, there is now ample of information available about individuals that can be obtained within seconds. Such information could be obtained by way of mining or just from information retrieval. This makes it necessary to enforce controls on data mining technologies as well as databases. Enforcing such a control is practically difficult task with respect to data mining. [8] This calls for developing new techniques to stop users from extracting information from the data whether available on server or web.

Stepping on the social aspect, there prevail cultures where privacy of individual is preached. Also, there exist certain cultures where it is difficult to ensure privacy. [9] That could be with respect to technological or political issues or the fact that people believe that privacy is not essential. Many technologies or technological solutions have been proposed for data security in general and confidentiality could be used for privacy. The big challenge is to prevent violation of privacy without prejudicing the benefits of data mining. [10]

Data mining is often used to detect terrorist
activities by mining data of individuals and finding unusual patterns and fraudulent behavior. Acting in faith of national security, data mining is used for counter-terrorism applications.\textsuperscript{[11]} When at one hand, all these applications can benefit humans and save their lives, at the other hand it possesses threat to the individual’s right to privacy. There arises the conflict between two is difficult. This scenario has led to the developing of such privacy preserving measures that would help prevent privacy violation and at the same time will allow us to have the fruits of data mining technologies.\textsuperscript{[12]}

Data mining techniques sometimes also discloses business related critical information which compromises free competition and therefore discloser of personal or confidential information should be prevented.\textsuperscript{[13]} Hence, it was important to address the issue of privacy preserving in data mining. Different sanitizing measures were proposed to conceal personal data and sensitive patterns.\textsuperscript{[14]}

Certain ways in which privacy concerns have been raised by data mining techniques are as follows:\textsuperscript{[15]}

The implicit pattern covering information about the data subjects that can be derived from result in the data mining process vs. the explicit nature of personal information extracted by way of traditional database retrieval techniques.

The probable use of only single database to extract information about data subjects vs. use of multiple databases to extract information regarding the data subjects. The use of “open ended” queries to find out information on associations about an individual or groups vs. using specific questions to derive data about relationships that are already known.

The non-predictive aspect of unknown information obtained about an individual from data mining vs. general predictive aspect of data derived from traditional database technique.

Information of public nature is mostly extracted about an individual through data mining process vs. the intimate nature of information retrieved using traditional techniques about individual.

We often talk about privacy getting compromised in the process of data mining. How can we define privacy? We have heard people saying that “keep the information about me from being available to others.”\textsuperscript{[16]} And the Webster’s Dictionary defines privacy as “freedom from unauthorized intrusion”. In data mining case, the use of personal data in a way has some negative effect on someone’s life which creates concern. So here we are trying to identify that line beyond which data mining will lead to violation of right to privacy or threat data security. So basically, if the data is not misused, for most of the people it does not amount to any kind of privacy violation. The problem arises once the data mining results or information is released and is open to the probability of being misused.\textsuperscript{[17]}

It becomes difficult to impose universally acceptable rules to differentiate between right and wrong and demarcate the line beyond which data mining would pose threat to privacy.\textsuperscript{[18]} When the database is handled by an authorized miner for a noble cause to achieve benefits legally, then it is very much within the limits of data protection and data privacy. But the moment data mining technologies are used by unauthorized person or user or local service providers, there arises a probability of individual’s right to privacy getting violated. Using this distinction and ensuring that a data mining project will not enable misuse of personal sensitive information and opens opportunities that “complete privacy” would present.\textsuperscript{[19]} The same concern arises while collecting data. While collecting data we might come across and learn about individual’s data items. An individual might not care about someone knowing some common information about them like- name, date of birth, gender etc., but getting to know all these information leads to identify theft.

**Individual Rights in Relation to Processing of their Personal Data:** Individuals do possess certain rights regarding their personal data or information they share with service providers.\textsuperscript{[20]} An individual need to be aware of those rights to protect their sensitive personal information from getting misused. Some of such rights to be kept in mind are:

**Access to data:** Rule 5, subsection 6 of the IT Rules directs that any person or body corporate on its behalf must allow providers of information or data subjects to examine the information they may have given. The above section provides:

“Body corporate or any person on its behalf permit the providers of information, as and when requested by them, to review the information they had provided and ensure that any personal information or sensitive
personal data or information found to be inaccurate or deficient shall be corrected or amended as feasible. Provided that a body corporate shall not be responsible for the authenticity of the personal information or sensitive personal data or information supplied by the provider of information to such body corporate or any other person acting on behalf of such body corporate.”[21]

**Correction and Deletion**

Rule 5, subsection 6 of the IT Rules[22] says that “the data subjects must be permitted to access to the data provided by them to check that any information found to be inexact or deficient shall be rectified or amended as feasible. Although the rules don’t directly talk about the deletion of data, they state in Rule 5, subsection 1, which corporate institution or person representing them must secure written consent from data subjects regarding the use of the sensitive information they provide”. The above subsection provides:

“Body corporate or any person on its behalf shall obtain consent in writing through letter or Fax or email from the provider of the sensitive personal data or information regarding purpose of usage before collection of such information.”

**Objection to processing:** Rule 5 of the IT Rules[23] says that the data subject or provider of information shall have the option to later withdraw consent which may have the choice to later withdraw the consent which may have been issued to the corporate institution previously; such withdrawal of consent should be stated in writing to the corporate body. On withdrawal of consent, the corporate body is forbidden from processing the personal information or data in question.

**Disclosure of data:** Data subjects have rights with respect to disclosure of the information they provide. The disclosure of sensitive personal information needs the provider’s prior permission unless either:

i. Disclosure has already been agreed to be in the contract between the data subject and the data controller or[24]

ii. Disclosure is required for compliance with a legal obligation.

There are exceptions to this rule, if an order under law has been made, or if a disclosure must be made to Government agencies mandated under the law to obtain information for the purpose of:

- Verification of identity.
- Prosecution or punishment of offences
- Detection, prevention and investigation of crime

Recipients of this sensitive personal information are barred from further disclosing said information.

**Suggestions and Discussions**

As the questions have arisen regarding the definition and limitations of privacy in data mining, let us give a bird eye view on the newly invented technology of Secure Multiparty Computation (SMC).[25] The basic idea behind SMC is that the parties those who are involved acquire nothing but the results.

The technology of SMC makes sure that the involved party learns or acquires nothing but only the results. SMC involves the involvement of the third party. There may be substantial communication between the involved parties, but SMC makes sure that the parties do not learn anything from the concerned communication.

From much possible approach one of the reliable approaches is Constraint-based data mining. “This part of research is concerned with improving the efficiency of the algorithms and the understandability of results through providing up-front constraints on what results would be of interest.”[26]

**Conclusion**

Our main task for now is to determine that “line” beyond which data mining would result in the violation of an individual’s right to privacy. When a database or data set is accessed from a system by an authorized person or an authorized miner with clear intention, it is pretty much within the limits of data security. But the moment, the information stored in the database or data sets are accessed by unauthorized persons for their personal use, there lies a probability of the information getting misused or misplaced. Nowadays data mining software are available online, so it is easier for those unauthorized dealers and miners to access the information and exploit them. This has increased the concern for data protection and privacy preservation among the individuals.

Looking at the concern for the privacy among the individuals various Privacy Preserving Data Mining technologies (PPDM) have been developed and introduced. Secure Multiparty Computation, Data Obscuring, anonymization, perturbation and
augmentation have also been implemented. But it should surely be appreciated how the competent authorities are taking necessary measure and ways to prevent any such data mining which is infringing individuals right to privacy and I must say that there is a long way to go and to develop the erring rod to maintain the check and balance in the abstract world by cyberspace.

**Ethical Clearance:** Not required as the researcher has just referred to some published works. The research is doctrinally undertaken, completely by the researcher himself.

**Source of Funding:** Self

**Conflict of Interest:** Nil

Abstract

Background: Patients on maintenance haemodialysis suffering from sleep problem, Exercise makes the patient tired and improves the circulation in the body which leads to induction of sleep. The present study aimed to evaluate the effectiveness of exercise regimen on quality of sleep of patients.

Materials and Method: A pre-experimental research design was used to assess quality of sleep among 30 patients with End Stage Renal Disease on Maintenance Haemodialysis. Patients were allocated to intervention group via purposive sampling technique. Intervention for intervention group included exercise for two weeks (5 days in a week). Interview based standardized questionnaire was used to assess the quality of sleep by using Pittsburgh Sleep Quality Index (PSQI) in association with clinical and lab values. Patients were followed on every day for two weeks by using phone call reliability and feedback form.

Result: Pre test sleep quality score was (9.766± 1.887) and post- intervention sleep quality score was (7.60± 2.175), there is a decrease in score of sleep; hence there is positive effect of exercise regimen on sleep. Lab values: calcium, platelets, chloride and albumin are having significant relation with sleep quality by using regression analysis.

Conclusion: Non pharmacological method are more effective to improve the quality of sleep among patient on maintenance haemodialysis having sleep problem.

Keywords: Haemodialysis, Sleep quality, Pittsburgh sleep Quality (PSQI), Ca, platelet, Chloride, Albumin.

Introduction

Sleep is a common problem among patients with end stage renal disease on maintenance hemodialysis due to excessive accumulation of fluids in the body. Most of the reported complaints are insomnia, restless leg syndrome (RLS), sleep-disordered breathing and excessive daytime sleepiness (EDS). It has been reported that 80% of ESRD patients receiving dialysis reports sleep complaints with daytime sleepiness. In healthy individual sleep is lead by decrease in sympathetic activity and increase in vagal tone that leads to reduction of blood pressure at night. According to Hildert Most of the Patients with ESRD are having sympathetic-vagal imbalance due to baro receptor reflex malfunctioning in which there is a hyperactivity of the sympathetic nervous system and decreased vagal tone.

As for the sleep - wake circadian rhythm melatonin hormone is responsible. It is secreted in less amount
during the daytime but increases its amount during the night, which helps in falling asleep. But in ESRD patients the amount of melatonin secreted by pineal gland is less which affects the sleep cycle.\(^5\)

Also there is overnight rostral shifting of fluid from legs toward neck and result in restriction and collapse of upper airway. Pathogenesis of Obstructive sleep apnea is unknown but Rosilene M, hypothesized that changes in neck circumference and severity of obstructive sleep apnea is related to overnight shifting of leg fluid volume in ESRD patients.\(^6\) Physical activity improves sleep quality and increase sleep duration. Exercises increase the circulation of blood in the body. Exercise makes the patient tired and reduces the stress, which help in induction of sleep. Hence simple to moderate exercise results in maintenance of good sleep quality among hemodialysis patients. The workout about 30 minutes in a day 5 times a week, if cant fit it even just having 10 minutes a day of walking, swimming or riding can help in getting night sleep (“National sleep foundation’’).\(^7\)

**Materials and Method**

A pre- experimental research design was conducted in dialysis unit of Fortis Hospital, Mohali. The permission taken from the Research and ethical committee of the Hospital. Written informed consent form were filled from the patients suffering from sleep problem.

Inclusion criteria of the study was Patients with End Stage Renal Disease, Above 18 years of age, Consenting for participation in study, who were able to walk, Patient able to carry out intervention and Patients who were willing to participate in the study. Exclusion criteria of the study was Patients with-Any other co-morbidity like liver disease, infected patients/HIV, Patients admitted in intensive care units, Any recent major post-operative patients, History of any analgesics medication (opioid and non opioid)and Patients going for evening walk as normal routine activity.

After fulfilling the inclusion and exclusion criteria, Sociodemographic data collected. Patients Lab Values: RFT’s, LFT’s and Urine test sample taken. Patient comorbidities data also collected.

Exercise intervention was provided to the patients. Patients were asked to do evening walk of (25-30 minutes) for consecutive two weeks (five days in a week). Phone call based reliability of exercise was done on daily basis from the day of starting till the end of intervention i.e., evening walk. Written feedback was taken in mid of the intervention period by using feedback form for assessing any difficulties, confusions and their experience during the walk. Subjects were evaluated on eleventh day of intervention period to obtain posttest information regarding clinical variables and sleep quality by using Pittsburgh Sleep Quality Index.\(^8\)

**Findings:**

<table>
<thead>
<tr>
<th>Table 1: Comparison of level of sleep quality among haemodialysis patients with End stage Renal Disease. N=30</th>

Table No 2 depicts the comparison of mean pretest and mean posttest scores of sleep quality among hemodialysis patients. Paired T-test used for the comparison which shows mean, mean difference, standard deviation t- value and p value. It shows significant result as p value is <0.005. P- Value is 0.001, it shows that our null hypothesis was rejected and research hypothesis was accepted i.e., “There is significant effect of exercise on sleep quality in patients with End Stage Renal Disease on Maintenance Haemodialysis”.

Table 4 depicts the association of clinical variables with the sleep quality. It shows the B coefficients, t value and p value.

A stepwise regression was performed, four variables were included in the final model such as calcium (B = 0.836, p value = 0.001), followed by platelets(B = 0.011, p value = 0.0002), chloride(B = -0.157, p value = 0.0s19) and albumin(B = -0.417, p value = 0.042).

The excluded variables were hemoglobin, TLC, urea, creatinine, phosphorus, sodium, potassium, vit D as they were not found significant.

Findings: Pre- test score was (9.766± 1.887)and the post test score of sleep quality was (7.60± 2.175).

P<0.001“There is significant effect of exercise on sleep quality in patients with End Stage Renal Disease on Maintenance Hemodialysis”.
There is decrease in percentage of fairly bad sleep lie from 90% to 53.3% and increase in percentage of fairly good sleep lie from 6.7% to 43.3%.

All the components were significant because there p value was <0.005 and daytime functions was not significant as its p value was >0.05.

As sleep medication was our exclusion criteria, no patient were chosen who are on sleep medication.

A stepwise regression test states that On the basis of standardized B coefficients the order of influence on sleep quality was calcium (B = 0.496), followed by platelets (B = 0.457), chloride (B = -0.335) and albumin (B = -0.289).

The excluded variables were hemoglobin, TLC, urea, creatinine, phosphorus, sodium, potassium, vitamin D as they were not found significant.

**Conclusion**

The total number of sample was 3090% of patients were having fairly bad sleep quality before the intervention. The pretest score is (9.7667 +1.887) and the post test score of the study is (7.600±2.175). The p value of study is .001; this showed that there is positive effect of the exercise regimen on end stage renal disease on maintenance haemodialysis. According to standardized B coefficients these four variables influencing the sleep quality of the patients and the B coefficient is calcium (B = 0.496), followed by platelets (B = 0.457), chloride (B = -0.335) and albumin (B = -0.289).

This states that only calcium, platelets, chloride and albumin are influencing the QOS of the patients. This means that except these four variables the result of good sleep quality is occurred due to the exercise

The researcher concluded from the study that there is a positive effect of an exercise on quality of sleep of patients which were on maintenance hemodialysis.

The Effects of Service Payment Retardation from National Health Insurance Claim to the Employee’s Work Motivation According to Theory of Frederick Hezberg in the Hospital

Nita Indah Lestari¹, Sri Hernawati², Sebastiana Viphindrartin³

¹Graduate Student, Magister Program of Public Health Education, Jember University, East Java (Indonesia), ²Medical Doctor, Faculty of Dentistry, Jember University, East Java (Indonesia), ³Economics Lecturer, Faculty of Economics and Business, Jember University, East Java (Indonesia)

Abstract

Introduction: In era of National Health Insurance, the number of insurance participants was in increase and recorded approximately about 203,28 million (77%) from the total population of Indonesia, this condition affected to the invoice amount which must be paid by Social Insurance Administration Organization (BPJS) to the related hospital which partnered with this organization. The implementation of this deal delivered to good effects from either the hospital or related organization¹¹. In Jember, it was indicated retardation or delay of service payment in certain hospitals. The retardation of service payment was very influential to the work motivation of employee which affected to the quality of service, the employee motivation was very significant to build quality performance for the employee. The accurate illustration which depicted this relation was that the motivation could raise high work satisfaction on employee, this condition was realized if the employee’s expectation and need could be realized in both material and non-material, if those were fulfilled, then their work motivation would be built. The objective of this research was to analyze the effects of service payment retardation from National Health Insurance claim to the motivation of employee based on Frederick Hezberg’s theory in RSD Balung.

Method: This research was included into quantitative research which exerted cross sectional research method. The total population of this research were all employees in RSD Balung Jember District, specifically in about 157 respondents. The method of data sampling was stratified random sampling according to the level within this research population. The total sample of this research was 60 respondents¹⁵. Further, the data collection was employed through questionnaire and was then analyzed through ordinal regression. Based on the research finding, it showed effects between service payment retardation from National Health Insurance claim to the employee’s motivation accordingly to theory of Frederic Hezberg.

Keywords: Service Payment Retardation, Motivation, Theory of Frederick Hezberg.

Introduction

Research Background: The government attempts to implement Universal Health Coverage gradually by issuing program of National Health Insurance (JKN), which is managed by Social Insurance Administration Organization (BPJS). In the era of National Health Insurance, the participants of this program keep increasing since 2018, it was recorded in about 203,28 million (77%) from the total population in Indonesia¹⁴. The increase of JKN participant number in many hospitals impacts to the huge amount of invoice which must be paid by Social Insurance administration Organization (BPJS). The retardation of service payment in some hospitals is also occurred in Jember. This retardation of
health service payment is very influential to the work motivation of employee which then impacts to the quality of health service, the employee’s motivation is regarded as very significant to realize quality performance for the employee\(^3\). The accurate image which can depict this relation is that the motivation can create high work motivation, this condition can be realized if the employee’s expectation and need are fulfilled well in both material and non-material, then, it will raise to their work motivation\(^2\).

The motivation is a whole process of encouragement or stimulation which given to the employee to have willingness in work sincerely without any forms of compulsion, moreover, the organization will be able to perform all programs if the employee within this organization are successful to do their tasks well according to their field and responsibility\(^1\(3\).

The theory of work satisfaction explains that the aspect which motivates work motivation of employee in order to fulfill their need in both material and non-material satisfaction. This aspect is considered as reward given to the employee\(^4\).

The purpose of motivation is to develop work satisfaction on employee\(^1\). The factor of motivator can raise the work satisfaction. Moreover, the theory of work motivation and satisfaction have been demonstrated by many experts. The theory of motivation from Hezberg has asserted two factors which can influence work motivation on employee in order to create their work satisfaction, as they are factor of motivator and factor of hygiene. The factor of motivator is consisted of achievement, recognition, the work itself, responsibility, advancement, the possibility of growth. Next, the factor of hygiene is consisted of work situation, wage or compensation, relation with co-worker and work safety. The implementation of motivator and hygiene factor in an organization can boost the improvement of employee’s work satisfaction, thus, it is summed that the individual will feel satisfied and motivated if they have accepted appreciation (salary, incentive and allowance)\(^10\).

In Jember, the service payment in several hospitals from JKN claim has been in retardation or delay, including to a hospital in Balung since 2018-2019. This situation is affected by a number of factors as internal and external factor. The internal factor is the factors which can occur in the hospital, for instance administration process of claim submission as well as lack of claim document files. The external factor is the factor might be raised from related parties of BPJS which go through certain budget deficit.

The research finding by NurFadhila & Syahrir (2017) has stated that the level of employee’s satisfaction regarding to the service becomes an indicator to indicate how far the success of service which has been offered by Social Insurance Administration Organization (BPJS). The service is related to the work satisfaction. Moreover, the work satisfaction cannot be separated from work motivation which is frequently the expectation of employee\(^3\).

Based on those backgrounds, the researchers are interested to identify the effects of service payment retardation from National Health Insurance (JKN) claim to the employee’s motivation based on theory of Frederick Hezberg.

**Method**

This research was included into a quantitative research which employed cross sectional research design. This research was conducted in RSD BalungJember. The research and data analysis was started in December 2019 – January 2019. The population in this research were all employees of RSD BalungJember District in approximately 157 respondents. The method of data sampling was slovin formula which was then presented per profession of health officer or non-health officer through lemeshow formula, it was resulted to 60 respondents. The variable of research was consisted of independent variable as retardation of service payment from JKN claim, while the dependent variable was employee’s motivation according the theory proposed by Frederick Hezberg. The instrument of data collection in this research was questionnaire. The result of data collection was then analyzed by exerting ordinal regression method. Further, this research has been tested ethically in ethics commission of health research of Faculty of Dentistry, University of Jember in regulation number 583/UN25.8/KEPK/DL/2019.

**Findings:** The research data was analyzed through ordinal regression and presented in two sections. The first section was general data, while the second was specific data of research.

Result of Ordinal Regression Test: p=0,000

The table has explained the result of data analysis which employed ordinal regression method in order to analyze the effects of service payment retardation from National Health Insurance (JKN) claim to the employee’s work motivation. Moreover, the result of data analysis showed that p value (0,000) a (0,05%) which was referred the effects of service payment retardation from National Health Insurance (JKN) claim to the employee’s work motivation.

Discussion

The research finding referred the effects between retardation of health service payment from National Health Insurance (JKN) claim and employee’s work motivation in RS Balung, which particularly resulted to the p value 0,000 (< 0,05). The appreciation in form of salary was the most complex task for the hospital in work environment, meanwhile it was the significant aspect for the employee, since the amount of salary and its punctuality in salary or wage payment would reflect the measurement of their performance among employees, families and society, while it was also significant for the behalf of hospital itself, because it would reflect the hospital attempt to maintain the human resource in order to build high loyalty and commitment in the hospital. Moreover, the motivation was a form
of support which functioned to stir the employee to be able to develop their performance, so they could realize and pursue the purpose of hospital\(^8\). The motivation was very important for the employee, because it was an aspect which affected, distributed and supported human behavior to be able to work with enthusiasm in order to achieve optimal result\(^{12}\). The accurate image which could illustrate this relation was that the motivation was able to raise high work satisfaction on the employee, this situation could be realized if the employee’s expectation and need was fulfilled in both material and non-material, then it would build work motivation on them\(^7\).

The purpose from this motivation was to improve work motivation on the employee. The factor of motivator could build work satisfaction. Further, the theory of motivation and satisfaction has been asserted by many experts. Those theories would keep developing, especially in sector of psychology, human resource management and organizational behavior. The implementation of work was very affected by an important factor, hygiene factor. The factor of hygiene was aimed to maintain the level of work motivation on employee, if this factor was given properly. But, if this factor was given improperly, it would impact to the decrease of enthusiasm and work performance of employee\(^6\).

The motivation which given to the employee was not that easy, since the organization must firstly consider several factors which could influence the employee’s work motivation. The theory of motivation from Hezberg has asserted two factors which could influence the employee’s work motivation in order to create their work satisfaction, as factor of motivator and factor of hygiene. The factor of motivator was consisted of achievement, recognition, the work itself, responsibility, advancement and the possibility of growth. While, the factor of hygiene was comprised of work condition, salary or compensation, relation with co-workers and work safety. Next, the implementation of both factors of motivator and hygiene in an organization could encourage the improvement of employee’s work satisfaction, therefore, it was concluded that the individual would feel satisfied and motivated if their received appropriate form of appreciation (salary, incentive and allowance)\(^5\).

The practice of motivator factor in an organization was able to encourage the improvement of employee’s work satisfaction, then, it was summed that the individual would feel satisfied and motivated if they received appreciation form the organization (salary, incentive and allowance). Reversely, the factor of hygiene would cause individual unmotivated in work, since the purpose of motivation was to improve the work satisfaction on employee\(^9\).

**Conclusions**

Based on the research findings, it was concluded that this research studied about the effects of service payment retardation from National Health Insurance (JKN) claim to the employee’s work motivation in the hospital. According to the data analysis in this research, it was found that the retardation of service payment could affect to the work motivation of employee in the hospital, moreover, the purpose of this motivation delivery was to improve the employee’s work satisfaction.

This research also explored the causal factors of employee’s work motivation, especially in the work area of hospital. Based on this research, the researchers suggested the next researchers to study this similar research focus in deeper, particularly on the factors which cause unmotivated individual either in direct or indirect.

Hyperpigmentation of Skin (Melasma) with Solitary Oral Pyogenic Granuloma Lesion: A Case Report

Nitin Tomar¹, Apekshaghai², Mayur Kaushik³, Mehwish Saleem⁴, Mrinalini Agarwal⁴

¹Professor, Department of Periodontology, ²Post Graduate Student, Department of Periodontology, ³Head of Department, Department of Periodontology, ⁴Senior Lecturer, Department of Periodontology, Subharti Dental College, Swami Vivekanand Subharti University

Abstract

The pyogenic granuloma is a relatively is an exaggerated tissue response to localised irritation or trauma. Histologically, pyogenic granuloma does not present as granuloma and is devoid of pus. It is filled with vascular channels filled with inflammatory fluid, connective tissue with immature fibroblasts and inflammatory cells scattered. It occurs most commonly in the gingiva and also lips, tongue and buccal mucosa are the other common sites. Melasma is a common skin condition hyperpigmentation of sun-exposed areas, especially on the face which is usually light to dark brown, symmetrical and irregular in appearance. Although melasma can affect all races and both sexes, it is more commonly seen in women of child-bearing age and in dark-skinned individuals living in areas with intense ultraviolet (UV) radiation. Hyper pigmentation on exposed areas such as the face can be a source of cosmetic concern for patients, that can negatively impact quality of life (QOL). The present case reports a localized inflammatory hyperplasia of the maxillary gingival of a 38 year male patient who was suffering from melasma. Melasma is a disorder of hyperpigmentation with psychological impacts affecting majorly the face. Excisional biopsy of the lesion revealed findings suggestive of Pyogenic Granuloma. Excision of pyogenic granuloma may also predispose to recession of interdental soft tissue.

Keywords: Gingival, melasma, inflammatory hyperplasia, pyogenic granuloma.

Introduction

Pyogenic granuloma (PG) is an inflammatory hyperplasia describing a large range of nodular growths of the oral mucosa.¹ PG is a common nonneoplastic growth of the oral cavity and the first case was described by Hullihen.² Even though various terms have been proposed earlier, Hartzell gave the current term of PG or granuloma pyogenicum.³ Melasma (from the Greek word, ‘melas’ meaning black) is a common, acquired, circumscribed hypermelanosis of sun-exposed skin. It presents as hyperpigmented macules that are hyperpigmented, symmetrical with serrations and geographical borders. The most common locations are the cheeks, upper lips, the chin and the forehead, but other sun-exposed areas may also occasionally be involved.⁴

Although melasma may affect any race, it is much more common in skin types that are darker than in lighter skin types and it may be more common amongst asian and hispanic races who live in areas of the world with intense solar ultraviolet exposure. Melasma is the most common pigmentary disorder among Indians. It is much more common in women during their reproductive years but about 10% of the cases do occur in men.⁵

Although PG is a common disease in the skin, it is rare in the gastrointestinal tract, except for the oral cavity and it is mostly found in keratinized mucosa. There are various factors such as chronic low-grade irritation, trauma, hormonal factors and certain kinds of drugs which are proved to be the causative factors in the development of PG. Oral PGs occur in the gingival in 75% of cases and precipitating factors include poor oral hygiene, local irritants and foreign material in the gingival. Although many lesions occurring in the oral cavity have got similar appearance as PG, a detailed history, clinical examination and a proper treatment plan
In this article, we will present a case report of a large pyogenic granuloma of the gingiva in a 38-year-old male patient and also will review the literature in detail.

**Case Report:** A 38-year-old male patient reported to the outpatient department of Subharti Dental College with the chief complaint of a growth in the gums in the upper left back tooth region since 2 months. The growth initially started as a small one, which progressively increased to the present size. Patient was asymptomatic 1-month back, but patient suddenly started to feel pain on eating food. The patient also stopped brushing in the area due to excessive bleeding from that region.

Soft tissue examination revealed a well-defined gingival growth in the dentulous 24-26 tooth region as a rounded vascular lesion (Figure 1). The growth was nontender and firm on palpation and on probing; there was severe bleeding from the site. The lesion was excised with electrocautery and was sent for biopsy (Figure 2). The biopsy report suggested the growth to be 0.5x0.5x0.3 cm in size, soft to firm to consistency (Figure 3 & 4). A provisional diagnosis of PG of the gingiva was given. Differential diagnosis of irritational fibroma and peripheral giant cell granuloma were given.

The patient was suffering from melasma (Figure 5) and was on medication for the same for past one month. His medication included usage of solset sunscreen gel to be applied twice a day at 8 am and 12 noon respectively, Brilanie serum and Capsule Lyos once a day for 30 days. There were relevant melasma spots on forehead and hands of the patient. Intraoral examination revealed a good oral hygiene.
**Figure 5: Melasma lesion on forehead with a V shaped appearance.**

**Discussion**

PG is a kind of inflammatory hyperplasia and also termed as granuloma pyogenicum. PG is a misnomer because the lesion does not contain pus and is not a granuloma also. PG is caused by a known stimulant such as calculus or foreign material in the gingival crevice resulting in a proliferation of connective tissue. In addition, one-third of the lesions occur after trauma.

Ainamo et al\(^7\) suggested that routine tooth brushing habit caused repeated trauma to gingival, resulting in these lesions. Furthermore, release of variety of endogenous substances and angiogenic factors, trauma to deciduous teeth, aberrant tooth development, occlusal interferences, drugs such as cyclosporin and selection of wrong healing cap for implants are some of the precipitating factors for PG whereas Neville\(^8\) stated that oral PGs occur in all age groups, children to older adults, but frequently seen in females in the second decade due to increased levels of hormones. It appears as an elevated sessile or pedunculated growth covered with red hemorrhagic and erythematous papules and show ulcerations and is covered by a fibrinous membrane. Clinically, the lesion can be slow-growing, asymptomatic and painless, but it may also grow rapidly sometimes.

Regezi JA et al\(^8\) stated that the treatment includes surgical excision of the lesion with the removal of irritants recommended for small painless lesions. Excision of gingival lesions up to periosteum with thorough scaling and root planning of adjacent teeth to remove all visible sources of irritation whereas Jafarzadeh H found other treatment modalities include Nd: Yttrium-aluminum-garnet lasers, carbon dioxide lasers, flash lamp, pulse dye laser, cryosurgery, sodium tetradecyl sulphate sclerotherapy and use of intralesional steroids have been proposed by clinicians.

He also stated that incomplete excisions, failure of removal of etiological factors contribute to the recurrence of these lesions. Taira JW\(^9\) found that a recurrence rate of 16% and also a case of multiple deep satellite lesions surrounding the original excised lesion in a case of Warner Wilson James syndrome have been reported. Velmann A\(^10\) said that there is a need for regular follow-up is also emphasized because of higher recurrence rate, especially in the gingiva.

Ortonne JP et al\(^11\) stated that sun exposure is known to be an important etiological factor in causing melasma, irrespective of sex. UV radiations increases proliferation and melanocyte activity, causing epidermal pigmentation, that occurs more intensely in melasmic areas with melasma than in unaffected skin.

Guinot C\(^12\) further substantiated by the findings that melasma usually improves during the winter and worsens during the summer months (or during other periods of intense sun exposure). Sarkar R et al\(^13\) found that prevalence is high in tropical regions and high elevation areas. Mahmoud BH\(^14\) recently reported infrared radiation and visible light have been found to cause melasma, although not as severely as UV radiation.

Sarkar R et al\(^13\) stated that according to the predominant localization of the lesions on the face, three patterns of facial melasma are recognized clinically: malar, centrofacial and mandibular. Centrofacial pattern type exhibits the forehead, upper lip, cheeks, nose and chin being affected, whereas the malar pattern distributes melasma on the cheeks and nose and the mandibular pattern covers the mandibular ramus. In this case report the patient presented with the centrofacial distribution of melasma.

According to Vázquez Me et al\(^15\) among men, the malar pattern is most common, representing 44.1 to 61 percent of male patients. The centrofacial variant is the second most common variant amongst men.

O’Brien TJ et al\(^16\) found that clinically, melasma is most commonly seen on the face, but melasma on other sun-exposed areas such as the arms, neck, sternal regions and back, have been seen in women. Extrafacial melasma affecting the upper body occurs mainly among elderly, menopausal women and might be associated with hormone replacement therapy.
Conclusion

This article seeks to report a PG in the maxillary gingiva with a skin disease (Melasma). Even though PG is a relatively common presentation, it is rare to find coinciding occurrence of pyogenic granuloma with melasma. Melasma has traditionally been considered to be a pigmentation disorder of the female sex, but the occurrence in men is not uncommon. Melasma has a multifactorial origin that is exacerbated by environmental factors such as sunlight, especially in those genetically predisposed to the condition. The etiopathogenesis of melasma in men is similar to that of women, except for hormonal factors, which are more prevalent in women.

Abstract: With the progress of human civilization there has been a marked development in every aspect of mankind which on the other hand has also resulted in increased number of deaths following unnatural causes. Medico legal autopsies thereby portray not only the causes of death but also reflect the socio economic and demographic profile of that particular region. The present study was conducted at Tezpur Medical College & Hospital, Tezpur, Assam to find out the various patterns of Medico legal autopsies during the period 1st January 2019 to 31st December 2019.

Keywords: Medico legal autopsies, deaths, unnatural, patterns.

Introduction

Autopsy/necropsy denotes examination of the dead body with a view to searching primarily for the cause of death. In 1302, a court in Bologna ordered the examination of one Azzolino, who had died under suspicious circumstances of alleged poisoning. [1] This procedure was carried out by two physicians and three surgeons, including Bartolomeo da Varignana. In the medico legal autopsy, the body belongs to the State for the protection of public interest until such time as a complete and thorough investigation into the circumstances attending the death has been completed. [2] Any or all portions of the body may be taken and kept for detailed examination as well as preserved for later trial purposes. [3] The increased numbers of unnatural deaths from road traffic incidents suggest an increase in the number of rash drivers without driving licenses, drinking and driving, lack of traffic rule knowledge, increased high speed vehicles and road conditions. Whereas deaths by suicide and homicide suggest that the mindset of the society is changing with increased intolerance, drug addiction, poverty and behavioral changes. [4,5] The present study is a retrospective study of the medico legal autopsies carried out at Tezpur Medical College & Hospital, Tezpur, Assam during the period 1st January 2019 to 31st December 2019 where a thread bare analysis was done as which age group, sex predominance, seasonal variation, socio economic condition, education, cause of death and nature of death the medico legal autopsies belong.

Material and Method

The study has been carried out in the Department of Forensic Medicine, TMCH, Tezpur from 1st January 2019 to 31st December 2019 by examination of the inquest report and dead body challan, personal interview of accompanying police, attendants of deceased, in case of hospitalized patients from hospital records and findings recorded in autopsy report of the various medico legal autopsies during that period. A total of 278 autopsies were carried out during 1st January 2019 to 31st December 2019.
Observation and Results

Incidence of male: female ratio. Out of the 278 cases 200 (71.94%) cases were of male and 78 (28.06%) were of female. Hence the male: female ratio was 2.6:1 which highlights a male preponderance.

Table No. 1: Age distribution of the cases.

<table>
<thead>
<tr>
<th>Age group</th>

<tr>
<td>Pending investigation</td>
<td>05</td>
<td>1.80</td>
</tr>
</tbody>
</table>

From table 5 it is observed that 136 deaths were accidental deaths followed by 103 deaths of suicidal origin.
Discussion

In our study out of the 278 autopsies 200 (71.94%) were of the male sex whereas 78 (28.06%) were of the female sex which is similar to the study carried out by Kishwar Naheed et al.\[6\]. The male preponderance of unnatural deaths may be attributed to the fact that males outnumber females in the general population in our state and also males lead a more stressful life than females carrying the responsibilities of the family and social lives and thereby make themselves more vulnerable.

From table 1 it is evident that most number of autopsies was done in the age group of 21 to 40 years followed by 41 to 60 years. The higher incidence of unnatural deaths in the young adult stage may be due to the fact that this is the period when they are by nature, trend to be more emotional, irrational and more aggressive and intolerant, thus making themselves more vulnerable to quarrels, commotion and instabilities of life.\[7,8\] Again, it is the time when man starts serious thinking to build oneself, one’s own family and society. So, when one does not get sufficient co-operation from the significant ones or if one faces repeated hurdles towards the goals, becomes frustrated which may result in the emotional outburst leading to quarrels, commission suicide, murder and accidental deaths.

From table 2 it is found that most number of autopsies was conducted during the month of January and March. The higher number of cases during the winter may be explained as most deaths were of accidental in origin due to low visibility during night time as a result of fog with indulgence in alcohol during driving.

From table 3 it is found that most number of autopsies was conducted upon the victims who have read up to class X and illiterate. The higher rate of people in this category may be attributed to the fact that most of them were leading a life style which requires much travelling to attend their work places which in turn makes them more vulnerable to accidents. More over lacking knowledge about road safety rules and indulgence in intoxicating substances are more common in this category which may be an important factor.

From table 4 it is observed that 79 deaths were due to head injury followed by 46 deaths due to poisoning and 45 deaths due to hanging. As head is most exposed vital region of the body it is more susceptible for injury and thereby death. Again as a result of advancement of the society and materialistic approach towards human life frustrations are likely to be present amongst the masses which may compel them to commit suicide.

From table 5 it is observed that 136 deaths were accidental deaths followed by 103 deaths of suicidal origin.\[7\] With the rapid process of human development machineries have become a part and parcel of our daily lives which may be either in the field of transport or industry thereby we are more susceptible to accidental deaths. Moreover due to increased level of stress and expectations in present day mankind suicidal deaths are also on an increasing trend.

Conclusion

The present study is an effort to evaluate the patterns of various medico legal autopsies from the view of Forensic Medicine personnel as to the cause, mode and nature of deaths and the socio demo graphic profile of the victims which in turn will be helpful in expediting methodologies for the policy makers and the society at large in prevention of unnatural deaths.

Abstract

Periodontal disease is a chronic inflammatory disease caused by colonization of bacteria that affects soft tissues and hard tissues that support the teeth. Inflammation and rejuvenation of alveolar bone are signs of periodontal disease. Fibroblasts also play a role in producing and maintaining extracellular matrix, cell proliferation and cell differentiation in response to prolonged tissue injury and chronic inflammation. The components of water hyacinth are very beneficial for health such as phenols, alkaloids, flavonoids, tannins. This study aimed to determine the concentration of EcengGondok leaf extract which can maintain the viability of human gingival fibroblast cells for 24 hours. The method human gingival primary cell culture was harvested, placed on a 96-well microplate. Each well on the microplate was given water hyacinth leaf extract with a concentration of 1 mg/ml, 0.5 mg/ml, 0.25 mg/ml, 0.125 mg/ml, 0.0625 mg/ml, 0.0312 mg/ml, 0.0156 mg/ml for 24 hours. MTT assay was carried out by adding MTT solution after 24 hours of incubation. Formazan optical density values are read by ELISA reader with a wavelength of 590 nm, viability is obtained by calculating the viability formula. Results are viability of human gingival fibroblast cells was good starting in the treatment group 0.125 mg/ml, 0.0625 mg/ml, 0.0312 mg/ml and 0.0156 mg/ml. Conclusion the highest viability of human gingival fibroblast cells in the treatment group of 0.0156 mg/ml was 75.98%.

Keywords: Water Hyacinth leaf extract, human gingival fibroblast cells, viability, MTT assay.

Introduction

Periodontal disease is a chronic inflammatory disease caused by colonization of bacteria that affects soft tissues and hard tissues that support the teeth. According to the results of the 2013 Basic Health Research (RISKESDAS), 25.9% of the population in Indonesia had problems with dental and oral health including periodontal disease, this number increased when compared to the results of Basic Health Research in 2007 which was 23.2%.\(^1\)

In the case of periodontitis bone reasorbition will be seen in the roastenology examination. One of the basic therapies that can be given in cases of periodontal disease is scaling and root planing, surgical intervention therapy and also given materials that can accelerate the regenerative process of cells that have been damaged.\(^2\)

Fibroblasts are the most common cells found in connective tissue throughout the body including the oral cavity and are the main source of extracellular matrix fibroblasts also play a role in producing and maintaining extracellular matrix. Fibroblasts play an important role in the wound healing process which is a response to injury and tissue.\(^3\)

In several studies, phytokomia of water hyacinth leaf

extract has proven that there are components in water hyacinth which are very beneficial for health such as phenols, alkaloids, flavonoids, tannins and essential oils (squalene). These components can act as antimicrobial, antioxidant, anticancer, antitumor and for the wound healing process.

The use of plant extracts as an alternative in the health sector should have very minimal side effects, are not toxic, do not cause allergies, are not cynogenic and do not cause complications in the body. Therefore, the use of plant extracts must be tested first, one of which is by viability testing in accordance with the terms and material in the field of dentistry.

The viability test is a cell-based test that is often used for screening compounds to determine whether the test compound has an effect on cell proliferation or shows a direct cytotoxic effect that ultimately causes cell death.

Various tetrazolium compounds have been used to detect living cells. The commonly used compound is MTT (3-(4,5-dimethylthiazol-2-yl)-2,5 diphenyltetrazolium bromide). In this study human gingival fibroblast cells were used because fibroblast cells are the most important cells in human periodontal tissue. This study aimed to determine the concentration of EcengGondok leaf extract which can maintain the viability of human gingival fibroblast cells for 24 hours.

Material and Method

This type of research is a laboratory experiment with the design of The Post-Test Only control group design. This research was conducted in the Stem Cell Institution of Tropical Disease (ITD) and Laboratory of the Faculty of Pharmacy, Airlangga University.

The tools and materials used are microscopy micro light, multichannel pipette 25 µl, shacker with magnetic stirrer, ELISA reader, scales, test tubes and shelves, rotary evaporator, grinder, filter paper, glass gourd, auctoclave, measuring cup, incubator, centrifuge, Buchner funnel, laminar flow, BIOH-T Proline micropipette 20-200 µl, bottle Roux, conical tube ep. TIPS 200µl, 96-well Falcon 3072 plate, water hyacinth leaf extract (Eichornia Crassipes), human gingival cell lines, culture media containing Alfa Modified Eagles Medium (αMEM), dimethyl sulfoxide (DMSO), ready-to-use MTT liquid, phosphate buffer saline (PBS), 10% SDS in 0.1 NHCL, 70% ethanol, sterile distilled water, trypsin versene.

Making Hyacinth Leaf Extract: Water hyacinth leaves are aerated for about seven days until dry. After drying, then grinding is done using a grinder to get 40 mesh of water hyacinth powder granule, as much as 500 grams of water hyacinth leaves macerated with 1000 ml ethanol solvent, then stirred with a stirrer for 24 hours then filtered using whatmann paper No. 40 which is placed on a Buchner funnel and obtained by filtrate, then centrifuged at 9000 rpm at 4 oC for 15 minutes, the sediment obtained is then evaporated using a rotary evaporator at 60 oC, evaporation above the waterbath, evaporation results then evaporated again until there is no residual ethanol content.

Stage of Fibroblast Cell Management: Gingival tissue was taken from free gingiva in tooth P1 for extracted orthodontic treatment, gingival tissue was washed with physiological solution to clean from blood, then placed in a transport medium to be taken to the laboratory, gingival tissue washed 3 times with PBS containing penicillin and streptomycin antibiotics to avoid the possibility of bacterial contamination. The gingival tissue was cut to approximately 1mm3 and covered with deckglass, then collagenase was added for 30 minutes at 37oC, then the tissue was washed and centrifuge for 6 minutes, then the cells obtained were cultured with a growing and incubated medium in a 5% CO2 incubator with a temperature of 37oC for 3 days.

Stage of Fibroblast Cell Culture: Primary human gingival fibroblast cell culture in the Alpha Modified Eagle’s Medium (αMEM). Culture was added with 150 µg/ml Fetal Bovine Serum (FBS) 10%, 10 µg/ml Fungizone 0.5%, 100 µg/ml 2% Citrate, confluent cells then dipasase to be propagated, cell medium removed, then washed with PBS, the cell is released with a 2 ml trypsin enzyme, then incubated safely 5 minutes at 37oC and 5% CO2, after the cell is removed then added a stopper and resuspended, centrifuged 25000 rpm for 6 minutes, pellets are planted on a 10 cm plate with αMEM medium.

Harvesting Cells: The cell growth medium is washed with PBS 10% as much as 5 mL to remove protein in the medium, PBS is removed using an aspirator with a wash movement, 25% trypsin as much as 2 mL is inserted to detach cells from the surface of the plate, put in an incubator for 5 minutes with temperature of 37oC and 5% CO2, cell conditions were observed with a light microscope to see cell distribution, human gingival fibroblast cells were taken from CO2 incubators.
then cell conditions were observed (80% confluent cell cultures were used for harvesting), cells were harvested according to harvest protocols. Cells are seen using a microscope. The container is tapped so that the cell is floating.

**Results**

According to the results of reading OD (Optical Density), the average results of the research shown in table 1 are obtained.

**Table 1: Absorbance results in the treatment group extracts of water hyacinth leaves for 24 hours.**

**Graphic 1: Percentage of Live Cells**

**Statistical Analysis:** The measurement results are tabulated according to each group sample, followed by testing the normal distribution using the Kolmogorov Smirnov Test with Sig>0.05. It can be concluded that the data are normally distributed, then homogeneity testing using Levene’s Test with Sig.<0.05 can be concluded that data is not homogeneous. After that, statistical tests were carried out using Kruskal Wallis at the significance level of Sig.<0.05 and significant differences were obtained, then continued by performing multiple comparisons using Mann-Whitney which concluded that all groups had significant differences except the concentration group 0.25 mg/ml against 0.125 mg/ml; 0.0625 mg/ml; 0.0312 mg/ml, concentration of 0.125 mg/ml against 0.0625 mg/ml; 0.0312 mg/ml, concentration of 0.0625 mg/ml against 0.0312 mg/ml.

**Discussion**

Water hyacinth is a plant that floats on the surface of the water (weeds) that can develop roots in the mud in shallow water which eventually becomes waste because it can grow wildly on the surface of the water so that it disturbs the growing ecosystem, according to some studies water hyacinth contains several substances that can help proliferation from the cell. Then in this study using fibroblast cell cultures from human gingiva where fibroblast cells play an important role in the wound healing process. Cell culture has several advantages,
namely high cell growth speed, cell integrity is maintained and cells are able to multiply in suspension.

Research on the viability test of water hyacinth leaf extract was carried out to determine the viability of water hyacinth leaf extract on human fibroblast cells, because in the field of dentistry it requires a healing process so that each material used must meet several requirements, one of which is not having a detrimental or toxic effect on the biological environment both local and systemic. Therefore the viability test is conducted to see the level of biocompatibility of a material, one of the method is by enzymatic testing with MTT reagent (3-(4,5-dimethythiazol-2-yl)-2,5-di-phenyl-tetrazolium bromide).10

This tetrazolium salt dissolves in water and produces a yellow solution, living cells can reduce MTT, while dead cells cannot reduce MTT because the enzymes in the cell no longer function 11. The basic principle is the work of mitochondrial enzymes in active cells that metabolize tetrazolium salts, so that the tetrazolium ring is broken by the dehydrogenase enzyme which causes the tetrazolium to turn into insoluble and purple formazan. Color changes are caused by tetrazolium salts being reduced by the metabolic activity of cells that form NADH or NADPH. This purple color will be measured by its absorbance, absorbance is the ratio of the intensity of light absorbed to the intensity of light that comes using a certain wavelength. The absorbance value can be said to be directly proportional to the concentration of substances contained in it, namely the more levels of substances contained in a sample, the more molecules that absorb light, the greater the absorbance value.12

Based on the results of the research in table 1, the absorbance results of the treatment group of water hyacinth extract for 24 hours and cell control and media control for comparison were obtained, the average value of the absorbance of the treatment group. Absorbance value is used to determine percent cell viability, if the absorbance value observed is smaller than the absorbance value of the control group, then the cell undergoes reduction or in other words the cell’s ability to proliferate is low. Conversely, when the absorptive value is higher than the control, the ability of cells to proliferate is high, if the level of proliferation is too high it can cause death from cells because of the possibility of changes in cell morphology.13

A material cannot be said to be toxic if the percentage of living cells after exposure to the sample is more than 50% which is in accordance with CD50. Statistically, the comparison of the control group with the treatment group 1 mg/ml, 0.5 mg/ml, 0.25 mg/ml, 0.125 mg/ml, 0.0625 mg/ml, 0.0312 mg/ml, 0.0156 mg/ml had a significant difference. From the results of the percentage of live cells it can be seen that the optimum dose of the treatment group extract of water hyacinth leaves for 24 hours is 0.0156 mg/ml.12

Based on phytochemical tests and several scientific studies regarding extracts of water hyacinth leaves contain several substances, namely flavonoids, alkaloids and tannins. Where alkaloids play a role in increasing regulation of various types of cytokines, namely TGFβ1, CTGF, PDGF, where the three cytokines function to control cell proliferation including fibroblast cells during the wound healing process. TGFβ1 is responsible for inducing fibrosis by encouraging HSCs to differentiate into miofibroblasts and increasing TIMPs. CTGF is produced by macrophages which will produce a profibrotic signal which causes stimulation of the proliferation of collagen which will produce HSCs.14

Flavonoids that act as antioxidants that inhibit the increase of oxidative stress on body cells, when flavonoids are absorbed usually there will be an increase in several biological functions including protein synthesis, cell differentiation and cell proliferation and angiogenesis. Then there is tannin which neutralizes proteolytic enzymes with the help of TGFβ1 which will cause an increase in TIMPs which will inhibit degradation of the extracellular matrix and directly support the occurrence of fibrillar collagen interstitial synthesis. Which will later facilitate cell growth by preparing the environment of cells that will regenerate.15,16

**Conclusion**

Viable hyacinth leaf extract against fibroblast cells, treatment with a concentration of 0.0156% with a percentage above 75.98%.

**Conflict of Interest:** There is no conflict of interest.

The Relation of Mixed Marketing with Patient Loyalty in Syekh Yusuf Gowa General Hospital

Nurfardiansyah Burhanuddin
Faculty of Public Health, Universitas Muslim Indonesia-90231

It is important for hospitals to have the right marketing strategy, with marketing programs conducted can improve the quality of service, with good service quality, it will be able to satisfy customers so that customers will be loyal. This study aims to determine the relationship between the mixed marketing with patient loyalty in the Syekh Yusuf Gowa Regional Hospital. This type of research is an observational study with a cross sectional study approach. The population in this study were all inpatients who used services at the SyekhGowa Regional General Hospital in a month. The sampling method was done by accidental sampling, which is 114 respondents. Data analysis in this research was carried out by testing hypotheses through the correlation test method. Bivariate analysis with correlation test shows that there is a relationship between the mixed promotion (P = 0.000), mixed service provider (P = 0.000), mixed physical facility (P = 0.012) and patient loyalty, but there is no relationship between the mixed process (P = 0.064) with patient loyalty. So, there is a relationship between the mixed marketing of promotion, mixed marketing of service presenters, mixed marketing of physical facilities and patient loyalty.

Keyword: Relation, mixed, marketing, patient, loyalty.

Introduction

The mixed marketing is a company’s tool to obtained the desired response from the target market, but more importantly is how to understand the mixed marketing from the customer’s perspective or perception\[1\]. If consumer perceptions of the quality of services provided are good, it will be able to increase customer or patient satisfaction. The impact of customer satisfaction is customer loyalty\[2\]. Customer loyalty is a loyalty that is shown by regular buying behavior in the long run through a series of customer decisions. Increased customer loyalty can lead to higher profitability and a more stable financial base\[3\].

Previous studies on the effect of patient perceptions and quality of doctor services on patient loyalty in Semarang showed that patients’ perceptions of doctors were not good and patient loyalty was lacking\[4\].

Based on the data on the number of inpatient visits to Syekh Yusuf Gowa Hospital in 2011, the number of patient visits decreased significantly by 12,398 patients\[5\]. By looking at these conditions, it is important for hospitals to have an appropriate marketing strategy, the marketing programs are efforts to improve the service quality. Therefore, the study wanted to find out the relation between mixed marketing and patient loyalty at Inpatient Hospital Syekh Yusuf Gowa.

Materials and Method

This type of research is an observational study with a cross sectional study approach. This research was conducted at Syekh Yusuf Regional General Hospital on February 14 - March 14, 2012. The population in this study were all inpatients who used services at Syekh Yusuf Gowa Regional General Hospital. The method of sampling with non-random sampling system is accidental sampling, which has 114 respondents.

Primary data were obtained by collecting questionnaires while secondary data were obtained through literature studies and related agencies. Data management using the SPSS program and presented in tabular form. Data analysis in this study was carried out through the Pearson correlation test using a p value of 5% or 0.05. If p value ≤ 0.05, then Ho is rejected, meaning that there is a significant relation between the independent variable and the dependent variable. If p value ≥ 0.05, then Ho is accepted, meaning that there is no significant relation between the independent variable and the dependent variable.

Source: Primary Data

Table 3 shows that there is a relationship between the mixed promotion (P = 0.000), mixed service provider (P = 0.000), mixed physical facility (P = 0.012) and patient loyalty because it has a p value less than 0.05 while the mixed process (P = 0.064) does not have a relation with patient loyalty because it has a p value greater than 0.05.

Discussion

The results showed that respondents who had a good perception about the mixed promotion had a higher percentage of 96 respondents (84.2%) and the statistical test results showed a p value (0.00) ≤ 0.05 which meant that there was a relation between the mixed promotion and patient loyalty. The results of this study also showed that respondents who had a good perception of the mixed service presenters were higher, namely 111 respondents (97.4%) and the statistical test results showed a p value (0.00) ≤ 0.05, which means there was a relationship between the mixed service presenters with patient loyalty. For the mixed physical facility variable, this study shows that respondents who have a good perception about the mixed physical facility have a higher percentage of 104 respondents (91.2%) and the statistical test results show p (0.012) ≤ 0.05 which means there is a relation between the mixed physical facility with patient loyalty. For the mixed process variable, respondents who have a good perception of the mixed process percentage are higher namely 107 respondents (93.9%) where the statistical test shows p (0.064) ≥ 0.05 which means there is no relation between the mixed process and patient loyalty.

The elements of physical facilities assessed by customers include exterior attributes (such as parking...
lots, parks, directions) and interior attributes (such as decoration, equipment, lay out)\[^{10}\]. The primary data obtained shows that one of the toilets in the hospital was clean and smells well, this is in accordance with the opinions of respondents who mostly agreed. Besides that, one of the secondary evidences at Syekh Yusuf Regional Hospital is quite good and complete with the availability of supporting facilities such as ATMs and canteens so that patients are interested in coming back. This illustrates that there is a relation between the mixed physical facilities and the patient loyalty in hospitalization. The results of this study are in line with previous studies in Makassar which state that there is a relation between physical facilities and patient loyalty. Customers often see physical evidence to evaluate services obtained before and after consuming the services\[^{7}\]. This research is also in line with the theory of Rambat Lupiyoadi, who concluded that the physical environment where services are created directly interacts with the customer and is interconnected. Based on this description, the management should pay attention to the facilities needed by patients in order to be added value.

The process includes the service process, including the stages through and the room lay out. The same service results can be different in value if the process is different\[^{11}\]. The primary data above stated generally well in the mixed process of 107 people (93.9%) but the correlation value ie p value indicates that there was no relation. The results of this study are not in line with previous studies conducted by Sari in 2009 which stated that the service process influences loyalty because it relates to how the service is provided to patients, although most of the patients’ perceptions are good but there are still many patients who complain of the long waiting time at the clinic, this condition can encourage patients to try services in other hospitals so that loyalty will decrease\[^{12}\].

**Conclusion and Recommendation**

The conclusion of this study is the relation between the mixed marketing promotion, mixed marketing service providers, mixed marketing physical facilities with patient loyalty in Inpatient Hospital Syekh Yusuf Gowa. However, there is no relation between the mixed process and the loyalty of patients in the Syekh Yusuf Gowa Regional Hospital.

Suggestions for management to improve the quality of services in Inpatient, especially for the process of focusing on patient satisfaction and establishing good communication with patients so as to increase patient loyalty to Syekh Yusuf Hospital. In addition, the Regional General Hospital of Syekh Yusuf is expected to further improve the service process that satisfies patients, such as improving service procedures and improving all activities in hospital. In further research, it is necessary to discuss other mixing variables which is not examined in this study. In addition, research efforts on the relation between mixed marketing and patient loyalty need to be increased.

Cardiac Ventricle Laceration in a Battered Child: A Case Report

Pawan Kumar Shukla¹, Swapan Debbarma², Ashish Ramesh Bhute³

¹ Junior Resident, ² Senior Resident, ³ Assistant Professor, Department of Forensic Medicine & Toxicology, All India Institute of Medical Sciences (AIIMS), Rishikesh-249203 Uttarakhand, India

Abstract

Cardiac laceration in child abuse cases is uncommon. Very few case studies are available illustrating the left ventricular rupture following blunt chest injuries. This article presents a case of sudden death of a two and a half year-old female child brought with history of fall on level ground while playing. The autopsy revealed multiple types of injuries over the whole body with duration varying from less than a day to more than 6 months old. Left ventricular rupture and liver laceration were the primary injuries contributing to death. Child abuse cases should never be examined with a preconception of finding the classical features of intracranial hematomas.

Keywords: Child abuse, left ventricular rupture, heart rupture, cardiac tamponade, autopsy, shaken baby syndrome, blunt cardio-thoracic injury.

Introduction

Ever since the first case of ‘Battered baby syndrome’ was described, child abuse cases are increasingly reported in clinical practice. Newer ways of violence against the child are often encountered. The classical description of ‘Battered baby syndrome’ i.e. due to shaking being the commonest¹,² to less common causes like beaten to death by parents or caregivers³, homicidal methanol poisoning⁴, homicidal snake bite⁵, intestinal perforations⁶, hypodermic needle insertion at various body parts of the child⁷. Very few articles are available depicting the use of less common method of child exploitation with an unusual outcome. The present case discusses the cardiac complications of blunt thoracoabdominal trauma in a child abuse victim.

Case Report:

e-mail: ashishbhute@gmail.com
A two and half year old girl child was brought for autopsy at our institution (Fig.1). History provided by the investigating officer was similar to the history narrated by the mother of child. As per the alleged history, child was playing inside her home along with her two elder brothers, suddenly fell on the ground and became unconscious. The mother tried to wake up the child by shaking off and by splashing water on face but child was unresponsive. Father was a truck driver by profession and was out of station for work. The child was brought to a nearby hospital within 1 hour of the incident. The primary care physician after complete examination declared the child brought dead on arrival. Police were intimated and forensic medicine opinion was sought regarding the case. As per the hospital papers provided with the inquest reports, there was no documentation of attempted cardio-pulmonary resuscitation or any external injury over the exposed parts of the body. Mother gave negative history of any congenital or acquired disease or previous hospitalization. But she admitted to history of frequent falls of child while playing sustaining recent swelling over the forehead and few old scratches over the limbs. As per mother, child was playful, social and never had a similar incident in the past.

The sudden death of an apparently healthy, playful child within 1 hour of incident and negative history of any disease was sufficient for suspicion of child abuse. An autopsy was performed including external examination, internal examination, toxicological analysis of blood and full-body x-ray.

External examination revealed sunken eyes, prominent bony margins, loss of subcutaneous fat and improper pigmentation. There were a total of 43 injuries over the front and back of the body which was of different types, sizes and ages. Out of all, 18 injuries were under 12 hours of duration prior to death and included bruises over the forehead, chest, back, and laceration on the inner surface of the lower lip. Multiple, comparatively large, bruises were present over the sternal area of the chest which were individually and/or collectively responsible for the cause of death (Fig.2). Multiple reddish tram-track bruises were present over the entire back and thighs, suggestive of being caused by a long, slender object.

Six equal-sized circular injuries of duration more than 1-week old were present at different parts of the body, suggestive of being caused by the burning end of cigarette or bidi or with material alike. Few old injuries were also present in the perineal region. The rest of the injuries were old scar marks and their duration varied from 2 weeks to more than 6-month.

Internal examination revealed contusion over the anterior half of the scalp without skull fracture. Thin patches of subarachnoid haemorrhages were present all over the brain. The brain was pale and showing features of oedema. Antemortem fracture of 4th and 5th rib of right side was present 1 cm lateral to the costochondral junction. Multiple ecchymotic patches were present in the surrounding soft tissues of heart and pleural surface of both lungs. Pericardial cavity contained about 100ml of liquid and clotted blood (Fig.3a). A 4cm, full-thickness, antemortem lacerated wound was present on the posterior wall of left ventricle (Fig.3b). Ecchymotic patches were present over the anterior surface of heart, root of aorta and near right auricle. Even though the body was emaciated but abdomen was distended. The incision revealed profuse flow of liquid and clotted blood which was approximately 500ml in volume. The Source of blood was searched for, which revealed contusion over the posterior surface of right lobe of liver along with two lacerations near caudate lobe (Fig.3c). Peri-nephric area of right side was contused along with reduced fat deposit.

Blood sample was collected and sent to forensic science laboratory for toxicological analysis whose report is still awaited, although stomach content did not reveal any unusual finding. X-ray did not show any recent or healing fracture of skull or long bones.
Discussion

In our present case, most of the findings are more in favor of blunt thoracoabdominal trauma. Various literature search guides us that the following cause could be attributed to the death of this child, commotio cordis\(^8\), right atrium rupture\(^9\), left ventricular rupture\(^10\), traumatic ventricular septal defect\(^11\), trauma-induced intra-cardiac thrombus\(^12\) and trauma-induced transection of abdominal aorta or spinal injuries\(^13\).

Since external examination revealed multiple bruises over the sternal area along with fracture of right side ribs and no injuries over the abdomen, death of the child could be ascribed more to chest injury rather than abdominal. Among the above-mentioned causes, right atrial rupture was less likely because the most accepted mechanism causing it is increased hydrostatic pressure subsequent to abdominal trauma. Trauma to abdomen transmits the hydrostatic force to right atrium through inferior vena cava. When the hydrostatic force exceeds the stretchability of right atrium, it results in rupture. However, liver laceration can occur either from a blow over the chest or abdominal\(^9\). Cardiopulmonary resuscitation (CPR)\(^14\) could be a valid reason for bruises over the sternal area. Since the child was brought dead to hospital and hospital records also did not mention any attempt of CPR so this aspect was ruled out. A high-quality CPR usually causes fracture of left side ribs but in the present case, ribs were fractured on the right side again disproving the concept of CPR attempt.

A similar case of child abuse has been reported\(^10\) describing life-threatening left ventricular rupture after blunt chest injury. The autopsy noted multiple bruises all over the body including genitals. Full-thickness laceration was present at the left ventricular apex with 150ml of blood in the pericardial cavity. Multiple fractures of both sided ribs and laceration of right liver lobe were present. The author opined that the resultant cardiac injury could be due to thoracoabdominal injury. The possibility of abdominal trauma was disregarded because there was no associated injury to inferior vena cava or right side of the heart, caused due to increased hydrostatic
pressure. The likelihood of thoracic trauma was also less convincing because two contradictory opinions were present regarding the same. A severe blow to the chest during end-diastolic phase of cardiac cycle, when the ventricles are full and atria empty, could cause the rupture of ventricles by raising the hydrostatic pressure to an extreme degree. But at the same time outflow tract of ventricles with one-way valve mechanism also reduces this pressure lowering the chance of tear. Furthermore, the overlying sternal injuries were concomitant or due to previous trauma remained uncertain. Crushing of heart apex between sternum and vertebral column was the best-suited mechanism for ventricle rupture.

Although the mechanism described for left ventricle rupture in the above case was contradictory but it was arguable for our case. In the present case, several findings were appreciable which guided towards a thoracic blow rather than abdominal. Multiple fresh bruises over the sternal area, right side rib fractures, ecchymotic patches over the anterior surface of heart, root of aorta and right auricle, all suggested repeated trauma over the chest simultaneously obstructing the outflow tract of ventricles and intensely increasing the intra-ventricular hydrostatic pressure resulting in rupture of left ventricle and liver. Alternatively, rupture due to compression grinding of the left ventricle between sternum and vertebral column cannot be denied.

**Conclusion**

Child abuse cases should never be examined with a preconception of finding the classical features of intracranial hematomas. Cardiac lacerations are the newly described variant of blunt cardio-thoracic injuries in cases of child abuse which are less common than cardiac concussion injuries but nevertheless encountered in clinical practice.

Biomarkers in Orthodontics: An Overview

Poonam Agrawal¹, Dhirja Goel²

¹Professor, Dept. of Orthodontics and Dentofacial Orthopaedics, ²Reader, Dept. of Pediatric and Preventive Dentistry, School of Dental Sciences, Sharda University, Greater Noida (UP)-201310

Abstract

A biomarker is a substance that is measured and evaluated objectively as an indicator of normal biologic processes, pathogenic processes, or pharmacologic responses to a therapeutic intervention. Tooth movement by orthodontic treatment is characterized by remodelling changes in the periodontal ligament, alveolar bone and gingiva. A reflection of these phenomena can be found in the gingival crevicular fluid (GCF) of moving teeth, with significant elevations in the concentrations of its components like, cytokines, neurotransmitters, growth factors and arachidonic acid metabolites. Knowledge of biomarkers present in the GCF may be of clinical use leading to proper choice of mechanical stress for better orthodontic treatment and lesser side effects.

Keywords: Biomarkers, orthodontic tooth movement, gingival crevicular fluid.

Introduction

Orthodontic treatment aims at the correction of dental irregularities and disharmony in jaw relations. Tooth movement induced by orthodontic force application is characterized by remodelling in the dental and periodontal tissues.¹ Orthodontic tooth movement (OTM) is characterized by abrupt creation of compression and tension in periodontal ligament (PDL) (Goutoudi, Diza et al. 2004). These force-induced strains alter the PDL vascularity and blood flow, resulting in local synthesis and release of various key molecules, such as neurotransmitters, cytokines, growth factors, colony-stimulating factors and arachidonic acid metabolites. These molecules can evoke many cellular responses by various cell types in and around teeth, providing a favourable micro-environment for tissue deposition or resorption (Simonet, Lacey et al. 1997; Cetin, Buduneli et al. 2004). Gingival crevicular fluid (GCF) contains inflammatory products, bacterial products and products of tissue break down. Noninvasive procedures to determine the changes in salivary constituents are used to diagnose several diseases in clinical medicine. Thus, examination of GCF is an ideal method of evaluating the tissue destruction during orthodontic treatment. GCF arises at the gingival margin and can be described as a transudate or an exudate. Clinically GCF can be easily collected using platinum loops, filter paper strips, gingival washings and micropipettes. A number of GCF biomarkers are involved in bone remodeling during OTM. The data suggest that knowledge of the biomarkers present in the GCF may be of clinical use leading to proper choice of mechanical stress to improve and to shorten treatment time and avoid side effects.

Gingival crevicular fluid: Gingival crevicular fluid (GCF) is an exudate that can be harvested from the gingival sulcus, which offers a great potential as a source of factors associated with changes sand destruction in the underlying periodontium due to orthodontic force application. The early phase of orthodontic tooth movement involves an acute inflammatory response, characterized by periodontal vasodilation and migration of leukocytes out of periodontal ligament capillaries. The mechanism of bone resorption might also be related to the release of inflammatory mediators that can be detected in gingival crevicular fluid.

Biomechanism of orthodontic tooth movement: Two interrelated processes involved in OTM are bone bending and remodelling of the periodontal tissues, including the dental pulp, periodontal ligament, alveolar bone and gingiva. The applied force causes the compression of the alveolar bone and the PDL on one side (pressure), while on the opposite side the PDL is stretched (tension).[2] Orthodontic forces change
periodontal tissue vascularity leading to the synthesis of various signalling molecules and metabolites. The released molecules generate cellular responses around the teeth, providing a favourable microbiological environment for tissue deposition or resorption.

The pressure-tension theory proposed by Schwartz in 1932 is the simplest theory describing tooth movement on mechanical loading. On the pressure side, the biological events are as follows: disturbance of blood flow in the compressed PDL, cell death in the compressed area of the PDL (hyalinization), resorption of the hyalinized tissue by macrophages and undermining bone resorption by osteoclasts beside the hyalinized tissue, which ultimately results in tooth movement. On the tension side, blood flow is activated where the PDL is stretched, which promote osteoblastic activity and osteoid deposition, which later mineralizes. The fluid flow hypothesis, describing a mechanism by which osteocytes respond to mechanical forces, states that locally evoked strain derived from the displacement of fluid in the canaliculi is very important. When loading occurs, interstitial fluid is squeezed through the thin layer of the non-mineralized matrix surrounding the cell bodies and cell processes, resulting in local strain at the cell membrane and activation of the affected osteocytes.

The sequence of events following orthodontic tooth movement can be characterized using suitable biomarkers. Proinflammatory cytokines: Interleukin-1 (IL-1), Interleukin-6 (IL-6), Interleukin-8 (IL-8), tumornecrosisfactor-ɑ (TNF-ɑ) and prostaglandin E (PGE). The analysis of the association between alkaline phosphatase (ALP) and bone metabolism, under healthy gingival conditions, is a suggestive indicator of histological and biochemical changes in bone turnover and therefore of the amount of tooth movement. Finally, specific properties of GCF ALP activity render this enzyme an interesting diagnostic tool in orthodontics.

**Biomarkers of orthodontic tooth movement:** A biomarker is a substance that is measured and evaluated objectively as an indicator of normal biologic processes, pathogenic processes, or pharmacologic responses to a therapeutic intervention. A good biomarker should be specific and sensitive and have the ability to inform about the biological condition in terms of periodontal tissue changes and their relationships with the particular phase of OTM.

</table>

**Metabolic products of para dental remodeling:** Glycosaminoglycans (GAG) were investigated in the flow of GCF at three stages of orthodontic treatment viz. before orthodontic treatment, during canine retraction and in retention, to relate them to tooth movement. Studies concluded that the increase in GCF volume during OTM and the decrease during retention were only partly due to changes in the severity of gingival
inflammation (Pender et al). The pyridinium derivatives, pyridinoline (Pyr) and deoxypyridinoline (dPyr), are structural elements that bind together collagen chains. Pyr is abundant in skeletal tissues, whereas dPyr is a minor component found predominantly in bone and dentin. These two molecules are used as markers to evaluate bone resorption in such cases as Paget’s disease and primary hyperparathyroidism. Pentraxin3 (PTX3), also known as tumor necrosis factor (TNF) stimulated gene 14 (TSG14), is a 45kDa glycoprotein with a 202 amino acids Surlin et al.[12] measured the levels of PTX3 in GCF in orthodontic young and adult patients in the first 2 weeks after the orthodontic appliance showing an increased GCF levels of PTX3 suggesting PTX3 involvement in periodontal orthodontic remodeling and the aseptic inflammation induced by the orthodontic forces. N-telopeptide (NTx) is a specific marker of bone resorption because of its crosslinked a2 (I) NTx. When multiple biochemical markers of bone turnover were compared, NTx was found to be a more sensitive measure of bone resorption. Hence, NTx might be an important marker of active periodontal bone loss and could be useful for analyzing site specific responses to periodontal therapy. Osteocalcin is a noncollagenous matrix protein of calcifying and calcified tissue. It is produced by osteoblasts and has been described as the most specific marker of osteoblast function. Matrix metalloproteins (MMPs) are chemokines may contribute to differential bone remodeling in response to orthodontic forces through the establishment of distinct microenvironments in the sites of both compression and tension. MMPs are enzymes that play a central role in PDL remodeling, both in physiological and in pathological conditions.

Inflammatory Mediators: Prostaglandin E (PGE2), specially, is able to mediate inflammatory responses and induce bone resorption by activating osteoclastic cells. Prostaglandins (PGs) are a group of chemical messengers and are derivatives of arachidonic acid. It has been found that PGs have an important role in promoting bone resorption. Although the exact role of PGs in bone resorption is not clear, it is thought to do so by stimulating cells to produce cyclic adenosine monophosphate, which is an important chemical messenger for bone resorption. Research proved that the application of orthodontic force increased the synthesis of PGs, which in turn stimulated osteoclastic bone resorption. The peripheral sensory nervous system contributes to the development of acute and chronic inflammatory processes through the local release of neuropeptides. With the application of physiologic orthodontic force, SP increases production of proinflammatory cytokines and formation of osteoclasts in dental pulp fibroblasts in patients with severe orthodontic root resorption. Transforming growth factor is a family of polypeptides produced by cells within the periodontium involved in many biologic activities, including cell growth, differentiation and apoptosis, as well as in developmental processes and bone remodeling. Epidermal growth factor (EGF) is another cytokine possibly associated with bone remodeling. Fibroblasts and stromal cells produce it. Uematsuet al. in a study reported a transient elevation of EGF levels in GCF after application of mechanical stress of an experimental tooth. Alfa-2 microglobulin (α2MG) enhances the biologic action of insulinlike growth factor I (IGF). They are a family of peptides that promote cell proliferation and differentiation and have insulin like metabolic effects. They have been associated with stimulation of the osteoblasts and its functions.

Interleukin1 (IL1) are cytokines that affect bone metabolism and OTM, has 2 forms – α and α– that code different genes have similar actions. It was recently found that the concentration of leptin in GCF is decreased by orthodontic orthodontic tooth movement and this conclusively proved that leptin may have been one of the mediators responsible for orthodontic tooth movement. IL-17 has been found to be increased in patients with periodontitis, while it was barely detectable in sera from periodontally healthy individuals. Tumor necrosis factor-α, another proinflammatory cytokine, was shown to elicit acute or chronic inflammation and stimulate bone resorption. TNF-α is a pro-inflammatory cytokine that is often overexpressed in periodontitis and is responsible for alveolar bone resorption during periodontal breakdown. TNF-α plays a pivotal role in the bone resorption process, thus helping in orthodontic tooth movement. Colony stimulating factors are specific glycoproteins, which interact to regulate production, maturation and function of monocyte macrophages CSF (MCSF) as well as granulocytes CSF (GCSF). They might have implications in bone remodeling and thereby during tooth movement. An important implication in tooth movement is played by the MCSF through an increased early osteoclastic recruitment and differentiation. In the future, optimal dosages of MCSF already correlated with measurable changes in tooth movement and gene expression will provide a great potential in accelerating clinically the rate of tooth movement. The TNF related
ligand receptor activator of nuclear factor kappa ligand (RANKL) and its two receptors, receptor activator of nuclear factor kappa (RANK) and osteoprotegerin (OPG), are known for involvement in bone remodeling process. In the bone system, RANKL is expressed on osteoblast cell lineage and exerts its effect by binding the RANK receptor on osteoclast lineage cells. This binding leads to rapid differentiation of hematopoietic osteoclast precursors to mature osteoclasts. Osteoprotegerin is a decoy receptor produced by osteoblastic cells, which compete with RANK for RANKL binding. The biologic effects of OPG on bone cells include inhibition of terminal stages of osteoclast differentiation, suppression of the activation of matrix osteoclasts and induction of apoptosis. Myeloperoxidase (MPO) is an enzyme found in polymorphonuclear neutrophil (PMN) granules and can be used to estimate the number of PMN granules in the tissues. Mean MPO activity increased in both the GCF and saliva of orthodontic patients 2 h after appliance activation and they might be a good biomarker to assess inflammation in orthodontic movement.

**Enzymes and enzyme inhibitors:** Cathepsin B, an intracellular lysosomal enzyme is known to play an important role in the initiation and perpetuation of inflammatory processes. The accumulation of cathepsin B in GCF has been shown to increase with OTM. They were increased around osteoclasts and played a role in the decomposition of exposed collagen fibers and collagen degradation byproducts. Alkaline phosphatase and acid phosphatase have been examined as bone turnover markers in orthodontic tooth movement. Bone metabolism is associated with alkaline phosphatase (ALP) and acid phosphatase (ACP), expressed, respectively, by osteoblasts and osteoclasts. Alkaline phosphatase is a ubiquitous tetrameric enzyme, localized outside the cell membrane. A biomarker of primary granule release from polymorphonuclear leukocytes is the lysosomal enzyme β glucuronidase (β G). Increased levels of this enzyme have been found in the GCF of adolescents treated with the rapid maxillary expander. Moreover, β G, as other biochemical mediators like IL1β, responds to direct and indirect application of mechanical force to teeth, with an increased level that is higher than following stronger forces. Aspartate aminotransferase (AST) is a soluble enzyme that is normally confined to the cytoplasm of cells, but is released to the extra-cellular environment upon cell death. The activity levels of AST in the GCF are considered to be important in regulating alveolar bone resorption during orthodontic tooth movement. Aspartate aminotransferase (AST) and lactate dehydrogenase activities in GCF have been measured to confirm the biological activity, which occurs in the periodontium during orthodontic treatment. They are soluble enzymes normally confined to the cytoplasm of cells then released to the extracellular environment after cell necrosis. Lactate dehydrogenase, an enzyme normally limited to the cytoplasm of cells, signals an increase in LDH during orthodontic tooth movement due to changes in the periodontal ligament. Lactate dehydrogenase (LDH), an enzyme normally limited to the cytoplasm of cells, is only released extra cellularly after cell death.

**Conclusion**

The orthodontic displacement of a tooth is the result of a mechanical stimulus, generated by a force applied to the crown of a tooth, which results in an acute inflammatory response in periodontal tissues, which in turn may trigger the cascade of biological events associated with bone remodeling. Orthodontic force application could be based on individual tissue responses. The problem of relapse can be solved up to some extent by considering bone turnover rates around each experimental tooth, however a simple noninvasive method is required for achieving these possibilities. The gingival crevicular fluid alkaline phosphatase levels in can be used as a diagnostic biomarker to assess the health and pathology of the periodontium during orthodontic treatment. It can be used in early detection of changes in the periodontium and can assess the efficacy and prognosis of orthodontic treatment.

Policy Study and Stunting Prevention in Surabaya

Queen Khoirun Nisa Mairo1, Sherly Jeniawaty1
1Lecturer, Department of Midwifery Health Polytechnic Health Ministry Surabaya, Indonesia

Abstract

Background: Nutritional Status Survey in 2017 showed prevalence of stunting toddlers in Indonesia was still high, which was 29.6% above the limitation determined by WHO (20%). Conducted study by Ricardo in Bhutta in 2013 stated that stunting toddler contributed against 1.5 million (15%) of toddler mortality in the world and caused 55 millions of children had lost their healthy life time every year. Result of Basic health research (Riskesdas) in 2013 stated that condition of consuming food for pregnant woman and toddlers in 2016-2017 showed in Indonesia, 1 from 5 pregnant women was malnutrition. Decrease of stunting rate only reached 4% in 1992 until 2013. Presidential Regulation number 42/2013 had determined National Movement of First Thousand Days of Life for increasing toddler’s nutritional status that was followed by development program, including its budget.

Method: This research was mix method research, which was a step in the research by combining two kinds of approaches, qualitative and quantitative. Besides, this research utilized gradual mix technique. Population in this research was Public Health Centers in Surabaya area. Meanwhile, the sample was all of policyholders in Surabaya, who were Head of Public Health Centers and midwives. This research utilized data analysis in gradual qualitative-quantitative. Not conflict of interest, source of funding self and ethical clearance taken from committee ethic. Hence, the analysis was conducted on qualitative data, then, it was followed by quantitative data.

Result and Analysis: Public Health Center of Pucang Surabaya still had the highest stunting rate among 10 Public Health Centers. Public Health Center of Tanah Kali Kedinding Surabaya had quite high increasing rate against stunting from 2017 until 2018. Almost all programs were appropriate with 1000 HPK (1000 first day of life) guidelines in area of Public Health Centers Surabaya that had been done by the midwives. According to FGD result, regulation and policies which were related to 1000 HPK, particularly for regulation of exclusive breast milk and PMBA which had been quite many either in was statute law, Government Regulation, Minister of Health Regulation, Decree of Minister of Health, or Regional Regulation. Handling stunting was done by synergy among central government, regional government, entrepreneur and community organization. High commitment from all health professions was much needed so that it could be able to hasten the decrease of stunting.

Conclusion and Suggestion: the implementation of 1000 HPK program had been conducted as an effort in reducing stunting rate. However, stunting problem still had not been solved. Therefore, it was needed cooperation mutually in cross sector for handling stunting problem, particularly in Surabaya City, East Java Province, Indonesia.

Keywords: Prevention Stunting, Policy Study, Surabaya.

Introduction

Nutritional Status Survey (PSG) 2017 showed prevalence of stunting toddlers in Indonesia was still high, which was 29.6% above the limitation determined by WHO (20%). Conducted research by Ricardo in Bhutta in 2013 stated that stunting toddlers contributed against 1.5 million (15%) of toddler mortality in the world and caused 55 millions of children had lost their healthy life time every year. Prevalence of stunting in Indonesia has quite stagnant rate from 2007 until
2013. WHO determined that limitation of nutrition problem was not more than 20%, thus, Indonesia was a country that had health problem for society. Moreover, this research aimed at studying the policy and gaps that could be solved through policy option which was through analyzing legal document and other literature and programs that had been developed. Then, it was conducted discussion form by involving experts in composing result as the policy option.

**Material and Method**

This research was mix method research, which was a step of research by combining two kinds of approaches, qualitative and quantitative. Population in this research was Public Health Centers in Surabaya. Meanwhile, the sample was all of policyholders in Surabaya area, who were Head of Public Health Center and midwives. This research utilized data analysis in gradual qualitative-quantitative. Hence, the analysis was conducted on qualitative data, then, it was followed by quantitative data.

**Findings:** Respondents in this research were midwives which the result of basic health research (Riskesdas) in 2018 showed that the decrease of stunting prevalence in National level was in 6,4% for 5 years period, from 37,2% (2013) to be 30,8% (2018). Meanwhile, for toddlers who had normal status increased from 48,6% (2013) to be 57,8% (2018). Meanwhile, the other toddlers suffered other nutrition problems.

**Description of Stunting in Surabaya:** Result of Nutritional Status Survey in 2017, stunting in Surabaya was 10,78 %, meanwhile, in 2018, it decreased to be 8,92 %. Research result for stunting data in 10 Public Health Centers in Surabaya in 2017 and 2018 as followed:

**Description of Stunting Survey based on 1000 HPK program in Public Health Center:** Surabaya is a city that implements 1000 HPK (1000 first day of life) program with good survey. In 10 Public Health Centers through midwives who had responsibility either in the inside or outside of the Public Health Center, it was obtained the result below:

**Table 1. Description of Stunting Survey based on 1000 HPK program in Public Health Center**
Almost all programs which were appropriate with 1000 HPK guideline in Public Health Centers in Surabaya had been conducted by the midwives.

**Description of Informant’s Characteristic:** Informant who participated in this research were 10 informants with varied characteristic. This research was conducted in Public Health Centers in Surabaya area and Public Health Office of Surabaya. This research was conducted in Public Health Center of Dupak, Public Health Center of Jagir, Public Health Center of Krembangan Selatan, Public Health Center of Tanah Kali Kedingding, Public Health Center of Mulyorejo, Public Health Center of Siwalan Kerto, Public Health Center of Gunung Anyar, Public Health Center of Sidotopo and Public Health Center of Sidotopo Wetan. Meanwhile, the informant was the policy maker and stunting program implementer in each agency.

**Result of Structured Interview Analysis:**

**Analysis of regional regulation system in Surabaya:** Every regulation that was conducted based on the policy, the regulation that was related to stunting was Government Regulation (PP) number 33/2012 about exclusive breast milk, Presidential Regulation number 42/2013 about national movement to accelerate nutrition improvement, planning guideline of national movement to accelerate nutrition for first thousand days of life or 1000 HPK movement had begun since 2013. Besides, it was also appropriate with planning of regional construction in chapter 260, chapter 261 and chapter 262 regarding stunting that was appropriate with planning of national construction, it was coordinated, synergized and harmonized by Regional Development Planning Agency (BAPPEDA) in Province level. It was also appropriate with 5 pillars of handling stunting, particularly in pillar 2 about national campaign and communication of behavior changes of communication strategy for behavior of stunting prevention and also there was a facility of stunting policy in regulation of minister of home affairs (permendagri) number 22/2018 about Regional Development Work Plan (RKPD) in 2019.

**Analysis of Fund Source in Stunting Prevention Program in Surabaya:** Analysis of fund source from central DIPA about technical orientation of neonatal maternal health, antenatal based on standards, SDIDTK, MTBS, SN-PKPR and Kespro catin etc., fund source from central DIPA about implementation of government matters that became regional authority which was funded by and at the expense of Regional development budget (APBD).

**Stunting Fund Allocation Policy:** Fund allocations of stunting prevention program were nutrition intervention, maternal and child health service, environment health, pregnant mother and 0-2 years old child, or household of 1.000 HPK. Effort in increasing the effectiveness from several initiative and program/activity through support from national leadership, priority decision and harmonization of this program needed coordination and technical support, high-level advocacy and cross-sectoral partnerships to accelerate target of nutrition improvement for society which was expected by focusing on nutrition improvement on first 1000 days.
of life. The policy maker and program implementer of cross sector had a power to improve the future through developing the intervention of sensitive nutrition that impacted on optimization of either individual nutrition or country. Furthermore, beginning to invest as soon as possible could result better human resource, break the poverty circle and increase economic development. However, the main goal was synergizing to break the cycle of nutrition problem for the improvement of future generation. Concerning with quite wide opportunity for effort in improving human resource against the impact of trans-generation, recently, Indonesia strengthened more the coordination from several sides.

Support for Allocation of Stunting Funds: Support for allocation of stunting funds facilitated regional government in internalizing SPM in regional development planning documents (RPJMD/RKPD), facilitated regional government in prioritizing SPM in budgeting documents (APBD), conducted a training and monitoring for implementation of government matters, facilitated the publication of Citizenship Registration Number (NIK) and newborn baby certificates.

Purpose of policy for special allocation funds (DAK) was in physique TA 2019 and as we knew that, DAK in physique was fund that was allocated in regional development budget (APBN) to certain region for donating physical certain activity which was regional matters and it was appropriate with national priority, such as providing basic public service infrastructure and facilities, both for fulfilling minimum service standard (SPM) and reaching either national priority or accelerating regional construction and region with certain characteristic for overcoming the differences in public services among regions.

Obstruction in Stunting Fund Allocation: Obstruction in stunting fund allocation was such as coordination in implementing intervention of either specific or sensitive nutrition, regulation that was related to handling stunting which had not been become as a general base for handling stunting, the access in implementing intervention of specific and sensitive nutrition still had not been integrated, it had not been optimal campaign of dissemination that was related to stunting. Besides, another obstruction was the regency/city was still late in fulfilling requirements for disbursement of funds. In addition, the requirements were making report of convergence of stunting prevention in regency level in previous fiscal year.

Regulation of Stunting Prevention Program against SPM: Regulation of stunting prevention program against SPM was managed by central policy of SPM PP number 2 in 2018 SPM, policy and regulation which were related to stunting was statute law (UU) number 36/2009 about health, UU number 18/2012 about food, RPJMN 2015-201. Moreover, it was needed synchronization of central and regional activities for regulation.

Related Policy with 1000 HPK: Related policy with 1000 HPK in Surabaya was conducted breast milk village program, companion donor “Towards Platinum City of Surabaya”, in English was “going toward the platinum generation of Surabaya” for prospective bride and groom class.

Legality Component Program: Legality component program, such as decree of work for Head of service, for Public Health Center had not been from the regency/city or from the Public Health Center itself, but there were the instruments in implementing program, such as SPM, regulation of minister of health (Permenkes) and Standard Operating Procedure (SOP) of Public Health Center, using Permenkes of 21 years in 2016 about the use of JKN Capitation Fund.

FGD Analysis: The implementation of Focus Group Discussion was conducted on Saturday, 7th September 2019 about policy study and stunting prevention in Surabaya and the respondents were 10 respondents. From the FGD analysis above, it was obtained policy study about policy of 1000 HPK which was there and it had been conducted, but the cooperation in cross society had not been occurred, synergy was between institute of central government and regional government and education institute. All of activities in society inserted with campaign for reducing stunting. After being conducted Focus Group Discussion (FGD) analysis, it was obtained policy recommendations:

- Synergy of program between Central Government and Regional Government in overcoming stunting.
- Monitoring about the implementation of 1000 HPK by society.
- Commitment of human resources for implementation in overcoming stunting in all sectors.

Discussion
Stunting was related to poverty. Concerning with
stunting toddlers was not only occurred on low/poor family, but also on middle/high family. Between poverty and stunting was like a vicious circle. 3

The poverty made nutritional adequacy in underprivileged families unfulfilled, thus, the malnourished pregnant mother would give birth the malnourished baby and stunting. Moreover, stunting toddlers who could not be intervened for first 1,000 days of life would grow up and have less productive and low quality of life. 4

Result of Nutritional Status Survey in 2017, stunting in Surabaya was 10.78 %, meanwhile in 2018, it was 8.92 %. 5 Policy of Presidential Regulation in 42/2013 about national movement to accelerate the nutritional improvement focused on rescuing first thousand days of life (1000 HPK) for stunting. In 2015, Surabaya selected to publish the policy of maternal and children safety. This research aimed at analyzing the rescue policy of 1000 HPK and decrease of stunting in Surabaya.

The success of nutrition improvement was a sequel from the success in food supply sector, behavior changes and the increase of knowledge, environment improvement and clean water facility supply, providing employment and the increase of income and also other various determinant factors. In line with it, handling nutrition problem could not only been conducted by government, but it also needed involvement and support from others, such as development partners, non-governmental organization, universities, professional organization and community organization. Hence, let’s cooperate to improve nutrition condition for Indonesian toddlers. We are in Ministry of People’s Welfare will do coordination to all activities which are done either by government or non-government in improving nutrition for society.

From quantitative data, it was seen that first sequence for stunting problem was seen in Public Health Center of Pucang (20.27 %) and this rate had been below national target, that was 28 %, which meant that it had been success to reduce stunting rate from cumulative percentage. However, if it was seen from the increase in previous year, it was known that in the average, it did not increase significantly. This was because most of Public Health Centers here had conducted the activity of 1000 HPK program.

More over, stunting was correlated with poverty. Nevertheless, case of stunting toddlers was not only occurred on low/poor family but also on middle/high family. In other word, it was like a vicious circle between poverty and stunting. The poverty made nutritional adequacy in underprivileged families unfulfilled, thus, the malnourished pregnant mother would give birth the malnourished baby and stunting. Moreover, stunting toddlers who could not be intervened for first 1,000 days of life would grow up and have less productive and low quality of life.

**Conclusion and Suggestion**

The implementation of 1000 HPK program had been conducted as an effort in reducing stunting rate. However, stunting problem still had not been solved. Therefore, it was needed cooperation mutually in cross sector for handling stunting problem, particularly in Surabaya City, East Java Province, Indonesia.

Estimation of Skin Radiation Dose from Common Radiographic Examinations: A Preliminary Study to Establish Diagnostic Reference Levels (DRLs)

Raed Mohammed Kadhim M. Ali1, Hussien Abid Ali Bakir Mraity2, Ban Hassan Hadi3, Sarah Hamed Dana3

1PhD Medical Physics, University of Kufa/Faculty of Medicine, 2PhD Medical Physics, University of Kufa/Faculty of Sciences, 3BSc Physics, University of Kufa/Faculty of Sciences

Abstract

The aim of this study was to estimate the skin radiation dose received by adults’ patients undergoing most common eight X-ray examinations. The study was conducted in three hospitals in three different Iraqi cities: Najaf, Babylon and Salah AL-Din. A minimum number of 10 patients were considered for each type of X-ray examination in each hospital. The skin radiation dose calculation was performed by mathematical equation using exposure factors, namely, X-ray tube voltage (kVp), tube loading (mAs) and source-skin distance (SSD). The skin radiation dose values were obtained for all patients involved in this study who undergoing skull (AP and Lat), cervical (Lat), chest (PA), abdomen (AP), lumbar (Lat), pelvis (AP) and knee (AP) examinations. The resulted data were analyzed and compared with international reference doses. The average skin radiation dose ± standard deviation (SD) for the three hospitals were 0.77±0.43mGy for skull (AP), 0.66±0.39mGy for skull (Lat), 0.63±0.34mGy for cervical (Lat), 0.28±0.25mGy for chest (PA), 4.36±2.92 mGy for abdomen (AP), 4.37±2.30mGy for lumbar (Lat), 1.65±1.09mGy for pelvis (AP) and 0.40±0.25 mGy for knee (AP) examinations. For majority of the considered radiographic examinations Balad general hospital recorded the highest skin radiation dose. Overall most of the recorded radiation doses were within the internationally acceptable dose levels with some variations amongst different hospitals.

Keywords: Dosimetry, mathematical calculation, general radiography, patient dose.

Introduction

Ionizing radiation (IR) is used in medicine in two main areas, diagnostic and therapeutic. In diagnosis, IR enable the explore of anatomical human body structures and determine their physiological abnormalities. The diagnostic imaging modalities include conventional X-ray procedures, fluoroscopic and computed tomography examinations. Nuclear medicine, which mainly use gamma rays, is another diagnostic procedure use IR. Diagnostic radiology and nuclear medicine have been reported as the largest radiation source of man-made exposures. Since 1980, the radiation exposure from medical procedures has increased by 600% in the US. This increment makes the medical imaging contribute up to 88% of artificial radiation sources to population in the US. Similarly, the medical imaging constitutes 96% of man-made radiation sources to the UK population. The global increase in medical radiation exposure is attributed to the tremendous increase in the number of radiographic examinations in many countries, particularly developing countries where radiographic examinations frequency is doubled or even tripled. The substantial increase in the frequency of CT examinations, which characterized by high radiation dose when compared to conventional
X-ray examinations, within the last few decades is another cause medical radiation exposure increment. Despite of this increase in medical radiation exposure, patients radiation dose from radiographic examinations are considered acceptable when compared to large benefits of these diagnostic procedures. Accordingly, any diagnostic procedure involve IR should be justified.

The concept of justification was recommended by the ICRP in their publication 103. According to justification principle, radiographers should not apply the IR to the patient unless the benefits of examination outweigh harms of radiation. The justification become an essential part of health professional duty in diagnostic radiography and nuclear medicine departments. Therefore, the quantification of radiation risk to patient from radiographic examination becomes very important.

From radiation protection view there is a main concern regarding justification. This concern is due to the variations of radiation dose to similar size patients subjected to same radiographic procedure by different facilities. This was firstly reported by the ICRP who documented that the dose variation factor ranged between 2 and 10. Accordingly, the ICRP introduced the concept of DRL within their publication 73 and developed it in their subsequent publications. DRL is a tool used in radiation protecting to optimize the radiation dose to patient from interventional and diagnostic procedures. In diagnostic imaging procedures involving IR, DRL is used to estimate whether the radiation dose from a specific procedure is extremely large or extremely small. For protection optimization purpose, DRL is insufficient and image quality should also be considered. Any radiological examination achieved with radiation dose less than DRL does not mean that the examination is optimized. Accordingly, the ICRP recommended the use of DRLs rather than the use of dose limits.

DRL is established for specific procedure using standard size, weigh 50-90kg, patients data. Phantoms are not recommended for the establishment of DRL. DRLs can be set locally for specific area of a country, nationally or regionally. In general DRL should be established for a reasonable number of facilities at least 10 machines with at least 20 patients for each procedure and the third quartile is the DRL. For local areas with 1-10 facilities median can be used as DRL value. The ICRP recommended the regular revision of DRL values every 3-5years. Accordingly, the assessment of radiation dose from radiographic procedures becomes of great interest by many researchers.

In Iraq there is no published DRLs yet and even there is limited number of published studies that consider the patient radiation dose from radiographic examinations. The aim of this study is to estimate the skin radiation dose from most common interventional X-ray examinations in three Iraqi Province as a preliminary step to establish local DRLs in each province which may be then developed to set national DRLs in Iraq.

**Material and Method**

This is a prospective study includes data for average size 240 adult patients collected from the main hospitals in three Iraqi provinces; Al-Sadder teaching (ST) hospital in Najaf, Al-Hillah teaching (HT) hospital in Babylon and Balad general (BG) hospital in Salah AL-Din. The radiographic examinations frequency data during the last 6 months in these hospitals was used to determine the most common eight examinations. These examinations include: skull (AP) and (Lat), cervical spine (Lat), chest(PA), abdomen(AP), lumbar spine (Lat), pelvis (AP) and knee joint (AP). Then for each radiographic examination, 10 patients data was collected from each hospital. For each patient the collected data include the X-ray tube potential (kVp), the product of X-ray tube current and exposure time (mAs) and the skin-source distance (SSD). Then these parameters were used for the assessment of skin radiation dose using the following equation:

\[
\text{Skin does (µGy)} = 418\text{(kVp)}^{1.74} \times \text{mAs/(SSD)}^2 \times (1/T+0.114)
\]

Where (T) is the total filtration of the X-ray beam which is constant (2.5mmAl) in this study because all the considered machines were from same manufacturer; SHIMADZU. The above equation was formulated into a simple programme using matlab to facilitate the process of mathematical calculations of patients skin radiation dose.

Since the patient identifying detail were not collected, the approval of the study protocol by the
local Ethics Committee in each hospital waived the requirement for obtaining informed consent.

**Results**

Tables (1-3) show exposure data along with calculated skin radiation dose for the considered radiographic examinations in terms of mean±standard deviation(SD).

The analyses on measurements throughout the three hospitals were performed demonstrating that the radiation doses presented in BG hospital (Table 1) tend to be the highest for most considered examinations when compared to the doses in the other two hospitals included in the study. The second highest radiation doses were reported at HT hospital (Table 2). However, the lowest radiation doses were recorded at ST hospital (Table 3). These variations in calculated radiation dose can be attributed to the relatively higher X-ray tube parameters used in BG hospital in addition to the smaller SSD. For all the included hospitals the radiation doses from abdomen (AP) and lumbar (Lat.) were the highest while the lowest recorded dose was from chest (PA) X-ray in HT and ST hospitals. The lowest radiation dose recorded at BG hospital was from skull lateral examination (Figure 1).

Figure (2) demonstrates the preliminary data of established DRLs for the eight considered radiographic examinations in the three hospitals. These data include the minimum, first quartile, median, third quartile and maximum skin radiation dose for each examination. According to the ICRP, the medians can be considered as DRLs due to the small sample size.

### Table (1): Exposure factors along with calculated skin radiation dose for the eight considered examinations in BG hospital.

Figure (1): Radiation dose comparison amongst the three hospitals for the eight considered examinations.
Discussion

The comparison of skin radiation dose amongst the three hospitals demonstrated that the skin radiation doses from most radiographic examinations were different. In spite of these differences, all the calculated skin doses were within the acceptable dose levels recommended by the European Commission (EC).\(^{(16)}\)

For skull (AP) examination the highest radiation dose recorded in HT hospital (1.147±0.09mGy), while the lowest dose was from BG hospital (0.194±0.06mGy). This can be explained by the low exposure factors used in BG hospital for this examination (Table 1) in addition to the small SSD used in HT hospital (Table 2). The preliminary DRL data for this examination in the three hospital was 0.982mGy median and 1.093mGy third quartile. These radiation dose data for skull AP examination is consistent with previous studies wherein the maximum acceptable skin dose is 5mGy.\(^{(16,17)}\)

As reported by the EC\(^{(16)}\), the calculated skin radiation dose from skull lat. X-ray in this study is lower than that from skull AP in the all considered hospitals. The lowest dose was 0.126±0.05mGy in BG hospital (Table 1). Equal mean radiation dose was recorded in both HT and ST hospitals (0.928mGy) but with different SD in each hospital (Tables 2 and 3). These recorded radiation doses in the three hospitals were within the acceptable dose for this examination, which is ≤3mGy. For the three hospitals the median and third quartile of the skin radiation dose were 0.853mGy and 0.975mGy, respectively (Figure2).

Regarding Lat. X-ray of the cervical spine, the highest dose was recorded at BG hospital (0.938±0.30mGy), while the lowest dose was recorded at HT hospital (0.320±0.03mGy) (Figure 1). This difference in calculated skin dose between the hospitals may be attributed to the different exposure factors as
well as the different SSD used in the hospitals (Tables 1 and 2). In comparison to previously published work, the radiation dose from C-spine lat. X-ray in this study, which was 0.63mGy, tends to be comparable. For instance, Kim, Choi(14) reported that the skin dose from this examination is 0.48mGy. The overall median and third quartile at the three hospitals is 0.56 and 0.84mGy, respectively (Figure 2).

Since chest X-ray is the most frequent radiographic examination, a large number of studies considered the radiation dose from this radiographic examination.(1,2,18) The majority of these studies concluded that the chest X-ray radiation dose in many countries was within the acceptable dose limit published by EC(16); 0.3mGy. In this study the average dose from chest X-ray was 0.28mGy with some differences amongst the considered hospitals. BG hospital recorded the highest radiation dose (0.616±0.11mGy) which was higher than the acceptable range and this may be due to the short SSD used in this hospital. However, the other two hospitals showed lower radiation dose than the recommended level, 0.143±0.02 and 0.076±0.02mGy and this may be attributed to the use of post-processing manipulation of the image in these hospitals. Similarly large differences amongst hospitals has been reported in Iran by Paydar, Takavar(18); 0.53mGy at one hospital and 0.095mGy at the other. Regarding the DRL data the recorded median and third quartile of radiation dose, from chest X-ray, were 0.140mGy and 0.544mGy. The radiation dose median is within the acceptable international limits while the third quartile is higher than those limits. This is particularly due to the extremely high radiation dose recorded at BG hospital. Accordingly BG hospital needs to consider the radiation from chest X-ray achieved in its radiography department.

Similar to chest X-ray, the highest radiation dose from abdominal X-ray was at BG hospital. The doses at the three hospitals were 8.112±1.17, 3.490±0.45 and 1.473±0.34mGy, respectively. All this dose data are within the internationally accepted dose level for this examination, which is 10mGy, but higher than that recorded in Korea by Kim, Choi.(14)

Regarding the radiation dose from Lat. lumbar examination, the radiation dose recorded at the three hospitals (Tables 1-3) are consistent with the internationally recommended dose levels(16) as well as the previously published work by Kim, Choi.(14)

The lowest dose from pelvis AP X-ray radiation was recorded at BG hospital; 0.290±0.10mGy. This dose look very small when compared to EC data.(16) This may be attributed to the use of post-processing of the image and may be the patients’ size attended this hospital less than the standard body size. However, at the two other hospitals the dose data, 2.798±0.30 and 1.857±0.37mGy, is consistent with that published by Kim, Choi.(14); 2.44±1.06mGy.

Finally, the radiation dose from AP knee X-ray examination at the three considered hospitals is consistent with that published by Kim, Choi(14) with highest dose was recorded at BG hospital.

**Conclusion**

For the three considered hospitals, the average estimated skin radiation dose from most radiographic examinations tend to be within the internationally acceptable limits. However, the ESD data for each hospital separately demonstrated that for some examinations the radiation dose were higher than acceptable limit and this mainly due to the wide dynamic range of digital radiography.

**Ethical Clearance:** The study protocol is approved by the local ethics committee in each hospital.

Sex Determination from Lower End of Humerus Using Morphological Traits in Indian Population

Rajan S.†, Surangama Chakraborty†

†Assistant Professor, Department of Forensic medicine & toxicology, VMCH Madurai

Abstract

One of the main objectives in forensic examination is identification. In case of skeletal remains examination, sex determination is one of the important parameters for identification. Here in this study, lower end of humerus is studied for sex determination by morphological method. As there is a difference in carrying angle between male and female, there should also be observable difference existing in lower end of humerus. Hence four morphological characteristic features of distal humerus including shape of olecranon fossa, angle of medial epicondyle, trochlear symmetry and trochlear constriction were assessed for sexual dimorphism and their accuracy in sex determination. When each of these features considered individually, the result was shape of olecranon fossa showed more accuracy (m:87%, f:69%) in sex determination and if any three of these features considered collectively accuracy in sex determination was (m:61%, f:72%).

Keywords: Sex determination, lower end of humerus, distal humerus, morphological traits.

Introduction

Identification is an important parameter in forensic examination of the dead and in case of skeletal remains, primary parameters of identification includes age, sex, stature and race.† Determination of age, stature, as well as race to an extent depends on the sex of the deceased. Sex determination is a simple task in fresh bodies, but in case of severely decomposed, commingled, dismembered or skeletonized bodies, sex determination is a challenging task.‡

In this study, an attempt is made to determine sex from the Humerus bone as it is one of the long bones possibly recovered in most of the forensic cases either complete or in a fragmented state. There are two methodological approaches for Sex determination from bones, morphological method and the metric method. Morphological method uses the physical visual differences expressed between males and females known as sexual dimorphism. Metric method uses differences in measurements of the traits between the sexes.§ Pelvis and skull show more accuracy in sex differentiation by morphology method than any other bones.¶ Commonly used method for sex determination in long bones is by metric method. The metric method for determining sex in humerus have been studied frequently and also yielded more accuracy results.‖ Morphology method of assessments are studied, but to a lesser extent. In this study, the lower end of humerus is chosen for sex determination as it in articulated state with ulna and radius show sexual dimorphism in carrying angle. The lateral deviation of the human forearm from the axis of the upper arm is more in females than in males (10–15 degrees in males, 20–25 degrees in females).‖ The differences in carrying angles between male and female imply that there may be also differences in morphology of distal end of humerus. Here in this study, morphological characteristics of distal end of humerus of south Indian population is assessed for any differences exist between male and female and whether can be used for sex determination.

Materials and Method

The samples for study included dry human humerus bones collected from dept of forensic medicine and anatomy of a medical college hospital in Madurai South India. Total number of bones collected for the study included 100 bones out of which 71 were male bones and 29 were of female bones. Bones from both the sides were included in the study.

Inclusion criteria:

Only matured skeletal bones were considered

Only specimens that were healthy were chosen

Exclusion criteria: Specimens exhibiting pathology, trauma, or any type of post-mortem damage were excluded

Bones showing advanced degenerative conditions were excluded

Distal end of humerus were studied for any visual morphological variation exist in male and female bones

- Morphological features considered were
- Olecranon fossa for its variation in shape
- Medial epicondyle for its angulation
- Trochlea for its shape and symmetry
- Trochlea for its constriction

These morphological features were outlined by Rogers.11

Each morphological feature is assessed for its sexual dimorphism and if any distinct feature is observed, they are grouped either into male or female

If does not show distinct feature grouped into indeterminate or ambiguous

Thus Bones are categorised into distinctly male, distinctly female and indeterminate or ambiguous

Their percentage of accuracy is calculated for sex determination from each of these morphological feature or as collectively from these morphological features.

A second observer was utilised to visually asses the morphological features independently to rule out intra observer error

Observation: Considering olecranon fossa, the shape ranged from triangular (where upper half of olecranon fossa forming an apex either pointed or rounded) to oval (where upper half of fossa is curved arc like). Triangular shape was more common in male and oval shape was more common in female (fig.1)

Considering the angle of Medial epicondyle, posterior edge of medial epicondyle either remains flat (i.e., remains parallel with other features of distal humerus when placed posterior surface facing upwards on a table) or it may show raised angulation. Most of the female bones did show a raised angulation whereas most of male bones medial epicondyle was flat and did not show angulation (fig.2)

Trochlear symmetry- trochlea consist of medial and lateral rim with constriction inbetween these two. If the medial rim of trochlea extends markedly downwards, it is considered asymmetrical or if extension of medial rim is slightly inferior to level of capitulum it is considered symmetrical trochlea.

Asymmetrical trochlea is common in male and trochlear symmetry is more common in female (fig.3).

Trochlear constriction: The inferior border between two rims of trochlea may show a smooth curvature or a marked midline constriction. Smooth curvature is common in male bones and marked constriction is commonly seen in female bones. (fig.3)

Statistical analysis: To establish the accuracy in sex determination from these morphological features of distal humerus statistical analysis was conducted using chi square test from the observations made from the bones. Intra observer error was also assessed using chi square test.

Results

Four indicators for sex determination from lower end of humerus were considered

Shape of olecranon fossa: Out of 100 bones 69 were triangular in shape 21 were oval in shape 10 were not able to categorise into either of the two. Out of 100 humerus 71 were male bones. Out of which 62(87.32%) showed triangular shape 1 (1.4%) show oval shape and 8(11.26%) were not able to categorise into either of the two. Out of 29 female bones 20 (68.9%) showed oval shape 7 (24.13%) showed triangular and 2 (6.9%) were not able to categorise. The chi square value was 57.0557 which was statistically significant with p value <0.05.
Angle of medial epicondyle: Out of 100 bones, in 34 bones markedly raised angulation were made out, in 56 no anulation were made out and in 10 bones it was indeterminate (which neither did show marked angulation nor flat). Out of 71 male bones 50 (70.42%) showed no angulation and 13 (18.3%) showed markedly raised angulation and 8 (11.26 %) were indeterminate. Out of 29 female bones 21 (72.41%) showed no angulation and 6 (20.69%) showed markedly raised angulation and 2 (6.9%) were indeterminate. The chi square value was 27.2144 which was statistically significant with p value <0.05

Trochlear symmetry: Out of total 100 bones 25 bones showed trochlear symmetry 54 showed asymmetry and 21 were ambiguous. Out of 71 male bones 49(69.01%) showed asymmetry trochlea 8(11.26%) showed trochlear symmetry and 14 (19.7%) were ambiguous. Out of 29 female bones 5 (17.24%) showed asymmetry trochlea 17(58.62%) showed trochlear symmetry and 7(24.13%) were ambiguous. The chi square value was 28.8795 which was statistically significant with p value <0.05

When these morphological features are considered collectively for sex determination. The male bones satisfying all four features of male characteristics were 29 in number (41%). The female bones satisfying all four features of female characteristics were 16 in number (55%). But if any three of the features together is considered, in male bones out of 71 bones 44 (61%) were accurately identified as male and in female bones out of 29 bones 21 (72%) were accurately identified as female.

**Fig. 1:** Left Humerus bone is female with oval olecranon fossa and right is male with triangular shape

**Fig. 2:** Female humerus on left with raised medial epicondyle angle and on right male humerus with no angulation

**Fig. 3:** Left side 2 bones with trochlear asymmetry and without constriction, right side 2 bones with trochlear symmetry and constriction
Discussion

In this study sex determination from lower end of humerus was done using morphological method by assessing various characteristic features of lower end of humerus like shape of olecranon fossa, angulation of medial epicondyle, trochlear symmetry and constriction. As there is variation in carrying angle in male and female there should also be variation in anatomical features at the lower end of humerus. Hence variation in these morphological features were assessed for sexual dimorphism and also their accuracy in sex determination. When each of these morphological features were considered individually, on assessment of olecranon fossa shape, out of 71 male bones 62 showed triangular shape with 87.32% accuracy and in female bones out of 29 bones 20 showed oval shape with 68.9% accuracy. In medial epicondyle 50 out of 71 male bones showed no angulation with 70.42% accuracy and 21 out of 29 bones show marked raised angulation with 72.41% accuracy. Considering trochlear symmetry 49 out of 71 male bones showed asymmetry with 69% accuracy and 17 out of 29 female bones showed symmetry with 58.62% accuracy. Considering trochlear constriction 43 out of 71 bones showed no marked constriction with 60.56% accuracy and 23 out of 29 female bones showed marked constriction with 79.31% accuracy. All were statistically significant with p value <0.05. When all these morphological features considered collectively in combination for sex determination accuracy was only 41% in male bones and 55% in female bones. When any three of these morphological features were considered for sex determination accuracy was 61% for male bones and 72% for female bones. The results obtained demonstrate that the morphological features of the lower end of humerus can be used for sex determination. Considered individually olecranon fossa shape was more accurate in sex determination followed by medial epicondyle, trochlear symmetry and trochlear constriction was less accurate compared to others at least in male bones. But when all four features combined are taken into consideration for sex determination it becomes less accurate as in only 41% of male bones showed all male characteristics, this may be due to bones satisfying all male features or all female features were less, as in many male bones trochlear constriction was unreliable. But any three of the features are taken into consideration for sex determination it was 61% for males and 72% for female bones which are statistically significant and reliable for sex determination. In study conducted by Vance et al.,12 on south African population, when three morphological variants including olecranon fossa, medial epicondyle angle, trochlear symmetry and were used in conjunction all males were classified with a 74% accuracy rate, while all females were classified accurately 77% which is quite par with present study. Also their study showed the angle of the medial epicondyle was seen as the most accurate feature followed by olecranon fossa, but in present study it was olecranon fossa more accurate. In study conducted by Falys et al.,13 on the documented skeletal assemblage of St. Bride’s, London, showed when morphological variants considered individually

Fig. 4A, B, C: Different variations of capitulum and trochlea complex observed in this study.
olecranon fossa was more accurate with 86.4% for male and 76.6% for female bones followed by angle of medial epicondyle 72.3% for male and 77.8% for female. Again which is quite par with present study. When considered collectively all features combined showed 72.4% in male and 80.4% in female. This was quite par when any three features taken in combination for assessing sex. But Rogers\textsuperscript{11} study found 100% accuracy for females and 85.7% accuracy for males (average 88.6%) when using a combination of characteristics where present study is largely deviant from it.

There was also an other observation made in this study which include the shape of capitulum and trochlea complex, where in male bones they appeared in few different variations, like capitulum a large body gradually tapers and merge with trochlea where no distinction can be made out between capitulum and lateral rim of trochlea followed by marked constriction and medial rim of trochlea (fig. 4A), other variation include capitulum is large but can be distinguished separately from lateral rim of trochlea by a smooth slight ridge formation of lateral rim of trochlea followed by smooth arched constriction from medial rim of trochlea (fig. 4B). In female bones this capitulum and trochlea complex where a clear distinction can be made out between capitulum and trochlea by a prominent, sharper lateral trochlear rim followed by a sharp constriction and then medial rim (fig. 4C).

**Conclusion**

Sex determination using morphological variants have been done by different authors on different population but these are mainly done on western population mostly of European and African population. As there are no any data or study on Indian population, this study was conducted and the results obtained indicate that, this morphological method of assessment of various features from lower end of humerus were statistically significant and can be used in sex determination of humerus bones.

A Revolution in Health Care Sector Through Data Sciences

Rajaram¹, Amit Kumar Pandey², Sanjay Saproo³, Sanjeev Bansal⁴

¹Research Scholar, Amity Business School, Amity University Noida, ²Associate Professor, Amity Business School, Amity University Noida, ³CEO, Hamilton Medical AG, Switzerland, ⁴Dean, FMS, Director, Amity Business School, Amity University, Noida

Abstract

Healthcare industry is undergoing a digital transformation. There is lot of work which is happening that leverages the newer technologies in the healthcare industry. Technological advancements will be driver for change for future ready health care industry. Health care industry, now understands the role of digital technology platforms and has started embracing it to be future ready.

Digital transformation in health care industry shall be another milestone in patient care and hospital management. Changing mind-set of care givers and customers will be a challenge for all players to think differently. Emergence of disruptive technology in health care industry has potential scope to provide error free services worldwide. This is a qualitative study in which challenges and opportunities of Technology in Health Care Industry will cover.

Keywords: Health Care industry, digital transform, artificial intelligence and disruptive technology.

Introduction

Healthcare industry is undergoing a silent transformation using the newer technologies such as AI, deep learning, big data etc. The work which has been done so far has been very encouraging and is all set to change the paradigm of the healthcare industry. Today’s patients are understanding the importance of health care and they are budgeting for the same. For future persecutions such expenses shall be increase accordingly¹.

The old rules will be rewritten and the complexion of the industry will change completely with newer players entering and dominating the field. Healthcare industry and its various components such as pharmaceuticals, hospitals and medical devices etc.All are set to undergo major transformation in their business models. Emergence of the new technology platform like Artificial intelligence, big data are used by many industries and initial trends are helping them to define their pros and cons. Another aspect of health care is to provide a safest service to their customer’s transparency and disclosure with the help of technology is playing crucial role².

Use of these emerging technologies to run business is not new and many industries have had initial success. For instance, ecommerce industry uses AI extensively to do predictive analytics and based on users’ search pattern and past history, suggests various options for buyers to consider. Similarly, many other industries are using AI and machine learning³ to improve their productivity.

Technology in healthcare—will incumbents rule the new world or will there be new companies:

With respect to the healthcare industry, there are many applications which are under development. Healthcare industry can greatly benefit for newer technologies as it will make the healthcare delivery more affordable, accessible and reduce medication errors. Even Artificial intelligence will help medical fraternity⁴ in getting second opinion(Dr Amit Kumar Pandey, 2018).

DOI Number: 10.37506/mlu.v20i4.1856
in this study, researchers will reveal various aspects of medical treatment pattern on the basis of big data and artificial intelligence.

All the major pharmaceutical companies are leveraging this and have established separate departments to uncover the potential. Novartis, Pfizer and several other major pharma companies are working on big data and artificial intelligence and have demonstrated that these new technologies are helpful. Digital therapeutics is another area of scope where software based solutions treat and support different kinds of diseases. Digital health care delivery system is the next frontier of curing chronic patients. It has been defined⁸ that (Sophie Park MPH., 2019) within the pharmaceutical industry there are many areas which are undergoing fundamental transformation. Drug discovery is being transformed with the use of new age technology. Bioinformatics, clinical trials are some of the key areas where maximum impact is being felt. Clinical trials have started using AI based apps and other features for cohort selection (patient selection) and patient monitoring. Big data is helping in identifying newer patterns in clinical trials and making it more predictive of the real world outcome.

Technology companies such as Google and Microsoft are providing platforms for various healthcare companies, so that they can build applications and improve healthcare outcomes. Microsoft is partnering with lot of companies in the healthcare segment and helping them improve their business processes and services. On one hand they are helping research based companies to understand disease patterns and make discovery more predictive while on the other hand, they also partnering with distribution and pharmacies to improve their supply chain and improve last mile connectivity for medicine delivery.

Microsoft has many services running on its cloud platform, Azure which is being used by various healthcare companies. Microsoft Genomics service, on Azure, enables scientists, data scientists and clinicians use cloud-based genomic processing services to manage the data-rich workloads. They have partnered with St. Jude Children’s Research Hospital to understand, treat and cure childhood cancer and other life-threatening diseases.

In India, Microsoft has partnered with Apollo hospitals to create an AI focused network for improving cardiovascular outcomes. Microsoft and Apollo have established National Clinical Coordination Committee (NCCC) to develop Cardiovascular Disease Risk Score using AI models. This committee consists of leading doctors from top notch medical institutes.

Google is another company which is betting big on healthcare. They are using their AI expertise and supporting healthcare companies in creating a new dimension for detection, diagnosis and treatment of diseases. Google is using its computer vision and predictive analytics to predict cardiovascular risk using patients eye scan. Normally, eye scan is used to check the signs for diabetic retinopathy. However, with advanced predictive analytics Google’s platform can not only predict the 5-year risk of patient developing retinopathy, it can also predict the cardiovascular risk. Based on past data, it has developed algorithm which has identified the relation between retinopathy and Cardiovascular disease and based on that it is able to predict.

These are just some of the examples and there is much deeper research being done now. Technology companies are primarily working as enablers and are set to transform the industry. It was a long awaited transformation and it will take more time to transform entire industry. Moreover, adaptation by the society shall be another hurdle, because changes is not a matter of overnight.

Radiology is another area which is being transformed by artificial intelligence. Due to AI’s power in reading and analyzing visual images, radiology is an area which will undergo significant disruption. Researchers at Stanford University have explored a model in which system driven diagnosis is used. To error is human and another study conducted on medical error (PAndey, 2018) where study concluded with the manmade error unintentionally. Medical care givers are always in precautionary mood to tackle the medical issues, but error take place anonymously. Burdened care givers may do mistakes while medical procedures but in the case of AI based services, rectifications of such issues are very easy. Work load of care givers reduce and chance of error is almost zero.

**Challenges before health care industry:** Future of technology in the healthcare looks bright, but it is not without its own sets of challenges. There are multiple challenges in the adoption of technology. Firstly, all the applications are still to be validated in real world settings. Secondly, healthcare is regulated industry guarded
heavily by the regulators. Any change in the existing
treatment or diagnostic patterns will need lot of data and
real world evidence before regulators make any change.
Additional challenge will be from incumbents, as many
of them will fear job losses for instance radiologists,
pathologists and many general physicians.

Though there are multiple challenges, however this
will also create newer jobs for data scientists and other
allied areas

**Measuring impact:** Though it is certain that
emerging technologies will impact the healthcare
ecosystem, however we will have to access the impact
and understand, if we are using technology only
because it is available or are we using it because it
really makes an impact. The impact has to be measured
on the core elements of healthcare delivery. Healthcare
delivery has several players ranging from hospitals to
physicians to pharmaceutical companies to pharmacy
chain to diagnostics. If we have to make an impact, then
we must create value which transcends all the elements
and eventually improves the life of the patient. Patient is
central and is the core theme for the healthcare industry to
effectively blend the two disciplines.

**Conclusion**

Data science and newer technologies are changing
the healthcare industry and are becoming an integral
part. Use of these technologies and tools will improve
the healthcare continuum and will make the care
more effective and predictive. Collaboration between
pharmaceutical companies and technology companies
will become the new normal and winners will be
the players who are effectively able to blend the two
disciplines.

While new technologies are likely to change the
narrative of the healthcare industry but the key outcome
should be measured by the impact it brings to patient’s
life. Any new technology should enhance patients
experience and must be measured by the impact it
creates on patient’s quality of life.

A technology based framework should be developed
by all stakeholders on which impact for each technology
should be measured. This framework should be the
guiding principal. Some of the key elements of this
framework are: does it improve the clinical outcome,
does it make the medicine more effective, does it help in
reducing the healthcare cost etc.?

Differences of Gender in HIV- Risky Sexual Behavior among Adolescents and Parental Support in Luwuk City

Ramli1, Fitrianty S. Lanyumba1, Marselina Sattu1, Winnie Tunggal Mutika2, Erni Yusnita Lalusu1, Ahmad Yani3

1Faculty of Public Health, Universitas Tompotika Luwuk Banggai, Indonesia, 2Gunadarma University, Indonesia, 3Faculty of Public Health, Universitas Muhammadiyah Palu, Indonesia

Abstract

The proportion of HIV AIDS prevalence currently continues to increase and disparate between women and men. Aim: to obtain an overview of HIV-risky sexual behavior among adolescents based on gender and parental support. This study was conducted using a cross-sectional study design on 385 adolescents (P = 50%) aged 15-18 years in high schools throughout Luwuk City selected through accidental sampling techniques. Adolescent sexual behavior and parental support were assessed using the Indonesia Global school-based student health survey (GSHS) Questionnaire. There were 26 adolescents (6.8%) had intercourse, men = 22 (85%) and women = 4 (15%). 9 adolescents (2.3%) had sex for the first time at age ≤ 11 years and 7 (1.9%) did it with four or more partners. 8 male adolescents (5.8%) and 1 female (0.4%) had intercourse with men and women (bisexual) and 48.8% of female adolescents did not know how to refuse an invitation to have sex. Parental support like communication is more frequent in females (39%) than males (33%). Better understand the problems of females (43.1%) than males (41.8%). There are still 10% of parents demeaning/dropping other males and 6% female. Most of the risky sexual behavior is found between male, while the support and attention of parents are mostly directed to female. There are needs to develop health education in elementary school to high school and counseling to parents.

Keywords: Sexual Behavior, Parental Support, Gender, Adolescent.

Introduction

Adolescence is a period of rapid growth and development both physically, psychologically and intellectually. The nature of adolescents has a great sense of curiosity, likes adventure, challenges and tends to dare to bear the risk of his actions without prior consideration.

Teenagers are residents in the age range of 10-19 years (WHO). The adolescent group accounts for 18% of the total population, which means that a fifth percent of the Indonesian population is adolescents and thus it becomes a threat regarding risky sexual behavior.1

The adolescent age group is one of the starting point phases of numerous health problems, including HIV and AIDS. As per the report of Risk and Protection: Youth and HIV/AIDS in Sub-Saharan Africa (2004), that adolescents and young adults who have sexually active are at greater risk than adults exposed to HIV, partly due to lack of knowledge and stimulation of sexual intercourse.3-6

Parental support is one pivotal factor in the formation of adolescent behavior.7 Several studies conducted in the adolescent age group have identified determinants of sexual behavior. Majority of this study that studied sexual behavior in Ethiopian teenagers already described potential contributors of adolescent sexual behavior such as awareness or attitude toward the risks of HIV and AIDS and communication of both parents and teenagers about health reproduction.8

Numerous studies showed different proportions of HIV and AIDS prevalence between males and females. Consequently, there is a need to analyze the gender difference with respect to determinants and sexual behavior among adolescents to determine effective intervention strategies. Therefore, this present study aimed to describe adolescent’s sexual behaviors and parental support by gender.

### Method

This present study was a cross-sectional study design conducted in four high schools (SMAN) in Luwuk City in May-June 2018. The population of the study was all high school students of 1st, 2nd and 3rd grades. The number of samples was 385 students calculated using a proportion of 50% (P=0.5). Samples were selected through an accidental sampling technique. Adolescent sexual behaviors and parental supports were assessed using Indonesia’s Global school-based student health survey (GSHS) Questionnaire. As many as 20 enumerators were students at the Public Health Faculty of Tompotika University, Luwuk. Prior to the study, a training was given to enumerators as well as preparing survey instruments. Surveys were carried out at different times. Data collection for SMKN 1 Luwuk was completed on May 22, 2018. Data collection at SMAN1 Luwuk and SMAN 3 Luwuk was completed from May 30 to May 31, 2018. Meanwhile, data collection for SMAN 2 Luwuk was carried out on June 4, 2018.

### Results and Discussion

Adolescence is a period of transition from childhood to adulthood. It is characterized by rapid physical changes, dramatic weight and height gains, changes in body shape and development of sexual characteristics such as enlargement of the breasts, development of the waist and mustache and depth of sound. This raises the interest of the opposite sex. In this development, the achievement of independence and identity is very prominent (increasingly logical, abstract and idealistic thinking) and more time is spent outside the family. 

The increasing prevalence of risky sexual behavior in Indonesia within a 5-year-period can be due to several factors including increasingly difficult life that requires both parents to work harder so they do not pay attention to their teenage children. In this study (Table 1) majority of the respondent’s father’s occupation are entrepreneurs such as salesmen, drivers, shipmen, building workers, etcetera. These types of working do not have fixed working time and tend to spend more time outside the home. Consequently, this also reduces the time to interact with the child. Under an economic perspective, the findings of this study indicate that the average family income is quite high (above the provincial minimum wage). Therefore, economic factors seem not to be a determinant in the formation of risky sexual behavior among adolescents.

Extramarital sex develops numerous negative impacts, such as unwanted pregnancy, decreased learning achievement, dropping out of school, depression and even increased suicide rates among adolescents the extramarital sex phenomenon among adolescents continues to increase. National data shows the greatest proportion of dating for the first time at the age of 15-17 years. At this age, concerns about not having life skills and appropriate knowledge are raised and thus adolescents are at great risk of engaging in unhealthy sexual behavior including extramarital sexual intercourse. In this present study, as many as 26 adolescents (6.8%) that are mostly males have had extramarital sex. Of those numbers, 9 adolescents (2.3%) had extramarital sex at the age of elementary school ((≤12 years old. Furthermore, 7 adolescents (1.9%) had sexual intercourse with ≥ 4 partners and 9 teenagers (2.3%) had sexual intercourse with both males and females (bisexual). Rates of condom use in adolescents who have premarital sex are also still relatively low. This will further increase the rate of transmission of sexually transmitted diseases. This study shows the rate of condom use in adolescents in the city of Luwuk is 3.9% (half of the proportion of adolescents who have premarital sex).

Adolescents and young adults who actively have sexual intercourse are prone to a greater risk of HIV, partly because of low education level and sexual arousal. In this study, only 46.8% of adolescents knew how to reject a pre-marital sex invitation. Majority of them are (51.2%) and only 38.8% are males. The results of this study show that parents are likely to communicate with female adolescents (39%) than male adolescents (33%). This is in line with the tendency for adolescents who have sexual intercourse to be higher in men (15.8%) compared to women (1.6%). Furthermore, 5% of male adolescents have had sexual intercourse with ≥ 4 and no data recorded for females.

Parental supports positively affect safe sexual behavior among adolescents. The findings of this study show that only 36.9% of parents always communicate with their children, 23.4% always can understand child’s problem and only 39% of parents really know their child’s activities. The relationship quality between parents and adolescents corresponds to various sexual behaviors. For example, teenagers who reported that they have active relations with parents are unlikely to be sexually active. The results of this study also found that family involvement is associated with the sexual behavior of adolescents. Changes during the teenage period including change in sexual behavior have health consequences not only during adolescence but also during life. The unique characteristics and importance of adolescence require explicit and specific attention in determining health
programs and policies. Therefore, there are needs of supervision and assistance from various parties that play a role in the development phase of adolescents, including family support from parents, siblings and other family members, the neighborhood and the school environment.

Schools can develop activities that can engage parents to actively participate in child’s developments both cognitive, affective and psychomotor. These are related to adolescent’s perspectives on family involvement. The strategic purpose must be focused on the development of family involvement in adolescent’s daily life by encouraging parents to monitor their children’s whereabouts and provide personal and academic support.

Healthy premarital sexual behavior is directly affected by intention and indirectly by norms, attitudes, subjective norms, peer norms, education of mother and availabilities of health information (15). Previous studies about sex education and sexually transmitted disease which are curriculum-based programs show that these types of programs effectively delay the initiation of premarital sex, decrease the frequency of sex, or reduce the number of sexual partners (16,17,18,19). These programs are focused on cognitive developments namely knowledge; on sexual health issues, pregnancy, HIV and other sexually-transmitted diseases as well as preventive measures, perception; about risky pregnancy, HIV risk and other sexually-transmitted disease risks; individual values about sexuality and abstinence; Perceptions of peer norms and behavior about sex; Self-efficacy to reject sexual activity or decrease the number of sexual partners; Communication with parents or other adults about sexuality, condoms, or contraception.

**Conclusion**

Most of the risky sexual behavior is found in male adolescents, while the support and attention of parents are more directed at female adolescents. There are needs of health education starting from junior high school level; there is a counseling board targeted for parents of students; schools need to develop activities that engage parents to actively participate in affective and psychomotor development and can establish communication between parents and adolescents; strengthened health education through electronic media that contains persuasive advertisements to prevent health problems in adolescents.

Effect of Marital Status on Completeness of Antenatal Care Visits among Childbearing Age Women in Rural Indonesia

Ratna Dwi Wulandari¹, Agung Dwi Laksono², Zainul Khaqiqi Nantabah²

¹Faculty of Public Health, Universitas Airlangga Surabaya, Indonesia. Campus C Mulyosari Surabaya, Indonesia.

Abstract

Marital status has a special meaning for pregnant women in Indonesia. A woman who is pregnant without a husband is a disgrace. The purpose of this study was to analyze the effect of marital status on completeness of antenatal care (ANC) visits among childbearing age women in rural Indonesia. The research utilizes the 2017 Indonesian Demographic and Health Survey (IDHS) data. The unit of analysis for women aged 15-49 years old in rural Indonesia. The sample size of 7,783 women. The dependent variable was ANC visits. The independent variable was marital status, education level, parity, wealth status and health insurance. Analysis using Binary Logistic Regression for the final test. The results of the analysis found that married women have 1.834 times higher probability than no spouse women to make complete ANC visits. While women living with partners found no significant differences with no spouse women. Married women have a better chance of making complete ANC visits than no spouse women and women living with partners. Other variables that also affect the completeness of ANC visits are age, parity, wealth status and health insurance. It could be concluded that marital status influences the completeness of ANC visits among childbearing age women in rural Indonesia.

Keywords: Marital status, antenatal care, maternal health, rural.

Introduction

The main causes of death of pregnant women in Indonesia in 2017 are hypertension in pregnancy and postpartum hemorrhage. According to the Directorate General of Health Service, these two causes should be minimized if Antenatal Care (ANC) quality standards can be maintained properly¹.

Previous research found that the low ANC visit in Indonesia is influenced by the level of knowledge of pregnant women about the benefits of ANC visits. The study revealed that more pregnant women were negative. Apart from the low level of knowledge, it is also likely due to the lack of husband support. On the other hand, it was revealed the attitude of the midwife who was deemed unfriendly during the ANC visit². Community perspectives are known to influence people’s access to health services³. Another study found that the distance factor of a pregnant woman’s residence to the ANC also influenced the motivation of the pregnant woman to visit. Great distances make mothers think twice about visiting ANC⁴. Long distances and expensive service costs are known to be one of the barriers to the public access to health services⁵,⁶.

The maternal mortality rate (MMR) is an indicator of the quality of life of women. Indonesia has succeeded in reducing MMR from 390 to 334 per 100,000 live births in 1997. Then experienced success again in 2007 reducing MMR to 228 per 100,000 live births⁷. MMR
in Indonesia experienced a fairly high increase in 2015. According to the 2015 Intercesnal Population Survey (SUPAS) to 305 per 100,000 live births. This position is high among countries in ASEAN. Indonesia is lower than the MMR achieved by Laos, while compared to other ASEAN members, Indonesia is still the highest\(^8\).

Early marriage may be one of the factors triggering the high MMR in Indonesia. In 2018, around 1.2 million women will marry at the age of fewer than 18 years. Nationally, the percentage trend of women aged 20-24 years whose age at first marriage is less than 18 in 2018 has increased. Note this figure when compared with 2015-2017. When compared between rural and urban areas, early marriage is more common in rural areas\(^9\). The phenomenon of early marriage in Indonesia is also supported by cultural practices by ethnic groups in Indonesia\(^10\)–\(^12\).

Based on the background, this study was conducted to analyze the effect of marital status on completeness of ANC visits among childbearing age women in rural Indonesia. The results of the analysis in this study help policymakers to minimize the impact of marital status on the completeness of the ANC.

**Materials and Method**

**Data Source:** The study utilizes the 2017 Indonesian Demographic Data Survey (IDHS) data. The unit of analysis was women aged 15-49 years old who had given birth in the last 5 years in rural Indonesia. Taking the 2017 IDHS sample using stratification and multistage random sampling method, to obtain a sample size of 7,783 women.

**Procedure:** The 2017 IDHS has obtained ethical clearance from the National Ethics Committee. The respondents’ identities have all been deleted from the dataset. Respondents have provided written approval for their involvement in the study. The author has obtained permission to use the data for this study through the website: https://dhsprogram.com/data/new-user-registration.cfm.

**Data Analysis:** The Ministry of Health of the Republic of Indonesia recommends that the ANC during pregnancy be done at least 4 times, namely in the first trimester 1 time, in the second trimester 1 time and in the third trimester 2 times. Based on this information, ANC visits are divided into 2 categories, namely incomplete ANC visits (<4 times) and complete ANC visits (≥ 4 times)\(^13\).

Marital status was divided into 3 categories, namely no spouse, married and living with partners. Other independent variables were age, education level, parity, wealth status and health insurance. Education level consists of 4 categories, namely no education, primary, secondary and higher. Parity consists of 3 categories, namely primiparous (<2), multiparous (2-4) and grande multiparous (> 4). Wealth status consists of 5 categories, namely the poorest, poorer, middle, richer and richest. Health insurance consists of 2 categories, namely not having health insurance and having health insurance.

At the initial stage, the Chi-square test was used for categorical variables and the T-test for continuous variables (age). Because of the nature of the dependent variable, Binary Logistic Regression was used for the final test to determine disparity. SPSS 22 software was used for all stages of statistical analysis.

**Findings:** Table 1 shows the cross-tabulation between marital status and other related variables. Based on ANC visits, all marital status categories are dominated by women of childbearing age who have complete ANC visits (≥4 times). By age, married women have a slightly older average age.

Note: *p <0.05; **p <0.01; ***p <0.001.

Based on education level, all marital status categories are dominated by women with secondary education. Based on parity, no spouse women and women living with partners are dominated by primiparous women, while married women are dominated by multiparous women.

Table 1 shows that based on wealth status, all marital status categories are dominated by women who have wealth status in the poorest category. Based on health insurance ownership, all marital status categories are dominated by women who have health insurance.

Table 2 is the result of the binary logistic regression test. Table 2 informs that married women are 1.834 times more likely than no spouse women to make complete ANC visits (OR 1.834; 95% CI 1.360-2.474). While women living with partners found no significant differences with no spouse women.

</table>
In the Indonesian context, women who become pregnant without a partner are disgrace\textsuperscript{14}. Women who are pregnant outside of marriage do not dare to go out and socialize with the community. This condition encourages not to make ANC visits. So it can be understood if the utilization of ANC is low.

Table 2 shows that age is one of the determinants of complete ANC visits. Table 2 informs that multiparous women are 0.685 times more likely than primiparous women to make complete ANC visits (OR 0.685; 95% CI 0.575-0.815). Grande multiparous women are 0.238 times more likely than primiparous women to make complete ANC visits (OR 0.238; 95% CI 0.181-0.313). This information shows that the higher the parity, the lower the possibility of making complete ANC visits. The effect of parity on the completeness of ANC visits was also found in several previous studies in China, Afghanistan, Guatemala, India, Kenya, Pakistan and Zambia\textsuperscript{15–17}.

Table 2 shows that women with wealth status in the poorer category are 2.073 times more likely than the poorest women to have complete ANC visits (OR 2.073; 95% CI 1.754-2.451). Women with wealth status in the middle category are 2.607 times more likely than primiparous women to make complete ANC visits (OR 2.607; 95% CI 2.113-3.217). Grande multiparous women are 0.238 times more likely than primiparous women to make complete ANC visits (OR 0.238; 95% CI 0.181-0.313). This information shows that the higher the parity, the lower the possibility of making complete ANC visits. The effect of parity on the completeness of ANC visits was also found in several previous studies in China, Afghanistan, Guatemala, India, Kenya, Pakistan and Zambia\textsuperscript{15–17}.

Table 2 shows that women who have health insurance are 1.464 times more likely than women who do not have insurance to make complete ANC visits (OR 1.464; 95% CI 1.286-1.666). This information shows that having health insurance is a supporting factor for a complete ANC visit. Information on the results of this study is consistent with the objectives of the National Health Insurance (NHI), which was initiated by the government since 2014. The NHI is intended to increase public access to health care facilities\textsuperscript{23}. The results of the analysis of this study indicate that NHI is on the right path.

### Conclusions

Based on the results of the study it could be concluded that marital status influences the completeness of ANC among childbearing age women in rural Indonesia. Married women have a better chance of making complete ANC visits than no spouse women. Other variables that also affect the completeness of ANC visits were age, parity, wealth status and health insurance.

Retrospective Analysis of Pattern of Injuries in Road Traffic Accidents: An Autopsy Based Study

Ravi Kumar Sharma¹, Himangshu Das², Anurupa Choudhury³

¹Senior Resident, ²Associate Professor, ³Assistant Professor, Department of Forensic Medicine, Gauhati Medical College and Hospital, Guwahati

Abstract

Accidents are a counter product of modernization and hasty life and are considered as a modern day epidemic. A study was undertaken in Department of Forensic Medicine, G.M.C.H. to study of the pattern of injuries in the victims of road traffic accidents. An autopsy-based, purposive random sampling technique was applied to select the study sample of 150 post-mortem examination cases of road traffic accidents. The data collected during the study period was thoroughly analysed. Results showed that almost 90% (89.33%) of the victims were male. At least 44 (29.33%) victims were of 21-30 years which was the most common age group involved. Early detection of the injury and prompt treatment are necessary in saving the lives of many of these victims. So, it is clear that multidisciplinary approach is required to prevent deaths resulting from vehicular accidents.

Keywords: Road traffic accidents, pattern, injury, fatal, prevent.

Introduction

Worldwide the number of people killed in road traffic crashes each year spastically estimated to be around 1.2 million, while the number of injured could be as high as 50 million.¹ It has been predicted that by 2020, Road traffic accident will rank as high as third among causes of disability adjusted life years lost.² 90% of the world’s fatalities on the roads occur in low- and middle-income countries, even though these countries have approximately 54% of the world’s vehicles. Road traffic accidents are the major cause of unnatural deaths among people aged between 15 and 29 years.

Estimates suggest that in India rate of death per 1000 vehicles is 1.3. According to the National Crime Records Bureau (NCRB)³ of India, the number of accidental deaths in Assam stood at 2384 in the year 2015, While Arunachal Pradesh and Sikkim reported 177 and 75 respectively in the same year. As per bibliometric analysis, our country contributed only 0.7% research papers and articles on road traffic injuries and had less than one article on road traffic injuries per 1,000 road traffic related deaths. Accidents hence have to be studied in terms of an epidemiological model (agent, host and environmental factors) and analyzed in respect to time, place and person distribution.

Material and Method

An autopsy-based observational, cross-sectional study was conducted at the Gauhati Medical College and Hospital, Guwahati from 1st July 2017 to the 30th June, 2018. A purposive random sampling technique was applied to select the study sample of 150 post-mortem examination cases of road traffic accidents subjected to medico-legal autopsy at the department of Forensic Medicine, Gauhati Medical College & Hospital. A pre-tested proforma was used by the investigator for interviewing the police personnels and relatives of RTA victim
Decomposed bodies and have been exempted from the study:

Cases with no definitive history have also been excluded from the study: Data about vehicular accidents were obtained regarding age and gender of the victims, time and place of accident, type of vehicle involved in the accident, the type of injuries sustained, type of road users (pedestrians, riders, or pillions), the outcome of the accident, etc., in a self-designed pro forma (questionnaire). Data collected for each parameter were tabulated and entered into the computer using the Microsoft Excel software for further analysis.

Results

Sex and Age of Victims: The age of the victims ranged from 5 years to 78 years. The victims were divided according to their age into 7 groups. The peak incidence was observed in the age group of 21-30 years comprising of 64 cases (27.24%) followed by 31-40 years age group with 57 cases (24.26%). The age wise distribution of cases is shown in the figure 1.

![AGE DISTRIBUTION OF VICTIMS](image)

**Fig. 1: Age distribution of victims**

It is observed that among the 150 cases studied, 134 were male comprising 89.33% and 16 were females comprising 10.66%. The male to female ratio in the present study is 8.37:1.

Time of Incident:

<table>
<thead>

</table>

Highest number of incidents of the present study occurred in between 6 PM to 12 midnight (36%) followed by almost equal number of cases in between 12 noon to 6 PM (34%).

Period of survival: A huge number of victims died instantaneously or on the spot (31.33%). 11.33% victims died within 1 hour and 23.33% died in between 1 hour to 6 hour.

Type of Victims and Vehicles involved: It is evident from figure 2 that a huge proportion of cases were pedestrians, 55 (36.66%) followed by 2-wheeler rider and occupant.
In the present study trucks and cars are the mostly involved vehicle, 37(24.66%) in case of trucks and 33(22%) in case of cars, followed by bus and motorcycle, each in 23(15.33%) cases. In 5 cases vehicle was not known.

**Pattern of injuries:** The numbers of cases with injuries in different sites of the body are shown in the table no. 2.

**Table 2: Site of injury of the victims**

</tbody>
</table>

In the present study most of the victims (65 or 43.33%) had injury on all regions of the body, followed by Chest+Head+Limbs (52 or 34.66%). None of the victims had injury only on chest. Along with other regions limbs are involved in most of the cases (140 or 93.33%).

Abrasion on the body was found in total 103 cases. Out of these, associated contusion was present in 80 cases and associated laceration was found in 33 cases. In 3 cases no external injuries were found as depicted in figure no. 3.

Lungs were injured in 77 cases (51.34%) among the total 150 cases. It was observed that heart was injured in a total number of 8 cases (5.34%). Liver was involved in 55 cases (74.32%) of total cases with intra abdomino-pelvic injuries. Lacerations were present on 48 cases (64.86%), Contusion on 3 cases (4.05%) and crush injuries over 4 cases (5.4%).
Spleen was involved in 29 cases: In 14 cases injuries were detected over kidney. Out of 14 cases, in 3 cases it was present over right kidney and in 7 cases injuries were present over left kidney while in 4 cases it was bilaterally present.

Cause of death: Coma without haemorrhage and shock is the most common cause of death (41.24%) followed by haemorrhage and shock without coma (32.67%). Death was instantaneous in 13.95% cases.

Discussion

In the present study, peak incidence was observed in the age group of 21-30 years comprising of 44 (29.33%) cases. This is closely followed by age group 31-40 years with 37 (24.66%) cases and 41-50 years with 25 (16.66%) cases. This means that 106 (70.67 % of total) people lost their in prime of their life. Age groups 0-10 years (7 cases), 51-60 years (11 cases) and >61 years (9 cases) have less number of cases. These findings are consistent with Goyal A. et al.(2014)⁴, Reddy N. B. (2014)⁵, Shrivastava S. R. (2014)⁶, Seid M. et al. (2015)⁷, Sharma S. M. (2016)⁸, Singh S.K. (2017)⁹, Smith et al. (2017)¹⁰.
In the present study males comprises a majority (89.33%) compared to female who were only 11%. Male to female ratio is 8.37:1 which is congruent with Goyal A. et al.(2014)\(^4\), Reddy N. B. (2014)\(^5\), Shrivastava S. R. (2014)\(^6\), Seid M. et al. (2015)\(^7\), Sharma S. M. (2016)\(^8\) and Singh S.K. (2017)\(^9\).

The reason for the male majority is the patriarchal setup of our society where men are exposed to outdoor activities to earn bread and other work, travelling between the home and place of work, while women mostly remain indoors at the home involved in household work.

Highest number of cases died in accidents that took place in between 6 PM to 12 midnight (36%) followed by almost equal number of cases in between 12 noon to 6 PM (34%). So total of 70% accidents are found to occur between 12 noon to 12 midnight.

These findings are consistent with NCRB (2015)\(^3\). This can be due to the people returning from place of work and activity at that time leading to traffic rush, fatigue of the people nearing the end of day, improper driving condition in the dark and people visiting commercial places more at that time of the day.

In this study a huge proportion of cases were pedestrians (36.67%) followed by two wheeler rider (32.67%). These findings are consistent with Sharma S.M. (2016)\(^8\).

High incidence of pedestrians (36.67%) among the victims (most common age group 30-41 years) may primarily be due to increasing number of people on the road, ignorance of the people about traffic rules and discipline, lack of proper walking lanes in the streets. Next are the riders of 2-wheeler majority of which comprises of students and young professionals (most common age group 21-30 years) whose enthusiasm for speed and adventure make them prone to such accidents. Poorly maintained roads and lack of balance of the vehicle itself are important factors.

In the present study trucks and cars are the mostly involved vehicle, 37 cases (24.67%) and 33 cases (22%) respectively, followed by bus and motorcycle, each in 23 cases (15.34%). Among these four wheelers are most common. These findings are consistent with, Goyal A. et al.(2014)\(^4\) and Sharma S.M. (2017)\(^8\).

Guwahati city is a huge business and education centre of North East India. So, lots of people travel to and from the city for all sorts of purposes like business and educational purposes. City has increasingly high number of 4 and 2 wheelers with same narrow lane roads. Parking facilities are inadequate, so vehicles are parked on already stressed roads. National highway passes through the outskirts of the city with lots of heavy vehicles. Construction activities are on rise due to economic growth.

In this study majority of victims died within 1 hour of accident including those who died instantaneously (total 42.66%). 35 victims (23.34%) died within 1 hour to 6 hour. Total 115 victims (76.67%) died within 24 hours following accident which is the most crucial period in management.

These findings are consistent with Reddy N.B. (2014)\(^5\).

These findings highlight the importance of the Golden Hour in the management of trauma and emergency. The first hour after any accident is the most crucial and survival increases if care and treatment is provided to victims on the spot and on the way to hospitals.

In this study, incidence of thoraco-abdominal injury among all cases of vehicular accident is 48.7%. In all the cases (150 cases) chest injury is associated with one or more other region injury. In majority of cases (43.33%) all regions of the body are involved. Head injury is associated with total 84.65% cases.

External injuries were found in 150 cases of the study. Among all the cases 4 (2.67%) victims have internal injury without external injury and 35 (23.34%) victims have external injury without internal injury. Abrasion is present in 18 victims and contusion is present in 43 victims. From the above observation it can be said that from external examination of a victim it is difficult to judge the extent of internal injury in a significant number of cases.

Laceration of lung is more common than contusion and bilateral involvement is more common than unilateral injury. Right side involvement is more common than left side. In three case lungs are crushed. Again lung involvement is most common in pedestrians.

Heart was injured in a total number of 8 cases (5.34%), on the basis of naked eye examination and histopathological examination. Laceration is more
common than contusion. In one case heart is found to sustained crush injury. Among the different types of victims, heart is most commonly involved in pillion rider (16.67%). These finding are almost consistent with Reddy et al. (2014)\textsuperscript{5} and El-Menyar (2016)\textsuperscript{11}.

In the present series, liver injuries were observed in 55 cases comprising the highest number of cases. Majority of the cases had involvement of right lobe of the liver and anterior surface of the liver. Similar findings have been described by Gushinge and Kadu (2017)\textsuperscript{12}. In the present study pedestrians have been found to be involved in 14 cases.

There were 29 cases of spleen injuries in almost all circumstances the spleen was lacerated (26 cases). Spleen is the next solid organ after liver to be injured most. Spleen injuries associated with rib fractures have also been reported by Reddy et al (2014)\textsuperscript{5}.

In the present study, kidney was involved in 14 cases (18.91%). Of these 14 cases, 2 cases were lacerated, 9 cases were contused and 1 was crushed. High incidence of kidney injuries was involved in the study of Gushinge and Kadu (2017)\textsuperscript{12}. In the present series majority was lacerated due to blunt force impact resulting from vehicular accidents.

In this study coma without haemorrhage and shock is the most common cause of death (41.24%) followed by haemorrhage and shock without coma (32.67%). Death was instantaneous in 13.95% cases.

**Conclusion and Recommendations**

Vehicular accidents continue to be a growing menace, incurring heavy loss of valuable man-power and human resources, along with a corresponding drain of potential economic growth. Primarily three factors comprise road safety - infrastructure (roadways), vehicle design and human behaviour. So, we suggest following strategies to prevent road traffic incidents -

- Enforcement of traffic laws especially to control speed, use of safety belts and road worthy vehicles should be enhanced.
- Safe crossings and sidewalks or separate paths and lanes for pedestrian and cyclists should be built.
- First aid at the scene of crash and appropriate medical care in emergency rooms is a must to save life of the victim.

Hospitals with trauma units should be built along major highways for quick access for post crash victims.

In modern days of busy life with stress and strains many people are fraught with worries and anxieties. This has a deleterious effect on the power of mental concentration which is very much essential in driving. Another important factor in incidents of road traffic accidents is that people talk on their mobile phone while driving which reduces concentration on vehicle by the driver. So banning of mobile phone while driving which is to be strictly implemented. Another detrimental factor in incidents of vehicular accidents is the influence of alcohol and drugs on the drivers. The use of alcohol measuring gadgets may solve this factor. Value of seat belt and crash helmets is very much important in preventing fatal injuries.

So, it is clear that multidisciplinary approach is required to prevent deaths resulting from vehicular accidents.

The Correlation between Bacteria and Parasite Patterns on Flies with Prevalence of Fly Vector-Borne Disease at the Market and the Landfill in Jember District, Indonesia

Riza Indira Fadillah Zam Zam1, Erma Sulistyaningsih2, Ancah Caesarina Novi Marchiant3

1Graduate Student, Magister Program of Public Health Education, University of Jember, East Java, Indonesia, 2Department of Parasitology, Faculty of Medicine, University of Jember, Jember, East Java, Indonesia, 3Public Health Lecturer, Faculty of Public Health Education, University of Jember, East Java, Indonesia

Abstract

Fly vector-borne diseases are the potential disease that can trigger an outbreak. The fly lives in a dirty place with poor sanitation, such as the market and the landfill. Some pathogens that can be transmitted by flies mechanically were bacteria such as Escherichia coli, Shigella, Salmonella, Vibrio cholera and parasites such as Balantidium coli, Entamoeba histolytica and Giardia lamblia. This study aimed to analyze the correlation between bacteria and parasite patterns on flies and the prevalence of fly vector-borne diseases. This research was conducted from May 2019 to March 2020. The flies samples were collected randomly at each research location, i.e., Tanjung Market and the Pakusari landfill. The bacteria and parasites identifications were carried out at the Microbiology and Parasitology Laboratory, Faculty of Medicine, University of Jember. The data of disease prevalence was collected in a cohort from the health centers around research locations. This study found three bacteria in market samples, 18 cases of fly vector-borne diseases and four bacteria in the landfill samples and 10 cases of fly vector-borne disease. The study indicated a significant correlation between bacteria and parasite patterns on flies with the prevalence of fly vector-borne diseases in the market, but no correlation in the landfill.

Keywords: Bacteria, Fly, Parasite, Vector-borne Disease.

Introduction

Fly vector-borne diseases are the potential disease that can trigger several extraordinary infectious diseases such as diarrhea, typhoid fever, dysentery and cholera. Flies are a type of vector that can carry germs on their bodies. They live close to humans and are often associated with sanitation problems. Environments with poor sanitation tend to attract flies as breeding place and feed them, they including the market and landfill. Those areas are suspected related to the incidence and spread of infectious diseases where pathogens originate from these places.

Fly can transmit the disease to humans mechanically by carrying microorganisms attached to their bodies to such media. Studies reported the pathogens that are transmitted mechanically by flies are Escherichia coli, Shigella, Salmonella, Vibrio cholera and parasites such as Balantidium coli, Entamoeba histolytica, Giardia lamblia. A species of fly, Musca domestica can transmit pathogens such as Campylobacter, E.coli, Salmonella sp., and Shigella sp16. Previous studies on the detection of fly vector-borne diseases found the occurrence of diarrhea, dysentery, typhus and cholera in Jember District 20196. The epidemiological study of vector-borne diseases showed the interconnection of three factors, i.e., human host, infectious agent (parasite, bacteria in

the fly’s body) and the environment where the place of the fly vector life. This study analyzed the role of flies in transmitting vector-borne diseases in Jember Regency, especially in an environment where the flies can breed and live easily, i.e., the market and the landfill.

**Method**

The research was conducted at the Tanjung market and the Pakusari landfill in May 2019 to March 2020. This research has received ethical clearance from the Ethical Committee of Health Research of Faculty of Dentistry, the University of Jember, with the reference number.632/UN25.8/KEPK/DL/2019. The sampling technique was carried out randomly at each location in November 2019. Researchers set a fly trap that was equipped with jackfruit bait with a strong aroma to catch flies. The caught flies were put into a sterile tube containing NaCl30ml and marking each location and divided into two parts. The sample was analyzed at the Laboratory of Microbiology and Parasitology, Faculty of Medicine, the University of Jember. The bacterial identification was performed by selective media culture and several biochemical tests. The identification of parasites was made by microscopical examination. The prevalence data of fly vector-borne diseases was provided in a cohort method from the health service around each research location. It was collected in the period of November-December 2019.

**Research Findings:** Bacterial identification of samples from the Tanjung Market found three types of bacterial patterns that are considered as *Escherichia coli*, *Salmonella* sp and *Shigella* sp. Meanwhile, the samples from the Pakusari landfill showed four types of bacterial patterns, which were suspected as *Escherichia coli*, *Salmonella* sp, *Shigella* sp. and *Vibrio cholerae*, as shown in Table 1 and Table 2.

**Explanation:** value = crosstab value; Asymp. sig = significance value
This study found three patterns of bacteria but no parasite around the market place. The prevalence of fly vector-borne diseases around the market was 18 cases. The statistical analysis using Chi-Square resulted value of 21,000 and a significance value of 0.013, which was fewer than $\alpha$ (0.05), indicated its correlation, as shown in Table 4. Furthermore, this research found four patterns of bacteria and no parasite around the landfill. The prevalence of fly vector-borne disease around the landfill was 10 cases. The statistical test by Chi-Square showed a value of 14,000 and a significance value of 0.082, which was higher than $\alpha$ (0.05), implicated no correlation.

**Discussion**

The method to analyze the pathogen can be performed by microscopic, selective media culture, as well as serological examination. In this research, a selective media culture examination was performed to identify bacteria. The Eosin Methylene Blue (EMB) identified Escherichia coli, the Salmonella-Shigella Agar (SSA) identified Salmonella sp and Shigella sp and the Thiosulfate-Citrate-Bile-Sucrose (TCBS) selected for Vibrio cholerae. For each media (EMB, SSA, TBCS), we conducted several biochemical tests such as Kligler Iron Agar (KIA), Indole test, Methyl Red (MR) test, Voges Proskauer (VP) test, MIO test and citrate test on each sample location. The KIA test on each agar media (EMB, SS, TBCS) measured the ability to produce slope (S), base (B), hydrogen sulfide (H$_2$S) and damp as the basis to identify a particular pattern of bacteria and its growth on each media$^5$. For the identification of the parasite on Giardia lamblia, Entamoeba hitalystica and Balantidium coli was done through the microscopical examination by 1000x magnification.

The sample from the market showed three types of bacteria, i.e., Escherichia coli, Salmonella sp., and Shigella sp, but no parasites. The result is in accordance with the research done by Safitri$^{16}$, which has found the dominant pattern of Escherichia coli, Salmonella sp., Shigella sp, and Staphylococcus bacteria within the fly around markets in Surabaya. Moreover, Escherichia coli bacteria was a group of Coliform bacteria that could stay in the human and cattle digestive tract. In a certain amount, Coliform bacteria could cause indigestion problems like diarrhea. According to Lima et al$^{12}$, E.coli was a pathogen that can cause diarrhea and transmitted to the human through fly mechanically. Escherichia coli, Shigella spp., Salmonella spp. bacteria around the Tanjung Market were found and derived from contaminated foodstuff, fruit and vegetable because of dust and soil exposure.

This research found 18 cases of fly vector-borne disease from around the market. The occurrence of fly vector-borne disease was affected by several aspects as personal and environmental hygiene and environmental sanitation. The dirty environment turns any kind of pathogens to grow and attract fly. The average flight distance of some flies was about 6-9 km from the breeding place$^5$. The population in that area has a high risk of infecting fly vector-borne diseases because bacteria can contaminate the foods and groceries. To keep the cleanliness of foodstuff, they needed to wash them with detergent to reduce the risk of pathogens such as E. coli, Shigella sp., Salmonella sp, to grow, which can be transmitted by the fly. The population who have a good hygiene practice would be prevented from the diseases. Furthermore, the individual with vulnerable conditions and had poor hygiene would be at risk of diseases.

The bacteria found on the flies around the landfill were Escherichia coli, Salmonella spp., Shigella sp. and Vibrio Cholera bacteria, but no parasites. This result was in line with the previous study by Yunita$^{18}$, which has found the Salmonella sp, Providencia, Escherichia and Vibrio in the fly body around the Sukawintan landfill. The typhoid disease occurs due to Salmonella sp infection in the intestinal tract$^{18}$. Salmonella sp in the landfill’s flies was suspected because of the stack of organic and inorganic trash that produced leachate, which can be a suitable medium for the microorganism such as bacteria and parasite to grow. A previous study by Yunita$^{18}$ has found fecal coliform bacteria such as Salmonella sp., Vibrio comma and Shigella in leachate. The pungent smell of leachate attracted flies to come close because they like to pungent smell and dirty place$^{5}$. The fly, which alighted in leachate or waste in landfills, directly carried pathogen bacteria on their bodies. The flies could fly up to 6-9 km$^{12}$. The long flight distance of fly enabled them from the landfill to fly and alight in residential areas around the landfill. The fly which carried pathogen might contaminate food and water, which further can cause diseases such as typhoid fever if consumed by human.

The statistical analysis showed no significant correlation between bacteria and parasites patterns and the prevalence of fly vector-borne disease at the landfill.
The reported vector-borne disease cases from the health care centers around the landfill in specific periods showed that the population around this landfill was avoided from dysentery and cholera. The occurrence of the disease is affected by the interaction between host, agent and environment. Cholera is caused by *Vibrio cholerae*, which is transmitted through contaminated foods and drinks by the fly as a vector. However, the dead *Vibrio cholerae* can not infect and cause disease on humans. However, the bacteria live at an optimum temperature of 18-37°C(10). *Vibrio cholerae* was assumed to be dead before it reached the host, so it would not cause disease around the landfill area. The other presumption was hygiene practice that has been implemented by the population around the landfill. The hygiene practice and healthy life behavior could prevent the individual from many kinds of infectious and transmissible diseases like diarrhea, dysentery, cholera(8).

This research also detected *Shigella sp.* from the landfill sample, but there was no dysentery case reported. The dysentery is an infectious disease caused by *Shigella sp*(4), which can be transmitted by contaminated food and water(16). When the *Shigella sp.* reaches the human digestive tract, the bacteria grow within colon epithelial cells, infect colonic mucosa and spread laterally into the surrounding cells. The infection occurs with a broad range of symptoms from asymptomatic, mild symptoms like watery diarrhea to severe symptoms like stomach cramps, nausea and vomiting, fever, anorexia and bloody feces with mucus(17). Dysentery usually occurred in a dirty environment and poor sanitation area. The residential areas around the landfill have enough distance and space among houses, reducing the risk of fly vector-borne disease transmission in the population. It was assumed that *Shigella sp.* bacteria, which transmitted by a fly vector, did not reach the host. Thus, the population around the landfill was avoided from dysentery.

According to Isma'il(9), the mechanism of disease transmission occurs in several ways, i.e., the way the agent leaves the reservoir, the transmission route to reach host and the port de entry to the host. The fly vector carried pathogen (agent) after leaving the location (reservoir) and went to the residential area would be the risk to cause disease. However, as long as the pathogen carried by fly did not reach to the host or get into the human body, the interaction of disease would not exist. The prevention of infection due to bacteria could be exerted by improving personal hygiene and maintenance of clean food and drink without contamination of pathogens carried by the fly(14). The vector control was also an aspect that was put into a serious concern to prevent the occurrence and transmission of fly vector-borne disease(2).

**Conclusion**

This research found three patterns of bacteria around the market and the landfill in Jember District during November–December 2019, i.e., *Escherichia coli*, *Salmonella sp.*, and *Shigella sp.* The most prevalent cases around the location were diarrhea and typhoid. There was a correlation between the bacterial pattern on the fly and the fly vector-borne disease. The fly was the potential mechanical vector for several vector-borne diseases. We suggested collaborating with the local government or healthcare service with aimed to plan the fly vector control program and fly vector-borne disease prevention, particularly in the area with a high prevalence of the fly vector-borne disease.

Effect of Malaria Parasite on Haematological Parameters: 
An Institutional Experience

Roopak Aggarwal1, Vineet Chaturvedi1, Sanjeev Kumar Singh1, 
Pinki Pandey2, Savita Agarwal1, Jasvinder Singh3

1Associate Professor, Department of Pathology, 2Professor and Head, Department of Pathology, 
3Post Graduate 2nd Year, Department of Pathology, Uttar Pradesh University of Medical Sciences, Saifai, Etawah

Abstract

Objectives: Hematological changes are among the most common complications encountered in malaria. This study analyzes and statistically evaluates the hematological changes as a diagnostic test for malaria in patient with acute febrile illness.

Method: Hundred samples were diagnosed positive by the Leishman’s stained thick blood film. The data were collected from the central lab, Uttar Pradesh University of Medical Sciences, Saifai, Etawah during May 2017 to August, 2019. Laboratory records of people suspected with malaria infection such as fever other signs and symptoms as medical doctor recommended were reviewed.

Results: The finding showed that 100 patients were diagnosed to have malaria by positive smear report by microscopy. Of these were 4 caused by P. falciparum, whereas 96 were caused by P. vivax. No patient with co-infection of P. falciparum and P. vivax were found. The following parameters were significantly lower in malaria-infected patients; red blood cells (RBCs) count, hemoglobin (Hb), platelets count, white blood cells (WBCs) counts, neutrophil, monocyte, lymphocyte and eosinophil counts, while Mean corpuscular volume, Mean corpuscular hemoglobin, Mean corpuscular hemoglobin concentration, neutrophil-lymphocyte ratio (NLR) and monocyte-lymphocyte ratio (MLR) were higher in comparison to non-malaria infected patients. Thrombocytopenia was present in 91% of malaria infected patients.

Conclusion: Patients infected with malaria exhibited important changes in most of hematological parameters with low hemoglobin, platelets, WBCs and lymphocyte counts being the most important predictors of malaria infection.

Keywords: Malaria, hematological parameters, anemia, thrombocytopenia.

Introduction

Since malaria parasites are able to attach to receptors on the red blood cell surfaces, it is expected that malaria parasite have effect on haematological parameters. Changes in blood cell parameters are already a well known feature of malarial infections. Malaria is a major cause of death in the tropical area of the world. Two hundred and nineteen million cases were reported worldwide in 2010[1]. Haematological changes are some of the most common complications in malaria and they play a major role in malaria pathogenesis. These changes involve the major cell types such RBC’S, leucocytes and thrombocytes[2-8]. Malaria infected patients tend to have significantly lower platelets, TLCs, RBCs and Hb level[2-4,6-8].

Fever and other signs and symptoms are known to be sensitive measures of malaria infection but they lack
specificity an positive values especially in areas where malaria is less prevalent \cite{3,9} and it may be difficult to distinguish the signs and symptoms of diseases from other viral or bacterial infections \cite{10}. Typically, microscopic slide examination of peripheral blood remains the most widely used test and is the gold standard for detecting malaria infection \cite{11}.

**Aim:** The objective of this study was to demonstrate the impact of plasmodium *falciparum* and plasmodium *vivax* infections as well as different parasite on blood cell parameters. The haematological parameters (Red blood cells, Leukocytes, Platelets, Haemoglobin level (Hb), Mean corpuscular volume (MCV), Mean corpuscular Haemoglobin (MCH), differential leucocyte count, lymphocyte-neutrophil ratio and monocyte-lymphocyte ratio of patients infected with malaria were investigated.

**Materials and Method**

Hundred samples were diagnosed positive by the Leishman’s stained thick blood film. The data were collected from the central lab, UPUMS, Saifai during May to August, 2017-2019. Laboratory records of people suspected with malaria infection such as fever other signs and symptoms as medical doctor recommended were reviewed.

About 2ml of whole blood was collected from patients via the anticubital vein with sterile syringes and needles, after disinfecting the puncture site with methylated spirit. Few drops of the blood from the syringe were used to make smears (both thick and thin on two different slides respectively) for the diagnosis of malaria parasites and differential white blood cell count. The Leishman staining method was used to stain the thick blood film and the thin film after it was fixed in absolute methanol for two minutes.

The slides were examined microscopically to confirm malaria parasitemia. The rest of the blood sample was emptied into ethylene diamine tetra acetic acid (EDTA) containing 4mg of the K2 EDTA salt. The sample container was inverted several times to ensure proper mixing of the anticoagulant and the blood, for determination of the complete blood count. Blood counts were performed using Sysmex XT-1800i.

The Analyzer provided data on WBCs, RBCs, Hb level, platelet count, MCV, MCH, RDW and five other differentials.

**Result**

The finding showed that 100 patients were diagnosed to have malaria by positive smear report by microscopy. Of these were 4 were caused by *P.falciparum*, whereas 96 were caused by *P.vivax*. No patient with co-infection of *P.falciparum* and *P.vivax* were found, maximum number of cases were seen in the 20-40 years age group. A leishman stained peripheral smear shows many red cells infected with trophozoites [Figure 1(i)], Schizonts and ring forms of *P.Vivax* [figure 1(ii) & 1(iii)]. Higher degree of parasitemia and RBC infected with *P. Falciparum* were seen [figure 2(i) & 2(ii)].
Mean values of RBC’s, WBC, Platelets and all absolute leucocyte components were significantly lower in patients with falciparum malaria compared to those with Vivax malaria and non- Malaria infected groups. Conversely, mean values of MCV, MCH, NL ratio and ML ratio were significantly higher in falciparum malaria than those with vivax malaria and non- malaria infected groups. A mean value of Hb was lower in patients with falciparum malaria than those with vivax and non-malaria infected groups.

**Leukocyte, RBC and Platelet Counts of Patients with P.falciparum and P.vivax:** Leukocyte counts were not significantly different in patients with P.falciparum malaria compared to those with P.vivax infection, for differential leukocyte counts neutrophil count was significantly higher in patients with P.falciparum compared to those with P.vivax infection. For RBC parameters, RBC count was significantly lower in patients with P.falciparum compared to those with P.vivax infection. In addition, other RBC parameters including MCV and MCH were significantly higher in patients with P.falciparum compared to those with P.vivax infection. Platelet count was significantly lower in patients with P.falciparum compared to those with P.vivax.

Discussion

This study confirms that haematological abnormalities in malaria infection are common. The findings in this study showed that during malarial infection there were peripheral blood changes such as anaemia, leucopenia and thrombocytopenia. Leucopenia was frequently seen in the malaria infected patients which was confirmed by other studies that have demonstrated leucopenia\[6,11\] and contrast with other study that had demonstrate leucocytosis\[3\].

Anaemia is one of the most common complications in malaria infection especially in younger children and pregnant women\[12\]. The pathogenesis of anemia during malaria infection is not clearly understood. However it thought to result from the parasite’s primary target on the red blood cell resulting in RBCs destruction, accelerated removal of both parasitized and non-parasitized\[13\], bone marrow dysfunction\[14\] and the level of parasitemia. This study reported a significant reduction of haemoglobin and RBC count whereas MCV, MCH level in patients infected with malaria were higher.

In addition to anemia, a reduction of platelet is another one of the well-known haematological changes observed in patients with malaria. In this study platelet count were significantly reduced in malaria infected patients. Thrombocytopenia occurred in 91% of malaria infected patients. These observations may imply that thrombocytopenia may be a marker of plasmodium infection, patients with thrombocytopenia were also likely to have anemia.

Thrombocytopenia seem to occur through peripheral destruction\[15\], excessive removal of platelet by spleen pooling\[16,17\] as well as platelet consumption by the process of disseminated intravascular coagulopathy (DIC)\[18\]. Immune mediated destruction of circulating platelets has been postulated as a cause of thrombopenia seen in malaria infection. Platelets have also been shown to mediate clumping of P.falciparum infected erythrocyte\[19\]. This could lead to pseudo thrombopenia, malaria infected patients have elevated levels of specific immunoglobulin G(IgG) in the blood which binds to platelet-bound malaria antigens possibly leading to accelerated destruction of platelets\[20\]. Platelet aggregation which is the platelet clumps are falsely counted as single platelets by the analyzer thus causing pseudo-thrombocytopenia\[21\]. Additionally during malaria infection, endothelial activation was activated.
and may contribute to loss of barrier function of the endothelium and organ dysfunction. This process may use platelets and their released proteins as an important regulator of endothelial permeability resulting in thrombocytopenia.\textsuperscript{19}

**Conclusion**

This study can concludes that patients infected with different malarial parasites exhibit important changes and differences in many haematological parameters. The most commonly changed parameters were platelet count, Hb, RBC, MCV, MCH, WBC, neutrophil and lymphocyte counts. Haematological investigation is relatively inexpensive and less technically sophisticated way for malaria parasite detection.

The present study has demonstrated that the haematological parameters are reliable and competent measures to diagnose severity of malaria infection, even at the early stages.

Biofilm Bacteria and Cholesteatoma on Chronic Suppurative Otitis Media

Rosydia Rahmawati¹, Nyilo Purnami², Artono²

¹Researcher, ²Lecturer, Department of Otorhinolaryngology-Head and Neck Surgery, Faculty of Medicine, Dr. Soetomo Teaching Hospital, Universitas Airlangga, Surabaya 60285, Indonesia

Abstract

Background: Chronic suppurative otitis media (CSOM) possibility to cause morbidity and mortality. Germ infections were a major factor in the long-standing inflammation of CSOM. Cholesteatoma is an epithelial cyst that containing keratin desquamation. The cholesteatoma present in CSOM patients is a kind of acquisita with several theories that have been believed to be the basis of its formation.

Objective: To explain the correlation between bacterial biofilms and cholesteatoma in CSOM.

Method: We performed the prospective collection of tissue during mastoidectomy surgery from CSOM patient. The tissue samples divided into two groups, cholesteatoma and non-cholesteatoma. All tissues group processed for scanning electron microscopy (SEM) analysis. The SEM results will be categorized into positive and negative bacterial biofilms.

Result: Statistical analysis using logistic regression test had p = 0.027 and risk ratio = 5.55. That means there was a significant correlation between bacterial biofilm and cholesteatoma in CSOM patients (p <0.05). CSOM with cholesteatoma has obtained the risk of bacterial biofilm by 5.55 times compared to CSOM without cholesteatoma.

Conclusion: There was a correlation between bacterial biofilms and cholesteatoma in CSOM patients. A quarter of cholesteatoma showed positive biofilms. CSOM with cholesteatoma has a risk of positive bacterial biofilm.

Keyword: Chronic Suppurative Otitis Media, Cholesteatoma, Bacterial Biofilm.

Introduction

Chronic suppurative otitis media (CSOM) possibility to cause morbidity and mortality that remains a major health problem in worldwide. Morbidity and mortality are caused by cholesteatoma in patients with CSOM. Cholesteatoma in CSOM is a decent media for biofilm bacteria. Biofilm bacteria in cholesteatoma are resistant to antibiotic administration resulting in persistent otorrhea that makes a wider damage and even more severe complications. This makes more complicates of the healing process CSOM patients with cholesteatoma.

The incidence of CSOM in Indonesia (1994-996) was to be about 8.36 million people and the prevalence of CSOM is generally about 3.8%. Research at the Regional General Hospital of Dr. Soetomo in 007-2008 got 61 cases of danger CSOM type that contains cholesteatoma and performed mastoidectomy surgery.

Cholesteatoma is an epithelial cyst that containing...
keratin desquamation. The cholesteatoma present in CSOM patients is a kind of acquisita with several theories that have been believed to be the basis of its formation. Cholesteatoma with infection is a synergy. Cholesteatoma, when formed are will continue to expand and absorb the water, therefore it is moist and invites infection. Debris cholesteatoma is a good culture medium for bacteria.

Germ infection is a major factor in the long-standing inflammation of CSOM. Some bacteria could be attached to the interface area, doing adhesions, aggregate and secrete the polysaccharide exopolymers that will form the glycocalyx matrix into biofilms. Germ infection is a major factor in the long-standing inflammation of CSOM. Some bacteria could be attached to the interface area, doing adhesions, aggregate and secrete the polysaccharide exopolymers that will form the glycocalyx matrix into biofilms. Biofilm bacteria get enough nutrition and have the ability to survive from unfavorable environments such as the body’s natural response. Biofilm bacterial resistance to antibiotic administration is suspected through several mechanisms, namely: failure of penetration, decreased growth rate, metabolic activity and new phenotypic variations. The growth of biofilm bacteria will lead to chronic infection characterized by inflammation and persistent tissue damage. These chronic infections persist despite antibiotic therapy and inflammatory responses and immunity from patients.

Research of biofilm bacteria on cholesteatoma of CSOM patients directly using electron scanning electron microscopy (SEM) that until now has not been done yet in Surabaya. From the above description researchers intend to conduct a study whether there was a correlation between bacterial biofilm and cholesteatoma in patients with CSOM who performed mastoidectomy surgery.

Method

This research was an observational analytic research. This type of analytical research was used to observe the association between biofilm bacteria and cholesteatoma in CSOM. This study used a cross-sectional design that the data collection of biofilm bacteria and cholesteatoma in CSOM was performed simultaneously. The research was conducted in November 2013 to June 2014 at Lotus Room of Surgical Installation Center Dr. Soetomo Teaching Hospital, Surabaya and Technical Service Unit of Electron Microscopy Faculty of Medicine Universitas Airlangga.

The sample (N=33) of this research was CSOM patient which treated in Outpatient unit of otorlaryngology Dr. Soetomo Teaching Hospital that planned a surgery mastoidectomy in invasive blood pressure (IBP) Dr. Soetomo Teaching Hospital. Tools for taking specimens (examination material) during mastoidectomy surgery was curettage & forceps. Biofilm bacteria examination tool was SEM JEOL brand and JSM-T100 Scanning Microscope that made in Japan. The specimen drying apparatus was a Critical Point Drying (CPD) and coating device with Vacuum Evaporator. The required material was 2% Glutaraldehyde fixation solution, buffer phosphate, osmic acid and alcohol of various concentrations. Amyl acetate was a preservative and pure gold as a coating.

During mastoidectomy surgery at Dr. Soetomo Teaching Hospital, the operator takes a pathological tissue in the form of granulation tissue or cholesteatoma then inserted in 2% of glutaraldehyde fixation solution and stored in a cooler temperature of 4°C for less than 2 hours. All the data collected were tabular and statistically, that processed using SPSS (SPSS. Inc. Chicago IL). It was conducted an inferential analysis to determine the correlation between bacterial biofilm and cholesteatoma in CSOM patients. The data obtained was nominal that will be analyzed statistically with logistic regression technique (α = 0.05).

Results

Characteristics of Research Subject: In this study obtained the youngest age was 8 years and the oldest 61 years, while the mean age was 25.78 years (SD = 13.90). The most age group was 11-20 years with 15 (45.45%) patients. The distribution based on sex was obtained by compared them, male: female = 1.1: 1. Most of the age group was the male with 17 (51.50%) patients. Clinical characteristics of CSOM patients in this study was include type of perforation, audiometry results, mastoid photo and complications. Clinical characteristics of patients with CSOM-save type has obtained the result that central perforation (50%) as the most perforated type. Hearing loss conduction type (58.34%) was the most number. Results of the most widely obtained mastoid image were the sclerotic type (75%) (Table 1). Clinical characteristics of patients with CSOM danger-type the total perforation was obtained in 11 (52.38%) patients. Results of mastoid images in the form of cavities were obtained 9(42.86%) patients and four patients not performed mastoid photos but computed tomograph (CT) scan. Fistel retro-auricular was the most common complication (Table 1).

The types of canal wall down mastoidectomy surgery was performed on 21 (63.64%) patients and mastoidectomy surgery canal wall up performed on 12 (36.36%) patients. Non-cholesteatoma tissue (granulation) was obtained in 17 (51.52%) patients and total cholesteatoma tissue was obtained in 16 (48.48%) patients (Table 2). The result of examination of 33 operational tissues was obtained biofilm (+) on 18 (54.54%) tissue and biofilm (-) at 15 (45.46%) network (Table 3).

Correlation Results of Bacterial Biofilm Analysis and Cholesteatoma in CSOM: The results of bacterial biofilm examination on cholesteatoma and non-cholesteatoma tissue. The examination was performed on 33 tissue mastoidectomy that resulting 16 cholesteatoma tissue and 17 non-cholesteatoma tissues. The results of the cholesteatoma tissue examination were obtained by biofilm bacteria (+) by 12 (75%) tissues and bacteria biofilm (-) by 4 (25%) tissue. The results of non-cholesteatoma tissue examination were obtained 6 (35.35%) biofilm bacteria (tissue) and biofilm bacteria (-) of 11 (67.9%) tissues. The statistical test with logistic regression was obtained p = 0.027 and risk ratio = 5.55. It means that there was a correlation between bacterial biofilm and cholesteatoma and without cholesteatoma with bacteria biofilm on the mastoid mucosa. The study also showed higher biofilm bacteria incidence in CSOM with cholesteatoma than CSOM without cholesteatoma. The difference between the two groups of CSOM on the presence of biofilm bacteria was statistically significant.

The results of this study support the theory that biofilm bacteria that have an important role in the aggressiveness of cholesteatoma in CSOM. Biofilm bacteria were obtained more in the cholesteatoma group than in the group without cholesteatoma with a risk ratio value of 5.55. This suggests that cholesteatoma in CSOM was a risk factor for the formation of biofilm bacteria.

The results of this study obtained bacteria biofilm (-) on 4 (25%) tissue cholesteatoma. Based on previous research bacteria biofilm is often found in cholesteatoma and there was a statistically significant relationship, however, biofilm bacteria was not a typical structure in cholesteatoma. Other causes of bacteria were not obtained in the form of biofilm because bacteria separate themselves from colonies into planktonic forms. This possibility occurs in mature biofilms and favorable environmental conditions.

This research has obtained a bacteria biofilm (+) on 6 (35.3%) of non-cholesteatoma tissue. This result was not a new discovery because it was also found in previous studies with a percentage of 14% - 54.5%. This due to the humid and warm conditions in the middle...
ear, ear canal and mastoid cavity in CSOM. CSOM without active-phase cholesteatoma was a good medium for bacteria to attach to the interface area. The type of bacteria that infects could also affect the formation of biofilms. Although the number was small its needed to be watched by otolaryngology specialists.

The characteristics of age were in accordance with WHO (2004) data which states that the prevalence of CSOM based on surveys in some countries that obtained in many school-age children. The incidence of CSOM with cholesteatoma in the United States of children aged 10-19 was found in 9.2 cases in 100,000 population. Similarly, in Israel, there was the incidence of CSOM with cholesteatoma in children aged 1-15 years by 39 cases in every 100,000 population.

Central perforation was including the safe type of CSOM because it is present a pars tensa and all edges of the perforation still have the rest of the tympanic membrane. Group of dangerous CSOM types are 3 patients who do not do audiometric examination because of patients with intracranial complications that do not meet the requirements of audiometric examination. Hearing loss in this study was similar to some previous studies. Rambe (2002) reported a type of hearing loss from 94 ears of CSOM patients who were conductive deafness was 75 (79.8%) of the ear, deafness was 16 (17%) ear and nerve deaf was 3 (3.2%) ear.

Results of the mastoid photo on most dangerous-type of CSOM was the form of a cavity. The shape of the cavity in the mastoid photo was due to the process of bone destruction as a result of the interaction between cholesteatoma and various inflammatory mediators. The results of radiological evaluation of this study were in accordance with previous research in patients with dangerous-type of CSOM that has obtained the description of destruction by 51 patients, sclerotic in 8 patients, while 9 patients performed CT scan. Fistel retroauricular were almost always due to cholesteatomas that not adequately treated.

The number of complications in this study was more than the research in the same place that shows patients of dangerous-type of CSOM by 39% that experienced complications. The study reported a cerebral abscess as the highest number of 28% followed by fistel retroauricular and subperiosteal abscess respectively 24%. There was no definite factor to explain the occurrence of the different complications experienced by each patient. However, this possibility due to the immune system between different individuals, the delay that came to the doctor, inadequate therapy and the possibility of genetic involvement.

Operation mastoidectomy canal wall down was breaking down meatus acusticus externus (MAE) posterior wall that separates the tympanic cavity with the mastoid cavity. Mastoidectomy operation of canal wall up trying to maintain MAE posterior wall. This complication might be due to the role of inflammatory mediators that could stimulate proteolytic enzymes resulting in bone destruction around granulation. In addition, complications could occur hematogen.

Cholesteatoma that associated with CSOM was a type of acquisition. Cholesteatoma causes erosion of the affected bone through the effects of suppression by keratin debris accumulation as well as the mediation of osteoclast-mediated enzyme-mediated by inflammatory mediators. Bone resorption possibility causes the destruction of the mastoid trabeculae, oleic erosion, labyrinth fistula, Nervus VII (N VII) exposure, duramater and lateral sinuses.

In this study, the tissue with a positive biofilm found the form of coccus bacteria clustered and surrounded by the formation of amorphous materials in the form of glycocalyx. While on the network with negative biofilm found the formation of bacteria coccus but not clustered or shaped sesil and not glycocalyx formation. This study was in accordance with previous studies conducted on the middle ear tissue of CSOM patients performed tympanomastoid surgery.

Conclusion

There was a correlation between bacteria biofilm and cholesteatoma in patients with CSOM. A quarter of cholesteatoma showed positive biofilms. Also, cholesteatoma was a risk factor for the formation of biofilm bacteria.

Ethical Clearance: This research involves participants in the process using a questionnaire that was accordant with the ethical research principle based on the regulation of research ethic regulation. The present study was carried out in accordance with the research principles. This study implemented the basic principle ethics of respect, beneficence, non-maleficence and justice.
Conflict of Interest: The authors have not found any conflict of interest related to this research so far.

Impact of Health Care Sector on Indian Economic Growth and Challenges: A Socio-Legal Analysis

Rubi Talukdar¹, Prabir Kumar Pattnaik²

¹Assistant Professor, ²Professor, Siksha ‘O’ Anusandhan National Institute of Law, Siksha ‘O’ Anusandhan Deemed to be University, Khandagiri, Bhubaneswar; Pin-751030, Odisha, India

Abstract

A large quantity of India’s population is reduced to destitution because of high coverage health-care expenses and also suffering from antagonistic consequences of poor health care services. India has accomplished several gains in the field of Health since the new millennium, such as, life expectancy at birth has increased, the infant mortality and maternal mortality ratio has fell down and the spread of contagious diseases such as HIV/AIDS has been controlled etc. Again WHO, recently officially declared India free from maternal and neonatal tetanus and also polio free. But at the same time, among the five BRICS Nations, namely (Russia, Brazil, South Africa, China and India), India is considered as the poorest performer on the health indicators. India has failed to sufficiently protect its citizens against poor quality of health care as well as financial risks associated with health expenditure.

Health Care Industries of a Country can play crucial roles not only in providing quality care and improving access to medicines for the citizens, but also in developing economic growth of the Country. Again, as it is universally accepted that Health is magnificent and efficacious investment for the economic growth of a Nation, this paper will analyze several major challenges that India need to be addressed, most notably the poor and ineffective regulation of the country, the rapid growth of commercialization of health care services, inadequate public expenditure along with very low level of public expenditure. Here the approach of Judiciary towards the various challenges surrounding the health care services in India will also be discussed.

Keywords: Health, Drugs, rules & regulations, Public Expenditure, Judicial approach

Introduction

The Union Government of India has reported numerous strategy activities, for example, The National Health Policy, 2017 (NHP, 2017) seeks to reach everyone in a comprehensive integrated way to move towards wellness. It aims at achieving universal health coverage and delivering quality health care services to all at affordable cost. India has recorded a few gains in human services part since the new thousand years. For instance, life expectancy at birth has ascended from 62.5 years (in 2000) to 66 years in 2013²; maternal death rate tumbled to 167 for each 100000 livebirths from 301 for every 100000 livebirths in the middle of 2001 and 2013³; the spread of HIV/AIDS has been controlled. WHO authoritatively pronounced India polio free in 2014 and in 2015 announced India free of maternal and neonatal tetanus.

Be that as it may, then again, because of various instances of hardships in health care administrations, individuals in India are confronting challenges for example catastrophe of sterilization death (Chhattisgarh),
incurred visual deficiency because of cataract operation (Punjab), demise of 100 people groups from utilization of illegal alcohol (Mumbai), expanding number of dengue cases all through the nation etc.4,5 India represents 27% of all the neonatal death and 21% of all the child deaths (younger than 5 years) in the world.6 Furthermore, over 6% of ladies are seriously undernourished which is among the most astounding in low-income and middle-income countries.7 The normal age of an individual having their first heart attack is 50 years, in any event 10 years sooner than in developed countries8. Among the five BRICS Nations, to be specific (Russia, Brazil, South Africa, China and India), India is considered as the poorest performer on health indicator.9 Despite a higher salary for every head and two decades of supported monetary development, the nation has fallen behind Bangladesh and Nepal on numerous health indicators. India has neglected to sufficiently ensure its residents against money related dangers related with health care expenses and keep on driving millions into poverty.10

As Health is eminent and effective venture for the financial development of a Nation, there are a few noteworthy difficulties that India should be tended to:

Expanding expenses of medications and unreasonable utilization of innovation: The Indian Pharmaceutical retail market, dissimilar to developed markets like Europe and US, is commanded by brandedgeneric items. At the point when the market is pegged at Rs. 87000 crore every year, the vast majority of the items accessible in the market are branded items sold by the private firms.11 The Government of India spending just around 0.1% of GDP on Government supported medications. So as to enable the client to purchase a less expensive however quality item, the Jan Aushadhi Campaign was propelled by the Government in 2008. The point was to give 361 medications in their exhaustive structure at sensible procedure through Government-run-pharmacies.12 The Government additionally embraces the solution of conventional medications in the public health facilities and furthermore gives the monetary allowance to get fundamental drug that ought to be conveyed at public health facilities free of expense through the National Rural Health Mission.13 The Department of Pharmaceuticals has drafted another pharmaceutical policy in 2012, that proposes to adjust the requirement for value command over prescription. The Drugs (Prices Control) Order of 2013 tries to authorize the costs of imperative prescriptions and controlled mass medications and details to ensure their accessibility in the Country.14 However, legitimate execution of these activities has been conflicting and shifted in State to State. The arrangement to build up in excess of 600 conventional medication drug stores by 2012, however against it just 170 drug stores had been opened in chosen States, of which 99 drug stores were workable, in October 2014. As of late, under Pradhan Mantri Jan Aushadhi Yojana (PMJAY), so as to make quality medications accessible at sensible costs to individuals, it has been chosen to open 3000 Jan Aushadhi Stores the nation over before the finish of 2017.15

Again Indian Medical Device Industry is likewise muddled. About 99% of medical devices in India are not controlled, for example, glucometers, ultrasound machines, endoscopes and ventilators and so on. Under the Medical Devices Rules, 2017, just around 20 devices, (for example, stents, orthopedic inserts, visual focal points and so forth) were covered among around 5000 sorts of medical devices in the market.16

Weak governance, accountability and ineffective regulation of the Country: The composers of the Constitution of India, referenced that among the three lists under Seventh Schedule, ‘health’ enrolled under the State list, with the goal that it is the prime duty of the State Governments to convey appropriate and viable health care services to the general population. Be that as it may, both the Central and State Governments need to work connected at the hip to guarantee effective health care delivery services, as right around 33% of subsidizing for medicinal services originates from the Central Government. One most significant obstruction of the wellbeing administration of our nation is that there is an insufficient combination between different offices inside the Ministry of Health further more, Family Welfare that manage wellbeing administrations, medicinal training, family welfare and different services identified with wellbeing, for example, services the individuals who manage water and sanitation. The Government of India, in the previous 6 years, presented a few new Laws and guidelines to strengthen administration of the social insurance framework in the nation, yet these laws and guidelines are not appropriately executed. For instance, the Clinical Establishment Act, 2010, which accommodates enrollment and guideline of clinical foundations and endorses least measures of offices and administrations to be given by them, has been authorized by just 9 of 29 States and the greater part of the Union Territories of India. The Mental Health Care Bill-2013 includes extraordinary measures to be embraced by
the Government guaranteeing everybody appropriate to get to emotional wellness care and treatment from government run or supported administrations. This progressive enactment was presented in Rajya Sabha and till date sitting tight for enactment. Responding to a Supreme Court of India’s order, The Central Government of India, in 2013, presented new principles for clinical preliminaries to affirm the security when testing new medications. Anyway the extent of these guidelines isn’t clear and explicit. As of late, the amended Medical Devices Rules are required to have sweeping effect on the therapeutic devices industry as this is the primary enactment in India managing medicinal devices. For this, the players engaged with the assembling, bundling, testing, dissemination, deal and import of medicinal gadgets must need to get acquainted with the new guidelines and need to actualize the significant arrangements to their business.

Low Public Expenditure on Health: The total expenditure on health per head in India tumbled from 4.5% of GDP in 2004-2005 to 4.0% of GDP in 2013-2014. However during this equivalent period, genuine open use per head expanded by 40%-a lot of this development was accomplished by 2009-10, with virtual stagnation since 2010-2011. In spite of this expansion, public health expenditure use as an extent of GDP stays low, at simply 1.28%of the Nation’s GDP in 2013-2014.

Public Health Expenditure is added to by both the Central and State Governments, leaving monetarily more fragile States increasingly powerless to low general wellbeing ventures. In spite of the fact that the Twelfth Five Year plan (2012-17) had required a change in perspective and suggested the Central Plan consumption (the Central Government’s help to State Governments for their yearly plans) to increment by about 34% consistently, use by the focal government has expanded by under 1% every year between 2008-09 and 2012-13. Then again, the genuine State consumption on wellbeing, for example in the wake of considering, has expanded by 7% per year. As an outcome, the focal government’s offer in general wellbeing use has stayed under 30% since 2010 and has decreased continuously. Spending discharges from the focal government are frequently said to be founded on the reserve absorptive limits of the states and in light of the fact that many state governments in India neglect to utilize dispensed assets inside the monetary year, genuine discharged spending plans are regularly a lot littler than promised. Although now and then outfitted as purposes behind diminishing budgetary allotments, these low absorptive limits may essentially reflect basic shortcomings in the health services framework that should be tended to with more resources and an alternate way to deal with arrangement and delivery of care.

India’s current foundation is sufficiently not to take into account the developing interest. While the private segment rules human services conveyance the nation over, a greater part of the populace living beneath the destitution line are dismissed in some way or another. They can spend Rs 47 every day in urban zones, Rs 32 every day in provincial territories and these individuals keep on depending on the less financed and less staffed open area for its human services needs, because of which their medicinal services needs remain neglected. Additionally, most of medicinal services experts happen to be focused around urban territories where purchasers have higher paying force, leaving country regions underserved, as the table beneath uncovers. India clings to the world normal in number of doctors, still 74% of India’s specialists take into account 33% of the urban populace, or close to 440 million individuals inside a nation with populace of in excess of a billion.

Judicial Approach towards ‘Health care’ in India: Health is regularly considered as a scientific discipline that requires ability, information and expertise of medication limited to the medicinal experts and researchers however it incorporates financial and political determinants just as characterized by the WHO. Right to health has been regularly constrained to right to health care that has frequently kept to the evenhanded discipline that requires ability, information and expertise of medication limited to the medicinal experts and researchers however it incorporates financial and political determinants just as characterized by the WHO. Right to health has been regularly constrained to right to health care that has frequently kept to the evenhanded discipline that requires ability, information and expertise of medication limited to the medicinal experts and researchers however it incorporates financial and political determinants just as characterized by the WHO. Right to health has been regularly constrained to right to health care that has frequently kept to the evenhanded discipline that requires ability, information and expertise of medication limited to the medicinal experts and researchers however it incorporates financial and political determinants just as characterized by the WHO. Right to health has been regularly constrained to right to health care that has frequently kept to the evenhanded discipline that requires ability, information and expertise of medication limited to the medicinal experts and researchers however it incorporates financial and political determinants just as characterized by the WHO. Right to health has been regularly constrained to right to health care that has frequently kept to the evenhanded
broaden restorative help for safeguarding human life. Disappointment with respect to an administration emergency clinic to give auspicious medicinal treatment to an individual needing such treatment, results infringing upon his right to life ensured under Article 21.

In State of Punjab v. Slam Lubhaya Bagga, [(1988) 4 se c 117] Hence, the right of a citizen to live under Article 21 throws on commitment on the State. So it is for the State to tie down health to its resident under Article 47. The Court additionally held that the State can neither inclination nor state that it has no commitment to give medicinal facilities. In the event that that were so it would be the infringement of Article 21. No State or nation can have boundless assets to spend on any of its undertakings. That is the reason it just favors extends that seem attainable. Similar remains constant for giving medical facilities to its residents. Arrangement of facilities can’t be boundless. It must be to the degree that funds license. In the event that no scale or rate is fixed, at that point on the off chance that private centers or medical clinics increment their rate to extreme scales, the state would be undoubtedly repay the equivalent. The guideline of fixing of rate and scale under such an approach is legitimized and can’t be held to damage Article 21 or Article 47 of the Constitution.

**Conclusion**

India is a land loaded with open doors for players in the medical device industry. India’s health care services industry is one of the quickest developing parts and in the coming 10 years it is relied upon to reach $275 billion. The nation has likewise turned out to be one of the main goals for top of the line demonstrative administrations with colossal capital venture for cutting edge indicative offices, in this way obliging a more noteworthy extent of populace. In addition, Indian health care consumers have turned out to be increasingly cognizant towards their health care services upkeep. Indian medical services area is tremendously enhanced and is loaded with circumstances in each section which incorporates suppliers, payers and therapeutic innovation. With the expansion in the challenge, organizations are hoping to investigate for the most recent elements and patterns which will have positive effect on their business.24

The Central government ought to contribute towards reinforcing the state health care framework system, give specialized help and money related impetuses, specifically to failing to meet expectations states and boost conspires that are adaptable in their application to oblige the extraordinary varieties between states. In the meantime, the states must take advantage of the expanded portion of expense incomes and work towards expanding the general wellbeing consumption. Networks must be effectively enabled to connect with this extreme vision of medicinal services. Conveying on its guarantee of guaranteeing a healthy India ought to be the highest need of the Indian Government. We trust that, when India achieves the achievement of 75 years of autonomy in 2022, no Indian ought to be denied their fundamental right to great quality health care services because of lack of administrations or facilities and no Indian should confront impoverishment because of health care.

Effect of Trunk Extensor Muscle Fatigue on Postural Stability in Women Undergone Lower Segment Cesarean Section

Rutuja Malavde¹, Amrutkuvar Rayjade²

¹Intern, Krishna College Of Physiotherapy, Krishna Institute Of Medical Sciences, Karad, ²Associate Professor, Department Of Musculoskeletal Sciences, Krishna College Of Physiotherapy, Krishna Institute Of Medical Sciences, Karad

Abstract

Background: Cesarean delivery involves thorough disruption of the anterior abdominal wall and is related with greater reports of postpartum pain and slower more painful recovery than vaginal birth. An increase in the inter-recti distance puts postural stability in hazard. It also weakens the abdominal muscles and influence their functions. This can result in an altered trunk mechanics, impaired pelvic stability and postural change, that leaves the lumbar spine and pelvis more susceptible to injury. Low endurance of back and hip muscles has been reported in women after delivery which can result into pelvic girdle pain and lumbar pain. There is lack of research on this topic, indeed this made us to study the effect of trunk extensor muscle fatigue on postural stability in women undergone lower segment cesarean section.

Objectives: To find the effect of trunk extensor muscle fatigue on postural stability in women undergone lower segment cesarean section.

Method: In this observational study, 37 women undergone cesarean section in age group 22 to 35 years were included. One- Leg Standing Balance Test and Functional Reach Test were the major outcome measures to assess postural stability in three conditions: No fatigue, Fatigue and Recovery Condition. Borg 6-20 scale was used to check the exertion level after inducing fatigue in women. Later, data was collected and analysis was done.

Result: Both One- Leg Standing Balance Test and Functional Reach Test showed a decrease from No fatigue condition to Fatigue condition. The results indicate that postural stability was significantly reduced in the Fatigue condition as compared to the No fatigue condition.

Conclusion: Trunk extensor muscle fatigue significantly reduces the postural stability in women undergone lower segment cesarean section.

Keywords: Cesarean Section, Postural stability, Muscle fatigue, One-leg standing balance test, Functional reach test.

Introduction

Postural control is a complicated task which requires the integration of visual, vestibular and somatosensory inputs from all over the body to determine the position and motion of the body in pace and also the ability to generate forces to control body position¹.

Muscle fatigue is an acute and activity- induced decline in the muscle force or muscle power². Muscle
fatigue is an important condition which comprises of sensorimotor integration and hence, postural control. Postural muscle fatigue such as trunk extensors may occur in many labour conditions demanding high tension in the muscle group. Such tension represents an important accommodating factor of the spinal alignment and stability produced lumbar discomfort or pain.

As there is an occurrence of changes in a pregnant women, static stability may get affected due to gestational weight gain and its asymmetrical distribution in the anterior abdominal region, adaptive postural changes necessary for the antero posterior center of gravity (COG) location readjustment, as well as the increased joint laxity, also there is a change in the transient stability in the postpartum period due to increased connective tissue laxity and altered posture. Along with the pregnant women, postpartum women’s postural stability may also get affected due to inadequate sleep and sleep deprivation. There are many other factors that may affect the abdominal muscle function after pregnancy, including the mode of delivery and physical activity levels. Cesarean delivery involves thorough disruption of the anterior abdominal wall and is related with greater reports of postpartum pain and slowers more painful recovery than vaginal birth.

There are several physiological processes occurring during pregnancy that has an impact on the mother’s musculoskeletal system. There is a substantial stretch of the abdominal muscles and common occurrence of increase in the inter-recti distance. Throughout the mother’s body hormones act on connective tissue, which result in joint laxity, particularly in pelvis. There is an increase in the importance and role of muscular stabilization, which is provided by the core muscles including, abdominal muscles.

After pregnancy many women experience an increase in the inter-recti abdominal muscle distance as a result of stretching and thinning of the linea alba. A widening of >2.7 cm at the level of umbilicus is considered as a pathological diastasis of therectus abdominis muscle (DRAM). Hormonal elastic changes of the connective tissue, mechanical stresses placed on the abdominal wall by the growing fetus and the displacement of abdominal organs can lead to occurrence of DRAM. It is very common and it can have negative health consequences for women after pregnancy. The abdominal wall plays an important role in maintaining posture, trunk and pelvic stability, respiration, trunk movement and abdominal viscera support. An increase in the inter-recti distance puts this function in hazard. It also weakens the abdominal muscles and influence their functions. This can result in an altered trunk mechanics, impaired pelvic stability and postural change, that leaves the lumbar spine and pelvis more susceptible to injury.

DRAM is quite common and is associated with the risk factors such as multiparity, maternal age and childcare responsibilities. There is an opposing evidence linking DRAM with weight gain and high body mass index (BMI).

Laxity in the supporting tissue is the source of muscle strain during actual birth. During Cesarean delivery, the lower back muscles are used, along with pelvic muscles and abdominals. Low endurance of back and hip muscles has been reported in women after delivery which can result into pelvic girdle pain and lumbar pain. Consequently, this study focuses on how trunk extensor muscle fatigue affects postural stability in postpartum period.

**Material and Methodology**

This study was done to find the effect of trunk extensor muscle fatigue on postural stability in women undergone lower segment cesarean section. The study was carried out in Krishna Physiotherapy Out Patient Department, Karad. An approval of the study was obtained from the institutional ethical committee of Krishna Institute Of Medical Sciences Deemed University. The purpose of the study was explained to the participants and consent form was taken. 37 women who underwent lower segment cesarean section was taken from Karad for study. The inclusioncriterias were those women undergone single Cesarean section 6 months back in age group between 22 to 35 years and those who do not perform core muscle exercise on regular basis. The exclusioncriterias were those women who underwent multiple cesarean section, having any musculoskeletal dysfunction and those having any psychological problem. One- leg Standing Balance Test and Functional Reach Test were the major outcome measures to assess postural stability. Order of testing was One- leg standing balance test followed by Functional reach test under three experimental conditions, No fatigue, Fatigue and Recovery. The dominant leg was first determined by asking the subject to kick a ball placed on the floor in front of her and the ‘kicking limb’ was considered.
as ‘dominant leg’. For One-leg standing balance test, subject was standing barefoot on a firm stable surface on the dominant leg with the other leg raised, arms crossed over the chest. Test was performed under eyes closed condition to avoid vision from interfering with the task of postural control. Time of one-leg standing was recorded in seconds using a stop watch. Test was terminated when the women had used her arms (i.e., uncrossed arms), used the raised foot (moved it towards or away from the standing limb or touched the floor), moved the weight bearing foot to maintain balance (i.e., rotated foot on the ground), or opened eyes. Three trials were given and best of them were taken as the final reading. Functional reach test was performed by the subject standing next to but not touching a wall with dominant arm closer to the wall at 90 degrees of shoulder flexion with a closed fist. Women had selected a comfortable stance with feet shoulder width apart. To keep foot positions and base of support constant, during reassessments in all three conditions, footprints were marked. The subject was asked to reach forward as far as possible without taking a step. The distance between the start and the end position was measured using the third metacarpal as the reference point and was recorded in centimeters. Three trials were given and the average of the three trials was taken as the final reading. To induce fatigue of trunk extensor muscles subject was made to perform dynamic trunk extensions until maximum exhaustion. For this task subject lied prone on a bench with the upper body unsupported in the horizontal plane and the lower limb secured to the bench with straps at the hips, knees and ankles. During the test, arms were held across the chest. The subject was instructed to raise her upper body to a horizontal position with the head and neck in neutral position and then lowering it back down. Time of 40 beeps/min was recorded using digital metronome application to ensure that the subjects perform the extensions at a consistent rate. Women were instructed to perform the extension movement as many times as possible till she was unable to continue due to muscle fatigue. After termination of the task postural stability was assessed immediately (Fatigue condition) using One-leg standing balance test and Functional reach test as described earlier. The subjective exertion level for the fatiguing task was assessed through the Borg 6-20 scale. For recovery of induced trunk extensor muscle fatigue, rest was given in a supported position. Further, recovery time was noted and to observe recovery in postural stability (Recovery condition) One-leg standing balance test and Function reach test was performed again and readings were noted. Women were asked to refrain from any strenuous physical activity for past 48 hours. Then, statistical analysis and interpretation was done for each candidate to find out the effect of trunk extensor muscle fatigue on postural stability in women undergone lower segment cesarean section.

Statistical Analysis:

For sampling size following formula was used

\[ n = \frac{4pq}{L^2} \]

(p = 70%, q = 30% and L = 15%)

\[ 4 \times 70 \times 30/225 = 37 \]

\[ n = 37 \]

Statistical analysis of the recorded data was done by using the software INSTAT App. Unpaired t test was used to determine p value (\(< 0.0001\)), which indicates it is extremely significant. Tukey Kramer Multiple Comparison Test was used to compare postural stability in three conditions: No fatigue, Fatigue and Recovery condition.

Participants mean age, BMI were 31.43 years and 23.73 kg/m² respectively. Mean rating of perceived exertion for the fatiguing task was 13.75±2.278 on Borg 6-20 scale. Statistical significance was set at P< 0.0001. Tukey Kramer Multiple Comparison Test was used to compare postural stability in three conditions: No fatigue, Fatigue and Recovery condition. OLST showed a decrease from No fatigue condition (12.736 ± 2.954 seconds) to Fatigue condition (8.059 ± 2.245 seconds). FRT showed a decrease from No Fatigue (36.25 ± 5.52 centimeters) to Fatigue condition (27.16 ±5.28 centimeters). The results indicate that postural stability was significantly reduced in the Fatigue condition as compared to the No fatigue condition.

To determine the recovery period for postural stability, mean value of the consecutive readings for OLST and FRT taken during the recovery condition were compared with the No Fatigue condition. It was observed that mean recovery time for OLST and FRT was 4.65±2.12 minutes. Further analysis showed no significant difference between the recovery time of one-leg standing test and functional reach test (two-tailed P = 0.999).

Discussion

The purpose of the present study was to find out the effect of trunk extensor muscle fatigue on postural stability in women undergone lower segment cesarean section. Trunk extensor muscle fatigue significantly affected postural stability as indicated by reduction in One-leg standing balance test and Functional reach test respectively from No fatigue to Fatigue condition. This result confirms our null hypothesis in accordance with previous reports.

Trunk extensors are mainly postural muscles which are involved in many labour conditions demanding high tension in the muscle group. The erector spinae and multifidus are used to maintain the body posture. Hence, fatigue in these muscles may cause difficulties in maintaining upright posture. The objective of this study was to find out the effect of trunk extensor muscle fatigue on postural stability in women undergone lower segment cesarean section.

In the present study the mean age group was 31.43 years. Although the age group included in this study was in between 22 to 35 years, out of 37 women postural stability of those of age group in between 30 to 35 years was affected. This may be due to following reasons: small sample size, late marriage, late pregnancy. Late marriage could be due to educational factor, self-dependency, cast discrimination, cultural discrimination, etc. Late pregnancy could be due to various reasons such as sedentary lifestyle, dietary factors, stress, etc.23

Out of 37 women, 26 were with normal BMI, 7 were overweight whereas 4 were obese. Participants mean BMI was 23.73 kg/m² respectively. This may be due to the hormonal elastic changes of the connective tissue, mechanical stresses placed on the abdominal wall and the displacement of abdominal organs that can lead to occurrence of diastasis rectus abdominis muscle (DRAM).16 There is an opposing evidence linking DRAM with weight gain and high body mass index (BMI).20

The mean period of LSCS was 7.78 years out of 37 women. This may be due to small sample size, elective cesarean delivery, medical reasons, etc.

Mean recovery time for OLST and FRT was 4.65±2.12 minutes as in Cesarean delivery there is thorough disruption of the anterior abdominal wall10 which causes lack of strength in the abdominal muscles. This results in weakening of the core muscles that ultimately leads to muscle fatigue. Also, it is related with greater reports of postpartum pain and slower more painful recovery than vaginal birth.10 Postural stability may get affected due to gestational weight gain,
increased connective tissue laxity and altered posture in the postpartum period. Consequently, this study focuses on how trunk extensor muscle fatigue affects postural stability in postpartum period.

**Conclusion**

Trunk extensor muscle fatigue significantly reduces the postural stability in women undergone lower segment cesarean section. Postural stability in No Fatigue and Recovery condition was similar as compared to Fatigue condition.

Influence of Dual Task Training in Indoor Versus Outdoor Environment on Physical Function and Social Activity among Elderly

S. Anandh¹, G. Varadharajulu², Mahendra M. Alate³

¹Professor & HOD, Physiotherapy in Community Health Sciences, ²Dean, Faculty of Physiotherapy, ³Statistician, Director of Research Office, Krishna Institute of Medical Sciences Deemed to be University, Karad

Abstract

The existential reality of elderly is that their physical efficiency is challenged as per their changes in living environment and degree of socialization. Numerous elements of every task performed unconsciously to intervene dual task (cognitive & motor or motor & motor) and so dual task activity training is essential.

Aim: To find the influence of dual task activity training in indoor versus outdoor environment on physical activity and social activity self-efficacy measure among elderly.

Objectives: a) To study the influence of dual task training in indoor environment on physical function & social activity self-efficacy measures among elderly. b) To study the influence of dual task training in outdoor environment on physical function & social activity self-efficacy measures among elderly. c) To compare the influence of dual task training in indoor & outdoor environment on physical function & social activity self-efficacy measures among elderly.

Material and Method: Group A subjects were treated in indoor (closed) environment and Group B subjects were treated in outdoor (open) environment with 38 subjects under each group. The duration of training intervention in each group is 60 minutes per session of exercise program including warm up & cool about period administered twice per week for 12 weeks duration. The pre-test measures was recorded on the first day at the start of treatment and the post-test measures after 12 weeks duration from the start of intervention for statistical analysis.

Results: The study predicted significant results of outdoor dual task activity with relation to timed 10 meter walk test promoting physical function and motivation to participate in social activities.

Keywords: Indoor Environment, Outdoor Environment, Dual Task activity, Functional Performance.

Introduction

Need of Geriatric Research and Public Health Need: The extent of adaptation towards their lifestyle changes, social participation and environment in which elderly perform their physical activities needs to be understood properly¹. The existential reality is that their efficiency in physical capacity needs are challenged as per their changes in living environment and degree of socialization.

The Nature of Dual Task Activity and Research Need: Numerous elements of tasks unconsciously intervene dual task. The transfer of training effects of daily needs is a challenge and so it needs to be practiced in both indoor and outdoor to prevent incomplete training with regard to fall prevention³.
Environmental Influence on Functional Performance in Elderly: Independent living among elderly comes with the belief when their cop abilities of self-care in the prevailing environment and completing tasks avoiding support.

Environmental Influence on Social Participation on Elderly: Social participation is meant to be a key dimension of healthy successful aging. The elderly needs to manage the distracting factors of environment to achieve the feeling of steadiness to enhance participation in instrumental activities of daily life, which lets an individual to live more independently in the community with good mobility.

Summarized Literature Review: Perfect tracking of the performance of dual task activity and estimating the individual’s progression is the basic requirement of methodology. Several studies are done pertaining to specific activity at indoor and outdoor environment. Older studies are found significant where the elderly enjoy and participate in involvement in physical activities which specifies regarding fear avoidance behavior had positive results. All relevant studies since 2005 had been considered to predict the research gap. There exists lack of studies with relation to environmental influences, with respect to indoor and outdoor training respectively.

Need of The Study: Attention and working memory seems to coincide during any task performance. The processing of information about/on holding two ideas in mind until completion of dual task within a brief period of attention stimulus in a given environmental situation is the normal physiological criteria to be met with. The individual preferences for the elderly and their comfort needs have to be valued during any form into physical activity training.

Material and Method: The research is an interventional study, pre - post study design with a sample size of 76 subjects utilizing random sampling method and the period of study was one Year. Inclusion criteria: All asymptomatic elderly, above the age of 65 years including both genders; retired senior citizens restricted to their residence most of the time; no history of fall for the past 12 months; ability to walk 20m without human assistance; ability to speak/read/communicate. Exclusion criteria: Medically unstable patients and patients with pacemaker; chronic illness & life threatening medical issues; all types of disabilities; uncooperative and psychiatric elderly patients; patients with paralytic limbs, vestibular dysfunction; subjects who are doing part time work, farm work or any other regular work are restricted from the study.

Outcome Measures: The pre - test & post - to test measures includes the following. 1. Timed 10-Meter walk Test 2. Timed Up & Go Test 3. Social Activity Self - Efficacy Measure.

Procedure: Group A subjects were treated in indoor (closed) environment and Group B subjects were treated in outdoor (open) environment with 38 subjects under each group. Intervention in each group is 60 minutes exercise program including warm up & cool about administered twice per week for 12 weeks duration. The pre-test and post-test measures was recorded on the first day at the start of treatment and post 12 weeks duration. The results recorded were considered for statistical analysis using Mean, standard deviation and unpaired t-test to compare two independent groups.

Exercise Procedure: 1. Jacobson’s relaxation: 05 minutes. 2. Free exercises in extremities and spine: 05 minutes. 3. Personal activities (Folding Bed sheet/ counting currency & Dressing self): 10 minutes. 4. Cognitive exercises (Loud reading, Writing/Drawing while listening to music & Brushing teeth with non-dominant hand): 10 minutes. 5. Dual task activity duration: 20 minutes (which includes reading/talking while walking: 05 minutes; follow the light/cues while walking: 05 minutes; obstacle walking: 10 minutes) 6. Recreational activity (catching & throwing ball): 05 minutes. 7. Relax breathing exercises: 05 minutes.

The Post-test result measures of Indoor versus Outdoor Dual task activity training in relation to timed up and go to test is not significant as p value is greater than 0.05 (> 0.05). The statistical values are found significant in dual task activity training in outdoor environment with unpaired-t test for timed 10m walk test and social activity self-efficacy measure since the p value is less than 0.05 (< 0.05). The statistical values are found not significant in dual task activity training in outdoor environment with unpaired-t test for timed up and go test since the p value is greater than 0.05 (> 0.05).

Discussion

To promote worthy independent living, therapeutic interventions in elderly should involve dual task activity stimulating sensory acuity\textsuperscript{10,11}. They should be well trained progressively in sudden stimulus driven activities in different environments for successful dual task activity performance and thereby preventing falls.

The 10 meter walk test has previously been used to describe differences in walking speed across the lifespan demonstrating that speed begins to decline by 50 years of age and continues to decrease to each progressive decade of life. Elderly who spend more time for outdoor environment are said to be physically active, walk longer distance than those who spend more time indoor environment. Thus there will be reduced risk of morbidity specifically, if they walk for longer distance as possible in outdoor environment.

Infrequent performance of outdoor walking has been proved as a marker for frailty and can increase the risk of morbidity & self-care declines to result in social isolation. In this study, the elderly were trained in an outdoor natural environment under supervision without risky additional barriers like sloppy surface, uneven terrain, traffic areas, noisy environment, etc., due to continuation of their participation ensuring safety. Dual task training is a therapeutic approach which has improved outdoor walking skills in elderly.

The results predict that social activity self-efficacy is significant which implies safe participation in physical activities indirectly. The results signify that outdoor environment is preferable to improve interest or pleasure in performing dual task activities. So, it enhances the physical activity participation in elderly. The higher degree of performance and practice of dual task activity training in outdoor environment makes them fitter with control over any environment preventing falls. Till date only few studies has examined the interactive effects of exercise and mood in older cohorts and so further research work is in need to elderly wellness\textsuperscript{12}.

The transformative exercise framework supports rehabilitation to wellness of elderly that emphasizes a linkage between many health professionals. The focus areas are rehabilitation, condition-specific exercise, fitness and lifetime physical activity emphasizing a range of options for promoting safe activities among elderly.

All participants that participated in the outdoor environment training had felt a comfort zone and positive physical ability in walking 10 meters and felt repeating it often. Even though the elderly showed performance variations in each session to a limit, it was found that outdoor environment were suitable for a greater extent. It is usual that elderly individuals modify the walking speed and balance control as per their fall related self-efficacy and fear factors to suit different environmental condition\textsuperscript{8}. Dual task activity training performed in
outdoor environment allows the elderly to engage themselves in challenging situations and adjusting to the environment in completing the task successfully. At the end of 12 weeks protocol it’s found that the performance of timed 10 meters/metered to walk to test has proved significant in outdoor training compared to indoor training which implies the need of preferable training environment to overcome barriers related to fall prevention. Natural environment creates a confidence promoting sensory awareness and cognition as felt by the elderly. In addition the better performance in outdoor environment can be utilized as a cost-effective and interest provoking method of physical activity training in elderly.

There exists clinical evidence that dual task activity training for elderly with mild to moderate form of delirium requires to be trained in simulated environment and outdoors. The invention of park fitness, big outdoor gyms for elderly is expanding with the initiation for promoting wellness for the elderly.

The “Timed up and go test” (TUG) are designed to measure basic mobility function. Limited equipment is required and very cost effective test which is therefore convenient in any form of clinical settings. As the timed up and go to test has many components which need stability, attention, uniform speed of performance, turning and changing positions the elderly found comfortable with performing in a safe indoor environment. It denotes some type of physical activity training is required in indoor environment too. Majority of the elderly have some difficulty in using foot wear comfortably or some minor physiological drop exists which was a considerable factor of non-significant result of relation to timed up and go to test. Early mobility deficit was found among most of the elderly which consistently improved on practice and duration. This has been found as a reason for non-significant results of relation to time up and go to test.

The reduced duration of completing 10 meters walking distance between outdoor environments signifies that the physiological symptom of perceived exertion was lower when compared to participants trained under indoor environment. There is significant evidence and this study provides additional weightage that there is long term functional health benefits of elderly exposed to outdoor environment training regularly. Thus the significant outcome of the study stands as a facilitator for the elderly who resists moving to outdoor environment due to any possible reason for special consideration to gender.

The significant results of self-efficacy in social activity imply that it is a positive predictor for improving physical activity. This will influence the instrumental activities of daily living in a long run promoting outdoor activity. In a nutshell, we can conclude that the dual task training brings back a lost skill.

**Feedback of Subjects:** 1. Easier and interested to perform exercises/participation in progressive physical activity in the absence of therapists. 2. Dual task activity training found to improve communication/improves/improved participation in instrumental activities and reduce fear factor. 3. Able to acknowledge & react to the physical demands as per progression.

**Clinical Implications:** 1. The patient has to recognize that his recovery and functional status is largely the result of his own efforts and utilizing his senses in a relaxed environment. 2. It focuses on the role of physiotherapists in addressing specific physical fitness needs of those at risk of falls.

**Conclusion**

The study predicted significant results of outdoor dual task activity in promoting physical function of timed 10 meter walk test and motivation to participate in social activities. In spite of the performance limits, the participants expressed that the natural feelings of outdoor environment (climate, mild sound, mixed visual stimulus in outdoor) were never experienced as distraction interrupting the training.

Emotional Intelligence Factors Influencing on Interpersonal Problem of Adults

S. Antonysamy¹, J.M. Asgarali Patel², A. Velayudhan³

¹Research Scholar, Department of Psychology, Annamalai Nagar, Annamalai University 608002, ²Dr. J. M. Asgarali Patel Head and professor, Department of Psychology, Annamalai University, 608002, ³Dr. A. Velayudhan professor and Head, department of psychology, Bharathiar University, Coimbatore, 641046

Abstract

The present research is an empirical effort made to study how the Emotional Intelligence factors influence on the interpersonal problems of adults. The sample-size is 500 comprising 200 teachers, 150 IT professionals and 150 nurses. The stratified random sampling method is adopted. The age ranges from 22 to 50 (Mean Age = 31.95). The research is executed with non-clinical samples. The tools adopted are: (1) Emotional Intelligence scale⁴ and (2) Inventory of the Interpersonal Problems⁸ (IIP-32). The participants are contacted individually by the researcher and data is obtained with the help of the above mentioned tools. The descriptive statistics and correlation are used for the statistical analyses. Results indicate that the dimensions of interpersonal problems are negatively correlated and it is statistically significant with the dimensions of emotional intelligence at the 0.01 level of significance as well as at the 0.05 level of significance. This finding supports the understanding and the development of effective strategies in psychotherapy.

Keywords: Emotional Intelligence, Interpersonal Problems, Non-clinical sampling, Psychotherapy, Adults.

Introduction

Emotional Intelligence: Emotional intelligence is a set of abilities to identify, understand, use and regulate emotions to promote greater emotional and personal growth¹¹. It is also referred as the appraisal and expression of emotion in the self and others, regulation of emotions in self and others and use of emotions to facilitate performance¹. The past 100 years, the cognitive intelligence (IQ) had been ruling the world. The individuals with high intellectual quotient were considered as smart in settling down with reasonable job, prestige and respect. But for last 40 years, emotional intelligence is taking the lead. The reason is that the problems encountered were not intellectually based, rather emotionally oriented. Hence in recent decades, there has been a growing interest in identifying oneself in emotional health and mental wellbeing.

The emotional intelligence embodies the interpersonal and intrapersonal competencies which is a central to the contemporary conceptualization of emotional intelligence. Gardner (1983) provides a compatible backdrop when he talks about the personal intelligence which includes intrapersonal intelligence and interpersonal intelligence. Intrapersonal competencies represent the abilities with which an individual manages and utilizes his or her own emotional states such as self-regard, emotional self-awareness, self management, assertiveness, independence, self motivation and self-actualization. The individuals with intrapersonal emotional intelligence are aware of their emotions, would express easily their thoughts and emotions and they possess the ability to control themselves¹³. Interpersonal emotional intelligence includes empathy, social responsibility and managing interpersonal relationship. The individuals with

e-mail: frantonysamyosm@gmail.com
interpersonal emotional intelligence could understand how others feel, communicate and get along with them. Intrapersonal person understands one’s emotions whereas interpersonal person understands the emotions of others.

**Interpersonal Problems:** The behavioral excesses and inhibitions in interpersonal relationship are defined as the interpersonal problems. It is regarded as a discrepancy between the roles in a social script. For example, when a person ‘A’ wants friendliness, but repeatedly experiences hostility, then the person ‘A’ is having an interpersonal problem which confirms the personal distress and prevents a person from functioning appropriately in social relationship. It occurs periodically and repeatedly in relationships because of specific responses and coping behaviors that result in a dysfunctional interactive style.

Interpersonal Problems are caused by Maladaptive coping strategies that are the unhelpful ways in which people habitually deal with interpersonal stress. The maladaptive coping strategies (schema) perpetuate the existence of interpersonal problems. For example, it may be an adoptive for a child to avoid an angry parent, withdraw from a detached parent, or surrender to a domineering parent. As the result, the child learned to withdraw, cling, attack or to surrender. These responses and behaviors served as adoptive function at some point in life (as a child), they tend to be problematic in adult relationship. When adults get triggered in relationships, they may stumble for a response which gives them temporary relief. Though these coping behaviors would produce short term relief, but in the long run, the very same coping strategies cause interpersonal difficulties. Hence the schemas (cognitive frame of reference being established on past experiences) determine who we are and direct how we live our lives, create the internal monologue which characterizes the thoughts, assumptions and interactions and forms each person’s individual worldview.

**Theoretical framework for Emotional Intelligence and Interpersonal Problems:** Emotional intelligence plays a significant role in the establishment and maintenance of interpersonal relationship. They are negatively associated. The individuals who scored high on the emotional intelligence scale are tend to have more positive and less conflictive relationship with others. The poor insight and difficulties with emotion-based decision-making suggested the possible deficits in the processing and interpretation of social and emotional information that impaired interpersonal relationship. The adults who are low on emotional intelligence, they experience more conflict and poorer relationship quality. From the related studies, it is clear that the variables such as the emotional intelligence and the interpersonal problems influence each other and they are negatively related.

**Significant of the research:** The review of the literature reveals that there is no study done with adult population in an Indian context in particular to the service sector such as teachers, nurses and IT professionals. This fills the research gap. The research would help the reader to understand the issues of emotional intelligence better. Consequentially this study will assist in counselling and psychotherapy towards creating awareness on emotional intelligence and strengthening the interpersonal relationship. As the result, the adults would have lesser interpersonal problems.

**Objectives:**
- To identify the levels of Interpersonal Problems among the respondent
- To identify the level of Emotional Intelligence among the respondent
- To find out the relationship between the responses of the respondent towards the Interpersonal Problems and Emotional Intelligence.

**Hypothesis:** Based on the above stated descriptions about the Interpersonal Problems and the emotional intelligence, the following hypothesis is being framed:

**Ho:** there is no significant relationship between the factors of emotional intelligence and Interpersonal Problems.

**Ha:** there is a significant relationship between the factors of emotional intelligence and Interpersonal Problems.
Method

Descriptive survey method was adopted. 500 samples were selected following the stratified random sampling method, consisting of 172 males and 328 females working as teachers, nurses and Information Technology (IT) professionals. The research was executed with non-clinical samples. The age was ranging from 22 to 50 (Mean Age= 31.95). The participants were contacted individually by the researcher and data was obtained with the help of the selected tools. Before the data collection was made, oral permission was obtained from the correspondent and principles of the concerning schools, healthcare centers and IT managers.

Instruments used:

**Emotional Intelligence Scale (EIS):** The Emotional Intelligence scale is developed and standardized for Indian Milieu. It contains 34 items with five-point rating scales as 5-strongly agree, 4-Agree, 3-uncertain, 2-disagree and 1-strongly disagree. The scale measures the ten dimensions of Emotional Intelligence namely, self-awareness, empathy, self-motivation, emotional stability, managing relations, integrity, self-development, value orientation, commitment and altruistic behavior. It has split-half reliability value of 0.88 and validity with 0.93. This scale is used for individual assessment, research and survey purposes. It does not require the services of highly trained test administrator. Based on this stated reasons, the EIS-scale was selected and used for this research purpose.

**Inventory of the Interpersonal Problems (IIP-32):** The inventory of Interpersonal Problems (IIP-32) is developed and standardized for adult. The scale consists of 32 items with five-point rating scale as 0-not at all, 1-a little bit, 2-moderately, 3-quite a bit and 4-extremely. The scale measures the eight dimensions of interpersonal problems namely domineering/controlling, Vindictive/self-centered, Cold/Distant, Socially inhibited, Non-assertive, Overly accommodating, Self-sacrificing, Intrusive/Needy. The total T-score (70 and above) was used as an indicator of severity of the interpersonal problems. It has the Crobach’s alpha with 0.88. Based on the stated reasons, the IIP-32 scale was selected and used for this research purpose.

**Analysis strategy:** The statistical program IBM SPSS 21 was used for the data analysis. The descriptive statistics were adopted. Karl Pearson’s moment correlation (‘r’) was used towards determining the significance, direction and strength of the relationship between the research variables.

**Result and Discussion**

The primary intension of the research is to find out the relationship between the dimensions of the Emotional intelligence and Interpersonal Problems.

</table>
The table-1 describes the distribution of adults’ scores based on the dimensions of emotional intelligence with their category, range, frequency, percentage, mean and standard deviation. The category is distributed with low, average and high with corresponding level of emotional intelligence. The adults with high score are considered to have high level of intelligence and are likely to have better interpersonal relationship. On the other hand, the adults with low score are considered to have low level of intelligence and are likely to have interpersonal problems.

Regarding the Self-awareness, it is observed that 62 (12.4%) adults obtained the low score between 1.00 - 2.99, 239 (47.8%) adults obtained the average score between 3.00-3.99 and 199 (39.8%) adults obtained the high score between 4.00 -5.00. The mean of self-awareness is 3.90 and the standard deviation is 0.63. This indicates that the level of self-awareness is average. With regard to empathy, it is observed that 51 (10.2%) adults obtained the low score between 1.00 - 2.99, 298 (59.5%) adults obtained the average score between 3.00-3.99 and 151 (30.2%) adults obtained the high score between 4.00 -5.00. The mean of empathy is 3.79 and the standard deviation is 0.54. This indicates that the level of empathy is average. It is also observed that on Self-motivation, 33 (6.6%) adults obtained the low score between 1.00 - 2.99, 264 (52.8%) adults obtained the average score between 3.00-3.99 and 203 (40.6%) adults obtained the high score between 4.00 -5.00. The mean of self-motivation is 3.94 and the standard deviation is 0.51. This indicates that the level of self-motivation is average.

With regard to emotional stability, it is observed that 68 (13.6%) adults obtained the low score between 1.00 - 2.99, 292 (58.4%) adults obtained the average score between 3.00-3.99 and 140 (28%) adults obtained the high score between 4.00 -5.00. The mean of empathy is 3.79 and the standard deviation is 0.57. This indicates that the level of emotional stability is average. On managing relations, it is observed that 34 (6.8%) adults obtained the low score between 1.00 - 2.99, 293 (58.6%) adults obtained the average score between 3.00-3.99 and 173 (34.6%) adults obtained the high score between 4.00 -5.00. The mean of managing relations is 3.91 and the standard deviation is 0.52. This indicates that the level of managing relations is average. With regard to integrity, it is observed that 62 (12.4%) adults obtained the low score between 1.00 - 2.99, 276 (55.2%) adults obtained the
the average score between 3.00-3.99 and 162 (32.4%) adults obtained the high score between 4.00 -5.00. The mean of integrity is 3.89 and the standard deviation is 0.62. This indicates that the level of integrity is average. On value orientation, it is also observed that 102 (20.4%) adults obtained the low score between 1.00 - 2.99, 261 (52.2%) adults obtained the average score between 3.00-3.99 and 137 (27.4%) adults obtained the high score between 4.00 -5.00. The mean of value orientation is 3.73 and the standard deviation is 0.73. This indicates that the level of empathy is average.

With regard to commitment, it is observed that 64 (12.8%) adults obtained the low score between 1.00 - 2.99, 270 (54%) adults obtained the average score between 3.00-3.99 and 166 (33.2%) adults obtained the high score between 4.00 -5.00. The mean of commitment is 3.99 and the standard deviation is 0.69. This indicates that the level of commitment is average. On altruistic behaviour, it is observed that 64 (12.8%) adults obtained the low score between 1.00 - 2.99, 280 (56%) adults obtained the average score between 3.00-3.99 and 156 (31.2%) adults obtained the high score between 4.00 -5.00. The mean of altruistic behaviour is 3.96 and the standard deviation is 0.65. This indicates that the level of altruistic behaviour is average. With regard to self-development, it is observed that 70 (14%) adults obtained the low score between 1.00 - 2.99, 272 (54.4%) adults obtained the average score between 3.00-3.99 and 158 (31.6%) adults obtained the high score between 4.00 -5.00. The mean of self-development is 3.95 and the standard deviation is 0.66. This indicates that the level of self-development is average.

The adults who score low on the dimensions of emotional intelligence are: self-awareness (62), empathy (51), self-motivation (33), emotional stability (68), managing relations (34), integrity (62), value orientation (102), commitment (64), altruistic behaviour (64) and self-development (70). This indicates that 11% of adults have interpersonal problems in their relationships.

</table>

The table-2 describes the distribution of adults’ scores based on the dimensions of Interpersonal Problems with their T-score, mean, percentage and standard deviation. As per the norms, the T-score less than 70 (<70) signifies that the adult does not have the interpersonal problems. On the other hand, the adults who have the T-score more than 70 (>70) denote that the adults have any one dimension or combination of dimensions of the interpersonal problems such as domineering, vindictive, cold, socially inhibited, non-assertive, overly accommodative, self-sacrifice and intrusive.

From the table-2, domineering is observed that out of 500 adults, 257 (51.4%) adults have obtained less than 70 on T-score and 243 (48.6%) adults have scored more than 70 on T-score. The mean ‘domineering’ score is found to be 68.02 and the standard deviation is 12.14. This indicates that 48.6% of adults have the interpersonal problems on domineering.
With regard to vindictive, it is observed that out of 500 adults, 379 (75.8%) adults have obtained less than 70 on T-score and 121 (24.2%) adults have scored more than 70 on T-score. The mean ‘vindictive’ score is found to be 64.11 and the standard deviation is 9.46. This indicates that 24.2 % of adults have the interpersonal problems on vindictive. With regard to cold, it is observed that out of 500 adults, 360 (72%) adults have obtained less than 70 on T-score and 140 (28%) adults have scored more than 70 on T-score. The mean ‘cold’ score is found to be 63.14 and the standard deviation is 10.63. This indicates that 28 % of adults have the interpersonal problems on cold.

With regard to socially inhibited, it is observed that out of 500 adults, 409 (81.8%) adults have obtained less than 70 on T-score and 91 (18.2%) adults have scored more than 70 on T-score. The mean ‘socially inhibited’ score is found to be 60.24 and the standard deviation is 8.43. This indicates that 18.2 % of adults have the interpersonal problems on socially inhibited. With regard to non-assertive, it is observed that out of 500 adults, 336 (67.2%) adults have obtained less than 70 on T-score and 164 (32.8%) adults have scored more than 70 on T-score. The mean ‘non-assertive’ score is found to be 63.77 and the standard deviation is 10.43. This indicates that 32.8 % of adults have the interpersonal problems on non-assertive. With regard to overly accommodative, it is observed that out of 500 adults, 469 (93.8%) adults have obtained less than 70 on T-score and 31 (6.2%) adults have scored more than 70 on T-score. The mean ‘overly accommodative’ score is found to be 57.91 and the standard deviation is 8.05. This indicates that 6.2 % of adults have the interpersonal problems on overly accommodative.

With regard to self-sacrifice, it is observed that out of 500 adults, 452 (90.4%) adults have obtained less than 70 on T-score and 48 (9.6%) adults have scored more than 70 on T-score. The mean ‘self-sacrifice’ score is found to be 55.82 and the standard deviation is 9.14. This indicates that 9.6 % of adults have the interpersonal problems on self-sacrifice. With regard to intrusive, it is observed that out of 500 adults, 336 (67.2%) adults have obtained less than 70 on T-score and 164 (32.8%) adults have scored more than 70 on T-score. The mean ‘intrusive’ score is found to be 63.77 and the standard deviation is 10.43. This indicates that 32.8 % of adults have the interpersonal problems on vindictive.

The obtained total score reveals that out of 500 adults, 375 (75%) adults have obtained less than 70 on T-score and 125 (25%) adults have scored more than 70 on T-score. The adult’s frequency that scored more than 70 on T-score is: domineering (243), vindictive (121), cold (140), socially inhibited (91), non-assertive (164), overly accommodative (31), self-sacrifice (48) and intrusive (164). This indicates that overall 25 % of adults have the interpersonal problems on the dimensions such as domineering, vindictive, cold, socially inhibited, non-assertive, overly accommodative, self-sacrifice and intrusive.

*Correlation is significant at the 0.05 level (2-tailed), **Correlation is significant at the 0.01 level (2-tailed).
The table 3 shows the correlation coefficient scores on the dimensions of emotional intelligence and the dimensions of interpersonal problems of adults. Pearson’s product moment correlation method is applied to find out the relationship between the dimensions of emotional intelligence and the dimensions of the interpersonal problems. From the table it is observed that the dimensions of interpersonal problems are negatively correlated and it is statistically significant with the dimensions of emotional intelligence at the 0.01 level of significance as well as at the 0.05 level of significance. Therefore the formulated hypothesis (Ha) that there is a significant relationship between the dimensions of interpersonal problems of adults and the dimensions of emotional intelligence is accepted.

**Discussion**

The present finding is in line with the earlier found results. The emotional intelligence and interpersonal problems are negatively associated. The individuals who scored high on the emotional intelligence scale are tend to have more positive and less conflictive relationship with others, more empathetic, self-monitoring in social situations which reflects the higher scores for social skills, displays more cooperation, close, affectionate responses towards the partners. Further the higher emotional intelligence among close friends indicates their higher self-perceived competence in reacting to their friend’s life events more positively. It confirms the earlier studies that the adults who were low on emotional intelligence, they experience more conflict and poorer relationship quality and highly related to social interaction anxiety. Thus the emotional intelligence plays a significant role in the establishment and maintenance of interpersonal relationship and contributes to the optimal social functioning. Theoretically low scores on emotional intelligence indicate higher interpersonal problems. In this present research, 11% of adults have scored low on the emotional intelligence that corresponds 25% of adults having interpersonal problems. This proves that the lower the score on the emotional intelligence would increase the possibility of having interpersonal problems. Hence therapeutically improving the emotional intelligence would create impact in reducing the interpersonal problems.

**Funding:** The source of funding is self. This research has not received any specific grant from any funding agency in the public, commercial, or not-for-profit sectors. The source of funding is nil.

**Declaration of conflicting interests:** The author declares that there is no conflict of interest. The conflict of interest is nil.

**Ethical Clearance:** Ethical clearance is taken from Center for Academic Research (CARE) Annamalai University, Psychology wing.

**Implication and limitation:** There research is done in an Indian context. This would help us to understand the importance of emotional intelligence in relation to the interpersonal problems: how these dimensions are related to each other and how the emotional intelligence would influence the emotions of the other persons. The finding would be helpful for developing strategies effectively in psychotherapy to improve the adult’s emotional intelligence which would be strengthened through awareness. As the result, the interpersonal problems would be reduced. On the other hand, the limitations as such, the sampling area covered in the present research is from non-clinical populations. Though the data were collected following the stratified random sampling, but the data was collected at the convenience of the researcher as well. Regarding the target population, young and middle adults were only included. The data analyzed for this study were originally meant for research purpose rather than for clinical analysis or making diagnosis.

**Conclusion**

Emotional intelligence plays a determinant role in the interpersonal relationship. Low level of emotional intelligence indicates the high level of interpersonal problems and vice versa. The interpersonal problems do not happen all of the sudden, rather the life experience forms the schema. The schema forms the emotional intelligence which embodies the interpersonal and intrapersonal competencies. That is the reason that individuals differ on the level of emotional intelligence. Hence improving the emotional intelligence through the psychotherapies would help the adults in enhancing their ability or competency to deal effectively with emotions. As the result, the adults would have lesser interpersonal problems.

The Difference of Dental Anxiety Level on Healthcare and Non-Healthcare Students

Sarah Amelia¹, Devi Listiani¹, Az Andini F.¹, Natalia Monique J¹, Awalia Aprilizahrani P.¹, Zakiya Rizki S.¹, Retno Palupi²

¹Undergraduate Student of Dental Medicine, Department Dental Public Health, Faculty of Dental Medicine, Universitas Airlangga Indonesia, ²Staff Lecturer, Department of Dental Public Health, Faculty of Dental Medicine, Universitas Airlangga Indonesia

Abstract

Background: Dental anxiety can be a problem, both for dentists and patients. Basic Health Research states that as many as 57.6% of Indonesian people suffer from dental and mouth problems and only 10.2% of that number goes to the dentist, which can be caused by dental anxiety. Someone who has dental anxiety will avoid and refuse to check the condition of their teeth, which will adversely affect the health of the oral cavity.

Purposes: Examining the differences in levels of dental anxiety in healthcare and non-healthcare students at Universitas Airlangga.

Method: This study uses a quantitative type of cross-sectional method involving healthcare and non-healthcare students and is carried out throughout on campus A and campus B of Universitas Airlangga by random sampling. Data collection procedures were carried out through the Corah Dental Anxiety Scale (DAS) questionnaire with a few modifications that were disseminated online. Then the data analysis was performed using the chi square method to get results.

Result and Discussion: Based on research that has been done, healthcare students have a low percentage of dental anxiety levels of 64.6% where non-healthcare students have a high percentage of dental anxiety levels of 42.9%. Different levels of dental anxiety may be influenced by different levels of knowledge about oral health and dental health.

Conclusion: There is a significant difference in the level of dental anxiety in healthcare and non-healthcare students at Universitas Airlangga.

Keywords: Dental anxiety, healthcare students, non-healthcare students.

Introduction

Dental anxiety can be a problem, both for dentists and patients. The term dental anxiety refers to the specific response given by a patient to a dentist’s actions that can be associated with anxiety or fear¹. The high incidence of dental anxiety in patients can lead to negative responses that can complicate dental health care measures so it is difficult to get optimal treatment results²,³.

If someone experiences dental anxiety, they will certainly avoid and refuse to check the condition of their teeth⁴,⁵. This can adversely affect the health of the oral cavity, such as tooth loss, dental caries and poor periodontal tissue conditions⁶. Based on the Basic Health Research in Indonesia on 2018, as many as 57.6% of Indonesian people, especially adults and adolescents,
suffer from dental and mouth problems, but only 10.2% of sufferers of the problem get treatment from dentists.

Anxiety and fear of a thing can arise when there is no or lack of knowledge and experience of a person to the thing. Among students, differences in the scope of studies will lead to different perceptions of a matter, one of which is about dental health. Students with a scope of study in the field of health will have a different perception than students in the scope of non-health studies of dental health which will make a difference in the level of dental anxiety. Therefore, the authors would like to see differences in the level of dental anxiety among healthcare and non-healthcare students.

This study has a general objective to determine differences in the level of dental anxiety in healthcare and non-healthcare students at Universitas Airlangga, with the specific purpose of analyzing the differences in levels of dental anxiety in healthcare and non-healthcare students at Universitas Airlangga. The author hopes that with this research, for educational institutions, it can be a scientific contribution in learning about dental anxiety and for students, it can be a means of adding insight, especially in the case of dental anxiety.

Research Method

This research is a type of quantitative research with a cross-sectional design, which is data retrieval in a certain period of time. Data collection from samples is done at the same time. The use of cross-sectional study is carried out in the same period, not in the past or future from the formulation of the existing problem. This type of research is more practical to examine the quantity of different levels of anxiety and fear in healthcare and non-healthcare students at Universitas Airlangga.

This research was conducted throughout Campus A of Universitas Airlangga and Campus B of Universitas Airlangga, because this study involve a sample of healthcare and non-healthcare students at Universitas Airlangga. The research targets that must be achieved at least are at least 50 campus A students at Universitas Airlangga and 50 campus B students at Universitas Airlangga as research samples.

In this study, questionnaires with closed questions were used as research instruments. Questionnaire with closed questions is a questionnaire that gives options or options to respondents to choose the answers available in the questionnaire. The questionnaire in this study consisted of 5 questions and will be distributed online to respondents.

Data taken from questionnaire related to dental anxiety. The questionnaire we used in this study was a modified version of the Corah Dental Anxiety Scale (DAS), which contained several additional questions to refer to the respondents’ feelings about local anesthetic injections with a main reference to the injection site, because the pain experienced with local anesthetic injections varied according to its location in the mouth. In addition, the simplified 5-point scale answering scheme is designed from not worried to very worried. The modified dental anxiety scale (MDAS) contains 5 multiple choice items including the following:

- If you go to the dentist for treatment tomorrow, how do you feel?
- If you sit in the dentist practice waiting room, how do you feel?
- If you find that your teeth will be drilled, how do you feel?
- If you do scaling and polishing on your teeth, how do you feel?
- If you are going to get an injection of local anesthetic in your gum, how do you feel?

Scores for each of the 5 response items are summarized to provide estimated values of dental anxiety. Other data that we will include in the questionnaire that will be given to the sample are Gender, Year Class, Faculty and Study Program.

The data was taken using an online questionnaire in the form of a google containing sample data source questions that will be distributed to students of the faculty of healthcare and non-healthcare faculty students of Universitas Airlangga.

Data was collected by distributing online questionnaires containing sample data source questions through social media or distributing messages through groups containing students from the healthcare and non-healthcare faculties of Universitas Airlangga. The study was conducted by random sampling of the study population. Data collection is done every day for one week until the data sample is met or more than the target data depending on the time specified for one week. If within one week the sample does not match the target data,
the data collection will continue until H + 3 from the predetermined timeline.

Data collected will be analysed using the Chi Square method. Chi Square is one type of non-parametric comparative test conducted on two variables, where the scale of the data for both variables is nominal.

The basic principle of the chi square test is to compare the frequency that occurs (observation) with the frequency of expectations (expectations). If the observed frequency values are the same with the expected frequency values, then there is no meaningful (significant) difference and vice versa, if the value of the observation frequency and the expectation frequency value are different, then there is a meaningful (significant) difference.

Based on table 1, the results showed that of 65 healthcare student correspondents, 42 of them had low levels of dental anxiety and 23 other students had high levels of dental anxiety. Whereas in the 49 non-healthcare student correspondents, there were 21 students who had low levels of dental anxiety and 28 other students had high levels of dental anxiety. Based on table 1, the significance value is 0.032. While the alpha standard value is 0.05. Significance values that were more than the alpha standard did not show significant differences, whereas significance values that were less than the alpha standard showed significant differences. So the results in table 1 can be said to be significant.

</tbody>
</table>

Based on table 2, the results are obtained that of 65 healthcare student correspondents, 1 of them felt afraid when going to visit the dentist, while waiting in the waiting room of the dentist’s clinic, as well as when it would be done to scaling and polishing. While of the 49 non-healthcare student correspondents, there were no students who felt afraid when they were going to visit the dentist and while waiting in the waiting room of the
dentist clinic, but there were 1 students who felt afraid of the act of scaling and polishing. In the drilling action, there were 5 healthcare students who felt afraid, while in non-healthcare students there were 9 students who felt afraid of the action. Fear most felt by students on the condition of care that requires the provision of local anesthesia on the gums, found 14 healthcare students and 11 non-healthcare students who are afraid of these actions.

Discussion

Based on the results of the study in table 1 related to differences in the level of dental anxiety in healthcare and non-healthcare faculty students at Universitas Airlangga shows that the healthcare faculty students have a low dental anxiety level of 64.6%, whereas in students from non-healthcare faculties have a low dental anxiety level of 42.9%. These percentages illustrate that healthcare faculty students in general have lower levels of dental anxiety when compared to students from non-healthcare faculties. These different levels of dental anxiety can be influenced by differences in the level of knowledge about oral health and dental health. Healthcare students are considered to have higher knowledge and awareness compared to non-healthcare students, so many healthcare students are more likely to take care of their health and one of them is dental and oral health. The main reason is because basically, healthcare students are already equipped with knowledge about dental and oral health, both basic and specific. With this knowledge that is considered good, there will be a sense of familiarity with the care actions that will be taken when patients come to visit the dentist. Whereas for non-healthcare students with lower levels of knowledge and information, there is no familiarity and there is no description of the treatment actions that will be taken when patients come to the dentist so that it will cause anxiety to fear.

Based on table 2 related to the results of a survey regarding fear of a certain dental care condition, the highest results were obtained for injections (local anesthesia) in the gums, which was 21.5% in healthcare students and 22.4% in non-healthcare students. This indicates that in general, patients feel anxious or afraid when they will get anesthesia. Fear of using anesthesia can be caused by the patient having never received anesthesia before, anxiety if the anesthesia process does not take place smoothly, fear if awakened/awakened during operative measures and anxiety about some of the side effects of the anesthetic drug itself.

The importance of proper diagnosis of dental anxiety cannot be underestimated. Identifying anxious patients helps dental health practitioners in planning treatment actions with appropriate procedures for patients. Some method that can be performed by dental health practitioners to deal with patients with dental anxiety is to do a communication approach to patients before treatment.

High levels of dental anxiety can be minimized by means of education about oral health and teeth, regular visits to the dentist at least every 6 months and from the communication and good relationships with patients.

Conclusion

There is a significant difference in the level of dental anxiety in healthcare and non-healthcare students at Universitas Airlangga.

Social Impacts of Child Marriage in Grobogan Regency, Central Java Province, Indonesia

Saratri Wilonoyudho\textsuperscript{1}, Lutfi Agus Salim\textsuperscript{2}

\textsuperscript{1}Profesor at Engineering Faculty, Semarang State University, Central Java, Indonesia, \textsuperscript{2}Associate Profesor at Public Health Faculty, Universitas Airlangga, Surabaya, East Java, Indonesia

Abstract

\textbf{Background:} The prevalence of child marriage in Indonesia has more than doubled in the last three decades but is still one of the highest in the East Asia and Pacific region. In the Grobogan District in 2016 an increase in the number of marriages at an early age in women was 36.5 percent. This study is a qualitative-naturalistic study. The main data source of this study is the results of Focus Group Discussions, interviews and observations and also supported by secondary data in the form of previous research results. The reason for early marriage is mostly due to the incidence of pregnancy outside marriage in adolescents. It is suspected that there is a relationship between early marriage, low level of education and poverty. Religious education, morals and strict control from parents, schools and communities must be done with a variety of strategies, because most of the reasons for early marriage are getting pregnant first.

\textbf{Keywords:} Child marriage, education, poverty, multi-strategies.

Introduction

The prevalence of child marriage in Indonesia has declined for more than twofold in the last decade but is still one of the highest rates in East Asia and Pacific. The National Social and Economic Survey conducted by the Central Bureau of Statistics in 2012 shows that 25 percent of 20-24 years old married women marry when they are under 18 years old\textsuperscript{(1)}.

Based on the IDHS in 2012, 17% of 20-24 years old married women marry when they are under 18 years old\textsuperscript{(2)}. Indonesia is one example of global progress towards removal of child marriage practice with five percent of prevalence decline between IDHS issued in 2007 and 2012.

Central Bureau of Statistics (BPS)-UNICEF’s report shows that the prevalence of child marriage in Indonesia is not only still high (with more than one-third girls marry before they get to adult or about 340,000 girls annually) but the prevalence has increased instead\textsuperscript{(3)}.

Furthermore, although girl under 15 years old marriage has declined, but the prevalence of 16 and 17 years old girl marriage increases continuously, showing that girls protection decline when they are 16 years old. It is important to note that child under 15 years old marriage may not reflect the actual prevalence since many of these marriages are disguised as above 16 years old or unregistered girl marriage\textsuperscript{(3)}.

There is a complex relationship between child marriage and education in Indonesia. Girls who marry before 18 years old have lower education level than unmarried girls, particularly after Elementary School. Besides, younger married children have lower education level than older married children. Girls tend not to continue their education after their marriage\textsuperscript{(3)}.

The percentage of 20-24 years old girl marriage gets lower in line with increasing education level. The percentage of Elementary School girl marriage (40.5
percent) is significantly different from they who continue 
their education to high school (5.0 percent). These 
numbers show that investment in secondary school for 
girls, especially high school, is one of the best ways to 
ensure that girls get to adulthood before marriage(3).

At regional level, in the 2013-2018 Regional 
Medium-Term Development Plan (RPJMD) of Central 
Java Province, the achieved target rate of marital age 
under 20 years old in 2016 is 1.19%. The rate of marital 
age under 20 years old in 2015 is 2.42%; while the rate 
of marital age under 20 years old in 2016 is 1.05%, 
which means that the decline is significant of 1.37%. 
The rate of marital age under 20 years old in 2016, in 
comparison with the target, has achieved the target 
defined in 2013-2018 RPJMD. In 2016, the highest rate 
of Marital Age Women or WUS under 20 years old is 
that in Batang Regency of 2.25%, while the lowest rate 
of WUS under 20 years old is that in Magelang City of 
0.30%. In Grobogan Regency, the rate of marital age 
under 20 years old in 2015 is 4.71% and declines to 
1.93% in 2016.

According to the data from the Ministry of Religious 
Affairs Office of Grobogan Regency, there are 21 men 
and 27 women who marry when they are under 16 years 
old in 2014. This number keeps increasing, consecutively 
to 21 men and 93 women in 2015, to 26 men and 127 
women in 2016 and there are 19 men and 17 women 
only in January 2017. The main reasons of these early 
age marriages are: unwed pregnancy of 927 people and 
in avoidance of adultery of 1,169 people.

From such initial data, it is clearly important to 
conduct a research of early age marriage for material to 
design policies or programs to reduce early age marriage 
rate and prevent any of its consequences.

**Method**

This research’s main source of data is numbers 
generated from Surveys conducted by BPS and relevant 
institutions, results of Focus Group Discussion (FGD) 
and, if possible, interview and observation results, 
supported with secondary data in the form of previous 
researches’ results. The secondary data are obtained 
from the results of surveys conducted by Central 
Bureau of Statistics and other institutions. These data 
and information are understood naturally without 
manipulation and arrangement using experiment or test. 
In other words, this research tends to be qualitative (4).

The research location is all administrative area of 
Grobogan Regency, which is determined based on the 
fact that this Regency has a relatively complex early age 
mariage phenomenon. The poverty rate of this Regency 
is relatively high with its rural culture.

**Results**

Grobogan Regency has child marriage problem. 
According to the data of the Central Bureau of Statistics, 
the percentage of 17-18 years old girl marriage in 
Grobogan Regency in 2013 is relatively high of 28.55%, 
but from the perspective of First Marriage Age <17 
years old, Grobogan Regency is in the first order of 
Child Marriage rate with a percentage of 34.95%. 
Meanwhile, according to the data of Family Planning 
Office of Grobogan Regency, there are 3,142 cases of 
child marriage in Grobogan in 2012, which increases to 
4,072 cases in 2014.

In 2015, there are 110 cases of women and 
children abuse, 3,225 cases of divorce and 5 cases of 
law enforcement from investigation to court order for 
women and children abuse. There are 25 cases of child 
dealing with the law with Restorative Justice Approach 
settlement, 55 cases of woman and children abuse under 
health care of trained health workers in Community 
Health Center and 11 cases of woman and children abuse 
with legal assistance service. Meanwhile, the percentage 
of active institutions is up to 50% with coverage of 123 
gender based violence service institutions.

There are three subdistricts in Grobogan Regency 
of which early age marriage rate is very high, namely 
Ngaringan Subdistrict, Pulokulon Subdistrict and Gabus 
Subdistrict. These three subdistricts are expected to poor 
area. Central Bureau of Statistics’s data show that the 
three subdistricts have no fertile land with irrigation(7). 
Gabus Subdistrict’s 3,901ha farm is rain-fed rice field, 
Pulokulon Subdistrict’s 5,665 ha farm is rain-fed rice 
field and only 10 ha is covered by irrigation and in 
Ngaringan Subdistrict, more than 3,000 ha farm is rain-
fed rice field.

According to BPS data, 65.14 percent of Pulokulon 
Subdistrict people and 73.53 percent of Gabus Subdistrict 
people are classified into poor family. In Ngaringan 
Subdistrict 86.76 percent of people are classified 
into non-prosperous family(7). This fact confirms the 
preumption that it is possible that poor families have 
their daughters married when they are young as an effort 
to release some of its economic burdens.

Prevalence of child marriage in Indonesia is not only still high (with more than one sixth girls marry before they reach adulthood or about 340,000 girls annually), but the prevalence has also re-increased. Moreover, although under 15 years old girl marriage has declined, but the prevalence of 16-17 years old girl marriage continuously increases, showing that girl protection decreases when they are 16 years old(3).

Table 3 shows that educational factor is likely to influence early age marriage or divorce. From the table, it is clear that they who are divorced/married mostly have Junior High School or lower education. The low education level causes unemployment and poverty. Having children married is one way to release parents’ responsibility or is caused by girl’s premarital pregnancy. From Table 3, it is clear that low education factor is expectedly the cause of high rate of divorce for young (under 20 years old) couples in Grobogan Regency. This assumption is confirmed in Table 3, that they who are married/divorced are mostly homemakers.

Discussion

The poor will utilize any existing economic sources in case of change to economic condition, one effort of which is to use family’s manpower, including children. Based on the phenomena, it is clear that education is the key to hold down the early age marriage rate\(^8\). If the reason they stop their education is the fee, Government’s role should be improved in providing education facilities.

It is expected that the occurrence of early age marriage in Grobogan is at least influenced by three factors, namely: women’s averagely low education, poverty and moral issue (premarital pregnancy). Cultural factor is not yet found. Woman who marry young tend to be less educated, raise children too early and not have decision-making power in household. In other words, adolescent marriage is unfavorable since they are basically in their adolescence that, according to psychological study, is a transitional phase from childhood to adulthood\(^5\)(\(^6\)). With adolescent’s transitional characteristics, they are supposed to be unstable, while marriage practically demands one’s high responsibility. Responsibility gets higher and heavier with Unintended Pregnancy. The expected impact to arise is conflicts which may impair child’s growth and development and continuity of family\(^3\).

Early age marriage is also expectedly caused by poverty. The poverty rate in Grobogan Regency in 2015 is 13.68%, relatively higher than the national average (11.13%) and that of Central Java Province (13.27%).

It is also important to note that under 15 years old
child marriage may not reflect the actual prevalence since many of these marriages are disguised as above 16 years old or unregistered girl marriage.

That there are many cases of early age marriage because of premarital pregnancy shows that social norms have declined in the society in line with globalization and information advancement. It is assumed that besides Grobogan Regency, many cases of student’s premarital pregnancy occur in various regions. The cause is expectedly the advancement of information technology, in which porn websites are easily accessed (9). Consequently, many students follow promiscuous lifestyle, that they have premarital sexual intercourse. Girls with premarital pregnancy certainly need psychological accompaniment so that their mental remains stable, particularly when facing their family’s or society’s anger (10). In rural environment, there should be real measure in monitoring, for example, city park should not be left dark, internet center should have no partition and students should always be controlled when they skip school (10).

Girl’s marriage in too young age causes early pregnancy and delivery, which are correlated with mother’s high death rate and abnormal condition since girl’s body is not mature yet to give birth (11). This fact also conforms to what is stated in the 2011-2016 Regional Medium-Term Development Plan of Grobogan Regency. The Infant Mortality Rate (IMR) in Grobogan Regency increases from 8.78 per 1,000 live births in 2011 to 17.44 per 1,000 live births in 2015.

Maternal Mortality Ratio (MMR) in Grobogan Regency is relatively high of 149.92 per 100,000 live births in 2015. This number increases from the 2011 actual MMR of 114.03 per 100,000 live births. The 2015 actual MMR in Grobogan Regency exceeds 2015 MDGs target of 102 per 100,000 live births. The common causes of maternal mortality are: severe eclampsia and hemorrhage(12).

Conclusion

Based on the study, the following conclusions are made:

• The high rate of early age marriage in Grobogan Regency is contributed to by moral issue;
• There is expectedly correlation between early age marriage and low education level in Grobogan Regency;
• Phenomenon of low education level and poverty is like an endless circle. Girls’ low education level is obstructed by poverty and it is poverty that leads to girls’ and their family’s low education level;
• Poverty expectedly causes parents’ financial problem, which drives them to have their daughters married, whether consciously or not, as a means to “release their responsibility” as parents;
• Early age marriage expectedly causes high maternal mortality ratio and under-five mortality rate and divorce rate at young age.

Suggestions:

• Religious and moral teaching and strict control of parents, school and society should be performed with various strategies, since the main cause of early age marriage is premarital pregnancy.
• To make incessant campaign of how dangerous early age marriage is by involving all parties: government, society figure, religious figure, village officials, school, religious study group, etc;
• To establish psychological consultation institution for adolescents in relationship, adolescents with premarital pregnancy, married adolescents and female adolescents with domestic violence. The government of Grobogan Regency may cooperate with NGO, higher education institution, hospital, etc. In this institution, parents are to be involved for familiar dialog with children so that they will not have unhealthy relationship;
• To enhance school’s participation to be the main priority. School should also provide special counseling service considering that moral crisis is at emergency level. Curriculum of danger of early age marriage, reproduction health and danger of sexually transmitted diseases, HIV, etc. should be the main concern.
• To provide sufficient fund to increase the poor’s “purchasing power” in education, besides relieving Educational Management Contribution, also scholarship program, additional food support, transportation support, or to change study method and hours so that poor children may still help their parents to work, while they can still go to school in the afternoon, etc.;
• Opportunity of allocated economic empowerment, particularly for girls, is very important to eliminate
child marriage, in the framework of protection to promote their education, skills and financial control.

- Access to economic services, financial institution, microeconomic development training, etc. should be prioritized. Various financial lending should be facilitated for girls who discontinue their education so that they will develop their skills and economy;

Profile of Death Due to Thermal Burns: A Retrospective Study

Shailendra Patel1, Jitendra Singh Tomar2, Ankit Pandey Jain3, Poornima Patel4

1Assistant Professor, Department of Forensic Medicine and Toxicology, Bundelkhand Medical College, Sagar (M.P), 2Assistant Professor, Department of Forensic Medicine and Toxicology, MGM Medical College, Indore (M.P), 3PG resident, Department of Forensic Medicine and Toxicology, MGM Medical College, Indore (M.P), 4Dental Surgeon at Aashirwad Dental Clinic, Sagar

Abstract

Fire is one of the important element of life, it is both useful (in cooking, producing warmth in winter, in cremation etc.) as well as harmful (by producing thermal burn injuries, blast injuries, forest fire, crop burning, volcanic eruption etc.) to the mankind. Burn injury is now becoming the major cause of death among unnatural deaths in various regions of the country and world. Majority of the burn cases occur at home due to smoking, defective electrical wiring, defective kerosene stove bursts, attempted suicides by self-immolation, homicidal burns of young women by husband or in-laws (dowry deaths). The present study was based on retrospective analysis of post mortem cases of thermal burns during the period from January 2018 to December 2018 in the Department of Forensic Medicine and Toxicology, Bundelkhand Medical College, Sagar (M.P). During this period total 349 autopsies were conducted, out of which majorities of death, 116 cases were due to burn. Majority of the victims were married hindu females belonging to age group of 21-30 years. Of these cases carbon soot particles in trachea were present in 7% of cases and kerosene smell was present in 21% cases. Most of deaths were accidental account for 78.44% cases. Police inquest was conducted in 76% of the cases and rest of the cases were magistrate inquest. In 52(44.82%) cases, 60-80% of Total Body Surface Area (TSBA) was burnt of all body parts upper extremities were commonly involved in about 96.55% cases. Accidental burn injuries are preventable and can be reduced by bringing about regulations to develop safer cooking appliances, promoting less inflammable fabrics to be worn at home and educating the community especially women.

Keywords: Thermal burns, Married female, Soot particles, Kerosene smell.

Introduction

Burns are the injuries that are produced by the application of dry heat such as flame, radiant heat and some heated solid substance like metal or glass to the surface of the body resulting in tissue destruction. In young adult population, about 40% burn is fatal.1

There are varieties of types of lethal and nonlethal thermal injury, including flame burns which char skin and singe hair, scalding from hot fluids and contact burns those result from touching hot objects. An estimated 180 000 deaths every year are caused by burns and among those, vast majority occur in low and middle-income countries. In India, every year 1000000 people are moderately or severely injured due to burn injury.2

Burn injuries are the 4th most common type of trauma all over the world, following traffic accidents, falls and interpersonal violence.3

The accidental burn injury is the commonest manner of burns.4 Accidental burn are commonly seen in females as most of the females (housewives) spend most of their time in household work especially in kitchen. Burn is also important mode of suicide and homicide in the world. Setting of fire to self (self-immolation) in public is done to attract the attention of government and media regarding political affairs, personal problems. Sometimes people resort to criminal acts like murder, rape and for concealing the facts, they try to burn the body of crime.

Dowry death is still a subject of major concern in our recent modern society in spite of strict law and amendment in the acts.5 Almost every day we read in newspapers and see in electronic media, cases of young
women either being burnt or provoked to commit suicide by the husband and in-laws, just for the dowry.\textsuperscript{6}

**Materials and Methodology**

The present study is a retrospective study carried out in the Department of Forensic Medicine & Toxicology, Bundelkhand Medical College, Sagar (M.P). A total of 349 autopsies were performed during the period of Jan 2018 to Dec 2018, out of which 116 thermal burn deaths were analysed. The detailed analysis of these cases was based on the inquest record, hospital records and evaluation of autopsy reports. Various parameters like age, sex, religion, carbon soot particles in trachea, presence of kerosene smell, type of inquest, manner of death, marital status, body parts burnt and TBSA burnt were taken into consideration. The information was compiled, tabulated and analysed.

**Results**

During the period of one year from 1\textsuperscript{st} Jan 2018 to 31\textsuperscript{st} Dec 2018, total 349 autopsies were conducted, out of which 116 (33.2\%) cases were due to burn. Out of total cases of burn, 22 (19\%) were male and 94 (81\%) were female and male: female ratio was 1:4.2. (Graph 1).

Taking age group into consideration, maximum incidence of burn injuries in males were noted in the age group of 21-30 years i.e. 8 (6.89\%) whereas in the age group of above 50 years no case was reported. The maximum incidence in females was noted in the age group of 21-30 years i.e. 48 (41.37\%) and minimum in the age group of 1-10 years i.e.3 (2.58\%) cases. Taking overall population into consideration, Maximum incidence of burn injuries were noted in the age group of 21-30 years i.e. 56 (48.27\%) and minimum in the age group of above 50 years i.e. 4 (3.44). (Table 1).

Looking into the marital status among the burn cases, married cases were higher 96 cases (82.75\%) as compared to unmarried cases 20 cases (17.24\%). Out of total married cases,80 (83.3\%) victims were female while the rest 16 (16.6\%) were male. Most of the victims belong to the Hindu community comprising 110 (94.82\%) and the rest 06 (5.17\%) were from Muslim community. Female victim predominance were seen in both Hindus (90 cases out of 110) and Muslims (4 cases out of 6).

Out of all burn cases, deposition of carbon soot particles in trachea was observed in 08 (7\%) cases. (Graph 2) Kerosene smell was present in 24 (21\%) cases, absent in 92 (79\%) cases.

Out of total 116 burn cases, magistrate inquest was carried out in 28(24\%) cases and police inquest in 88(76\%) cases. In most of the burn victims the manner of death was accidental in 91 cases (78.4\%) followed by suicidal in 18 cases (15.5\%) and 07 cases (6\%) shows homicidal pattern. (Graph 3)

Distribution of burn cases according to involvement of Total Body Surface Area (TBSA), shows that in majority of burn cases (52.6\% cases) TBSA was above 60\%, followed by 35.3\% cases with 41-60\% of TBSA. Only 12\% cases died with TBSA less than 40\%. In 10.34\% male cases, TBSA involved was 41-60\% and in females, in 39.65\% cases TBSA involved was 61-80\%. (Table 2).

In burnt areas upper extremities were most commonly affected i.e. in 112 (96.55\%) cases, followed by head, neck and face in 105 (90.51\%) cases. Genitalia was the least affected and involved in 27 (23.27\%) cases. (Table 3).

Discussion

In the present study of deaths due to burn injuries, female (81%) dominates male (19%) in the incidence on the basis of sex, which is similar with the finding of other similar studies. Females were more susceptible to burn injuries as they spend most of their time in the kitchen and are involved in the activities which require fire like cooking food, making tea, boiling water etc. As we see in rural area most of the houses have no proper equipment for cooking and other fire related work, so in such area female are more prone for burn injuries. But in fewer studies slight male predominance was also observed. The reason for male predominance could be occupational hazard.

Age group of 21-30 years have maximum incidence of deaths due to burn in both males i.e. 8(6.89%) and females i.e. 48(41.37%). Similar findings were observed in other studies. This age group of 21-30 years is the young adult group and is the most common age for marriage in this area of study.

In the present study, it was observed that 96 (82.75%) victims were married and 20 (17.24%) were unmarried. Out of the females 80 (68.96%) were married and 14 (12.06%) were unmarried in contrast to males 16 (13.79%) were married and 06 (5.17%) were unmarried. Similar finding was also noted in other studies. Majority of victims were married female, this might be because of their involvement in domestic cooking work and dowry deaths.

Most of the victims belonged to the Hindu community i.e. 110(94.82%) as compared to Muslims i.e. 06(5.17%). Among the Hindus, majority of victims were female i.e. 90(81.8%) as compared to males i.e. 20(15.2%). which is similar to the findings of previously mentioned studies. This is because in this part of the world and more specifically in this region Hinduism is the most commonly followed religion, resulting in increased incidence among Hindus.

Out of total 116 burn cases, soot particles were found in trachea in 08(7.0%) cases, which is almost similar with the finding of Mishra PK et al, who found soot particles in 5.55% cases. But different from the findings of Das KC et al, who found soot particles in trachea in 18.05% cases, Nath D et al, who found in 34.07% cases and Mazumdar A et al, who found soot particles intrachea in 19% cases.

In the present study kerosene smell was found evident in 24 (21%) cases. This finding in our study is near to the finding of Mishra PK et al, who observed kerosene smell in 27.5% of cases. Whereas on the contrary Chaudhary BL et al in their study observed smell of kerosene in only 4% cases. This might be due...
to its easy availability and its extensive use in household purposes for cooking and in lighting lamps in the rural areas as there is less availability of cooking gas and electricity in rural areas. Many people use kerosene as a fuel for motor vehicles and it is also a major fuel for aircraft engines.

On the basis of manner of deaths, majority of deaths were accidental in nature i.e. in 78.44% cases followed by suicidal i.e. 15.51% cases. This may be due to involvement of females in domestic cooking. This was responsible for accidental cases and marital maladjustment resulting in suicidal cases. Homicidal deaths are less comparatively i.e. in 6.03% cases and commonly seen in case of dowry killing may be by husband or in-laws. In this study majority of deaths were accidental in nature, which is similar to other studies.6,7,8,13,20

In present study, majority of the victims i.e. 102 (88%) had more than 40% of Total body surface area (TBSA) burn and there are fewer number victims i.e. 14 (12%) below 40% TBSA burn. In studies by Mishra PK et al11 revealed 86.3% mortality over 40% TBSA. Similarly, in studies from Adamo C et al22 revealed 100% mortality over 40% TBSA and Gupta M et al23 also shows similar finding, 80% mortality rate in burn over 40% TBSA. Similar finding were also noticed in study by Mangal HM et al6 showing 92.8% mortality over 40% TBSA burn and Tomar J et al5 shows 100% mortality over 50% TBSA. All these studies signify that burn of 40-50% TBSA and above was fatal resulting in large number of deaths even at tertiary care centre.

In present study upper extremities were most commonly involved in 112 (96.55%) cases, followed by head, neck and face in 105 (90.51%) cases. Similar findings were observed in the study done by Tomar J et al5 with most of the cases involving upper limbs (93.5%), followed by chest and abdomen (86.11%), lower limbs (63.8%) and genitalia (14.81%).

In present study upper extremities were most commonly involved in 112 (96.55%) cases, followed by head, neck and face in 105 (90.51%) cases. Similar findings were observed in the study done by Tomar J et al5 with most of the cases involving upper limbs (93.5%), followed by chest and abdomen (86.11%), lower limbs (63.8%) and genitalia (14.81%). In contrast to the present study, Buchade D et al7 found that Head, face & neck region was most commonly affected in 206 (86.91%) cases, followed by chest in 174 (73.41%) cases.

Conclusion

Our present study and other above discussed studies, shows that married females are commonly affected due to burns because they are commonly involved in domestic cooking work. Most of the burns are accidental and can be prevented by following the safety instructions like putting the lights off while going out, wearing tight and cotton cloths while cooking, not leaving a fire source unattended etc. The government should work in the direction to reduce the incidences of burn by bringing about regulations to develop safer cooking appliances and educating the community especially women on safer first aid practices. The government along with various working groups and the NGOs, including the doctors need to put in more sincere effort. Proper knowledge and training should be given to all the factory workers involve in fire work in order to prevent accidental burn among male and females both. The present study is concluded with the hope that the given suggestions will help in reducing the number of burn injuries.

Conflict of Interest: Nil

Source of Funding: Self

Ethical Clearance: It’s a retrospective study and identity of the deceased is nowhere disclosed. Therefore, the approval of Institutional Ethics Committee is not required.

Abstract

Death of humans is often investigated for the causes, in case of crime (such as Murder), accident or disease that may continue to kill other humans. Death occurs due to natural causes or unnatural causes. The study of profile of medicolegal autopsies help us in determining crime rate, accident and common diseases in that particular area and also helpful in preventing unnatural deaths, improving healthcare system and reflecting law and order situation of that area. The present study was based on retrospective analysis of the autopsies performed during the period of January 2018 to December 2018 in the Department of Forensic Medicine and Toxicology, Bundelkhand Medical College, Sagar (M.P). A total of 349 autopsies were conducted during this study period, of which majority of victims were male 195 (56%) cases. Age group of 21-30 years having maximum number i.e. 128 (36.7%) cases. Natural death accounted for 12 (3.4%) cases and unnatural death 323 (92.5%) cases. The major cause of death among unnatural deaths was burn in 116 (33.23%) cases, followed by road traffic accident (RTA) in 106 (30.37%) cases and poisoning in 40 (11.46%) cases. Burn was the major cause of death in our study, this may be due to smoking, defective electrical wiring, defective kerosene stove bursts, attempted suicides by self-immolation, homicidal burns of young women by husband or in-laws (dowry deaths).

Keywords: Burn, RTA, Poisoning, Natural Death, Unnatural death, Homicidal.

Introduction

India is a vast country with great diversities and regional variation among its population in their living, culture, festivals, food habits and other daily livelihood and this regional variation may affect the death trends.¹ So the mortality pattern is different in different region of India. The pattern of mortality is a key indicator of the consequent health effects.²

In our modern society, RTA among males and burn among females are the major causes of death in different regions. NCRB data shows 4,45,514 RTA cases in 2018, of these deaths occurred in 1,52,780 cases. Major cause of death in RTA is due to over speeding (55.2%) followed by careless driving or overtaking (27.3%) during 2018.³ In India, every year 100000 people are moderately or severely injured due to burn injury. An estimated 180 000 deaths every year are caused by burn and among those, vast majority occur in low and middle-income countries.⁴

Autopsy ensures to establish the identity of the body if unknown, to ascertain the time since death and the cause of death, to find out the manner of death, whether it was homicidal, suicidal or accidental. In case of new born infants, the question of live birth, viability and cause of death assume importance and

should be determined. The objective of present study is to describe the distribution of autopsies on the basis of basic parameter such as age, sex, months, manner of death and cause of death.

**Materials and Methodology**

The present study is a retrospective study carried out in the department of Forensic Medicine & Toxicology, Bundelkhand Medical College, Sagar (M.P). A total of 349 autopsies performed during the period of Jan 2018 to Dec 2018 were analysed. The data was collected from inquest record, medical record and post-mortem reports. Various parameters like age, sex, month, religion, manner and cause of death were taken into consideration. The information was compiled, tabulated and analysed.

**Results**

In a study period of one year, total 349 autopsies were conducted from 1st Jan 2018 to 31st Dec 2018. Out of which, 195 (56%) cases were male and 154 (44%) cases were female having female: male ratio of 1:1.26. (Graph 1).

On the basis of age group, maximum number of males belonged to the age group of 21-30 i.e. 64 (18.33%) cases followed by age group of 31-40 years with 33 (9.45%) cases. In females 21-30 age group had maximum number of cases i.e. 64 (18.33%) cases followed by the 11–20 years age group with 34 (9.74%) cases. Taking overall population into consideration 21-30 years age group had maximum number of cases i.e. 128 (36.7%) cases. Number of males and females were same in the age group of 21-30 years i.e. 64 cases. Female number was dominating over male number in age group of 11-20 years i.e. 34 out of 60 cases and 71-80 years i.e. 02 out of 03 cases. (Table no. 1).

In the present study, maximum autopsies were conducted in month of April with 41 (11.74%) cases, followed by 40 (11.46%) cases in the month of May. Month of November showed the least number of cases i.e. 17 cases (4.87%). Deaths of females were more compared to males in the month of July i.e. 15 out of 28 cases and November i.e. 11 out of 17 cases.  

Out of the total 349 cases, the cause of death was determined in 335 (96%) cases. Out of these 335 cases, in 12 (3.4%) cases the cause of death was natural, whereas in 323 (92.5%) cases it was unnatural. The cause of death could not be determined in 14 (4%) cases. (Figure 2). Out of 323 unnatural deaths, manner of death was accidental in 263 (81.4%) cases, suicidal in 57 (17.6%) cases and homicidal in 03 (1%) cases. (Figure 3).

Distribution of cases according to cause of death showed that maximum number of deaths were due to burn i.e. 116 (33.23%) followed by death due to RTA in 106 (30.37%) cases, poisoning in 40 (11.46%) cases and snakebite in 21 (6.01%) cases. The least number of deaths were observed in case of assault, gunshot, blast injuries and cut throat account for 01 (0.28%) case in each followed by animal attack i.e. 02 (0.57%). Deaths due to asphyxia were in 17 (4.87%) cases which include hanging, strangulation and drowning cases. Deaths due electrocution, fall from height and railway track accident accounted for 08 (2.29%), 05 (1.43%) and 04 (1.14%) cases respectively. In our study deaths due to pathological disease like coronary artery disease, liver and uterine pathology accounted for 12 (3.43%) cases. Nearly in 14 cases, cause of death could not be identified hence cause of death remains open and various sample had been preserved and sent for investigation to find out the actual cause of death. The major cause of death in males was RTA (27.22%) followed by Burn (6.3%) and in females, it was burn (26.93%) followed by poisoning (5.73%). (Table no. 3).

Discussion

In the present study, out of total 349 autopsy cases, 195(56%) were male and 154(44%) were female. In study by Rathod AL et al[1] and Radhakrishna KV et al[6] similar finding with male predominance were observed, accounted for 69.5% and 74.62% respectively. Similar finding with male predominance were also observed in other such studies.[2,7,8,9,10,11] The reason being that as males are bread earners and females usually do house hold work, which make males more vulnerable to accidents, violence and stress. Males also indulge more in alcoholism, smoking etc than female population which make males more prone to accidents and early natural deaths.

Age group of 21-30 years showed maximum numbers of deaths among both sexes i.e. 128 (36.7%). This finding is also consistent with the studies by Rathod AL et al[1], Radhakrishna KV et al[6] and Bhahbor R et al[7] in which these age group involve 473 cases (27.1%), 340 cases (25.6%) and 257 cases (24.71%) respectively. It’s an adult age group which is mostly involved in most of the activities and hence more vulnerable than other age groups.

In the present study, out of total 323 unnatural deaths, most of the deaths were accidental in nature i.e. 263 (75.35%) followed by suicidal deaths i.e. 57 (17.6%) and homicidal deaths i.e. 03 (1%). This finding is similar in the study conducted by Ramalingam S et
al[8] and Singh D et al [12]. But our findings differ from the findings observed in study conducted at Government Medical College and Hospital, Chandigarh where accidental deaths constitute 49.56%, suicidal deaths constitute 38.55% and homicide deaths constitute 4.44% cases.[13]

In present study, the maximum number of deaths were due to burn (33.23%), followed by RTA (30.37%) and poisoning (11.46%). This finding is similar with the study conducted by Mugadlimath A et al [14] in which major cause of death was burn in 37.5% cases followed by RTA in 22% cases. But unlike our study, RTA was the major cause of death in study by Rathod AL et al[1], Radhakrishna KV et al [6], Bhabhor R et al [7], Ramalingam S et al[8] and Atrey A et al [15]. In our study major cause of death among males was RTA account for 48.71% followed by burn i.e. in 11.28% cases, which is similar with the study conducted by Rathod AL et al [1] and Vinay Kumar M.S. et al [16], in which RTA among males account for 87.4% and 78%. Similar finding also observed in other such studies also. [1,6,7,8,15,17,18,19] This is due to congested and overcrowded roads with an increase in the number of vehicles and poor traffic sense leads to increased number of vehicular accidents. Major cause of death among females was burn in 61.03% cases followed by poisoning in 12.98% cases, this similar finding of burn as a major cause of death among females was also observed in the study conducted by Mugadlimath A et al [14] and Mishra PK et al [20]. This is because they spend most of their time in kitchen and involve in the activities which required fire like cooking food, making tea, boiling water etc.

**Conclusion**

Our study concludes that burn was major cause of death among all deceased in Sagar region of Madhya Pradesh. So, government should work in the direction to reduce the incidence of burn by bringing out regulations to develop safer cooking appliances and educating the community especially women on safer first aid practices etc. RTA was major cause of death among males. So, traffic rule awareness program should be started, motor vehicle driving legislation must be strengthened and reinforced on time to bring down the numbers at the casualty.

Age group of 21-30 years in both males and females were most commonly involved in all death events which shows their vulnerability in meeting the death due to any cause of death. The mortality can be reduced by proper implementation of government policies and traffic rules.

**Conflict of Interest:** Nil

Abstract

Oral Health is an important component of general health and to maintain oral health oral hygiene plays a major role. It has also become clear that causative and risk factors in oral diseases are often the same as those implicated in the major general diseases. The objectives of the study were to assess the knowledge and attitude of mothers regarding oral hygiene of under five children, to find out their relationship between knowledge and attitude and to determine the association of knowledge and attitude score of mothers regarding oral hygiene of under five children with selected variables. The research approach adopted for the study was quantitative research approach and design was descriptive research design. The study was conducted at selected rural areas of Ambala, Haryana. A total of 200 mothers having under five children were selected by using purposive sampling technique. The tool used for the data collection consisted of Selected Variables and knowledge questionnaire to measure knowledge of under-five mothers. The Reliability of the tool was calculated by Cronbach’s alpha and it was 0.81 for rating scale. Themajor findings revealed that mean of knowledge score was 19.1 and mean of attitude score was 60.9 in the study. There was a significant association found between the level of knowledge and demographic variables i.e. type of family (p=0.00), Have dental problem before (p=0.03), Method used for oral hygiene (p=0.00) and concerned about oral health (p=0.00) in the present study. Hence,It was concluded from the study that the mothers have good knowledge and positive attitude regarding oral hygiene of under five children

Keywords: Oral hygiene, Knowledge, Attitude, Under five children.

Introduction

“Even pearls are dark before the whiteness of his teeth.”

Dental carries is infectious disease and mother is the major primary source of infection for their children. Children under the age of 5 years generally spend most of their time with parents and guardians, especially mothers, even when they attend pre-school or nurseries. Poor attitude of parents towards oral health of infants and young children are associated with increase caries prevalence¹.

India, a developing country, faces many challenges in render in oral health needs. The majority of Indian population resides in rural areas of which more than 40% constitute children. This main aim of this study is imparting oral health education to mothers regarding
oral hygiene of their under-five children who belong to the socio-economically disadvantaged.\(^2\)

The parent’s belief toward children’s oral health plays an important role to improve their children’s oral health. In spite of the fact that early childhood caries has been widely studied and preventive programs implemented in certain countries, early childhood caries is more commonly seen in socially disadvantaged groups, who are lacking of health care systems. Hence, it is essential to assess the knowledge, attitude and practices about their children’s oral health which will help the health providers to understand the reasons for development of oral diseases in children and failure to get them treated\(^2\).

Good oral hygiene has been promoting oral health and preventing oral diseases like periodontal disorders and dental caries and justifying the slogan that “A clean tooth never decays.” Poor oral hygiene practices are an important factor among the causes of periodontal disorders. Moreover the failure of removing plaque and debris that is, not maintaining good oral hygiene and it has been one of the major etiological factors for the initiation of dental caries. Hence, the importance of oral hygiene against diseases like periodontal disorders and dental caries is quite evident\(^3\).

Aims and Objectives

1. To assess the knowledge of mothers regarding oral hygiene of under five children.
2. To assess the attitude of mothers regarding oral hygiene of under five children.
3. To find out the relationship between knowledge and attitude of mothers regarding oral hygiene of under five children.
4. To determine the association of knowledge and attitude score of mothers of regarding oral hygiene of under five children with selected variables.

Methodology

The study was conducted during the month of February-march 2019 at selected rural areas of Ambala, Haryana India. A sample of 200 mothers of under five children participated in this study with the prior permission. The ethical clearance was obtained from the sarpanch of the respective villages. A written consent was obtained from the mothers of under five children who were enrolled in the study. Quantitative research approach with Non Experimental Descriptive survey design was used in this study. The study includes the mothers who were having under five children and willing to take part in the study. A total of 200 participants were enrolled for the study by using Purposive sampling Technique. Data was collected by using Sample Characteristics, Structured Knowledge questionnaire and Structured Attitude Scale.

Description of Tool

**Section-I: Sample Characteristics:** It consist of items regarding the selected Sample Characteristics. The selected Sample Characteristics include Age, Number of children, Type of family, Education of mother, Education of father, Occupation of mother, Occupation of father, Distance to nearby health facility, Have dental problem before, Dental problem is a major health issue, Method used for oral hygiene, Concerned about oral health, Main source of oral health information and Socio Economic Status.

**Section-II: Structured Knowledge Questionnaire to assess Knowledge of Mothers of under five children:** A structured questionnaire was develop to assess the knowledge of mothers regarding oral hygiene of under five children. It consist of 35 multiple choice questions.

**Section III: Description of Attitude Scale Questionnaire:** The standardized tool was used to assess the attitude scale of mother’s regarding oral hygiene of under five children. The tool was used on the basis of previous research evidences, based on extensive review of literature and seeking opinion of experts and guides. It consist of 25 items in which 13 items were Positive and 12 items were Negative.

**Procedure:** The permission was taken to conduct the study from the Respective Villages of Ambala, Haryana. The Consent was taken from the participants prior to the study. The sample Characteristics, Structured Knowledge Questionnaire and Structured Attitude Scale Questionnaire was administered to Mothers. To obtain a free and frank response, the participants were assured about their confidentiality of their response. Purpose of the study was explained to sample subjects before data collection. It was found that it took 20 minutes to complete the questionnaire. The items were found clear and understandable.
Results

Section-I: Frequency and percentage distribution in terms of level of knowledge and attitude of mothers regarding oral hygiene of under five children as given in table 1 and table 2

Table 1: Frequency and Percentage Distribution in terms of level of Knowledge of Mothers regarding Oral Hygiene of under Five Children. N=200

<table>
<thead>

<td></td>
</tr>
</tbody>
</table>

Table 4 depicts that r value 0.06 which was found to be significant at 0.05 level of significant. Thus there was a positive relationship between knowledge and attitude of mothers regarding oral hygiene of under five children.

Section-IV: Association between the level of knowledge and attitude of mothers regarding oral hygiene of under five children with the selected demographic variables showed there was significant association of knowledge score with type of family with p values (0.00*), education of mother (0.00*), Education of father (0.01*), Occupation of Mother (0.02*), Occupation of Father (0.00*), have a dental problem before (0.03*), method used for oral hygiene (0.00*), concerned about oral health (0.00*), main source of oral health information (0.00*) and there was significant association of Attitude Scale with age of Mother (0.03*), Type of family (0.00*), Education of Mother (0.01*), Occupation of Father (0.00*), Distance to nearby health facility (0.00*), Visit to dentist (0.02*), Have a dental problem (0.01*), Dental problem is a major health issue (0.00*), Concerned about oral health (0.00*) and main source of oral health (0.05*).

Discussion

The present study was conducted to assess the knowledge and attitude regarding oral hygiene among mothers of under five children.

Findings of the present study indicated that 46.5% of mothers had good knowledge regarding oral hygiene of under five children. These findings are consistent with the study conducted by Suresh BS, Ravi Shankar TL, Chaitra TR, Mohaptra AK, Gupta V to assess the mother’s knowledge about preschool child’s oral health, which revealed that mothers had (73.8%) good knowledge regarding oral hygiene.

Findings also revealed that the 90.5% of mothers...
of under five children had moderately favorable attitude towards oral hygiene of under five children. These findings are consistent with the findings of the study conducted by Moallemi, Z., Virtanen, J., Ghofranipour, F. and Murtomaa, H. (2008) to assess the influence of mothers’ oral health knowledge and attitudes on their children’s dental health, which revealed that mothers had (92%) positive attitude regarding oral hygiene5.

**Conclusion**

The finding of the study shown that mothers of under five children have average knowledge and had moderately favorable attitude regarding oral hygiene. There is negative correlation between the knowledge and attitude of mothers regarding oral hygiene of under five children.

**Ethical Clearance:** The permission was obtained from the sarpanch of the respective villages and written consent from the mothers of Under five Children.

Load of Firearm Cases in Male at SMS Medical College, Jaipur

Shanti Lal Pargi\textsuperscript{1}, Lovekumar Bhagora\textsuperscript{2}, Deepali Pathak\textsuperscript{3}, R.K. Punia\textsuperscript{4}, Rohit Kumar Meena\textsuperscript{5}

\textsuperscript{1}Assistant Professor, Dept. of Forensic Medicine, Ananta Institute of Medical Science & Research Center, Rajsamand, Udaipur; \textsuperscript{2}Assistant Professor, Dept. of Forensic Medicine, Geetanjali Medical College, Udaipur; \textsuperscript{3}Associate Professor, Dept. of Forensic Medicine, SMS Medical College, Jaipur; \textsuperscript{4}Professor, Dept. of Forensic Medicine, SMS Medical College, Jaipur; \textsuperscript{5}Senior Resident, Dept. of Forensic Medicine, SMS Medical College, Jaipur, Rajasthan

Abstract

Introduction: A Firearm is a thermodynamic machine in which the potential energy of the gun-powder is transformed into the kinetic energy of the projectile.

Aims and Objective: To assess the load and analyze the male cases of firearm injuries.

Material and Methodology: The present prospective study had been conducted in the Department of Forensic Medicine, SMS Medical College & Hospital, Jaipur, Rajasthan during the period of One & half year from May 2014 to October 2015. All cases of firearm injuries that were received dead or live at SMS Hospital and its attached Hospitals, Jaipur was included in our study.

Result and Observation: In our study majority of firearm injury case [43 cases (40.78%)] were observed in the age group of 20-29 years followed by the age group of 30-39 years [28 cases (27.18%)]. Majority of the incidences of gun-shot injuries were homicidal in nature (80.58%) followed by accidental episodes (14.56%). Land and property disputes were the most common reason behind firearm injuries in this study (42.72%) followed by revenge & robbery (15.53% & 13.59 % respectively); Majority of the incidences occurred during evening in 43 cases (41.75%), followed by afternoon 40 cases (38.83%). There was presence of firearm entry wound in all victims. Overall, 52 cases (50.49%) had a single entrance wound, 13 cases(12.62%) had two entry wounds, In summer season 43 cases (41.75%), spring 24 cases (23.30%), winter 20 cases (19.42%), autumn 16 cases (15.53%), were reported in studied cases. In majority of the cases (81.55%), there was no exit wounds while one exit wound was found in 17 cases (16.51%). In rest of the two cases, two exit were found in two cases.

Conclusion: The results of the present study support the argument that rigorous pursuit of campaign firearms without a license and country made guns may prove useful in reducing the number of firearm injuries in society.

Introduction

A Firearm is a thermodynamic machine in which the potential energy of the gun-powder is transformed into the kinetic energy of the projectile\textsuperscript{1}.

Firearms and explosives constitute convenient means of destroying human life from considerable distance, providing opportunity to the offender to escape;
it has been the weapon of choice for gangsters, terrorists, extremists, antisocial and anti-national elements for eliminating their victims. Its use is increasing in recent years because of easy availability due to manufacture of huge amount of arms, ammunition and explosives and free smuggling across the international borders 2.

Data on firearm injury in a particular geographic area can also give the reflection of its law and order situation. A low value can be described in favour of peace, harmony and security to human life 3.

There is growing concern about the indiscriminate use of firearms on a large scale, particularly in the last decade. The availability of firearms known as small arms and light weapons (SALW) has been described as a cancer spreading across the developing world 4.

This study was thus undertaken to assess the load of gun-shot injuries among in Jaipur region and to ascertain the medico-legal and socio-demographic profile of cases presented at SMS Medical College, Jaipur during the study period along with associated deaths in Jaipur region to look for reason behind them; and also to suggest few recommendations which may prove useful in bringing down the toll of firearm injuries in this region.

Aims and Objectives:

To assess the load and analyze the cases of firearm injuries and associated deaths reported at the Department of Forensic Medicine, SMS Hospital, Jaipur during the study period (May, 2014 to October, 2015).

To study the load of firearm injuries and associated deaths reported at the Department of Forensic Medicine during the study period.

To study the medico-legal profile of firearm injuries.

To study the socio-demographic profile of victims of firearm injuries.

Material and Methodology

All the cases of firearm injuries, irrespective of age, gender and socioeconomic status received at the casualty of SMS Hospital, Jaipur, dead or alive, later admitted to various wards of SMS Hospital, Jaipur were included in the study. All cases of firearm injuries that were received dead at SMS Hospital and its attached Hospitals, Jaipur was autopsied at the mortuary of SMS Hospital, Jaipur and included in the study. Also the cases of non fatal firearm injuries admitted to various wards of SMS Hospital and its attached hospitals, Jaipur were included in the study after receiving an informed consent for the same. All the observations were recorded in the pre proposed Performa as detailed above. The results of the present study were further compared to other contemporary studies from various parts of the country.

Observations and Result

Table 1: Age and Sex Wise Distribution of Firearm Injuries Cases.

</tbody>
</table>

In majority of the cases [84 cases (81.55%)], there were no exit wounds while one exit wound was found in 17 cases (16.51%). In rest of the two cases, two exit wound were found in two cases.

Discussion

Maximum numbers of cases were from 20-39 years of age (67.96%) with peak incidence in 20-29 years (40.78%) which are the productive and active members of the society. The observations of the present study were similar to those of Patowary AJ et al., Sachan R et al, Kumar K et al (peak incidence between 21-40 years of age in all). However, the results of the present study are variable from those of Kumari S et al with majority number of cases in 11-20 years followed by 21-30 years. The probable reason for this variation is the minor cultural and periodical differences as most other studies from the same state also report the highest incidences of such cases between 21-40 years.

Homicides [83 cases (80.58%)] were the most common manner of firearm injuries in the present study followed by 15 cases (14.56%) accidental and 02 cases (1.94%) suicidal firearm injuries. The manner remained undetermined in 03 cases (2.91%). Homicidal intent was predominant in most other studies Sachan R et al, Kumar K et al and Kumari S et al. Other studies have considered either only homicidal Patowary AJ et al or suicidal firearm injuries. The preponderance of homicide in gun-shot injuries is explainable as these deadly weapons are generally used in planned manner or more so impulsively in a planned assault. It is not very easy to procure such weapons and not that very easy to carry it due to legal restraints, so, they are not
the weapon of choice in fights and assaults. They are mostly used in planned episodes of homicidal or suicidal injuries. Accidental injuries with firearms are also not uncommon as users are prone to such episodes while cleaning, maintenance or erratic handling of loaded guns. Accidental injuries were seen in this study in 16.52% cases but these results are quite high as compared to studies of Kumar K et al and Kumari S et al.

Land and property disputes were the most common reason behind firearm injuries in this study [44 cases (42.72%)] followed by revenge 16 cases (15.53%) & robbery 14 cases (13.59%); group quarrel accounted for another 5 cases (4.85%) and there were 03 cases each (2.91%) for defense and love matters/sexual jealousy. In 9 cases (8.74%), the motive remained undetermined. As per Kumar K et al the motive remained undetermined in a single case of accidental firing (1.73%). This difference is attributable to the variation in the proportion of accidental incidences in the two studies. There were 10 cases of purely accidental gun-shot injuries where motive was lacking. According to Patowary AJ et al, most cases were due to militant activities, encounters, riots, robberies or family quarrel. This variation from our study is due to the regional variations in the areas of study as Guwahati and Imphal are militant activity prone areas. The results of the present study are quite similar to those of Sachan R et al. But, in slight variation with Kumar K et al where maximum homicides occurred for personal enmity. The motives behind the homicidal attack with firearm weapons were well represented in different cases with property land disputes majorly responsible followed by personal enmity and robbery.

Most of the events of firearm injuries occurred during evening hours (41.75%) followed by afternoon (38.83%). These are the hours of work and business, thus prone to activity during which the untoward event took place. 8.74% incidences took place in morning hours. Thus, it was observed that in 47.57% cases, the incidence took place in broad daylight and 52.43% cases occurred after sunset; as also reported by Kumar K et al. The late night hours witnessed the least numbers of gun-shot injuries (8.7%) in the present study which is in contrast to the findings of Kumari S et al. The suicides (two cases) were committed in morning and evening each.

None of the season was poorly represented by episodes of firearm injuries and deaths. However, summer season was most flooded with events of firearm injuries in the present study (41.75%) followed by spring (23.30%) and winter (19.42%). This is quite explainable as maximum events in this study took place for land disputes in villages. Summer season is a comparatively relaxing one for those engaged in Agriculture as the main crop of this region is through by the end of spring. After the harvest of the crop, the disputes probably come to surface owing to distribution of revenue generated.

Exit wounds were present in only 84 cases (18.26%) i.e. in majority of the victims, firearm exit wounds were not present. These are quite less in number due to the predominance of distant fires in this study. In the present study, a single exit wound was found in 17 cases (16.51%) and in 2 cases (1.74%) there were two exit wounds. These results are quite low in comparison to those of Kumar R et al and, Kumari S et al who reported presence of exit wounds in 61.36% & 60% victims respectively.

**Conclusion**

This study indicated that the most common victims of firearm injuries were young males of bread earning age followed by youth which raises concern towards this issue. Certain changes may minimize mortality and disability due to firearm injuries, also reducing the costs to the community. As a result of the invention of more advanced firearms and availability at the global level, death rates due to firearm injuries have increased recently. There is a powerful correlation between acquisition of a firearm and its use in murders, suicides and unintentional deaths. So, there is a need to decrease the number of firearms used and sold in India.

The results of the present study support the argument that rigorous pursuit of campaign firearms without a license and country made guns may prove useful in reducing the number of firearm injuries in society. Educational efforts and individual, community and societal approaches are needed to alleviate firearm related injuries.

Abstract

The development of an effective vaccine against malaria is essential. Domain Duffy-binding-like (DBL)2β in Plasmodium falciparum erythrocyte membrane protein 1 (PfEMP1) protein is one of the vaccine candidate proteins because of its binding capacity to ICAM-1 receptor. However, the high polymorphism needs epitope identification before formulating a peptide-based vaccine. This study aimed to identify the conserved epitopes in PfEMP1-DBL2β by an immunoinformatic approach. The protein sequences were analyzed to predict the hydrophobicity attributes, T-cell and B-cell epitopes. T-cell epitopes were identified using the NetCTL and Propred server and analyzed for population coverage rate using the IEDB analysis tool. Moreover, the Bepipred 2.0 and Kolaskar Tangaonkar method combined with the K-means clustering were used to predict the B-cell epitopes. This study found that the hydrophobicity value of PfEMP1-DBL2β recombinant protein is 32.62, indicating that this protein is soluble and potentially fit into HLA alleles active site. Two conserved antigenic CTL epitopes with near 90% population coverage rate in the malaria target population were identified. For Th cell epitopes, the NN-align algorithm showed no overlapping strong binding epitope positions for three chosen Indonesian and African alleles. Three B-cell conserved epitopes were identified at the position of 77-89, 236-254 and 360-377 amino acids with one cluster overlapping with ICAM-1 determinant binding area. The predicted conserved epitopes within the protein in this study are valuable in constructing a subunit peptide-based malaria vaccine candidate. A further experimental study is needed to validate this approach as the next step in vaccine development.

Keywords: DBL2β, epitope, immunoinformatic, malaria, PfEMP1.

Introduction

Malaria is one of the most important infectious diseases; it is responsible for 400,000 deaths each year worldwide. Indonesia is one of the countries that have more than 100,000 increasing cases in 2017(1). WHO has several strategies and recommendations to control malaria. A vaccination is considered a great and effective solution as a prophylactic treatment for infectious disease, especially for severe malaria-causing high morbidity and mortality (2).

Pathology of severe malaria involves aggregation and adhesion in microvascular of vital organs called cytoadherence. This mechanism reduces and further obstructs blood flow resulting in organ failure. Besides, cytoadherence can contribute to immune evasion mechanisms causing the spleen’s inability to destroy the infected erythrocyte(3). The cytoadherence is mediated
by Plasmodium falciparum erythrocyte membrane protein-1 (PfEMP1), a protein expressed by the parasite and deposited on the surface of infected erythrocyte which can bind to various host cell receptors. PfEMP1 is a complex protein and consists of several domains, one of them is the Duffy-binding-like (DBL)2β domain that has an affinity toward Intercellular Adhesion Molecule-1 (ICAM-1) receptor found in endothelial cell of microvasculature including the brain(4).

The adhesion of PfEMP1 domains to several host receptors plays an essential role in mediating severe malaria pathogenesis, thus makes this protein as a target in developing the peptide-based vaccine. However, the complexity of the parasite’s life cycle, high antigenic switching rate and immune evasion ability of the parasites are the major problems(5).

The development of the current vaccine is focusing on the discovery of subunit epitope-based vaccines that incorporate one or more semi-purified or even purified antigens. To develop a subunit vaccine, determine the immunological properties of the target protein in generating protection is critical since some peptides may be immunosuppressive or even enhance the disease. Peptides associated with protective epitopes are preferable vaccine candidates, but testing out every peptide as an epitope for their ability to generate protective immune response has several limitations. Aside from time and labor consuming, most peptides expressed during in vivo infection is not expressed the same during in vitro cultivation. Analyzing every individual peptide that is abundant in cultivation also ineffective and difficult(6).

Due to these problems, the immunoinformatics approach has been utilized to identify subunit vaccine candidates from bacterial, viral and parasite genome sequences. This approach called reverse vaccinology works by analyze the genome sequence in silico and predict the feasible peptide with the ability to act as an epitope and thus have the protective capacity(7).

Method

Analysis of protein hydrophobicity: The amino acid sequences of PfEMP1-DBL2β protein from Indonesian isolate cloned by Sulistyaningsih (9), which was deposited at the NCBI (https://www.ncbi.nlm.nih.gov/) with the accession number AGJ83325.1 were retrieved and subjected to check its hydrophobic attribute by using Peptide Property Calculator Program (http://www.biosyn.com/PeptidePropertyCalculator/PeptidePropertyCalculator.aspx).

T-Cell Epitopes Prediction for MHC I and MHC II: The binding of antigen to major histocompatibility complex (MHC) molecules possess a significant role in determining whether an antigen is immunogenic or not. Prediction of the T-cell epitope in developing a subunit vaccine can diminish the experimental step to identify the suitable epitopes in vaccine design. In this study, T-cell epitope prediction for MHC I was done by using NetCTL (http://www.cbs.dtu.dk/services/NetCTL/), an online server for predicting epitopes of human cytotoxic T lymphocyte (CTL) based on protein sequence input. The epitope prediction was conducted by combining the prediction of MHC Class I affinity, TAP transport efficiency and proteasomal cleavage for 12 MHC I supertypes. This tool has better predictive performance compared to several other tools in large scale data(11).

T-cell epitopes prediction tool used in this study was the Vaxijen 2.0 online antigen prediction (http://www.ddg-pharmfac.
This server was developed to predict protective antigens from several hosts and capable of classifying antigen based on its physicochemical properties, resulting in an antigen probability report for each protein. With the threshold set on 0.5, this prediction server can perform with an accuracy of 87%\(^1\). T-cell epitopes for MHC I alleles with the highest probability as a protective antigen were subjected to conservancy analysis with IEDB tools (http://www.iedb.org/) with a 100% threshold compared with Pf11_0521 sequences (accession number XP_001348176.1) and analyzed for its coverage within-population by keeping the parameters on default. The population coverage analysis resource tool determines the ratio of individuals predicted to react toward a given set of epitopes.

Major histocompatibility class II (MHC Class II) is another major part in initiating an immune response. This molecule is normally found on antigen-presenting cells (APC) to present antigens derived from extracellular protein. Because MHC Class II interacts with other immune cells such as lymphocyte T helper cell (CD4\(^+\)), identifying peptide that have an affinity with this molecule is important in vaccine design. Prediction of the binding peptide with MHC Class II was completed by using ProPred (https://webs.iiitd.edu.in/raghava/propred/), an online server to predict antigenic epitopes for 51 HLA Class II alleles based on the amino acid coefficient table. This server can locate the promiscuous binding region from the input protein. The default threshold was put on 3% to limit false-positive results\(^1\). The affinity values for the predicted promiscuous peptides were evaluated using several tools available in the IEDB server. The NN-align algorithm was chosen due to its better predictive performance than other method for HLA-DR peptide binding prediction, such as SMM-align and NetMHCIIpan\(^1\). The predicted peptides were analyzed against three HLA-DR alleles from the malaria target population (Indonesian, East Africa and West Africa) chosen from Allele Frequency Net Database (http://www.allelefrequencies.net/default.asp) and the affinity was showed as IC50 values.

**Explanation:** Antigenicity score, as predicted by VaxiJen 2.0 server ≥0.5, showed that the peptides were classified as an antigen and able to induce host immune response.

**Research Findings:**

**Hydrophobicity Attribute Analysis:** The PfEMP1-DBL2\(^\beta\) protein was subjected to measure the hydrophobicity attribute by using the Peptide Property Calculator program. Protein with hydrophobicity <50% is soluble in aqueous solution, while hydrophobicity >50% is considered partially soluble or insoluble. The more soluble in the aqueous phase, the bigger the probability of the protein to fit into MHC molecules active site cleft\(^8\). Based on the Peptide property calculator program, the hydrophobicity value of PfEMP1-DBL2\(^\beta\) protein was 32.62, indicated that this protein is fully soluble in the aqueous phase.

**T-Cell Epitopes Prediction:** NetCTL prediction tool showed a total of 137 epitope sequences reacting with 12 MHC I alleles supertypes, with 31 sequences reacted with multiple supertypes (Supplementary Table 1). Each epitope sequence was analyzed for the antigenicity using VaxiJen 2.0 server, showing antigen probability classification. IEDB conservancy analysis tool further analyzes conserved sequences compared with Pf11_0521, a PfEMP1 protein isolated from Tanzania children. Two conserved T-cell epitopes from MHC I were generated, as listed in Table 1. Both conserved sequences met the criteria of the default threshold level in VaxiJen 2.0, which is ≥0.5.

**Identification of B cell epitope clusters:** The B cell epitopes within PfEMP1-DBL2\(^\beta\) were identified using two method, i.e., Bepipred 2.0 and Kolaskar-Tangaonkar method in the IEDB server. Both method were chosen because of their accuracy. The Bepipred 2.0 is the latest epitope predictor that identify epitopes from peptide crystal structures. It was presumed to give higher quality prediction than other available tools\(^16\). Moreover, the Kolaskar-Tangaonkar method uses the physicochemical properties of amino acid and their frequencies of occurrence to predict protein antigenic determination\(^17\). With default parameters, both method gave antigenicity scores as a result, which is categorized using the K-means clustering method and depicted in a heat map showed epitope densities of the amino acid sequence.
Population Coverage Analysis of MHC I Epitopes: Highly polymorphic MHC molecules remains a challenge for researchers in developing an effective vaccine. The high number of HLA allelic sequences identified were showed as a widely varying binding specificity of MHC molecules and expressed at different frequencies in different ethnicities. Because malaria is endemic to only several populations, choosing the suitable peptides that reacting with the most expressed MHC alleles in target populations is necessary for rational vaccine design.

IEDB population coverage analysis tool calculates the percentage of individuals predicted to react with a given set of epitopes. Two conserved epitopes of MHC I molecules exhibited different coverage rates in several different populations known as the malaria-endemic area, as depicted in Figure 1.

![Figure 1: Predicted Population Coverage Rate (%) of two conserved MHC I epitopes (YIPQRLRWM and WMTEWAEWY) of DBL2β-PfEMP1 recombinant protein Indonesian isolate in the malaria target population.](image)

For epitope prediction based on its affinity with MHC II alleles, the Propred prediction generated 31 epitope sequences that act as promiscuous peptides (Supplementary Table 2). In the same manner with epitope prediction for MHC I allele, Vaxijen 2.0 server was used to analyze the antigenicity score and classify each peptide into an antigen and non-antigen, resulted in 17 epitope sequences predicted as antigen.

The prediction analysis of T cell epitopes affinity toward the MHC II allele used the NN-align algorithm in IEDB\(^{(15)}\). The IC50 values distribution between each amino acid position was presented in Figure 2. Epitopes with scores lower than 50 nm were considered as strong binders, 50-500 nM as intermediate binders and >500 nM as weak binders. Figure 2 also showed that the strong binding amino acid positions are different among the three target population HLA-DR alleles chosen in this study.
**B cell epitopes prediction in PfEMP1-DBL2β protein:** Two techniques performed determination of the B cell epitopes presence in PfEMP1-DBL2β protein, i.e., the Bepipred 2.0 algorithm\(^{(16)}\) and Kolaskar-Tangaonkar method\(^{(17)}\). Subsequently, the antigenicity scores and epitope density regions on each amino acids were used as a variable in the K-means clustering method to generate a heat map showed in Fig 3. This method has been used to differentiate regions with a higher concentration of epitopes\(^{(18)}\).
Figure 3: A heat map depicted the distribution of epitope dense regions throughout the DBL2β-PfEMP1 amino acid sequence. The regions were determined based on Bepipred 2.0 algorithm and Kolaskar-Tangaonkar method, clustered by the K-means method. Each amino acid categorized into high, medium, low and non-epitope based on its antigenicity score. The red color represents a region with high antigenicity score epitope, orange indicates a region with medium antigenicity score epitope, yellow depicts region with low antigenicity score epitope and black denotes regions with no B-cell epitope. Potential B-cell epitope clusters are speculated positioned in the area with overlapping red and orange colors between two method (black arrows).

The Bepipred 2.0 algorithm predicted different epitope cluster regions from the Kolaskar-Tongaonkar method. We hypothesized that the overlapping position between two method as a potential B cell epitope clusters with maximum antigenicity score.

Within the 558 amino acid sequence designated in the heat map, the K-clustering method predicted several epitope clusters with the highest antigenicity, as shown in Table 2. One of these epitope clusters coincidentally aligned with the Y motif area of PfEMP1-DBL2β protein\(^{(19,20)}\).

**Table 2. B-cell epitope sequences and position within DBL2β-PfEMP1 protein**

**Explanation:** B-cell epitopes prediction in overlapping area and their position within DBL2β-PfEMP1 protein. The first two epitopes located in the semi-conserved area and one aligned with the Y motif, which is a conserved area as well as a binding area with ICAM-1 receptor.

**Discussion**

The development of a malaria vaccine is still facing many obstacles. High antigenic switching rates and immune evasion ability of the parasites often cause a specific antigen-based vaccine not able to generate the expected immune response. Retrieving information about antigen immunogenicity through in vitro or in vivo experiments needs considerable time and resources, scientists call for another approach to obtain the information prior to the true experimental procedure, i.e., the bioinformatic approach, it is a powerful tool to analyze antigenic protein properties in order to design an efficient and effective vaccine\(^8\). In this study, an immunoinformatic approach towards PfEMP1-DBL2β protein from Indonesian isolate cloned previously by Sulistyaningsih\(^9\) was used to analyze the potency of the recombinant protein to bind to T cell and B cell lymphocyte.

The major histocompatibility complex (MHC) molecule is a group of receptors on the cell surface and has a major role in the immune response. Peptide sequences expressed on MHCs are called T Cell epitopes. Generally, MHC is classified into two classes; MHC I molecules with β2 microglobulin subunit, which can be recognized by CD8 co-receptors (Cytotoxic T Cell/CTL) and MHC II molecules with β1 and β2 subunit which can be recognized by CD4 co-receptors (T helper cell/Th cell).

A part of the antigenic protein bind to MHC molecules that can be recognized by lymphocyte T cell and capable of inducing an immune reaction is called immune epitopes\(^{21,22}\). Total 31 MHC I epitopes predicted in this study were subjected to population coverage analysis, showed that two conserved MHC I epitopes from PfEMP1-DBL2β Indonesian isolate protein (YIPQRLRWM and WMTEWAEMY) have almost 90% coverage rate in East Africa and West Africa. The coverage rate indicates that a vaccine design based on these presumed epitopes might be performed efficiently for most of the population in East and West Africa, where the incidence of malaria is the highest\(^{31}\).

Using different algorithm predictions from the MHC I epitopes for CTL, the analysis for Th cell epitopes mediated by MHC II molecules, showed 17 promiscuous peptides predicted to be antigenic. The potency of PfEMP1-DBL2β protein from Indonesian isolate as a T-cell epitope-based subunit vaccine was analyzed by the NN-align algorithm to identify its immune epitope. The study used three different HLA alleles commonly found in the Indonesian and African populations (HLA-DRB1*04:05, HLA-DRB1*07:01 and HLA-DRB1*11:01), there are several epitopes found with IC50 values under 50. Even though hydrophobicity values of this protein showed that it potentially fits into the active site cleft of HLA alleles, epitopes mapping depicted in Fig 2 showed that there are no overlapping epitope positions for the three alleles with IC50 values under 50. It indicated that HLA alleles polymorphic variations still pose as a factor affecting PfEMP1-DBL2β protein from Indonesian isolate affinity toward MHC Class II molecules. Additional allele variants may allow broader population coverage and can be very useful in T lymphocyte cell epitope-based vaccine development\(^{21}\).

Aside from lymphocyte T cells’ immune responsibility, lymphocyte B cells also have some essential functions in specific antibody production. Peptide regions that bind to lymphocyte B cell receptors are called B cell epitopes. The epitopes analysis on lymphocyte B cell was done by using two algorithms, i.e., Bepipred 2.0 and Kolaskar-Tangaonkar Method. Both predictions showed the antigenicity scores for every amino acid composing PfEMP1-DBL2β protein from Indonesian isolate, which was subsequently categorized based on epitopes density area in the sequences and depicted as a heat map. Fig 3 showed different epitope clusters position between two prediction method in the heat map. Several overlapping clusters were observed at the position of 77-89, 236-254 and 360-377, implicated locations of B cell epitopes with the highest antigenicity and density.

An epitope located at the position of 360-377 is coincidentally aligned with one of the few conserved areas in PfEMP1-DBL2β protein, called Y motif\(^{19}\). The Y motif is known as conserved residues that have functioned as a binding area with ICAM-1 receptor found in cerebral vasculatures. Binding between ICAM-1 and PfEMP1-DBL2β domain via Y motif is essential in the pathogenesis of cerebral malaria\(^{23,24}\). A shared conserved epitope cluster is important in malaria vaccine development because, with the high antigenic switching rate of PfEMP1, this cluster can be recognized by the
immune system and potentially able to generate a cross-reaction between parasite isolates\(^\text{25,26}\). Several studies showed that cross-reaction between PfEMP1 isolates do exist, P. falciparum infection in tourists who just come back from an endemic area have antibody with wide cross-reaction and persistent for more than 20 weeks post-infection\(^\text{27,28}\). This phenomenon, also found in placental malaria, mediated by var2CSA, showed polymorphism but wide cross-reaction toward different isolates\(^\text{29}\). The molecular base for this cross-reaction toward specific antigen has not been fully understood, but polymorphic shared epitopes between PfEMP1 isolates are expected to have a major role\(^\text{4,30}\).

**Conclusion**

The vaccine development to combat malaria as a global health problem is an important issue. In addition to advancements in technology, performing in silico study through an effective and efficient immunoinformatic approach provides ease in analysis protein immunogenicity prior to in vitro or in vivo experimental tests for vaccine development. In this current study, the immunogenicity value of PfEMP1-DBL2β protein from Indonesian isolate was conducted by Th cell and B cell epitope predictions. Homolog with DBLβPF11_0521 protein found in Tanzania children, the PfEMP1 from Indonesian isolate has B cell epitopes located in the conserved Y motif area, making it a potential subunit peptide-based malaria vaccine. A further experimental study concentrated on the delivery mechanisms and the in vitro or in vivo experimental of interaction with the immune system is needed to validate this approach as the next step in subunit peptide-based vaccine development.

Effectiveness of Video Assisted Teaching on Testicular Self Examination

Shenbagapraba N.¹, Sathu Roslin¹, Thivya N.¹, Yaga Jeyanthi M.², L. Lakshmi³

¹Assistant Professor, ²Associate Professor, ³Professor, Department of Community Health Nursing, Chettinad College of Nursing, Chettinad Academy of Research and Education, Kelambakkam, Kanchipuram District, Tamilnadu, India

Abstract

Testicular cancer is one of the most treatable types of cancer for around 4% of cases. More than 96% of men with early stage testicular cancer will be completely cured. Even cases of more advanced testicular cancer, where the cancer has spread outside the testicles to nearby tissue, have an 80% chance of being cured. Testicular cancer is the most common cancer in males between the ages of 15 and 35. The study topic was “Effectiveness of Video Assisted Teaching on Testicular Self Examination among young adult men in a selected college at Kanchipuram District, Tamil Nadu, India. The objective of the study were to assess the pre-test knowledge on testicular self examination among young adult men, to assess the effect of video assisted teaching on testicular self examination among young adult men, to associate between pre-test, post-test knowledge regarding testicular self examination among young adult men with selected demographic. Quasi-experimental research design was used for this study. The sample consist of 50 adult men. Self-structured questionnaire was used to assess the knowledge on testicular self examination among young adult men. The data collection period was one week. The data was collected in 50 adult men in the age group between 18 to 35 years in a selected College, Kanchipuram District, the sample was selected by purposive sampling technique. The data was analysis and tabulated. The study results shows that majority 16% having inadequate knowledge, 80% having moderate knowledge & 4% of them having adequate knowledge regarding testicular self examination after the video assisted teaching the study results shows that majority 74% having adequate knowledge, 26% having moderately adequate knowledge and none of them were having inadequate knowledge regarding testicular self examination.

Keywords: Effectiveness, Testicular Self Examination, Video Assisted Teaching, young adult, Men.

Introduction

Testicular cancer is one of the most treatable types of cancer for around 4% of cases. More than 96% of men with early stage testicular cancer will be completely cured. Even cases of more advanced testicular cancer, where the cancer has spread outside the testicles to nearby tissue, have an 80% chance of being cured. Testicular cancer is the most common cancer in males between the ages of 15 and 35.⁴

The testicles are an important part of the male reproductive system because they produce sperm and the hormone testosterone, which plays a major role in male sexual development. The different types of testicular cancer are classified by the type of cells the cancer first begins in. The most common type of testicular cancer is known as ‘germ cell testicular cancer’, which accounts for around 95% of all cases. Germ cells are a type of cell that the body uses to help create sperm.³
**Material and Method**

**Research Approach:** Descriptive Research approach

**Research Design:** Quasi experimental design

**Research Setting:** The study conducted in a selected college.

**Population:** Adult men who were in a selected college.

**Sample:** The age group between 18 to 35 years in a selected college.

**Sample Size:** \( n = \frac{[\text{DEFF} \times \text{Np}(1-p)]}{[(d^2/ Z_{1-\alpha/2}^2) \times (N-1) + p^*(1-p)]^{.50}} \) .50 samples .

**Sample Technique:** Purposive sampling technique

**Findings:**

**Section A:** Frequency and percentage distribution of demographic variables to Effectiveness of Video Assisted Teaching on Testicular self examination among young adult men in a Selected college.

**Age:** The maximum 60% of the sample belongs to the age group between 21-24 years, 40% were in the age group between 17-20 years.

**Education Status for Father:** The maximum 34% of the sample belongs to the secondary, 34% of the sample belongs to the Primary Education, 20% were in the higher education, 12% of the samples were illiterate.

**Education Status for Mother:** The maximum 40% of the sample belongs to the secondary, 28% of the sample belongs to the Primary Education, 20% were in the higher education, 12% of the samples were illiterate.

**Section B:** Distribution and percentage of pre-test knowledge on Testicular self examination.

The study results shows that majority 16% having inadequate knowledge, 80% having moderate knowledge & 4% of them having adequate knowledge regarding testicular self examination.

**Section C:** Distribution and percentage of post-test knowledge on Testicular self examination among young adult men in a Selected college.

The study results shows that majority 74% having adequate knowledge, 26% having moderately adequate knowledge and none of them were having inadequate knowledge regarding testicular self examination.

**Section D:** Comparison of Pre-test and Post-test Knowledge on testicular self examination.
It depicts that Pre-test level of knowledge regarding the Effectiveness of Video Assisted Teaching on Testicular Self Examination mean score was 4.33 and the Post-test mean score was 8.47 which projects ‘t’ value of -15.70 which was statistically significant at p <0.05 level. The ‘t’ value is greater than the table value hence the research hypothesis is accepted. The post-test knowledge score is greater than the pre-test knowledge score. There is a significant difference between pre and post test score. This indicates the Video assisted teaching on the Testicular Self Examination is effective in increasing the knowledge level among young adult men.

**Section E:** Association between post-test knowledge regarding Testicular self examination.

It reveals that there is significant association between the levels of knowledge regarding the Testicular self examination with age, educational status of mother, education status of father, occupational status of father, occupational status of mother, place of living area, family history of testicular cancer and aware of self examination p<0.05. Thus the researcher rejects the null hypothesis and accepts the research hypothesis.

**Discussion**

It deals with the discussions in accordance with the objective of the study and hypothesis. The study was conducted to assess Effectiveness of Video Assisted Teaching on Testicular Self Examination among young adult in selected college, Kanchipuram District, Tamilnadu. A total of 50 samples were selected by using purposive sampling technique; the knowledge level of samples was assessed using a self-structure questionnaire. The collected data were analyzed by using the descriptive statistic and inferential statistics. This chapter discusses the findings of the study derived.

**Summary:** This chapter deals with the analysis and interpretation of the collected data from the Effectiveness of Video Assisted Teaching on Testicular Self Examination among young adult in selected college. The data collected was tabulated and analyzed using descriptive and inferential statistics, frequency and percentage were compared to summarize the sample characteristics. Mean, mean percentage and chi square were used to compare the Effectiveness of Video Assisted Teaching on Testicular Self Examination.

Knowledge, Awareness and Attitudes About Research Ethics among Faculty and Post Graduate Students of the Medical & Dental Professionals in Professional Institutions

Shivananda S.1, Vidya G. Doddawad2, Ravi Vaswani3

1Associate Professor, Department of Oral and Maxillofacial Surgery, JSS Dental College and Hospital, A Constituent College of JSS Academy of Higher Education & Research, Mysore-570022, 2Associate Professor, Department of Oral Pathology and Microbiology, JSS Dental College and Hospital, A Constituent College of JSS Academy of Higher Education & Research, Mysore-570022, 3Former Registrar, Professor, Department of Internal Medicine, Yenepoya Medical College, A Constituent College of Yenepoya University, Mangalore-575018

Abstract

Introduction: The research ethics plays a very vital role in the collection, analysis, reporting and publication of details about research subjects, in particular active acceptance of participant’s right to privacy, confidentiality and the informed consent of the participant.

Aims: To assess the Knowledge, awareness and attitudes about research ethics among the faculty and students of medical and dental colleges and the requirement for a regular teaching about research ethics among the faculty and students of medical and dental colleges.

Materials and Method: A cross-sectional study was conducted by assessing the responses to 39 selected basic questions regarding Knowledge, awareness and attitudes about research ethics among a total of 415 faculty members and post graduate students of the medical and dental institutions in Mysore city of Karnataka state. The online questionnaire was created by using Google forms. The questionnaire was made into 5 categories. Chi-square tests was used to determine, in bivariate analyses, the association of each of the independent variables. The students t-test was done to assess the respondents scores on the 5-point Likert scale ranging from 1 to 5. The average of their scores were compared among the various variable like their specialty and academic position by using the ANOVA test.

Results: A total of 415 responses were obtained from the participants of the study. The response tabulated under various sections clearly showed deficiency in the understanding of research ethics. The P value was kept at 0.05 for this study.

Conclusion: The participants of the questionnaire survey showed that the institutional ethics committees would be very useful for promoting health research and are imperative for appraisal of the health research projects. The requirement for a regular teaching about research ethics among the faculty and students of medical and dental colleges is very important. Further study in this area is very much needed.

Keywords: Research ethics, Knowledge, Awareness and attitudes, Students, Faculty, Professional college.

Introduction

Research is defined as the systematic investigation into and study of the materials and sources in order to establish facts and reach new conclusions. It consists of three steps: to pose a question, to collect data to answer the question and to present an answer to the question.
The research ethics provides guidelines to apply moral regulations and professional codes of conduct in the various steps of research\(^2\). The research ethics provides guidelines for the responsible performance of research on human participants.

**Need for the Study:** Good knowledge about research ethics among the faculty and PG students in Health Institutions has become very important for the benefit of researcher & his team, to provide good quality of ethically made research not only for the benefit of the participants of the study, but for the whole humanity\(^5\).

**Research Question/Hypotheses:** What is the knowledge and awareness about research ethics among the among faculty and post graduate students of the medical & dental professionals in professional institutions?

How much ethics in research is being practiced among the faculty and post graduate students of the medical & dental professionals in professional institutions in their speciality?

**Materials and Method:** Out of 800 available sample size about 415 faculty members and 385 post graduate students of the medical and dental institutions in Mysore city of Karnataka state were included in the study group.

Source of Data: The faculty and post-graduate students of various dental and medical colleges in Mysore city of Karnataka state.

Inclusion Criteria: The faculty and the post graduate students of Institutions in Mysore city of Karnataka state who are interested to participate in the online questionnaire study.

Exclusion criteria: The participants who are not willing to give written the consent to answer the questions in the online questionnaire.

**Study design and settings:** The responses to 39 selected basic questions regarding Knowledge, awareness and attitudes about research ethics among a total of 415 faculty members and post graduate students of the medical and dental institutions in Mysore city of Karnataka state.

A link for answering the online questionnaire survey was sent to the Head of the Institution/Principal through an email and were requested to circulate the link for the study to all the faculty and post-graduate students of his/her dental or medical Institutions.

The participants of the online questionnaire survey were allowed at any time to withdraw from the questionnaire study before submitting their response.

To protect the confidentiality of the participant, the survey did not contain any type of information that will personally identify the participant like their email ID, name, designation or the name of their Institute.

The questionnaire was made into 5 categories. Before beginning the questionnaire, the in the first category we had set of questions to collect the demographic information of the participants like age, gender, academic position, prior participation in human research subjects, number of research projects involved in and their prior training in research ethics.

The second part of the questionnaire was used to assess the participants self-awareness towards ethical principles and functions of the ethical committees.

In the third part of the questionnaire the respondents were asked to choose their response about research ethics committee from a 5-point Likert scale ranging from 1 to 5.

In the fourth part the respondents were asked again choose from the 5-point Likert scale regarding their attitudes towards practicing of research like obtaining the informed consent from the participant, the involvement of vulnerable individuals in their study, confidentiality and conduct of research in a responsible manner.

The fifth part of questionnaire had questions regarding assessment of knowledge about research ethics with questions on case scenarios.

The data was collected and stored in a password protected electronic format.

This study was a self-funded by the Principle Investigator and the participants were not given any kind of monetary benefits for their participation.

**Timeline for the study:** The online questionnaire survey will be carried out for a period of three months from September to October 2018.

**Statistical analysis:** The Chi-square tests was used to determine, in bivariate analyses. The students t-test was done to assess the respondents scores on the 5-point
Likert scale ranging from 1 to 5. The average of their scores were compared among the various variable like their speciality and academic position by using the ANOVA test. The P value was kept at 0.05 for this study.

**Results**

A total of 415 responses were obtained from the participants of the study. Out of this we had 273 respondents as female and 142 respondents as male. Among these 225 respondents were from the medical speciality and 190 were from the dental speciality.

The results obtained are tabulated in the Graph 1 and table no 1 to 3.

The responses to attitudes towards the research ethics committees and research ethics education. We can clearly observe here that most of the respondents suggest that the research ethics should be taught as a mandatory postgraduate module and the members of a research ethics committee should receive training in research bioethics and also all investigators should have some training in research ethics.

The participants responses to attitudes regarding practices in research ethics, was a bit surprising to know that the response to the question of getting informed consent from patients is necessary for use of their biological samples in research showed mixed response, wherein many respondents not being aware of the mandatory requirement of consent from the participants for using their biological samples for study purpose.

**Discussion**

The participants of the questionnaire survey showed a high acceptance for the requirement of research ethics committee and were had a truistic opinion that the institutional ethics committees would be very helpful and useful for promoting health research and are imperative for appraisal of the health research projects.

It was very evident from our study that most of the respondents were aware of the research ethics committee’s importance in doing health research. Majority of our respondents showed that they already had prior knowledge about research ethics and have undergone some type of training. Though about 67% of the population have shown that they had prior training in research ethics. The proportion of the respondents (34%) who have mentioned that they have not attended any type of research training, were all postgraduate students. Whereas the professors, reader/associate professors, senior lecturers have mentioned they had attended any type of research training programs earlier.

The results of our study regarding acceptance of regional ethics committee by the medical and dental speciality of various academic positions at multicentric level was found to be very complaisant with findings of the study by Hadir F. El-Dessouky et al. (2007).³

The findings of our study congruous with the study done by R. Sudhakara Reddy et al. (2018)⁴Their suggestion regarding having a teaching module in research ethics was found to be consistent with the results of our study done on both medical and dental speciality
and at multicentric study unlike the single centre study involving only the dental professionals by R Sudhakara Reddy et al.⁴

We conducted this study as there were only very few studies done earlier including all the various parameters.⁵,⁶,⁷,⁸

We had several limitations in our study. Firstly, for our study the responses from the participants were obtained through a convenience sampling. Hence, due to potential selection bias, the responses of our participants might not be representative of their respective faculties and post graduate students in each of the participating institutions.

Despite these limitations, our study provided the details about faculty and post graduate students in the medical and dental speciality the knowledge and awareness with ethical principles that steer the conduct of research and their awareness of the roles of the institutional ethics committees, the extent of their previous training in research ethics and their attitudes towards issues in research ethics and the towards institutional ethics committees.

The findings of our study highlight the need for conducting a well-structured research ethics training to faculty and post graduate students of the medical and dental speciality possibly as part of an obligatory module during their academic progress and postgraduate course.⁹,¹⁰ The participants with prior training in ethics comparatively with participants without training in research ethics were more likely to agree with several questionable practices regarding research ethics.¹¹,¹²

**Conclusion**

The results of the study also helped us to assess the requirement for a regular teaching about research ethics among the faculty and students of medical and dental colleges. We recommend that the central and local health educational bodies should implement teaching of health research teaching modules in the health education in India among all the faculties and students in health institutions.

Studies should also be done at regular intervals to assess their knowledge, awareness, attitudes and practice of research ethics before and after the taring in research ethics. The information obtained from such studies will be very useful and also guide to construct improved training programs and modules on research ethics.

Effectiveness of Healthy Emotional Expression among Girls and Boys Experiencing Anxiety and Suicide Ideation

Shweta Negi¹, Roopali Sharma²

¹Research Scholar, ²Professor, Amity Institute of Psychology & Allied Sciences, Amity University, Noida, Uttar Pradesh

Abstract

As we know both genders are different and so are their needs, challenges and phases of lives. Exposure to both the gender is more or less the same these days as parents want both their kids to live a similar life. But with more freedom and liberty comes more sense of responsibility, which is missing in the current generation. They demand great deal of freedom but do not understand how to utilise it. Teenagers are very fragile and easily influenced by people around them. Harming oneself and trying to end their lives have become a status symbol for them. It was found that among 13-15 years of anxiety scores girls tends to display more anxiety and also greater improvement after the intervention. In 16-18 years of age group anxiety was found to be high among girls. Whereas the prevalence of suicide ideation was found to be more among the boys in both the age range of 13-15 years and 16-18 years than the girls.

Keywords: Anxiety, Girls, Harming oneself, Intervention and Suicide Ideation.

Introduction

WHO stated by 2020 there will be large amount of population who will die due to committing suicide and the estimation is about 1.53 million people.⁶ We live in a time where challenges are evolving in everyday basis. Things are unpredictable and so are the thought processes. According to Gross 1998,1999, Emotional expression is the verbal and non-verbal way of conveying one’s emotional experience.⁷ Whereas Elliotts & Jacob, 2013 stated that expression is a process wherein an individual express their ideas, thoughts and feelings in any format i.e speech, writing or in any other way.⁸

Anxiety: According to E. David Leonardo & Rene Hen (2008) anxiety as a state where the organism prepares himself/herself to create a response against potential threats.⁹

Browne (2018) said anxiety is a feeling of uneasiness, worry, tension about the things whose results are uncertain. There are multiple symptoms of anxiety through which one can understand that if an individual is experiencing anxiety for example, heart palpitation, restlessness, muscle tension etc.¹⁰

Symptoms of Anxiety: According to APA some common complaints shared by people who experience anxiety are difficulty in sleeping, lack of concentration, palpitations, shortness of breath etc.¹¹

Types of Anxiety Disorders: Generalised Anxiety Disorder - Individuals with GAD are always in the hunt of danger in the space and are very observant. People are unable to control their preparedness and observe even the minutest activity very carefully. Generalized anxiety disorder is “characterized by chronic excessive worry accompanied by three or more of the following symptoms: restlessness, fatigue, concentration problems, muscle tension and sleep disturbance”.¹²

Phobias: National Institute of Mental Health Worldwide stated there is about 5-12% people experience phobic disorders. Phobias are based on irrelevant belief of an individuals¹³

Types of phobias are:

• Specific Phobia
• Social Phobia
• Agoraphobia

Panic Disorder: Taylor explained Panic disorder as an abrupt surge of intense attack rising to a peak when
thoughts of particular stumble are present. Here the person experiences attack of intense terror which results in physical symptoms such as feeling uncomfortable, feels like urinating, difficulty in breathing or sweating (C Barr Taylor 2006).14

Post: Traumatic Stress Disorder -Caroline Vaile Wright, Linda L. Collinsworth, Louise F. Fitzgerald in 2009 explained that Post- Traumatic Stress Disorder is a result of distressing experiences in an individuals’ lives.15 According to DSM–V some of the common symptoms include over attentiveness, indulging in past, can’t focus on current activities, anger and depression.16

Separation Anxiety Disorder: It is mostly found among children. Usually when they stay apart from their parents Separation Anxiety Disorder is experienced (G Masi, M Mucci, S Millepiedi - CNS drugs, 2001).17 It is considered as disorder as the level of anxiety among the children is excessive and inappropriate.

Suicide: According to ED Klonsky, AM May, By Saffwe 2016, found out that one of the dominant reason for deaths are ‘Suicide’.18 It is a process of taking one’s own life and is an important reason of death worlds wide. In 2008 Matthew K. Nock, Evelyn J. Bromet, Christine B. Cha, Ronald C. Kessler, Sing Lee & Guilherme Borges understood that this low phase of life also involves a feeling of hopelessness and helplessness.19

Suicide Ideation: It was understood most of the people who displays suicidal thought do not end up indulging in the act of ending their lives. (Alexis M. May, E. David Klonsky, 2016).20 According to Nock, M. K., & Favazza, A. R. (2009) it is a deliberate effort to destroy one’s body tissues.21 Inability to deal with one’s life circumstances create a cycle of negative thoughts and the person end up ending their lives in the process. According to M. David Rudd, 1989, problem of youth suicide is a great concern.22

Healthy Emotional Expression: Facing challenges and obstacles in life journey is natural and common across all human existence but how we manage the state of mind in those dire circumstances decides the mental health of an individual. Edward J. Murray Daniel L. Segal, 1994 has stated that by practicing relaxations method like, yoga, meditation etc, last but not the least by letting those disturbing emotions go and by not pondering upon them again and again and it is recommended that one shall strive for healthy means of expressing emotions.23

In 2014, Davide Margola, Sara Molgara, Tracey A. Revenon did a research to identify which is a more effective mode of written expression. Benefit-Focused or Standard Expressive Writing on Adolescents’ Self-Concept. Two groups were made to identify the potential benefits of the two method and it was found out that in the initial 5 years more than 200 students reported in favour of Benefit Focused writing method.24

Carmen P. McLean, Anu Asnaani Brett T. Litz Stefan G. Hofmann in 2011 discovered on two parameters i:e Anxiety and Social Anxiety. These two genders of 20,013 samples size were tested for almost a year long time to come on any conclusion. It was concluded that women are more prone to report anxiety where as no gender difference were found to be effective when it comes to social anxiety.25

Caroline Smith, Heather Hancock, Jane Blake-Mortimer Kerena Eckert (2007) did random trial with yoga and relaxation to identify which method is more effective in terms of giving relief from Stress and Anxiety. This process was repeated for over 10 weeks and researchers came down to the conclusion that both method are equally effective in terms of giving relief to people with high stress and anxiety.26

Sheese, B. E., Brown, E. L., & Graziano, W. G. (2004) found the impact of expressing emotions via e-mails. 546 participants were selected for the same and were randomly categorised into long and short term traumatic writing. it entire process was repeated for 5 weeks. By the end of 5 weeks it was found out that participants reported positive physical and mental health.27

Stacey H. Kovac PhD, Lillian M. Range (2002) found the relevance of expressive writing and repeated the process of expressing emotions using pen and paper for 20 minutes for 4 days. It was found out that there was a reduction in the suicidal thoughts of people when they got the outlet of negative emotions.28

Lewnisohn, P.M., Goltib, I.H., Lewinsohn, Seeley, Allen in 1998 tried to identify the impact of gender on experiencing anxiety and it was found out that female undergo the impact of Anxiety more than men.24

Material and Method

Study population, sample size and data: The study started diagnosing 400 children with suicide
ideations and anxiety of various severity levels, part of Delhi/NCR schools, due to the exclusion criteria 340 students were dropped. The study at the end consist of 60 participants classified as Early and Late adolescents, of which 30 were females, consist of 50% of sample and remaining 30 boys were 50%.

Independent samples t-test - allows us to compare two groups of observations, all of which have come from the different group of people but possibly with a different mean for each condition. One has two experimental conditions and has used different participants in each condition. Systematic improvements in the parameters are noticed with corresponding magnitude of such effect in the population of interest. Further to support the significance of such comparisons, effect size is duly reported for every experimental phase evaluation using $r$ (Rosenthal, 1991; Rosnow & Rosenthal, 2005), Cohen’s $d$. Mean differences are evaluated using $p$-value, $t$ statistics, error bar graph, all the comparisons denoted by $p < .01/.05$ or $***$ are highly significant at both the levels of significance 1% and 5%.

**Intervention Plan:** For 3 and a ½ months students with anxiety and suicidal ideation issues were called for 1 hour for one to one interpersonal therapy sessions (30 adolescents for each group – 13-15 year and 16-18 year). The intervention focused on enhancing social support and decreasing interpersonal stress by attacking anxiety and improving interpersonal skills.

The plan is for the student to become more aware of his or her ability to deal with interpersonal problems that have kept him or her from being able to actively manage the symptoms of anxiety and suicide ideation. Three method were used to unburden the emotions, they are as follows:

a. Relaxation Therapy
b. Written Expression
c. Verbal Expression

**Tools:**
1. State – Trait Anxiety Test by Sanjay Vohra
2. Suicidal Ideation Scale by S. Sisodia & V. Bhatnagar

**Result**

![Figure 1: Depicting mean response of anxiety scores for boys and girls before and after intervention, observed in the sample of 13-15 years of school](image)

Figure 1 displays the pre and post intervention anxiety scores of boys and girls for 13-15 years of age group. Pre – intervention score for boys was 53.53 whereas the post intervention score was 41.06. For girls the pre intervention and post intervention score was 56.38 and 40.54 respectively.
Figure 2: Depicting mean response of Anxiety scores for boys and girls pre and post intervention, observed sample of 16-18 years of school students.

Figure 2 indicates Anxiety scores of boys and girls of 16-18 years age group. It was found that before intervention boys got the score of 52.62 whereas girls obtained 57.35. After intervention boys scores came out to be 42.85 and girls displayed major improvement and secures 42.82.

Figure 3: Depicting mean response of S.I scores for boys and girls before and after intervention, observed sample of 13-15 years of student.

Figure-3 displays the pre and post intervention S.I scores of boys and girls for 13-15 years of age group. Pre – intervention score for boys was 79.94 whereas the post intervention score was 60.82. For girls the pre intervention and post intervention score was 60.82 and 55.54 respectively.
Discussion and Conclusion

The aim of the current research work is to establish if three techniques i.e relaxation therapy, written expression and verbal expression are used together for the duration of 3 month would it lead to different impact on anxiety and suicide ideation scores on boys and girls in 13-15 and 16-18 years of age groups. To understand the impact of work students with Anxiety and Suicide Ideations were identified to initiate the research work. It was a great task to collect the consent of the parents to work on such a sensitive issue and also to control the withdrawal rates during the process.

Results indicates that in the age range of 13-15 years Anxiety scores for girls are found to be 56.38 (pre – intervention) and 40.54 (post – intervention) whereas boys secured the score of 53.53 (pre- intervention) and 41.06 (post- intervention). It was found girls displayed high tendency of anxiety and also a marked improvement in the state after the therapy was provided. The anxiety scores of boys and girls of 16- 18 years age group was found out to be 52.62 for boys before intervention, whereas girls obtained 57.35. After intervention boys scores came out to be 42.85 and girls displayed major improvement and secures 42.82. In 13-15 years of age group suicide ideation pre – intervention score for boys was 79.94 whereas the post intervention score was 60.82. For girls the pre intervention and post intervention score was 60.82 and 55.54 respectively. Suicide ideation scores of boys and girls of 16- 18 years was found to be 87.46 before intervention, whereas girls obtained 83.65. After intervention boys scores came out to be 72.38 and girls displayed major improvement and secures 68.29. Previous studies states the fact that during the developmental years of children conduct behavior leads to some amount of impulsivity in them.

Haravuori et al., 2017; Ranta et al., 2018 examined underpins exhibit based, organized mediations focusing on emotional wellness issue. It is perceived a developing acknowledgment of the requirement for early interventions. It can be concluded that both the gender experiences the impact of social world but they vary due to individual differences. Girls seems to be more effected with anxiety issues, on the contrary boys have reported greater tendency for suicide ideation.

Karyn E. Schweiker-Marra, William T. Marra (2010) Studies have proved the fact that pre writing the post writing of the anxiety and it has been found out that there is the marked change in writing expression.
and students reported less Anxiety issues. Stacey H. Kovac, Lillian M. Range in 2002 observed resistant in suicidal thoughts when participants jotted down the feelings.

It can clearly be concluded that the therapy is found to be effective in both the genders though the amount in which each gender experience it is different and so is the impact of the therapy.

Conflicts of Interest: Authors declares no conflict of interest

Funding: Self

Ethical Clearance: This study was entirely done for the benefit of the children. Prior consent was taken from the parents as well as from the schools to conduct the research procedure.

²Assistant Professor at DPSRU, Delhi

Abstract

Background: The best source of nutrition for an infant is Breastfeeding. Breastfeeding is superior for infant as comparison to the normal milk. A secretion of the mammary gland is called human milk with changing composition. Foremilk i.e. colostrum is different in nature in comparison to hindmilk i.e. mature milk. Human milk offer various benefits to both infant and mother because of its composition. This review article highlight the importance of Breastfeeding.

Objective: To study the importance of Breastfeeding.

Method: Various articles have been reviewed from Google Scholar to highlight the importance of Breastfeeding to both infant as well as mother.

Results and Conclusion: Various researches have demonstrated developmental, immunological, health and nutritional, psychological benefits of human milk in both developing as well as developed countries. Hence, breastfeeding should not be regarded as a choice but an important factor for health issue.

Keywords: Colostrum, Infant feeding, Maternal health.

Introduction

Proper magnification and development of children to their full prospective is ensured through the proper nutrition during infancy. Extensive researches have been carried out which demonstrates that breastfeeding is considered as an excellent origin of nutrition for a little one and is advantageous for both mother and young one¹.

Breast milk is extremely superior for infant feeding as compared to the normal milk. A discharge of the mammary gland is called human milk with changing composition. Foremilk i.e. colostrum is different in nature in comparison to the hind milk i.e. mature milk. Human milk contains all the nutrients needed for the child for optimal growth and development. Breast milk composed of various nutritive elements such as proteins, lipids, carbohydrates, minerals, vitamins and trace elements which are of utmost significance to attain the needs of the nutrition required by an infant. Various components which are immune-related like IgA, leukocytes, lysozyme, lactoferrin, interferon, nucleotides, cytokines and other components are also included in human milk. Various crucial fatty-acids, enzymes, hormones, factors which are growth related, polyamines and other compounds which are active biologically plays an utmost important role in the benefits related to the health associated with breastfeed. Hence, breast milk is a true functional food. It offers both small-term benefits and long-term benefits in context to health and development by not only providing nutrients but also by providing bioactive substances.²

Mothers who are full time employed mostly skip or delay expression of their milk. Major factors which leads to completely wean the children from breastfeed are return to job, insufficiency of milk supply and shortage of pumping time of milk.³

e-mail: neerja.thukral@gmail.com
According to American Dietetic Association, absolute breastfeeding for first 6 months of life deliver proper nourishment to the infant and combined feeding along with breastfeed till 12 months of age is considered as a perfect feeding for infants.\(^4\)

Lactation is considered good for well-being of mother also as it lessen the possibility of ovarian cancer or breast cancer, diabetes (type 2) and postpartum depression. Few researches suggest that lactation reduces the risk of premenopausal breast cancer.\(^5\)

Children who exclusively breastfeed have higher IQ rather than those who does not breastfeed because of the existence of unique fatty acids which exists in mother’s milk. Since, breastfeed is an ideal food for infant and risk factor which is modifiable, all women should be encouraged to breastfeed.\(^6\)

Benefits of Breastfeeding:

- **Prevention of Infections:** Breastfeed helps in decreasing the incidence rate and severity of broad range of infections like respiratory tract infections, otitis media, necrotizing enterocolitis, etc.

- **Protection of Immune System:** Exclusive breastfeeding lowers the incidence rate of allergies like asthma, atopic dermatitis, eczema, celiac disease, etc.

- **Diabetes, Obesity and Cardiovascular Risk:** Breastfeeding results in reduction of obesity rates to 15% to 30% in adolescence and adulthood. Breastfeeding also results in decrease in prevalence of insulin dependent (Type 1) diabetes insipidus and non- insulin dependent (Type 2) diabetes mellitus, cardiovascular diseases, etc.

- **Malignant Diseases:** Breastfeeding results in lowering the incidence of acute lymphatic leukemia, through stimulation or modulation of the immune response.

- **Neurodevelopmental Outcomes:** Breastfeeding may be associated with an advantage measured in terms of cognitive development which persists into adulthood.

- **Preterm Infants:** Breastfeeding not only decreases the rate of illness after NICU discharge but it also lowers long term failure of growth and neurodevelopmental ailments. Neurodevelopmental consequences includes finer maturation of brainstem, better outcomes on tests (cognitive and developmental tests) and better development of visual system.

**Other Health Outcomes:** It also results in decreasing the rate of unanticipated death syndrome of infant in the first year of life.

**Maternal Health Benefits:** It has numerous benefits on maternal health also like increase in concentration of oxytocin, decreasing the blood loss during menstruation, decreases chance of breast cancer and ovarian cancer, reduce possibility of postpartum depression, lactational amenorrhea, promotes bonding as well.

**Benefits for Community:** Various benefits of breastfeeding includes reduction in annual health care estimate and healthful living programs, decreases absenteeism of parental employee with association of loss of income of family, reducevigor demands for manufacture and transfer of unnatural feeding products.\(^7\)

**Discussion**

Human milk has a balance of nutrients which includes carbohydrates, cholesterol, essential fatty acids, long-chain polysaturated fatty acids, saturated fatty acids, medium chain triglycerides, low protein and sodium content as well as an ideal ratio of calcium-phosphorus that makes it easily digestible. According to WHO, the infants should be breastfed exclusively for 6 months.

The evidences report that breastfeeding is important and gold-standard for infants in terms of regulating growth and development, providing proper nutrition, developing immune response and to post-partum women as well in order to improve their health, lose weight, decrease post-partum depression and evidences of certain illnesses.

Cognitive development also has been found to be enhanced with breastfeeding due to genetic variations in metabolism of fatty acids. Studies have also suggested that DHA and AA needed for intellectual development are linked with altered gene expressions in synaptic plasticity. Thus, it can be said that human milk or breast feeding for infants is crucial for an overall development and is irreplaceable immunological source.\(^8\)

**Conclusion**

Various researches have shown that breastfeed can offer various significant benefits to infant, mother as well as community. We should support breastfeed as it is the most cost- efficient way which helps in minimizing the possibility of disorders as well as mortality. Breastfeed
should be supervised as a major public health issue. Healthcare providers play a vital role in promoting breastfeeding. Moreover, there should be proper facilities to promote the awareness and supporting the campaign of breastfeeding.

Abstract

Background: Sexual violence against women and children has been recording an alarming rise in India. In the majority of cases, it involves younger individuals who are more vulnerable to victimization. Social and cultural factors are also considered to play a pivotal role in such offences.

Objective: This study aimed to assess the social and demographic factors of sexual offence cases brought for medical examination to identify the high-risk population.

Method: This is a retrospective study carried out in the Department of Forensic Medicine & Toxicology, JSS Medical College, Mysuru, Karnataka from January 2017 to December 2019. This study is based on the information obtained from medico-legal reports of the victim examination of alleged sexual offence cases.

Results: In the prescribed study period, 30 victims were examined. Majority of the victims belonged to the age group between 11 years to 20 years amounting to 70 % of the cases. 11 (36.6%) victims were still pursuing their secondary or higher secondary education. Unmarried victims were the maximum. In 19 (63.3%) cases, there was a consensual type of sexual activity and in most of these cases accused was a known individual.

Conclusion: The present study shows that younger age females are more vulnerable to the sexual assault especially those who belong to lower socioeconomic status and in the majority of these cases, type of sexual activity is consensual. Hence, formal education regarding legal implications associated with such sexual acts will go a long way in preventing their occurrence.

Keywords: Rape, Victim, Sexual offences, Socio-demographic profile.

Introduction

One of the verses from Manu Smriti says, Yatra Nari Astu Pujyante, Ramante Tatra Devataa – meaning “Gods reside in places where a woman is worshipped.”

In a country like India, where traditionally women are supposed to be referred to as Shakti - the ultimate power, they have now turned into inanimate objects.

Rape is among the highest forms of crime experienced by women in all sectors of society. In recent years, there has been an alarming rise in the ratio of rape in India.¹ Crime is a manifestation of myriad complex factors. The genesis of crime can be traced to the interplay of various social, economic, demographic, local and institutional factors. They together influence education, employment, parenting/family relationships,
societal cohesiveness, emotional stability, mental health, anonymity, criminal orientation, residential stability, leisure etc. which in turn influences the nature, pattern, frequency and volume of crime.\(^2\)

NCRB data in 2018 recorded 59% crime rate against women, one rape is reported every 15 minutes in India. Every fourth rape victim across the country in 2018 was a minor, while more than 50 per cent of them fell in the age category of 18 to 30 years. In 94 per cent of the cases, the offenders were known to the victims who were family members, friends, live-in partners, employers or others.\(^3\) In the present study, efforts are made to study the social and demographic factors so that we can identify the high-risk population at the earliest and stringent legislative measures can be taken to safeguard the interest of the victims and society at large.

**Materials and Method**

A three-year retrospective study was carried out in the Department of Forensic Medicine and Toxicology, JSS Medical College, JSS Academy of Higher Education and Research, Mysuru from January 2017 to December 2019. This study is based on the record of sexual assault victims who were brought for medico-legal examination in the department. The details regarding age, socio-economic status, marital status, place of incidence and relationship with the assailant were noted. The data was entered on the predesigned datasheet, tabulated and then statistically analyzed.

**Findings:** A total of 30 victims were examined in the study period. 21 victims (70%) were in the age group of 11-20 years, among them 5 each belonged to the age group of 11 to 14 Yrs and 18 to 20 Yrs respectively. 11 were in the age group of 15-17 years. In three cases the victim’s age was less than 4 years. Majority of the accused belonged to the age group of 21 -30 years (Fig 1). The age difference between the victim and the alleged accused in the majority of the cases was in the range of 0-5 years and 6 – 10 years (Table 1). In 23(76.6 %) cases, the victim belonged to the low socioeconomic status, 4 victims belonged to middle socioeconomic status and 3 came from high socioeconomic status. Table 2 depicts the educational status of the victims examined. Among 30 victims, 11 were still pursuing their education.

Unmarried victims were the maximum amounting to 22 (73.3%) cases (Table 3). In three cases the victims were 15 yrs, 16 yrs and 17 yrs respectively who were married against the provisions of law. In 10 (33.3%) cases incidence occurred in the hotel/guest house premises (Table 4).

In 93.3 % of the cases, the alleged accused was a known person (Table 5). The manner of offence in 19 (63.3 %) cases was of consensual type; among them in 11 cases (36.6 %) consent was invalid since the age of victim was less than 18 years. In 8 (26.6 %) cases there was forceful sexual act and in 3 (10 %) cases the victim denied any kind of sexual contact.

Discussion

In the present study, the age of victims ranged from 3 years to 35 years. Individuals between 11-20 yrs (70%) were the most affected and among them, 80.9 % were less than 18 years of age. Hence this study suggests that teenagers are more vulnerable for such offences. Similar results were observed in various studies conducted across India on the populations of South Bangalore, Maharashtra and Assam.4-6

In our study, the majority of the victims came from the lower socio-economic background. The study conducted by Runarsdottir E et al affirms this finding, they suggested that low socioeconomic status is an indicator of social disadvantage; for females, it may independently contribute to the risk of sexual abuse.7 Similar view was expressed in a study intended to assess the magnitude and the issues related to child sexual abuse.8

In a study conducted on rape victims at Kolkata, they found that in most of the cases, the sexual assault occurred outside the house.9 Similar findings were noted in the present study in contrast to the study conducted by Haridas S et al and Gangmei Agatha et al who found that the most of these incidences occurred at accused’s house.10,11
In this study, most of the sexual assaults were committed by known individual constituting 93.3% of the cases. Similar results were found by certain other researchers.12,13

Findings of the present study reveal that manner of offence in most of the cases was the consensual type of sexual act, the majority of the victims being unmarried and still pursuing their education. A similar opinion was expressed in a study conducted in Surat, wherein the authors reported that in 83.7 per cent of the cases the sexual activity was with mutual consent.14

Our study reveals that in 36.6% of the cases although sexual act took place with mutual consent, consent of the victim was invalid as per Indian law since the age was less than 18 years. Among them, 30% of the victims were between 16 – 17 years of age.

Honourable Justice V Parthiban of the Madras High Court opined in the order concerning Criminal Appeal No. 490 of 2018 that the government should consider to redefine the word “child” to mean a person below 16 years of age instead of 18 for purposes of the Protection of Children from Sexual Offences (POCSO) Act 2012. Noting that many of the POCSO cases involved minor teenage girls in sexual relationships with teenage boys, Justice Parthiban said:

“When the girl below 18 years is involved in a relationship with the teenage boy or little over the teenage, it is always a question mark as to how such relationship could be defined, though such relationship would be the result of mutual innocence and biological attraction. Such a relationship cannot be construed as an unnatural one or alien to between relationships of opposite sexes. But in such cases where the age of the girl is below 18 years, even though she was capable of giving consent for a relationship, being mentally matured, unfortunately, the provisions of the POCSO Act get attracted if such relationship transcends beyond platonic limits, attracting strong arm of law sanctioned by the provisions of POCSO Act, catching up with the so-called offender of sexual assault, warranting severe imprisonment of 7/10 years”.

In the western world, in countries like the UK, some states of the USA and Canada the age of consent for sexual intercourse is 16 yrs. In France and Brazil, it is 15 years and 14 years respectively.16 However in India, in case a boy and girl below 18 years have sexual intercourse with mutual consent, only the boy is liable for punishment which is detrimental against the natural justice for the boy. Hence, the government has to sensitise the younger individuals about the legal provisions and its implications in such scenarios.

Education Department can take initiatives to educate the children about various provisions of Protection of Children from Sexual Offences Act 2012 since most of these cases involved minor teenage girls in consensual sexual relationships with young boys.

**Conclusion**

The present study shows that instances of a sexual offence are higher in younger age females especially among those who belong to lower socioeconomic status. In the majority of these cases, the type of sexual activity is consensual with the known person. Since most of these victims had completed or were pursuing their secondary/higher secondary education, formal education concerning legal nuances associated with such consensual sexual acts should be imparted to reduce their incidence. There is a need for further studies with a bigger sample size so that the high-risk population can be identified and educated effectively.

Mother’s Knowledge of Continuing Immunization in the Jagir Public Health Center Working Area

Sofina Setiawati¹, Lutfi Agus Salim²

¹Undergraduate Student in Department Biostatistics and Demography, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia, ²Associate Professor in Department Biostatistics and Demography, Faculty of Public Health, Universitas Airlangga, Surabaya, Indonesia

Abstract

Immunization is a priority program in Indonesia that is implemented from the central government to the regions. Immunization is an effort to reduce morbidity, disability and death from diseases that can be prevented by immunization. The child’s basic needs including natural immunizations must also be fulfilled by parents. The purpose of this research is to measure mother’s knowledge of continuing immunization in the Jagir Public Health Center working area using descriptive research method. The number of samples is 200 people with random sampling technique. Data collection was carried out through interviews using questionnaires and observations. The results of the study that the majority of respondents in 3 villages working area of Jagir Public Health Center know the existence of Jagir Health Center immunization services is very good with an average percentage of 96.5%.

Keywords: Immunization children, mother’s knowledge.

Introduction

The WHO began to set the immunization program as a global effort with the Expended Program on Immunization in 1974, which was resolved by the World Health Assembly (WHA). Efforts to achieve this goal various programs based on Primary Health Care have been implemented to improve health status. Coverage of child immunizations in WHO countries still reaches 85% of babies worldwide have been immunized and there are 19.9% of infants and children have not been fully vaccinated and remain at risk of disease. Several indicators used by WHO to measure the success of these programs include infant mortality (IMR), under-five mortality rate, maternal mortality (MMR) and life expectancy. One indicator of the MDGs is to reduce child mortality by targeting to reduce the mortality rate of children under five years old (toddlers) by two-thirds in the number from 1990 to 2015 meaning that it decreased from 97 per 1000 live births to 32 per 1000 live births. Followed with health indicators in the 2015 Sustainable Development Goals (SDGs) which is the third goal, namely health insurance and health promotion for all ages.

WHO estimates that TB cases in Indonesia are the third largest in the world after China and India, assuming the prevalence of acid-fast bacillus (+) 130 per 100,000 population Since 1991, pertussis cases have emerged as frequently reported cases in Indonesia, around 40% of pertussis cases attack toddlers. the incidence of tetanus in Indonesia for urban areas is around 67 per 1000 live births, while in rural areas the figure is about 23 times higher at 1123 per 1000 live births with approximately 60,000 infant deaths each year. Furthermore, Hepatitis B is estimated to cause at least one million deaths per year. As for the case of polio, the latest data reported in total there are 295 cases of polio scattered in 10 Provinces and 22 districts/cities in Indonesia. Likewise, with the case of measles, the number of events recorded 30,000 cases reported annually. Cases of diseases that can be prevented by immunization that are of great concern lately are reported that several regions in Indonesia have been declared to have occurred in the Extraordinary Events diphtheria. The mortality rate due to diphtheria in Indonesia is around 15% and continues to increase. The results of the 2007 Indonesian Health Demographic and Survey (IDHS) showed that infant mortality in Indonesia was 34 per 1000 live births. This figure is lower than the
infant mortality rate in 2002 to 2003 which reached 35 per 1000 live births\(^{(1)}\). Thus, immunization is an effective effort to emphasize infant mortality\(^{(2)}\). The Indonesian Ministry of Health has compiled a program as an effort to suppress diseases that can be prevented by immunizing children, such as the Immunization Development Program for children since 1956. The success of infants in getting five basic types of immunization (HB0, BCG, DPT-HB, Polio and Measles) is measured through a complete basic immunization indicator. Basic Health Research Data notes, in 2007 the coverage of complete basic immunization in Indonesia averaged 41.6%. Then it increased in 2010 with an average coverage of 53.8%. In 2013 the average coverage of complete basic immunization increased again, namely 59.2%.

Immunization comes from the word “immune” which means immune or resistant. Immunization is the provision of immunity against a disease by entering something into the body so that the body is resistant to diseases that are endemic or dangerous to someone\(^{(3)}\). Immunization is an attempt to actively raise/increase a person’s immunity against a particular disease, so that if one day exposed to the disease will not be sick or only experience minor illness. Some infectious diseases that can be prevented with immunization include: tuberculosis, diphtheria, tetanus, hepatitis B, pertussis, measles, rubella, polio, inflammation of the lining of the brain and inflammation of the lungs. Children who have been immunized will be protected from various dangerous diseases, which can cause disability and death.

There are several things that affect the achievement of immunization coverage targets, including false rumors about immunization, the community believes that immunization causes children to become sick, disabled or even die, community understanding, especially parents who are still lacking about immunization and parents’ motivation to provide immunizations in children is still low. Anti-immunization Black Campaign is currently ‘intense’ in several regions in Indonesia, both through seminars and anti-immunization talkshows. Aside from general activities, they also carry out movements through social media such as Twitter, Facebook, mailing lists, or blogs. Halal-haram vaccines, conspiracies and vaccine side effects that can cause disability, autism, or even death are the main issues raised by the anti-immunization group.

The role of a mother in the immunization program is very important, so an understanding of immunization is needed. Likewise with knowledge, beliefs and health behaviors of parents. Lack of socialization from health workers causes problems in the lack of understanding, understanding and compliance of mothers in immunization programs. Based on these data it can be concluded that promotive and preventive efforts have not run optimally.

Globally, an estimated 2-3 million deaths per year have been successfully prevented due to diphtheria, measles, pertussis, polio through immunization, but there are still around 22 million babies in the world who have not received complete immunization and 9.5 million are in the South East Asian region, including Indonesia. This situation is driving global steps in raising awareness of the world community through the implementation of immunizations. Basic health research (2013) states that there was an increase in the number of complete basic immunization coverage from 2007 to 2013. In 2007 the rate of basic immunization coverage was 41.6% and in 2013 the number of complete basic immunization coverage increased to 59.2%. However, in 2013 there was an incomplete basic immunization coverage of 32.1% and 8.7% of children had never been immunized\(^{(4)}\).

Complete basic immunization coverage in Surabaya City in the last five years has always been above 85%. In 2018 complete basic immunization in the city of Surabaya was 97.77%. This figure has met the 2018 Strategic Plan target of 93.83%. Meanwhile, according to the Puskesmas, there were 56 Puskesmas (88.89%) that reached the 2018 Renstra target.

The purpose of this study was to measure the mother’s knowledge regarding continuing immunization in the Jagir Public Health Center in 2019.

**Method**

This research method uses descriptive approach. Bogdan and Tylor define as a research procedure that produces descriptive data in the form of written or oral words from the people or behavior observed \(^{(5)}\). This research was conducted on mothers who are in the working area of Jagir Public Health Center in Surabaya. The subjects in this study were mothers who had 1-2 years old babies in Jagir Urban Village, Surabaya. The subject chosen randomly aside from 3 village.
Result

The results of research on maternal knowledge of immunization are described in the following table:

**Table 1. Knowledge of Respondents Towards Immunization Services at Jagir Public Health Center in 2019**

<table>
<thead>
<tr>
<th>No</th>
<th>Village</th>
<th>Knowing the existence of immunization services at Jagir Public Health Center</th>
<th>Total</th>
</tr>

</tbody>
</table>

In table 5, it can be seen from the results of the respondents above the majority or more than half of the community respondents in the work area of the Jagir Public Health Center in 2019 who have toddlers who have received further immunization at 70%.

**Discussion**

According to the Health Act No. 36 of 2009, immunization is an effort to prevent infectious diseases, especially to reduce child mortality. An understanding of immunization is needed by parents as a basis for meeting children’s health needs. Provision of basic immunization in children must be based on the existence of a good understanding from parents about immunization as an effort to maintain children’s health through disease prevention efforts. So parents are expected to be aware of and have a positive understanding of immunization. The results showed that the majority of respondents in 3 villages in the work area of Jagir Public Health Center knew that there was an immunization service at Jagir Public Health Center namely, Jagir village 98.5%, Sawunggaling village 97.1% and Darmo village 95.5% in this result indicated the respondent’s knowledge coverage is good enough.

The quality of immunization services that are less than optimal will certainly waste resources that have been spent such as operational costs, vaccines, immunization logistics, manpower and time. Even what is most concerning for all of us is the failure of immunization will threaten the occurrence of illness, disability or death in children. Basic immunization is very important given to infants aged 0-11 months, in the early days of a baby’s life, babies are very susceptible to the disease and if the baby is exposed to the disease it will cause physical, mental, disability and cause death. Immunization is done so that the baby can continue to grow and develop optimally in a healthy state. In order to be achieved, immunization coverage must be maintained high and carried out evenly.

Furthermore, the results of the study showed that of the 3 urban villages, Darmo Urban Village at least indicated that this village needed more attention or the Public Health Center could be more active in informing that there was an immunization service at Jagir Public Health Center, while the majority in the Jagir Public Health Center work area from 3 villages show that the majority of respondents have toddlers and the percentage of respondents who have toddlers in Darmo is 71.2%.

Immunization is a way to actively raise/increase a person’s immunity to a disease, so that if one day he is exposed to the disease it will not be sick or mild illness. Infectious disease is the biggest cause of mortality and morbidity in children, so it is very important to do preventive measures through basic immunization. Children have the right to protection from infectious diseases. Children should not receive incomplete immunizations without consideration of consequences for both the child and the community.

According to the Indonesian Ministry of Health (2001), the purpose of immunization is to prevent illness and death of infants and children caused by frequent outbreaks. The Indonesian government strongly encourages the implementation of the immunization program as a way to reduce morbidity, mortality in infants, toddlers/pre-school children.

The results of this study also showed that respondents who knew of continuing immunization services at Jagir Public Health Center in Darmo Village were 69.7%. Regarding the benefits of immunization, the majority of respondents in Darmo Village answered that the benefits of continued immunization are to increase the body’s defense and protection against infections and various serious diseases, which is 74%. And from the results of the study above shows that toddlers in Darmo Village who have received further immunization at 69.7%.
Conclusion

Immunization is a way to actively raise/increase a person’s immunity to a disease, so that if one day he is exposed to the disease, he will not get sick or mild illness. From the results of the above research it can be said that the majority of respondents in the 3 urban areas of the Jagir Public Health Centre work area know that the Jagir Public Health Center immunization service is very good with an average percentage approaching perfect that is 97%.

Based on the above research results it can be concluded that knowledge for basic immunization for infants is very necessary because after all complete basic immunization is very important for toddlers and not only that here also the relationship between the role of parents is needed, especially the mother is very important in providing basic immunization with status baby immunization. Because after all, if minimal parental knowledge of complete basic immunization will affect the health of the toddler.

Performance and Perception of First MBBS Students Towards Simultaneous One Sitting Web Based Assessment for Introductory Topics in Anatomy, Physiology and Biochemistry

Sudakshina Chakrabarti

Associate Prof. of Anatomy Saveetha Medical College Chennai

Abstract

Web-based formative assessment tools have become widely recognized education as valuable resources for self-directed learning. Introducing Google forms for simultaneous assessment of first year subjects in MBBS students is a time saving acceptable approach.

Objectives: To introduce a simultaneous online web based assessment tool (Google forms) for first year MBBS students.

To evaluate the perception and attitude of the first MBBS students towards the assessment tool (Google forms).

Method: 122 first year medical students were informed about an simultaneous one sitting test 4 days prior for the introductory topics in Anatomy, Physiology and Biochemistry. A web page link was shared with the students in their google account and student were asked to reply to the 45 questions asked in the google form. The performance of the students were analyzed in the spread sheet. After completion of the test student were asked to fill 20 questions feedback form each questions were based on Likert scale to evaluate their attitude and perception towards the online assessment of Anatomy, Physiology and biochemistry at a single sitting. The feedback questionnaire was analyzed.

Results: On analyzing the feedback questionnaire it was shown 75 % of students felt answering in google forms are fairer and 65% felt its better than pen and paper assessment. 79% of the students had trust in google forms as they felt cheating cannot be easily done in this tool. 68% of the students felt marking is more accurate in this tool. On analyzing the performance of the students it is seen, 61.4 % of the students were above 50% of the total score out of which 27.04% of the students scored more than 75% . Only 16% of the students were below the 25% of total score.

This study thus showed, students were interested in using the new tool in assessing their knowledge and they too wanted to use the link for revising their subject in future..

Keywords: Formative assessment, integrated assessment, Feedback questionnaire, Google form.

Introduction

Modern era students are familiar with the emerging technologies and its uses. These technologies can be utilized as learning resources, can be well accepted among students as it is beneficial and popular among them. Self assessment helps the students to identify the weak areas and thereby they can focus on it. An ideal assessment method should be reliable, valid, cost effective, feasible and acceptable to students and teachers and should be easy to use and unbiased. No single method of assessment can meet all these

requirements. Each and every method of assessment has some strengths and weaknesses which should be critically analyzed and combination of few method can be used.\textsuperscript{2,3} Multiple studies showed beneficial impact of formative assessments on overall performance of the students by increasing students active participation, preventing procrastination and providing immediate feedback on their performance. Online administration of formative assessments has great advantages, including easy accessibility and availability, interactive features, immediate and individualized feedback and automated scoring which can positively motivate the students to practice and take up these tests.\textsuperscript{4,5,6,7}

Google Forms is a component of Google Docs, which is a free, web-based tool for managing various kinds of files including text documents, spreadsheets and presentations. With Google Forms, a teacher can create a set of questions and invite students to respond to those questions, either through e-mail or on a web page. Google Forms can be used in any course as long as the students have access to computers and internet.\textsuperscript{8,14} Medical council of India’s new policies are recommending integrated teaching of basic science subjects with clinical aspects and system wise approach. As we are integrating the subjects teaching through horizontal and vertical approach the assessment too needs to be simultaneous and integrated to get a positive impact.\textsuperscript{9} Thus the attempt to integrate the medical subjects should not stop with the teaching alone it should be extended over to the assessment of the subjects learnt in the form of common assessment of the coordinated subjects taught during a particular year in medical curriculum. This study attempts to evaluate the performance and perception of students in using google forms for assessment of their knowledge acquired through a MCQ test for integrated assessment of introductory topics taught in Anatomy, Physiology and Biochemistry in a single sitting.

**Method**

Institutional ethical clearance was received prior to the study. Consent was taken from the First MBBS students of 2019-20 batch for the study. The introductory topics in Anatomy Physiology and Biochemistry was taught which included General Anatomy and general embryology, General Physiology, nerve and muscle physiology and in Biochemistry it was Eukaryotic cell its organelle and cell cycle. 45 Multiple choice questions were framed in google forms 15 questions for each subjects. Each MCQ item contained a stem and four options. Correct option if chosen was awarded 1 mark. Incorrect option is given 0. Students were informed about simultaneous test 4 days prior. 122 medical students present on the Day of the test and they tookup the simultaneous test of all three subjects in Google form. Students were asked to log into their google accounts using the internet service provided by institution in their smart phones or Apple I pads. The web page containing the 45 questions were given to them and they were asked to open and answer the questions. Technical help was provided if some failed to access. After completion of the test students were given a questionnaire for feedback to evaluate their attitude and perception towards web based simultaneous assessment of Anatomy, Physiology and Biochemistry at a single sitting. The performance of the students was analyzed in spread sheets and recorded. The feedback questionnaire consisted of both 20 structured open and close ended questions framed after literature review appropriately validated and each question rated on a five point Likert scale. Data was analyzed by SPSS software and descriptive statistics was used. The feedback questionnaire had four main components i.e. 1. Perception and attitude of the students towards using google forms for MCQ test 3. Reliability of the questions and appropriateness using the tool 4 Practicality of using an integrated assessment and user friendliness. (Table 1,2,3,4).

**Results**

122 first year medical students took up the survey with the feedback questionnaire on simultaneous assessment by Multiple Choice question in google form answered online. In the questions determining the attitude of students towards the new online tool 55% of the students felt live answering to the questions in google forms was not stressful and 70% of student felt the tool was interesting and enjoyable. About 47% of students wanted to recommend the tool to their peers and solve questions in this format. (table-1)

75 % of students felt answering in google forms are fairer and 65% felt its better than pen and paper assessment. 79% of the students had trust in google forms as they felt cheating cannot be easily done in this tool. 68% of the students felt marking is more accurate in this tool. (table- 2).

Majority of the students felt the MCQ questions were appropriate and was not too difficult and was relevant to the topics taught. 55% of the students felt its
easy to score marks in MCQs in google form. 76% of students felt they can use the MCQs in google form in revising their lessons in future and its good for recalling. 77% of student felt the MCQ questions had improved their knowledge and critical thinking. (table 3).

In the next observation the practicality of simultaneous assessment of questions from all the subjects of first year in a single testing format was assessed. 66% of students preferred simultaneous assessment as it was less stressful and easy and 78% of students felt it is less time consuming. 67% of the students felt simultaneous assessment should be included partly in university examination. About 29% of students felt preparing for simultaneous one sitting assessment is tedious and confusing as they have to read all the three subjects for preparing. (table 4).

Table 5 (Analyses the performance of the students in MCQ test) shows the total number of responses and percentage of correct responses to the MCQs in google form. About 72.96% of total responses were correct. Table 6 shows the performance of the students in the integrated test. 61.4% of the students were above 50% of the total score out of which 27.04% of the students scored more than 75%. Only 16% of the students were below the 25% of total score.

This study not only shows that students were interested and accepted using google forms as assessment tool it also shows students performed quite well in simultaneous assessment of all three first year subject in a single test setting. The future prospect of this study is reflected in their eagerness in using the tool for other topics in an integrated way and their desire to include simultaneous online assessment in university exams.

The NYC School of Medicine Online Self Assessment Tool (SOMOSAT) an online self assessment tool consisting of >450 MCQs covering multiple specialities in medicine was administered to the second year medical students accurately predicted student performance on future exams. Students also performed better in future exams and it was helpful in filling knowledge gaps. Similarly in this present student felt integrated self assessment in google forms were regarded by 77% of students to improve their knowledge and critical thinking. Online simultaneous formative assessment promotes self directed learning and also time saving especially in medical curriculum. The study conducted by Kavitha et.al in OBG department did not show a significant difference in performance of the students in summative exams who had participated in prior online formative assessment test to those student who had not attended. 11

In a study conducted by Bijoy et.al. on web based formative assessment tool for renal pathology unrestricted and optional access was given to quizzes for medical students and performance of quizzed and nonquizzed students were observed and it showed the quizzers performed statistically better than nonquizzers in their exams. 89% of students felt the quizzes improved their knowledge. In the present study too majority of students wanted self assessment formative MCQ test in future to fill their knowledge gaps, revising their subjects and wanted to recommend to their peers. 12

This study not only aimed at teaching general Anatomy, general Physiology and cell biology in Biochemistry in an integrated manner but also the assessment was conducted as a single test from all the three specialities. This integrated simultaneous approach which is new of its kind has provided a bird’s eye view of the topics taught in three different subjects well integrated and timed not only during teaching but also while assessing the knowledge of the students.

Currently Medical Council of India has revised teaching and learning in undergraduate medical course to competency based medical education with early clinical exposure and horizontal and vertical integrated teaching learning approach. Implementation of simultaneous one sitting assessment the curriculum too needs to be integrated thoroughly. Assessing how students use basic science concepts in clinical reasoning which is vertical integration should go hand in hand with understanding and relating within the particular year too through horizontal integration. Simultaneous one test approach for multiple specialities taught in the same academic year at a single sitting is not only time saving but also prepares the medical graduates to prepare for PG entrance and international competitive exams in future. 13

Figure 1
Conclusion

Assessment has always formed an integral and important part of teaching and learning process, especially in formal medical education. Online web based assessment offers a range of benefits in improving the process of learning and on the other hand reduces the workload for teachers and administrators. This study introduces usage of Google forms in assessment of knowledge of introductory topics in basic science subject in a simultaneous single sitting formative exam pattern. The main benefits in this type of assessment process include the elimination of time and space restrictions existing in the case of paper or face-to face exams. At the same time, as google forms are self assessment tools the student is able to gauge their performance too thus this immediate feedback allows for a genuine formative evaluation. In this study first year medical students were exposed to Google forms and E assessment that too in an integrated simultaneous common questionnaire for all three subjects of first year and its intended that this process of assessment will be recommended to university curriculum committee to introduce online google form based formative assessments in a formal way as an assessment tool in future.

Changing Trends in Teaching Method for Medical Students-Prosection Versus Dissection of Cadavers

Sudakshina Chakrabarti
Assoc Prof of Anatomy, Saveetha Medical College & Hospital Chennai

Abstract

Background: Cadaveric dissection is considered a tool for studying structural details of the human body. Prosection is demonstrating anatomy of wet specimens preserved and already dissected by experts. In prosection students get to see multiple wet specimens, museum specimens already dissected by experts and learn by observing the structures.

Methodology: Study is conducted on 30, 1st year MBBS students divided randomly into 2 groups each having 15 students-- Group A and Group B. Informed consent is taken from all the participants prior to the study. The second part of study conducted on final year MBBS students on their view on cadaveric dissection.

The anatomy of the neck region which extends over 8 hours of dissection classes are taught to the group A by traditional dissection demonstration method. The same is taught to Group B by prosection technique. The following day the performance of the students are assessed by a spot identification test consisting of 15 questions each of 2 marks pertaining to the specimens as a practical test. In the second part of the study feedback is taken in form of a validated questionnaire from final year MBBS students about their view on cadaveric dissection.

Results: The performance of the spot identification test conducted on the students was analysed uniformly and corrected by 2 experts. The results shows the performance of group B (Prosection group) was significantly better than group A (p value 0.034 at 95% CI). On analysing the feedback majority of final year students liked dissection on cadavers and they felt it promoted group learning and future knowledge on surgical instruments and skills.

Conclusion: This study suggest that utilizing prosections of the neck region specimens seem to be advantageous pedagogical approach for teaching Gross Anatomy. Based on the views on cadaveric dissection of final year students it is better to adopt combined approach and expose students to both techniques dissection and prosection.

Keywords:- Prosection, Dissection, demonstration, specimens questionnaire.

Introduction

A good knowledge of clinical Anatomy is fundamental and indispensable to efficient and safe clinical practice and for the understanding of other subject disciplines such as physiology, pathology and surgery for a medical students.

Cadaveric dissection is considered a tool for studying structural details of the human body. Major part of practical working in gross anatomy consists of cadaver dissection by students. This method of learning human gross anatomy is time-honoured and highly effective recent years. Time and again the relevance and value of dissection as a tool for teaching anatomy to medical students have been under discussion at different
Due to cultural practices which makes availability of cadavers difficult and also increase in number of students in medical course there is a rapid decline in student cadaver ratio. The high costs, time intensity, the requirement for highly skilled teachers and the emotionally challenging nature of cadaveric dissection as well as being a cause of significant psychological distress among medical students have been cited as its potential disadvantages of cadaveric dissection. This has ultimately resulted in using newer techniques to teach Gross Anatomy. Not only the student cadaver ratio is unfavourable there is also a need of completing the syllabus of gross Anatomy in a limited time frame available for first year MBBS. With reduction in contact hours less emphasis being given to the basic science courses in the pre-clinical years of medical education and with the need for integration has resulted in the need for educators in the anatomical sciences to develop new pedagogical approaches which are more time efficient at the same time do not compromise students learning experiences.

Prosection is demonstrating anatomy of wet specimens preserved and already dissected by experts which is being considered as an effective teaching tool in Anatomy for undergraduate medical students. Thus in prosection students get to interact with multiple wet specimens, already dissected by experts and learn by observing the structures. Students working together to learn from prosected materials may spend more time focused on the learning objectives than students dissecting in a team where most of them are just passive observers. Students working with multiple prosected specimens have the opportunity to view several variations, rather than the single variation which may or may not be present in their dissection cadaver. With the present integrated medical curriculum and less time allotted for basic science subjects there is a need to judiciously manage the time available. Complete dissection of cadaver by first year medical students is time consuming and there no concrete evidence as whether it is required or not for a medical graduate. Dissection skill is not a required competency for undergraduate medical student as per medical council of India curricular regulation. Not only prosected specimens an increasing number of computer assisted learning tools (CAL) have been introduced to fill in the practical aspects of teaching human anatomy especially for cross sectional anatomy. Newer techniques like plastinated specimens are also being used and used increasingly. This study is an attempt to introduce prosection as a regular tool in teaching Anatomy to first year MBBS students as an alternative to cadaveric dissection. This study also assesses the perception of final year medical students on the importance of dissection in learning gross anatomy as a feedback using a validated questionnaire and whether they would prefer dissection.

**Objectives:**

- To compare the performance of the students who are taught Gross Anatomy of neck region by dissection versus students taught by prosection method.
- To assess the perception of students towards including prosection in regular teaching method in Gross Anatomy.

**Material and Method**

Project proposal approval was obtained from Institutional ethical committee in Saveetha Medical College & Hospital. Study was conducted in two parts.

- 30 randomly selected 1st year MBBS students were divided randomly into 2 groups each group of 15 students.
- Group A and Group B. Informed consent is taken from them after explaining the study.
- Permission to conduct the study was taken from the HOD of Anatomy department and permission of taking help from other teaching staffs was obtained from the head of department.

The anatomy of the neck region which extends over 8 hours of dissection classes was identified which includes a. Midline structures of neck, b. anterior triangle and c. posterior triangle dissection and demonstration. The above regions are taught to the group A by traditional dissection demonstration method. The same regions are taught to Group B through interactions by experts on already dissected preserved wet specimens and museum specimens by prosection technique.

Group B classes are taken in the museum and they were not allowed to dissect for the study period. Classes being taken in respective groups simultaneously is being shown in Fig 4.

Both groups were given an extra of 2 hours for revision of the specimens and at the end of 10 hours of Dissection classes the following day the performance of the students are assessed by a spot identification test consisting of 15 questions each 2 marks pertaining to the
specimens as a practical test conducted at the end of the session.

Once the study period was over the Group B students were allowed to dissect the neck.

In the second part of the study informed consent was taken from 150 final year medical students of the same college. A validated self framed questionnaire in Likert scale of 10 questions was used to assess the perception of final year MBBS students about cadaveric dissection. Internal validity of the questionnaire was tested using Cronbach’s alpha. The total questionnaire Cronbach’s alpha value was calculated as 0.613 which is acceptable. Each participant was given 10 minutes to fill the form which was collected back for analysis. The questionnaire is shown in table 3

Performance of the 30 first year MBBS students of Group A and Group B was statistically analysed. The questionnaire collected from the final year students were analysed SPSS version 21 was used to analyze the data.

**Results**

The performance of the spot identification test conducted on the first MBBS students Grp A and Grp B was analysed uniformly and corrected by 2 experts. The results are shown in Figure 1.

The Mean score, Median and standard deviation was calculated and plotted in table 1

Difference of mean value between two groups ia 3.00, standard error is 1.348. Applying paired t test it was seen at 95 % confidence interval the P value obtained is <0.05 . table 2 and Fig 2 So the difference in the performance of the two groups is significantly better in Group B students taught by prosection technique than group A students taught by cadaveric dissection and demonstration.

The responses of the questionnaire was analysed by percentage and frequency. On analysis of the questionnaire filled by final year MBBS students it was seen they preferred cadaveric dissection. 71% of students agreed that orientation and consistency of gross structures are better observed in cadaveric dissection. 87% students felt visual memory of the structures were better after dissection. 77% of students strongly agreed that dissection helped them to learn how to use basic surgical instruments in future years. 81% of the students felt dissection promoted group learning and discussion. 90% of the final year students felt they learnt to respect the dead in dissection hall. Thus cadaveric dissection is favored strongly among final year students. Table 3 & Fig 3.

Discussion

This cross sectional study conducted in two parts first part was to analyze the performance of first year MBBS students to two different pedagogical approach of teaching and learning gross Anatomy which clearly showed a significantly better performance of student taught by prosection technique and the second part of the study which was a survey conducted on final year students with a questionnaire which clearly showed final year students preferred dissection. In 2004 a study was conducted to consider the arguments related on use of cadavers for teaching Anatomy and to put forward the rationale in removing cadaveric dissection from a new medical school. They developed a curriculum design, assessment and evaluation process based on imaging, clinical skills and living anatomy for teaching Anatomy to first year students.15

In another review paper it is seen that Africa and USA are the leading areas where medical schools are offering cadaveric dissection. In Canada several medical schools have retained compulsory cadaveric dissection in their undergraduate program. In Asia data suggest India has continued teaching anatomy with cadaveric dissection. In European countries and Australia cadaveric dissection is not rampantly used. Many medical schools in UK and Australia are offering optional cadaveric dissection for undergraduate students.10,11,12.

In a another similar study conducted by Nnodim J O et al on two matched group of preclinical students the students belonging to the group taught by experimental prosection technique performed better in the practical exam and multiple choice question test and difference was statistically significant.2 Present study too has a very similar result and difference in performance of the two groups is statistically significant p value 0.034.

A questionnaire study conducted on first year medical students on their views on cadaveric dissection showed 76% of students are excited and most of them did not have fear of dead 65%. 85% felt cadaveric dissection gives better result than only demonstration on prospected specimens and 70% wanted dissection to be continued in Anatomy.13 These findings are very similar to our present study where final year students preferred cadaveric dissection in Anatomy and most of them liked dissection classes during their first year. Table 3 & Fig 3

Journal of Anatomical Record invited faculty of four prestigious medical schools of US to represent the changing views of cadaver teaching in Anatomy and usage of technology to replace cadaveric teaching. In that discussion Kimberly S Topp from University of California brought out the concept of pre dissected specimens and bodies for teaching Anatomy in alternative to cadaveric dissection by students. Though diagrams, animations, digital simulations do provide idea about the anatomical structures they are oversimplified. Ruff an author from John Hopkins has the view that there is definitely a sense of curiosity and satisfaction in hands on dissection especially appreciating the variations and organs in each cadaver. The texture of the structures, variations, reality of the specimens can be well appreciated in prospected specimens too.14

Though students complained of horrifying thoughts, anorexia, nausea, loss of appetite, fainting attacks, eye irritation etc on exposure to cadavers and dissection in first few days of their exposure to cadaveric dissection still dissection and prosection are learning tools in Anatomy which cannot be substituted by other method.16

Conclusion

This study suggest that utilizing prospected specimens for pedagogical teaching of the gross anatomy of neck region seem to be advantageous for students in identifying structures in the practical spotter examination and score higher marks. The performance of the first year students was statistically better for group B students taught by the above method. On analysing the view point of final year students on cadaveric dissection using questions based on Likert scale it showed students preferred dissection during their first year while learning Anatomy. Thus keeping in mind the final year medical students view point and better performance of first year students taught by pedagogical approach using prospected specimens it is concluded that both traditional teaching using cadaveric dissection and teaching with prosectedspecimens should be done hand in hand. This study findings show that complete removal of cadaveric dissection from MBBS curriculum would not be welcomed by medical students and there is a need of cadaveric dissection according to the survey. Thus it is recommended that cadavers can be judiciously used for teaching specific regions of gross Anatomy and students should be encouraged to participate in dissection. Prosection should also be included as a pedagogical approach in teaching gross Anatomy for improving the performance of the students in examinations.
Ethical clearance obtained from institutional ethical committee prior to the study.

Comparison of Quadriceps Muscle Girth Using Ultrasound Imaging In Supervised vs Unsupervised Post Operative ACL Reconstruction

Sumit Saxena¹, Aparna Sarkar², A.K. Naik³

¹PhD Scholar, Amity Institute of Physiotherapy, Amity University Uttar Pradesh, India, ²Professor Physiology, Amity Institute of Physiotherapy, Amity University Uttar Pradesh, India, ³Professor, Department of Orthopedic, Dr. RML Hospital, Delhi, India

Abstract

Injury to the anterior cruciate ligament (ACL) is one of the most common knee ligament injuries. The ACL injury is a sprain or tear of the anterior ligament (ACL). Effective exercises will reduce the risk of ACL injury. An ACL injury in athletes is a higher incidence than other general public, such as soccer, basketball, hockey, etc. The aim of this study was to compare the effectiveness, recovery rate and variance in both knee-affected and non-affected muscle girth readings in supervised v/s unsupervised patient groups after the patient underwent ACL reconstruction surgery. The participants were divided into two groups (A-Supervised and B-Unsupervised) through a random sampling. The supervised exercise in group A performed according to the WILK protocol at RML hospital and un-supervised group B performed the same WILK protocol at home. The ultrasound scans were performed after 2-4 weeks and 12-14 weeks post operation to measure the muscle girth in both the groups. The study findings indicated the significant difference in recovery rate as well as the difference in between supervised v/s unsupervised groups i.e. the difference of affected and unaffected knees based on ultrasound imaging was higher in un-supervised group compared to supervised group (a difference of 2.3 mm in post-operation muscle girth after 12-14 weeks). The ultrasound reading of the muscle girth after 2-4 weeks post-operation showed a decline in the recovery of the muscle girth in both the groups (9% and 8% for supervised and un-supervised groups respectively). This reduction in the muscle girth value as compared to the pre-operative values was due to arthroscopic effect, which showed there was a transient deactivation of the muscle take place due to surgery. The ultrasound reading of the muscle girth after 12-14 weeks post-operation showed a different progressive recovery of the muscle girth in both the groups as 31% and 10% for supervised and un-supervised groups respectively. We concluded that supervised exercises was better than unsupervised exercises for the early recovery after ACL recontraction.

Keywords: Quadriceps; Muscle girth; ACL; Ultrasound; Recovery.

Introduction

The knee is a weight-bearing joint which operates as a fulcrum between tibia and femur. ACL is present in the knee and the bone structure of the knee joint is made up of the tibia, femur and patella¹². The knee is basically a pivoted joint that is held together by the Posterior Cruciate (PCL) ligaments, Medial Collateral (MCL), Anterior Cruciate (ACL) and Lateral Collateral (LCL)³⁴. The ACL is located diagonally in the knee as is shown in the below figure, keeping the tibia from sliding out before the femur and also giving rotational steadiness to the knee. The ACL is one of the four primary ligaments inside the knee that associate the femur to the tibia⁵⁻⁷. ACL tends to be at risk as it prevents posterior displacement of the distal femur on the tibia. ACL can tear due to twisting type of force acted at the joint in such
ACL reconstruction may be defined as the functional restoration of the ACL to its native dimensions, collagen orientation and insertion sites. ACL Reconstruction is the technique in which the tunnels are placed in the centre of the native femoral and tibial insertion sites. It can be done either through a single bundle or double bundle. Anatomic ACL reconstruction can be used in both single and double-bundle reconstructions and also to Augmentation surgery. Complete restoration of the native ACL may not be possible, because of the complex nature of the ligament. However, the surgeons always attempt towards close proximity.

ACL injuries received the greater attention of orthopaedic surgeons and due to their deep analysis of the subject, it became possible to treat such injury. Previously, the cases of ACL were not reported so frequently in India as in the current scenario due to the absence of sufficient analytical skills & required tools. But now the incidences of ACL has increased and after an ample amount of research in this field, the surgeons are able to perform ACL Reconstruction successfully. There is as low as 2.5% chance of recurrent instability due to rupture of the reconstructed ligament or maybe poor surgical technique. The post-operative examination was carried out by a non-operative observer. On the first postoperative day, digital anteroposterior and lateral knee radiographs were completed without a strap. For the direction and inclination of the tunnel on the frontal and sagittal planes, the femoral tunnel was evaluated in radiographs. The follow-up was done weekly, then at 2-3 weeks, three months and one year. During 1-year follow-up, a practical performance review was conducted with the Lysholm knee scoring system. A rolimeter (Rolimeter TM for measuring anterior/posterior knee joint laxity by aircraft) was used to assess previous tibial translation quantitatively. Pivot shift testing was performed. The main objective of the study was to compare and to find out the relative progression of muscle girth readings in supervised v/s unsupervised ACL reconstruction patient.

**Material and Method**

Eighty-two subjects (73 male 9 female) at the age group of 18-40 yrs were enrolled for this study between November 2016 to December 2018. All the participants had undergone ACL reconstruction surgery at RML hospital Delhi. The selection of participants was volunteered and their consent for performing Ultrasound imaging was provided formally. The participants were divided into two groups as Group A: Supervised and Group B: Unsupervised. The average age of participants in supervised and unsupervised groups were 27.5 and 28.5 years respectively. The inclusion criteria were Post-operative anatomic ACL reconstruction. The exclusion criteria were any degenerative changes, bone infections, any previous injury in lower limb other than an ACL injury, any metabolic disorders like diabetes, obesity.
and hypertension, any meniscal or PCL injury and Pre-operative MRI Scan confirming ACL tear only no associated injury to menisci or other ligaments.

**Assessment:** Detail assessment was performed according to the assessment performa measuring the mid thigh circumference and special tests and strength of the muscle. WILK protocol was adopted for the strengthening exercise for both the groups for a duration of 3 months post operative.

**Measurement of quadriceps muscle girth:** Ultrasound is most commonly used in the assessment of soft tissue disease or fluid collection detection and may also be used to visualize other structures, such as cartilage and bone surfaces. All measurements in patients were performed three times: measurements were performed on the Kranzbüchler ultrasound machine, Medizinische Systeme GMBH, Germany, using a 7.5 MHz linear probe (Medizinische). During the measurements, the subjects lay on their backs with stretched/extended legs, their muscles relaxed and their feet in a neutral position. Both legs were examined for both the groups and muscular girth was measured by horizontal and vertical scanning of the upper leg, in the centre of the upper leg and 5 cm proximal and distal from the centre. In their central segments, m. vastus intermedius and m. rectus femoris have square shapes. The reproducibility of the ultrasound procedure was calculated by several measurements of 10 healthy volunteers over one day, as a change in muscle volume can not be predicted in such a short period of time. The error of this process was calculated on the basis of the variations and the uncertainty coefficients of these measurements.

**Statistical tests:** The SPSS 24 (Statistics System for Social Science) was used for statistical analysis. The paired t-test and was performed, which was having a significance p-value (less than 0.05). The findings of the one pair sample statistics for supervised group is having a mean value for study group is 14.3 mm, for normal/un-effected limb is 15.2 mm. Whereas the standard mean difference of 0.9 mm for three month post operative to normal. Furthermore the standard error value of 0.24 and 0.36 for three month post operative and normal respectively. On the other hand the values for supervised group is having a mean value for study group is 12 mm, for normal/un-effected limb is 15 mm. Whereas the standard mean difference of 03 mm for three month post operative to normal and furthermore the standard error value of 0.29 and 0.38 for three month post operative and normal respectively.

Muscle dimensions were measured on off-line scans using Image J software (available http://rsb.info.nih.gov/ij/docs/index.html). Muscle thickness was measured as the greatest vertical distance between the anterior and posterior borders of RF from their inside edges. Measurement of quadriceps muscle girth:

**Results**

The figure 2 showed the data for supervised and un-supervised groups. The following information was tabulated in the Excel spreadsheets: sex, age, ms mid quad for normal, ms mid quad in pre-operation, ms mid quad in 8 weeks of operation and ms mid quad in 12-14 weeks of operation for both supervised and unsupervised groups. A total of 164 participants were divided into two groups, i.e. 82 in each group. The pre-operative values of muscle girth for supervised was 10.83 mm and for unsupervised was 10.93 mm. The ultrasound reading after 2-4 weeks post operation for supervised group was 9.83 mm and for un-supervised was 10.11 mm respectively. Both the readings of post operative 2-4 weeks, was having a downwards recovery of the muscle girth. The findings of the one pair sample statistics for supervised group is having a mean value for study group is 14.3 mm, for normal/un-effected limb is 15.2 mm. Whereas the standard mean difference of 0.9 mm for three month post operative to normal. Furthermore the standard error value of 0.24 and 0.36 for three month post operative and normal respectively. On the other hand the values for supervised group is having a mean value for study group is 12 mm, for normal/un-effected limb is 15 mm. Whereas the standard mean difference of 03 mm for three month post operative to normal and furthermore the standard error value of 0.29 and 0.38 for three month post operative and normal respectively.
Discussion

The ultrasound reading of the muscle girth after 2-4 weeks of post-operation showed a decline in the recovery of the muscle girth in both the groups (-9% and -8% for supervised and un-supervised groups). This reduction in the muscle girth value as compared to the pre-operative values was due to arthroscopic effect, which showed there was a transient deactivation of the muscle which took place due to surgery. The ultrasound reading of the muscle girth after 12-14 weeks post-operation showed a significant progressive recovery of the muscle girth in both the groups (31% and 10% for supervised and un-supervised groups respectively). This progression in the muscle girth value as compared to the pre-operative values (the difference between the progression in the two group) is significant (21%), is due to the approach in supervised exercise vs un-supervised exercise, where the focus is for isolated muscle activation of the knee. The statistical data analysis provided a comprehensive understanding of the gain in the muscle girth and the data would be inferred that the recovery rate in supervised group is relatively approaching towards the normalcy, whereas in the un-supervised group the difference in the affected and normal is relatively higher i.e. it is deficient of recovery of muscle strength post operatively. It was also observed that in the un-supervised group, the muscle atrophy was very significantly visible in comparison with the supervised group. Furthermore it was also observed that the functional strength required post operatively for the knee was lacking in the un-supervised group. This study also reflected the importance and the significance of the exercise done under supervision where the physiotherapist and the patient could adopt focused approach to develop the required muscle strength and substitution of the other muscle groups could be avoided, which was lacking in the unsupervised group, where patients are complying with the exercise protocol but unable to discriminate the muscle group to be strengthened and using the gross muscles for the thigh leading to the imbalance of the muscle strength between the agonist and the antagonist group i.e. knee extensors and knee flexures muscles.

Conclusion

With the above study the authors concluded that supervised exercises in post operative ACL reconstruction plays a very significant role for the recovery and also reduces the chances of post operative complications remarkably.
**Ethical Clearance:** Taken from the ethical committee of post graduate institute of medical education & research, Dr. Ram Monohar Lohia Hospital, New Delhi approved the study.

Abstract

**Introduction:** Breastfeeding has been widely recognised as benefiting for infants and mothers. It could avoid haemorrhage after giving birth (postpartum). The study aimed to observe the association between exclusive breastfeeding, blood volume and blood duration in a postpartum period.

**Method:** This was an analytic study with a cross-sectional design. The number of samples was 56 postpartum women who were chosen by purposive sampling method. A questionnaire was used in collecting data by interviewing the respondents. Data was analysed using descriptive statistic and chi-square test.

**Result:** There were 78.57% respondents breastfed exclusively and 21.43% did not breastfeed exclusively. In this study, exclusive breastfeeding related to bleeding duration \((p=0.00)\), while blood volume was not associated with exclusive breastfeeding \((p=0.06)\).

**Conclusion:** There was a relationship between exclusive breastfeeding and blood duration. Meanwhile, exclusive breastfeeding was not associated with blood volume.

**Keywords:** Exclusive Breastfeeding, Blood Volume and Bleeding Duration.

Introduction

Providing exclusive breastfeeding is an important intervention to reduce neonatal, infant or child morbidity and mortality. It is a good strategy as well for child survival. Breast milk is a very good intake in the first thousand days of birth because it provides complete nutrition for baby and it is ideal for the few first months as it is nurture provided by the nature\textsuperscript{1}. Breastfeeding infants is the best way to improve nutrition and the quality of human resources.

Breastfeeding optimizes the development of nerves and the brain, provides immune substances against disease and builds the emotional bond between mother and baby\textsuperscript{2}. Breastfeeding not only give benefits for baby but also for mother. Early initiation of breastfeeding could reduce the risk of postpartum haemorrhage\textsuperscript{3}.

Postpartum Haemorrhage (PPH) is a major determinant in maternal morbidity and mortality\textsuperscript{4,5}. The consequence of excessive blood loss during childbirth is a significant problem. According to World Health Organization (WHO) in\textsuperscript{3}, it is estimated that around...
800 women die every day because of preventable disease during pregnancy and postpartum, in which 99% of the death are in developing countries. Among ASEAN countries, Indonesia is on the fifth in terms of maternal death. The main cause of the deaths is complications during pregnancy and mostly occur during the postpartum period which was mainly caused by haemorrhage. WHO defines PPH as a blood loss of 500 ml or more, while severe PPH is defined as vaginal bleeding more than 1000 ml within 24 hours after birth. By this definition, around 14 million cases of postpartum haemorrhage (PPH) occur each year, affecting about 6% of all women giving birth around the world. There was some research about PPH in Indonesia have been carried out. However, this study focused on exclusive breastfeeding, related to blood volume and duration of bleeding after birth.

**Method**

This study is an observational study with cross-sectional design which was conducted in Kassi-Kassi Primary Health Centre (PHC) area, Makassar, Indonesia. This study focused on exclusive breastfeeding at one month of postpartum period. Sampling method used was purposive and the number of samples was 56. The criteria of sample:

Inclusive criteria: women who have a baby aged 1 month and live in Kassi-Kassi PHC area, the women breastfed exclusively (breast milk only) and did not have health problems related to their labour.

Exclusive criteria: women did not breastfeed exclusively and have health problems during the postpartum period.

For data collection, a questionnaire was used as a research instrument. The questionnaire was consisted of some questions such as characteristic of respondents, parity, type of labour, sanitary pad change and duration of bleeding. Respondents were interviewed directly when visiting PHC for their baby’s immunization. Data were analysed by using SPSS program and the result was showed in frequency and cross-tabulation table. Chi-square test was applied to observe the association between exclusive breastfeeding, blood volume and duration of vaginal bleeding.

**Findings:** The number of samples which was analysed in this research is 56. Table 1 shows that of 56 respondents, most of them aged 20-35 years (89.29%) and only 3.57% aged under 20 years. The highest education level is university, 53.57% respondents who graduated from university and 7.14% was junior high school. In this study, most of the women were housewife (60.71%) and a civil servant (7.14%).

The percentage of respondents who are parity 1 and 2 is 57.14% and 42.86 respectively. For the delivery process, the vast majority of respondents gave birth through vaginal birth (96.43%) and caesarean only 3.57%.

In terms of breastfeeding, 78.57% breastfed exclusively and 21.43% non-exclusive. Most of the women (96.43%) have blood volume loss <500ml and only 3.57% more than 500ml. For the duration of vaginal bleeding, less than 14 days (78.57%) and 21.43% more than 14 days.

Table 2 and 3 show the association between exclusive breastfeeding, blood volume and duration of vaginal bleeding. All respondents (100%) who breastfed exclusively have blood volume < 500ml (table 2). However, the percentage of women who did not breastfeed exclusively and had blood volume < 500ml was high as well (83.3%). Respondents who did not breastfeed exclusively and had blood volume >500ml was 16.7%. Chi-square test revealed that there was no association between exclusive breastfeeding and blood volume (p=0.06).

Table 3 shows that 97.7% of respondents who breastfed exclusively and the duration of vaginal bleeding was under 14 days. Meanwhile, respondents who did not breastfeed exclusively and had bleeding duration > 14 days were 91.7%. The percentage of women who did not breastfeed exclusively and had bleeding duration < 14 days was 8.3% and mother who breastfed exclusively but had bleeding duration > 14 days was 2.3%. Chi-square test show that exclusive breastfeeding related to the duration of vaginal bleeding (p=0.00). These results can be observed in the following tables (Frequency table and cross tabulation table).

Discussion

Exclusive Breastfeeding and Blood Volume:
Breastfeeding is the most effective way to ensure the health and survival of both infants and mother. WHO recommended providing exclusive breastfeeding (6 months) for a child without giving any formula milk and any food. In this research, exclusive breastfeeding was defined as an activity breastfeeding of respondents who gave breast milk only to their baby at least for 1 month. The result of this study revealed that all the respondents who breastfed exclusively had blood volume < 500ml. However, the data showed that the percentage of the mother who did not provide exclusive breastfeeding and had blood volume < 500ml is high as well. The result of this study suggested that there was no association between exclusive breastfeeding and blood volume.

World Health Organization (WHO) and The United Nation Children’s Fund (UNICEF) recommends early initiation of breastfeeding within one hour of birth to stimulate breast milk production. It also stimulates uterine activity which can reduce the risk of heavy bleeding and infection. Maternal death in the postpartum period can be caused by the amount of blood (volume) that comes out after delivery. The simple and easy strategy to reduce the Maternal Mortality Rate (MMR) and Infant Mortality rate (IMR) is breastfeeding directly (early initiation) and breastfeed exclusively to baby because breast milk contains Immunoglobulin which can prevent infection and diarrhoea.

Nipple stimulation, either manually using a breast pump or by encouraging the baby to suckle is a method to reduce bleeding after birth. It can be used immediately after childbirth to increase the secretion of the hormone called “oxytocin”. Thereby, if the mother breastfeeds the baby immediately after giving birth, postpartum bleeding can be prevented or blood volume will be lower. When oxytocin is released or the level increase, it causes uterus contraction and helps the uterus back to the normal size which can lead to the reduction of postpartum bleeding. Early initiation and the breastfeeding frequency immediately after birth will reduce the amount of vaginal blood loss and improve uterine involution. Some studies found that breastfeeding related to postpartum haemorrhage. A retrospective cohort study which analysed birth cohort (n=3671) and conducted in New South Wales (NSW) Australia (2015) showed that breastfeeding and skin-to-skin contact immediately after giving birth may be effective in reducing PPH for women at any level of risk of PPH. A quasi-experimental study (n=50) conducted in Alexandria, Egypt (2004) revealed that early breastfeeding had a statistically significant effect (p=0.001) on post-birth blood loss. The early breastfeeding group of women lost less than 150 ml of blood; the later breastfeeding group lost 300 ml or more. A study which was carried out in Tegal regency, Indonesia (2015) showed that there was a relationship between early breastfeeding and postpartum haemorrhage.

However, this study, conducted in Kassi-Kassi PHC, Makassar city of Indonesia, showed a different result with the previous studies that stated breastfeeding influences vaginal bleeding after birth. This study suggested that exclusive breastfeeding was not related to blood volume after birth. The results showed that although all women who breastfed exclusively had blood volume < 500ml, the percentage of women who did not breastfeed exclusively and had blood volume < 500ml is high as well (83.3%). This result could be explained that exclusive breastfeeding is not the only one strategy to prevent blood volume loss > 500ml or postpartum haemorrhage, but at least breastfeeding and skin to skin contact immediately after childbirth should be encouraged to stimulate and release oxytocin hormone that helps to reduce vaginal bleeding. The result of this study is similar to systematic review found that there is not a significant difference between nipple stimulation (breastfeeding) versus no treatment concerning the incidence of PPH (>500ml) and blood loss in the third stage of labour.

Although this study revealed that there was no association between exclusive breastfeeding and blood volume, exclusive breastfeeding has many benefits both infant and mother. It is not only can prevent haemorrhage but also prevent complication in a postpartum period. Thereby, it could reduce maternal morbidity and mortality after birth.

Exclusive Breastfeeding and Duration of Vaginal Bleeding: Duration of vaginal bleeding in this study is how long the bleeding occurs in a postpartum period, whether less than 14 days or more than 14 days. The result showed that the percentage of women who breastfeed exclusively and had bleeding duration < 14 days is very high and proportion of mother who did not provide exclusive breastfeeding and had bleeding duration > 14 days is very high as well. The results of
this study revealed that exclusive breastfeeding is related to the duration of vaginal bleeding.

In the process of lochia discharge, there are stages which require certain period of time. The time needed to release lochia depends on the smoothness of the discharge, if the lochia discharge smoothly, the time required will be faster, that is ≤ 14 days and conversely, if the lochia is not smooth, the time required will also be longer that is > 14 days. This study is supported by research which stated that mothers who experience stress during pregnancy and childbirth can cause breastfeeding problems whether breastmilk release or not. The hormones responsible for the lactation process are prolactin and oxytocin. Women who are being stress will affect the release of the hormone from neurohypophysis that leads to a blocking of the let-down reflex when the baby is being breastfed. These hormones have a role in stimulating the process of uterine contractions that influence lochia discharge.

A study in Indonesia shows, of the 30 respondents who breastfeed their baby (early initiation), there were 25 respondents (83.3%) who had high normal uterine fundus. A decrease in the normal uterine fundus occurs because blood (lochia) which release after birth lasting <14 days. Conceptually the dominant factor influencing the return of menstruation or bleeding after childbirth is a hormonal regulation factor. The hormone that has an important role in bleeding begins with the release of the prolactin. This hormone is secreted by the anterior pituitary gland due to the stimulation of baby suction when suckling in the mammary areola area. Suction stimulation will be continued to the spinal cord through sensory nerve impulses and passed on to the brain, namely to the hypothalamus. In the next process, the hypothalamus will give a command to the posterior and anterior pituitary glands. The posterior pituitary gland secretes the hormone oxytocin which is useful for smoothing out breast milk. If the production of the hormone prolactin and the hormone oxytocin continues smoothly, it affects the uterus and ovaries. This effect is related to the smoothness of breast milk discharge needed by the baby at any time. Continuous suction in the mammary areola area gives a positive effect of myoepithelial cell contractions so that breast milk is quickly excreted. It will also have an impact on the uterus so that no bleeding and duration of bleeding will be shorter.

The let-down reflex coincides with the production of prolactin by the anterior pituitary, stimulation originating from the baby’s sucking is continued to the posterior pituitary (neurohypophysis) which is then excreted oxytocin. Through the bloodstream, this hormone goes to the uterus, causing contractions. The contraction of the squeezing milk breast that has been made, out of the alveoli and into the duct system and then flows through the ductus lactiferous into the baby’s mouth.

Neurohypophysis periodically secretes oxytocin (pulsatile). This process stimulates milk secretion from breastfeeding by causing contraction of myoepithelial cells in the alveoli and small milk ducts. Ejection or breast milk discharge is a reflex that is initiated by the suction of the nipple which stimulates neurohypophysis to release oxytocin. Breastfeeding also speeds up uterine involution because repeated stimulation of the nipple will release oxytocin which causes contraction of the uterine muscle.

WHO recommends providing exclusive breastfeeding for babies until 6 months. Providing exclusive breastfeeding to infants will increase uterine involution thereby reducing postpartum complications. Breastfeeding also has a positive impact on the mother because the baby’s sucking will cause uterine contractions that prevent post-partum bleeding. During breastfeeding, oxytocin releases after childbirth also reduce uterine bleeding and prevent about one-fifth of neonatal deaths. Therefore, a health provider should provide nutrition and lactation counselling for women during pregnancy and after childbirth.

Conclusion

This study found out that all of the women who breastfed exclusively had blood volume loss <500ml, but the percentage women who did not breastfeed exclusively and had blood volume loss <500ml is high as well. Thereby, this study suggested that there was no association between exclusive breastfeeding and blood volume loss. Meanwhile, exclusive breastfeeding related to the duration of vaginal bleeding after birth.

Abstract

Community empowerment is one of the global strategies for health promotion so that community empowerment is very important to do so that the community as the primary target has the will and ability to maintain and improve health. The Healthy Living Community Movement Program (GERMAS) is basically a public health effort through community empowerment. This study aims to analyze the process of community empowerment in the implementation of the Healthy Living Community Movement Program (GERMAS) in post-disaster areas. This type of research is qualitative using a phenomenological study approach. Data collection is done by in-depth interviews, document review, FGD (Focus Group Discussion), and documentation. The results showed that the implementation of community empowerment in the Healthy Living Community Movement Program (GERMAS) by conducting integrated collaboration with related sectors such as Empowerment of Family Welfare (PKK), National Narcotics Agency (BNN), Ministry of Religion, Office of Women’s Empowerment and Child Protection and banking. Incentives for health cadres are budgeted by the Health Office of the City of Palu in the amount of Rp. 150,000 (one hundred and fifty thousand Rupiah) per quarter.

It was concluded that community empowerment in the implementation of GERMAS in the post-disaster area of Balaroa Village was in the aspect of partnerships in the form of cooperation with various cross-sectors in that program, integration of GERMAS with other priority programs such as GALI GASA, coordination with all stakeholders by involving community leaders, youth leaders, and the K5 task force. From the aspect of the budget in the form of budget allocation in every financing activities of the program and providing incentives for cadres. From the aspect of evaluating activities in the form of a final report on activities, the residents have cultivated vegetables and other plants in their own yards.

Keywords: Community Empowerment, Germas, post-disaster.

Introduction

The condition of public health in Indonesia is currently experiencing major challenges namely the three burden of disease (triple burden) because there are still infectious diseases, increasing non-communicable diseases (PTM) and diseases that should have disappeared again. The country of Indonesia faces changes in disease patterns or what is often called the epidemiological transition in the last 30 years. The biggest causes of death and illness in the 1990s were infectious diseases such as upper respiratory infections (ARI), TB, diarrhea, etc.¹

There are many health problems in general that occur in Indonesia, especially in the city of Palu, which has experienced natural disasters due to the earthquake, tsunami, and liquefaction on 28 September 2018. Palu City which is the center of government and economic heart of Central Sulawesi Province affected by the disaster recorded 1,649 people died, 2,549 people were injured, 265 were missing and 152 were estimated to be buried and have not been evacuated due to the incident. This caused the paralysis of Palu City from various aspects, there were around 62,359 inhabitants in refugee camps, 66,926 houses were thought to be damaged. Various problems especially in the health sector that arise at this time actually do not need to occur if the community plays an active role in accordance with their respective roles ranging from awareness of maintaining personal health, family, environment, health program planning and supervision. The Healthy Life Community Movement Program (GERMAS) launched by the government through Presidential Instruction No. 1 of 2017 is basically a public health effort through community empowerment. Community empowerment in the health sector is the main target of health promotion. Community empowerment is one of the global strategies for health promotion so that community empowerment is very important to do so that the community as the primary target has the will and ability to maintain and improve health.

At the initial stage, GERMAS began with a focus on three activities, namely carrying out 30 minutes of physical activity every day, consuming vegetables and fruit and regular health checks at least once every 6 (six) months as an early detection effort disease. These three activities can be started by yourself and your family.

Thus an analysis of community empowerment is needed in the implementation of GERMAS in the post-disaster area of Palu City. This study aims to analyze community empowerment in the implementation of GERMAS in the post-disaster area of Palu City.

**Material and Method**

This type of research is qualitative using a phenomenological study approach. A sampling of informants was carried out using a purposive sampling technique, namely determining the sample of research informants by means of deliberately selecting or appointing them to be informants. The subjects used as informants in this study were 10 (ten) people. The method in collecting data in this research is in-depth interviews, Focus Group Discussion (FGD), documentation.

Data obtained through in-depth interviews in this study were analyzed using content analysis. Content analysis involves a process designed to condense raw data into categories or themes based on valid conclusions and interpretations. The process of content analysis in qualitative research begins with data collection, to support the drawing of valid and reliable conclusions, the reduction of data tailored to the objectives of the study.

**Results**

**Empowerment Stage:** The results of research on community empowerment related to the analysis of the power supply stage can be listened to through the following in-depth interviews with informants:

Research questions about how to analyze the steps of the Power Giving Phase related to partnerships in the implementation of GERMAS in post-disaster areas in Balaroa Village?

"... During this time we are collaborating with the GALI GASA program, the K5 task force, PKK, BNN, including the Ministry of Religion, women empowerment, child protection, banking assistance, GERMAS is integrated with other parties ..."

"... Since we entered the emergency response, the post-disaster period, the transition period, the reconstruction and recovery period, we have done everything, besides GERMAS, there are also special treatments, health services, and reproductive health posts. So post 24-hour public health during the emergency response period. We cannot work alone because of limited manpower so that after the disaster many parties involved were involved there but continued to coordinate with the puskesmas because of our work area."

Research questions on how to analyze the steps for the Empowerment Phase in relation to budget support in implementing GERMAS in the post-disaster area of Balaroa Village?

"... In 2020, which is usually 50 people/village to 100 people/village. Last year needed 3 tents, now it needs 6 tents. Funding from the Regional Budget ..."

"... What is important is that if there is a listing of the director, there is a hook in the RPJMD, then every
year the budget will come out. The allocation last year was quite large because of the activities almost every week ... “

The excerpts from the interview results above explain that the budget support for GERMAS in the Palu City Health Office has increased but is not significant from previous years, where there are an increase of 2 (two) times the financing volume of 50 people every village to 100 people every village, from the needs of 3 (three) tents to 6 (six) tents. This is reinforced by the explanation of the Regional Development Planning Agency (BAPPEDA) of Palu City that the budget allocation for GERMAS is annually and is quite large.

Related to research questions about incentives for cadres in the implementation of GERMAS in the post-disaster area of Balaroa Village?

“... If from BOK 50 thousand/month. I have been given incentives starting from my work in 2011. Received quarterly .. “

“... Cadre incentives from our government, a month of 50,000 are received per quarter. So the officers here take the funds in the new service, we are here to channel ...

From the interview excerpt above that up to now the incentive for health cadres in Balaroa Village is budgeted by the Palu City Health Office and then distributed by Sangurara Health Center every quarter of Rp. 150,000 (one hundred and fifty thousand Rupiah) every quarter.

Related to research questions regarding the evaluation of the implementation of GERMAS in the post-disaster area of Balaroa Village?

“... Activity reports start from Integrated healthcare center (posyiandu) cadres, village health post (poskesdes), and community leaders who were completed in the public health center (puskesmas) report. In addition, around 4-5 community groups have been formed which independently carry out activities related to GERMAS without any intervention from the local government, community awareness to conduct clean and healthy lifestyles is better, formed Community-Based Health Efforts (UKBM), and before the disaster, residents had already grown vegetables and chilies in their own yards.

**Discussion**

Community empowerment in the health sector is more aimed at increasing community participation in the health sector. Community participation is the activity of involving the community in a program. It is expected that with high community participation, a health program can be more targeted and have greater leverage for behavior change because it can create a value in the community that the health activities are from us and for us.

Community empowerment is an effort or process to foster awareness, willingness and ability of the community to recognize, overcome, maintain, protect, and improve their own welfare. Community empowerment in the health sector is an effort or process to foster awareness of the willingness, and ability to maintain and improve health.

The Healthy Life Community Movement Program (GERMAS) is a systematic and planned action taken jointly by all components of the nation with awareness, willingness, and ability to behave in a healthy manner to improve the quality of life. GERMAS can be done by doing physical activities, consuming vegetables and fruits, not smoking, not consuming alcohol, checking health regularly, cleaning the environment, and using the toilet.

The interview excerpt above explained that the evaluation of the implementation of GERMAS was reported in the form of reports by Integrated healthcare center (posyiandu) cadres, village health post (poskesdes) and community leaders who were completed in the public health center (puskesmas) report. In addition, around 4-5 community groups have been formed which independently carry out activities related to GERMAS without any intervention from the local government, community awareness to conduct clean and healthy lifestyles is better, formed Community-Based Health Efforts (UKBM), and before the disaster, residents had already grown vegetables and chilies in their own yards.

Based on the results of research on the analysis of community empowerment in implementation GERMAS conducted in Balaroa Village, Palu City, shows a picture of the implementation of community empowerment through stages. The discussion of these stages is described as follows:

**Empowerment Stage:** The stage of giving power itself or empowerment. At this stage, the authority is
given to identify the problem and the right strategy to overcome the problem of community empowerment in implementing GERMAS. Community empowerment activities at this stage appear in the form of partnerships, utilization of potential and resources, integration of activity programs and evaluations in the implementation of the GERMAS.

Explore and develop the potential of each community member so that they can contribute according to their ability to jointly planned programs or activities. Community contribution is a form of community participation in the form of energy, thoughts or ideas, funds, building materials, and other facilities to support health businesses.

According to Sari and Sulistiowati, the tasks of the public health center (puskesmas) are so numerous and not possible to be done by the public health center (puskesmas) themselves, it needs support from various parties. A partnership is one of the important health promotion strategies to be implemented, which must begin with the identification of community leaders in order to form a tiered and sustainable partnership. The implementation of GERMAS in all villages in the city of Palu is integrated with the Gali Gasa Program which is also a priority and priority program in the city of Palu.

In addition, the provision of incentives for health cadres in every community empowerment activity related to GERMAS carried out in Balaroa Village has been carried out by the Palu City Health Office through the Sangurara Health Center by providing incentives of Rp. 150,000/quarterly. According to the research results of Bhattacharayya et al., 2001, giving awards in the form of cash to cadres does have an advantage. The advantage of money as a cadre incentive can be asked to work longer hours to achieve certain goals, supervision can be carried out strictly so that the program can be implemented quickly, regular work routines and service quality can be maintained, negative reinforcers such as dismissal or punishment that can be used to encourage desired performance and payments are also seen as helping to build economic equality in populations that lack economies. In line with this, the WHO (World Health Organization) sees the need for cadre payments as a long-term program sustainability effort.

Even so, the provision of incentives in the form of cash causes a weak sense of volunteerism from cadres. Wirapuspita revealed that monetary incentives can improve the performance of cadres, but the incentive management system by the government can reduce the voluntary nature of cadres and weaken community empowerment. Bhattacharya et al., incentives in the form of money have losses, which can lead to jealousy and hostility if not all CHWs (Community Health Workers) or other communities that work are paid, thereby damaging their commitment and their relationship with the community. CHWs (Community Health Workers) those who receive salary or wages can see themselves as government employees or NGOs rather than as community servants.

Based on the results of the study, it is important for posyandu managers and coaches, both at the village office, sub-district, public health center (puskesmas), health offices and city government levels to consider giving and managing money incentives to cadres, so that the provision of incentives can be on target and the desired goals can be achieved.

**Conclusion**

At the power supply stage in the implementation of the Healthy Life Community Movement Program (GERMAS) in the post-disaster area of Balaroa Village in the aspect of partnerships in the form of collaboration with various cross-sectors, integration with other priority programs such as GALI GASA, coordination with all stakeholders involving community leaders, youth leaders, and K5 task force. From the aspects of the budget in the form of budget allocation in every financing activities of the Healthy Living Movement Program (GERMAS) and providing incentives for cadres. From the evaluation aspect of the activity in the form of a final report on the activities of the Healthy Living Community Movement Program (GERMAS) that has been carried out, the residents of Balaroa Village have been cultivating vegetables and other plants in their respective yards.

Design and Guidelines for Early Stimulation to Optimize Toddler Development in Maritime Communities in Kelurahan Lapulu Abeli Puskesmas Working Area in Kendari City

Nurjannah

Lecturer of Department of Nursing, Health Polytechnic, Ministry of Health, Kendari

Abstract

The first three years of a toddler is a golden period for optimal brain growth and development. Growth and development of infants will be in line with the optimal age increase, if appropriate stimulation is carried out routinely, this study aims to analyze the effectiveness of early stimulation guidelines to optimize the development of infants in maritime communities. This research method is a quasi experiment with pre and post test design with control group. The population in the study were all toddlers with a sample of 30 people (case group of 15 people and control of 15 people). Sampling is done by simple random sampling. Data were analyzed using paired T-Test to analyze differences in development before and after the administration of early stimulation, and pooled T-Test to analyze the effect of early accumulation on toddler development by comparing the development between case groups and control groups. The results of the study found that the provision of early stimulation was effective in optimizing the development of children under five in the maritime community in Posyandu, Lapulu Village, the working area of Abeli Puskesmas, Kendari City in 2018.

Keywords: Early Stimulation, Toddler Development, Maritime Society.

Introduction

To achieve good human qualities, it is necessary to foster children as early as possible from the womb, the age of the child, until the child becomes an adult. Toddlerhood is a period that really determines the quality of human resources, because the growth and development of children is determined by the condition at the time of infancy. Toddlerhood is often stated as a critical period in order to get quality human resources, especially in the first 3 years period is a golden period for optimal brain growth and development. The development of the ability to speak in toddlers with the language of creativity, social awareness, emotional and intelligence goes very fast. Growth and development will be in line with the normal increase in age if routinely given the appropriate stimulus, so that toddlers will grow and develop normally as well, so that it will increase human resources in the future.

Comprehensive and quality child development is carried out through stimulation activities, and early interventions for toddler growth and development. Toddler development is greatly influenced by guidance from parents by providing stimulation in the form of guiding the toddler, so that development can be in accordance with the age of the toddler. Early Childhood Growth and Development (SDDTK) stimulation and detection is carried out to get quality children. A simple means of monitoring growth and development is the Pre Development Screening Questionnaire (KPSP). Monitoring efforts are made to stimulate development by following up the complaints of parents related to the growth and development problems of infants and toddlers.

Method and Method

This research is a quasi-experimental research with a pre-post test with control group design. This design aims to determine the effectiveness of early stimulation guidelines after being given an intervention or treatment on a variable, then the results of the treatment are compared with the control group, i.e. the group that is not subject to treatment.
This study compared the intervention group for early stimulation in infants as a treatment group with the group that did not intervene as a control group. This study uses two measurements, namely before and after the intervention. Measurements made before the intervention (O1) are called pretest, and measurements made after the intervention (O2) are called posttest. 7

The population in this study were healthy toddlers who did not experience health problems during the last 3 months as many as 118 people in the PudaiKelurahan and Lapulukelurahan, the Abeli Health Center in Kendari City. Sampling of toddlers as many as 15 intervention groups and 15 control groups with regard to matching age groups, and gender. Retrieval of initial observation data (pre-test) by measuring the development of infants using the KPSP Ministry of Health 2014 measurement tools before giving early stimulation. Provision of intervention by training toddler mothers to do early stimulation of development accompanied by the provision of a media booklet that contains technical instructions on how to do stimulation to mothers of toddlers 8,9.

Results

The results showed that maternal education with the highest frequency of secondary education was 16 people (53.3%) and low frequency was S1 as much as 1 person (3.4%) (Table 1).

**Discussion**

Good education and supported by a good nurturing environment, good mother-child interaction through nurturing greatly affect the development of good children. Development requires stimulation/stimulation, especially in the family, for example the provision of toys, child socialization, involvement of mothers and other family members in children’s activities.¹⁰

The link between education and the mother’s knowledge in providing early stimulation to her child is also supported by the results of research that found that there is a relationship between maternal knowledge about infant growth and development stimulation with the development of toddlers aged 12-36 months in Posyandu Kasihibu Banyu UripKlego Boyolali.¹¹

Children who are entrusted in TPA have better development than those raised by parents because TPA has good parenting standards, has professional caregivers, a comfortable and attractive place, and there is a complete play area to stimulate toddler development. Basically, all activities in TPA are intended to stimulate children to meet the optimal development needs.¹²

This is in line with the opinion which says that in parents with a high and good education, parents can receive well all information from outside, especially how to care for children properly and healthier. This is in line with the results of research on the relationship between the level of parental knowledge about stimulation and gross motor development of children aged 0-5 years in BumiAji Village, Anak Tuha Subdistrict, Central
Lampung Regency. As a result, there is a relationship between parents’ knowledge about stimulation and gross motor development in children aged 0-5 years.\textsuperscript{13}

The level of education of respondents with high frequencies in high school education was 16 people (53.3\%) and the presence of higher education (S1) of 1 person (3.4\%) contradicts the opinion that the characteristics of coastal communities that lack education, slums, tend to let children develop with less than maximum stimulus and greatly affect the cognitive, personality, physical, emotional, social development of coastal children.

Nutritional factors have a big influence on children’s growth and development so they cannot be underestimated. Fulfillment of children’s nutritional needs must also be supported by the active role of parents, an environment that stimulates all aspects of child development, and is also supported by the active role of children.\textsuperscript{14} Environmental factors include aspects of physical needs, aspects of compassion (compassion), and aspects of care (education and relationships). Secondary education with good relationships will support children’s development as well.\textsuperscript{10}

1. Toddler Development Before and After Early Stimulation Giving Interventions: The results of this study indicate that there are differences in the development of toddlers in the provision of early stimulation which is indicated by the increase in development that is in accordance with the age of all toddlers in the intervention group after giving early stimulation.

An increase in development is appropriate for all respondents in the case group after an early stimulation intervention for 15 days continuously every day, this indicates the importance of providing early stimulation, especially in infants to stimulate optimal development. The optimal development of infants will determine the optimal future of children and also better in the future.

Every child needs regular stimulation as early as possible and continuously at every opportunity. Stimulation of child development is carried out by parents, people closest to the child, surrogate mother or child caregiver, other family members and other adults. In this study, of the 15 respondents as controls also found that there were 10 respondents (66.7\%) who did not experience growth despite the increase in age, and still remained in the category of dubious development. Less optimal development that occurs in the control group is caused by suboptimal early stimulation done to the toddler. This finding is in line with the opinion that psycho-social development is greatly influenced by the environment and interactions between children and their parents. Child development will be optimal if social interaction is maximally pursued in accordance with the needs of children at various stages of development.\textsuperscript{15}

Provision of stimulation is more effective when paying attention to children’s needs in accordance with the stages of child development to the fullest. In the early stages of development the child is in the sensory motor stage. Giving visual stimulation to children will increase children’s attention to their environment, children will be happy by laughing and moving their whole body so that it will stimulate all sensory body to develop optimally, both physically, psychologically and socially.\textsuperscript{16,17}

2. Provision of Effective Early Stimulation to Influence Toddler Development in Maritime Communities: The results showed that there were developmental differences between the intervention group and the control group after the intervention was given early stimulation (p <0.05). This shows that the provision of early stimulation is effective to optimize the development of toddlers in the maritime community in Posyandu, Lapulu Village, the working area of Abeli Health Center, Kendari City in 2018.

This is confirmed by research on 30 mothers who have babies aged 0-1 years in the Kemayoran District of Surabaya. The act of maternal stimulation of infant gross motor development in the good category. The better the stimulation action given by the mother, the better will be the effect on the normal and appropriate gross motor development of the baby.\textsuperscript{18}

In this study, it was found that all respondents (100\%) experienced optimal development after routine early stimulation for 15 days with a continuous carried out by mothers of toddlers has a positive effect on improving the development of toddlers. This is evident from the results of the study found that in infants who get early stimulation on a regular basis every day every time the child needs to show optimal improvement in development.

**Conclusion**

Preparation of guidelines for early stimulation
to optimize the development of children under five in the maritime community in Posyandu, Lapulu Village, the working area of Abeli Puskesmas, Kendari City. The compiled guidelines refer to the guidelines for early stimulation in KPSP (Pre Development Skrening Questionnaire) Children at the Basic Service Level (Kemenkes RI, 2014) and adjust to the characteristics of the maritime community with their daily activities as fishermen. There is a difference in the development of toddlers in maritime communities in Lapulu Kelurahan in the area of Abeli Puskesmas in Kendari City in 2018. Provision of early stimulation is effective in optimizing development in toddlers in maritime communities in Posyandu in Lapulu Kelurahan in the Abeli Puskesmas working area in Kendari City in 2018. This is shown after early stimulation all in the intervention group were in the appropriate development, whereas in the control group there were still largely in the doubtful development.

Analysis of Factors Affecting the Workload of Health Workers in the Namrole Public Health Center and Wamsisi Public Health Center in South Buru Regency

Harun Pattah1, Muhammad Alwy Arifin2, Indar2, Darmawansyah2, Anwar Daud3, Aminuddin Syam4, Anwar Mallongi3

1Magister Program Department of Health Administration and Policy, Public Health Hasanuddin University, 2Professor of Department of Health Administration and Policy, Public Health Hasanuddin University, 3Professor of Department of Environmental Health, Public Health Hasanuddin University, 4Senior lecturer of Departemen of Nutrition, Faculty of Public Health, Hasanuddin University

Abstract

The workload on health workers in Public health centers can be seen from aspects such as tasks that are carried out based on their main functions. The purpose of this study was to analyze the factors that influence the workload of health workers in the Namrole Public health center and the Wamsisi Public health center in South Buru Regency. This type of research is a quantitative cross-sectional study design. The population in this study were all health workers with the status of civil servants who worked in the Namrole Public health center as many as 73 officers and Wamsisi Public health center as many as 27 officers. The sampling technique in this study was proportional random sampling to obtain a sample of the Namrole Public health center as many as 58 officers and Wamsisi Public health center as many as 22 officers. The results showed that there was no influence of the level of education on the workload of health workers in the Namrole Public health center and the Wamsisi Public health center in South Buru regency (p = 0.622 > 0.05). Working time significantly affected the workload (p = 0.000 < 0.05) and years of service are protective factors for the workload of employees at the Namrole Public health center and the Wamsisi Public health center in South Buru regency (p = 0.053 > 0.05). To the Regional Government of South Buru Regency to emphasize more regulations related to working hours, especially for employees at public health care centers, so that they are able and comfortable to carry out their duties and functions effectively and efficiently with optimal work time and not excessive.

Keywords: Workload, work time, Wamsisi Public Health Center, Namrole Public Health Center.

Introduction

Workloads on healthcare personnel in public health centres can be seen from aspects such as tasks that are executed based on their main functions. Tasks that carried out include basic tasks, additional tasks/double, the number of patients who should be served, the working capacity in accordance with the education of health workers, the working time used to work on the task in accordance with the working hours of the day, as well as the completeness of facilities that can help the health workforce in solving their work well.1

The Public health Center is a healthcare facility that organizes public health efforts and first-rate individual health efforts, with a greater emphasis on promotive and preventive efforts, to achieve the highest degree of public health in its working area2.

Based on the results of the research Nafizta, showing the calculation and analysis of the workload of...
the nurses using the work sampling method resulted that
the workload on 6 working days of nursing workers in
the public health center Poncol differ. Nursing personnel
workloads are the highest on Mondays and Thursdays
during long working hours, while for short working
hours the highest workload of caregivers is on Saturday.  

Namrole Public Health Center and Wamsisi Public
Health Center are two public health centres located in
the South Buru regency. Namrole Public Health Center
and Wamsisi Public Health Center is a health service
with inpatient unit based on the visit data that is obtained
shows that patients who come to the public health center
are many and tend to increase, since the NHI era, number
of visits in Namrole Public Health Center in 2018 as
many as 13,858 patients and in 2019 as of October
17,157 patients 4 Meanwhile, in the Public health center
of Wamsisi in 2018 as many as 7,556 patients and in the
year 2019 as of October 4,934 patients 5. The aim of the
study was to analyse the factors affecting the workload
of healthcare personnel at the Namrole Public Health
Center and the Public Health center of South Buru
Regency.

Materials and Method

This research uses quantitative research method
of cross sectional study design. The population in this
research is all health officers who are the status of
civil servants who work in the Namrole Public Health
Center, which is 73 officers and the Public health center
of Wamsisi is as many as 27 officers. The sampling
technique in this study is proportional random sampling
so that the information obtained by the Namrole Public
Health Center is as many as 58 officers and the Public
health center of Wamsisi is as many as 22 officers. Data
collection is obtained through a live interview using a
questionnaire.

Results

Based on table 1 shows respondents who are 26–35
years more than 55 people (68.8%), while the respondents
are the least in the age group of 18-25 who are 9 people
(11.2%). According to the gender the number of female
respondents was more than 69 people (86.2%), while
male respondents were only 11 people (13.8%) While
based on the working area of the number of respondents
working in the Namrole Public Health Center as many as
58 people (72.5%), while the respondents who worked
in Wamsisi public health centers as many as 22 people
(27.5%).

Table 2 shows that from 50 respondents that the variable is located from 80 respondents there are 75 people who are highly educated, who are 54 people (72%) Of those who felt a mild workload and 21 people (28%) The rest feels its burden is quite heavy. Meanwhile, out of 5 low-educated respondents were 3 people (60%) That feels it has a lightweight workload and 2 people (40%) have heavy workloads. Statistical test result X² Fisher’s Exact Test obtained the value P = 0.622 or value p > 0.05, thus Ho accepted and Ha rejected. So it can be concluded that there is no meaningful relationship between the level of education and the workload of health workers in the Namrole public Health Center and Wamsisi Public Health center in 2020.

Based on the working period variable table 2 shows that from 80 respondents there were 55 people who had sufficient employment, of which 49 people (89.1%) Of those who felt a mild workload and 6 people (10.9%) The rest feels its burden is quite heavy. As for 25 respondents who have a less working period, there are 8 people (32.0%) That feels it has a lightweight workload and 17 people (68.0%) Others feel that the workload is quite heavy. The test result of the Ikchi-square Statistic is derived from the value p = 0.000 or P value < 0.05, thus Ho rejected and Ha accepted, so that there is a meaningful relationship between the working time with the workload of health care in the Namrole public Health Center and the Wamsisi public health center in 2020.

Discussion

Effect of education on workload: From the analysis results with the X² statistical test Likelihood Ratio obtained the value P = 0.622 (P > 0.05), thus there is no link between the level of education with the workload. It is in accordance with the research of Umamah which proves that there is no link between the level of education and the workload. The research is also in line with the findings of Veny Yuliani (2017) which proves there is no link between the level of education and the workload with the value P = 0.17 > 0.05.

Meanwhile, Maryam (2017) states that performance is heavily influenced by the internal factors of workload
i.e. education level. This is because the higher the mastery of one’s intellectual degree, the more it is open ability to increase the productivity of its work. In addition to the higher level of education of a person, the likelihood of analyzers in addressing problems is also higher.

**Effect of working time on workloads:** Everyone has been stressed and will experience it, but the levels vary and within the same period. Nurazizah states that stress is a thorough response from both physical and mental bodies to any demands or disturbing changes, threatening security and individual self-esteem.

Working in a public health center in every opportunity will meet patients with varying characteristics that impact different conditions and workloads. For that, Nurses should act as all-round personnel, have initiatives, behave creatively and have a broad insight with the motivation of hard work, intelligent, sincere and quality work. The types of patients who are hospitalized or treated in an inpatient room can be viewed as a claim to health care if not managed properly, it will result in stressful work.

The results of this research in line with the research of SrieWulandari, et al. (2017) said that the workload in the Emergency Instaltance space is heavy because it has to do the treatment of patients who come quickly and precisely. According to research Nurazizah is known to occur decrease in overall brain function. With a tool that can display the picture of the brain using advanced technology, it is found that more severe damage occurs in areas responsible for attention, complicated planning, complex mental processes and on the area of decision making.

The excess sleep time also poses a problem, theoretically if the body is too much sleep, then blood circulation becomes slow. The impact will be about the whole body, because metabolism will also slow down. If it happens for a long time then the condition will cause a variety of problems. According to him, shift work affects health in the first 5 (five) years, called the adaptation phase.

**Effect of working period on workload:** Through analysis with the Chi-Square test obtained the value $P = 0.000$ ($P < 0.05$), thus there is a relationship between the working period and the workload. The results of this study are in line with the findings of Zulkifli, DKK (2018) stating that the longer working life is closely related to the experience and understanding of the better job description. This experience and understanding will assist in addressing the problem (stresor) that exist in the prevention of stress due to excessive workload.

Meanwhile, the results of this research are contrary to the research results of VennyYuliandi which says that there is no relationship between the working period and the workload with the value $P = 0.91$ ($p > 0.05$). This is due to the longer the working period, the greater the burden and responsibilities of the employees. The difference in workers whose work period is less than 5 years still needs self-adjusting with the working environment and any work risk that can occur. Because of the negative impact for a company if it gives a mental workload too high or too low for employees, it provides special attention to the right mental workload for its employees. Additionally, respondents who experienced the dominant heavy workload have been working long enough (> 5 years). It can be assumed in addition to the effect of demands on speed of work, thoroughness and prudence there are also other factors that cause heavy workload that is also boredom due to the destruction of the work.

In overcoming the boredom of work because the specialization of work is required the right solution. Changing tasks can increase the stimulation of mental workers or passions, as well as the involvement of their duties, so that it can improve performance within the company. Many companies do a variety of work boredom prevention measures to make workers not feel bored with the activities that must be done daily, by conducting work rotation, involving workers in decision making, conducting the meeting of all employees, giving the opportunity to do leave, and many other things. All these activities aim to prevent or reduce the boredom of work on employees.

**Conclusion**

The research concluded that there was no level of education on the workload of healthcare personnel at the Namrole Public Health Center and the WamsisiPublic Health center of the South Buru regency ($p = 0.622 > 0.05$), the working time significantly affects the workload ($P = 0.000 < 0.05$) and the working period is a protective factor against personnel workloads in the Namrole Public Health Care Center and the wamsisiPublic Health center of the South Buru regency ($p = 0.053 > 0.05$). To the local government of South Buru Regency to be more emphasized regulation related to working hours.
especially for employees at the Public health Care center, so that they can afford and comfortably fulfill their duties and functions effectively and efficiently with optimal uptime and not excessive

Abstract

Smoking has become a serious problem for all nations of the world. The threat of the adverse effects of smoking on the health of pregnant women has shown an adverse effect. Pregnant women affected by tobacco smoking may give birth to low birth weight babies (LBW), preterm birth and stillbirth. The religion of a person can play a role in changing the attitude of a society towards bad actions. The teachings of Islam through verses of the Koran teaches to create environmental conditions that are appropriate for a pregnant woman. Achieve safety in the fabric of human life through prevention of negative behaviors that lead. Realizing a healthy family environment situation. Creating a harmonious family full of happiness and meeting physical and spiritual needs.

Keyword: Tobacco smoke, pregnancy, Qoran, pregnant outcome.

Introduction

Smoking has become a global public health problem. Since the beginning of the 20th century tobacco smoke consumption has increased throughout the world. Around 1.1 billion people aged 15 years and over are smokers. Smoking not only has an effect on active smokers but also has the potential to be a health disorder for those around them exposed to cigarette smoke.¹² According to the World Health Organization (WHO) in the Global Tobacco Epidemic report, smoking is a global health problem that causes death in 5 million people every year.³⁴ The adverse effects of smoking on pregnancy are widely known, the prevalence of smoking in women has decreased in high-income countries in 50 years, but the prevalence has increased in middle and low income countries.⁵⁶

Passive smoking is estimated to cause death in 1.0% of the world’s population, 603,000 deaths in children and adults and the number is increasing every year. Secondary smokers are people who are exposed to cigarette smoke from the environment (environmental tobacco smoke, ETS).⁷ Exposure to secondary tobacco smoke during pregnancy is often associated with various health problems for mothers and the babies. Various studies have shown pregnant women who are exposed to cigarette smoke increase the risk of babies born. Pregnant women exposed to tobacco smoke have the possibility to give birth to low birth weight babies (LBW), give birth pretermly and stillbirth.⁸–¹² Exposure to tobacco smoke during pregnancy also increases the risk of babies born with Respiratory distress syndrome.
Medico-legal Update, October-December 2020, Vol. 20, No. 4

(RDS), being treated in intensive neonatal care and early neonatal complications.\textsuperscript{13}

Religion also pays serious attention to the effects caused by smoking. The religious teachings adopted by a pregnant woman also have a strong influence on her pregnancy. That research shows 47\% rate believes that spiritual is very influential on a pregnant woman’s pregnancy. This indicates that religious teachings are the most important part and basic needs in pregnancy. Islam based on the Qur’an Surah Maryam verse 16 contains instructions to Maryam who will enter the labor process. Mary is a symbol of the role of a woman who is pregnant must do something positive for herself. Self-protection Maryam who is pregnant is part of the teaching of protection against external interference that can endanger her and prepare herself carefully in accepting her responsibilities as a mother.

**Effect of Smoking on Health:** Cigarettes contain a variety of harmful substances including nicotine, cotinin, cadmium carbon dioxide, asbestos, arsenic, benzene and radon gas.\textsuperscript{14,15} Nicotine is a water-soluble bioactive alkaloid with parasympathomimetic effects and addictive substances. Nicotine is obtained from the leaves and stems of the tobacco plant Nicotianatabacum which originates from North and South America. Tobacco was later introduced to Europe for pleasure effects and some medical benefits.\textsuperscript{16}

Exposure to secondhand smoke significantly increases the risk of lung cancer in adult smokers and increases the risk of asthma, lower respiratory tract infections and decreases lung function in children. Smoking increases the risk of apnea during sleep and exacerbation of asthma in the adult population and pregnant women. Active and passive smokers increase the risk of tuberculosis infection.\textsuperscript{17}

**Tobacco Smoke Exposure on Pregnant Women:** Pregnant women who are exposed to cigarette smoke from the environment or passive smokers have the potential to be a health problem in the community, about 22-30\% of non-smokers women are exposed to cigarette smoke from the environment.\textsuperscript{18} Data from other studies show that 37\% of pregnant women are passive smokers.\textsuperscript{19} Nicotine is a major component of smoking, its effects on pregnancy have been found in several studies.\textsuperscript{1}

Nicotine and carbon monoxide can cause various disorders for the fetus, ranging from disorders of the placenta to disorders of the fetal circulation.\textsuperscript{9,14,20,21} Smoking during pregnancy is not only dangerous for the mother but also the fetus in her womb.\textsuperscript{22} Smoking in pregnancy can cause preterm birth, miscarriage, ectopic pregnancy, antepartum bleeding, placenta previa, small babies for gestational age, small baby head circumference, increased risk of low birth weight babies (LBW) and congenital anomalies. The effects of smoking on pregnancy that cause adverse effects on birth are well known, but the effects of pregnant women as passive smokers have not been so widely studied and understood.\textsuperscript{18}

Pregnant women are an active risk group for cigarette smoke both actively and passively. ETS smoke is a complex mixture consisting of most of the smoke emitted from the smoker’s body plus the smoke produced by burning cigarettes and the surrounding air.\textsuperscript{2} Exposure to ETS in pregnant women causes increased levels of CO, nicotine and cotinin in maternal serum or urine, in infants and in amniotic fluid. The influence of ETS on pregnant women can occur from the first semester to the third semester. Pregnant women are usually exposed to ETS in various places with different duration of time. Places that have the potential to become ETS exposure locations include at home, at work and the outside environment.\textsuperscript{10}

The physical environment has an important role in determining the weight of babies born and their health in the future. Research in Jordan shows that ETS exposure in non-smoking pregnant women causes an increased incidence of low birth weight babies (LBW). Increased ETS exposure increases the risk of LBW infants. All ETS exposure in the home, office and outside environment has the potential to reduce the weight of babies born. It was also found that second and third semester exposures were the most vulnerable time of exposure causing LBW. LBW infants tend to be more at risk for neurological problems including cerebral palsy, seizures, severe mental retardation, respiratory diseases and other morbidity.\textsuperscript{10} Research shows that smoking during pregnancy increases the risk of preterm birth by 25\%.\textsuperscript{6}

ETS exposure also specifically has an influence on preterm birth.\textsuperscript{23,24} Smoking is known to cause an increased risk of spontaneous and elective preterm birth, but has a stronger relationship with spontaneous preterm birth. Passive smoking in pregnancy also has a risk of preterm birth both spontaneous and elective.\textsuperscript{20} Elective preterm delivery is likely to be related to cigarette-
related obstetric complications such as placenta previa, placental abruption and impaired fetal growth. Research shows that smoking during pregnancy increases the risk of preterm birth by 25%. ETS exposure also specifically has an influence on preterm birth.

Smoking can also increase the risk of preterm rupture of membranes through several mechanisms, namely: (1) smoking decreases immunity and becomes a predisposing factor for infection, (2) smoking decreases copper levels and ascorbic acid in the blood. The micronutrients can cause a decrease in the elasticity of the membranes and increase the risk of rupture of the membranes. Both of these mechanisms have the potential to cause preterm birth.

The Quran Views Of Smoking: Based on the negative effects of smoking in the order of human life, the Quran forbids all forms of actions that lead to harm and adverse effects of a human action or policy (QS. Al-Baqarah; 2: 195). This proposition becomes the basis for the prohibition of all human attitudes and actions that can threaten his survival. The teachings of the Quran require human life in good condition. Every part of his life must avoid evil and harm and survival threaten. In Surah al-Nahl verse 97 explains that everyone who does a joint activity, then positive things must be a priority in the environment:

Whoever works righteousness, man or woman, and has Faith, verily, to him will We give a new Life, a life that is good and pure and We will bestow on such their reward according to the best of their actions.

The teachings in this verse are aimed at all people without having to distinguish roles in the sex in doing good. The responsibility of doing good is an obligation that must be done for those who believe if they want to perfect their faith. Salih is the opposite of alfasad (bad or error). Positive deeds, salih must be a priority scale for humans. Because salih is a real thing in human life, it should be the spearhead in the order of life.

The Qur’an requires human life in the circumstance of thayyibah. Hayatanthayyibah is a picture of a life that deserves goodness. The state of life that meets the healthy requirements and meets both the material, psychological and spiritual needs so as to create a good and comfortable life without being overwhelmed by anxiety and boredom. Good and comfortable are not based on the availability of material, so the material will not affect/damage the desire for religious obligations.

The Quran And Tobacco Smoke Exposure On Pregnant Mother: The goal as a family is to be achieved is the realization of the sakinah, mawaddahwarahmah as revealed in surah Arrum verse 21: that God has planted the potential in each family to live happily, meet each other’s needs and maintain harmony with one another.

And among His Signs is this, that He created for you mates from among yourselves, that ye may dwell in tranquillity with them, and He has put love and mercy between your (hearts): verily in that are Signs for those who reflect.

Life is full of peace with the pronunciation of Yaskunu in the above verse using the verb expression, giving a signal that the family must keep trying to find and maintain peace in family life so that all the hearts of family members are always calm. The word mawaddah in the context of this verse means love and love for all life activities and gives birth to a sense of comfort. Family members must have a good relationship, a sense of caring gives birth to a safe and loving situation, mercy.

A pregnant woman with the responsibility of maintaining the health of the fetus (hifz al-nasl) it contains is very dependent on a healthy environment. A healthy environment will play an important role in creating a comfortable situation and giving birth to high-quality offspring and a person is not justified in making efforts to eliminate the comfort of others, including in the family. Conversely, in an environment that threatens the lives of women and fetuses due to smoking, which is conceived, stated: “If a man kills a believer intentionally, his recompense is Hell, to abide therein (For ever): And the wrath and the curse of Allah are upon him, and a dreadful penalty is prepared for him.” (Al-Nisa [4]:93), “And those who annoy believing men and women undeservedly, bear (on themselves) a calumny and a glaring sin.” (Al-Ahzab [33]: 58).

Conclusion

Various studies showed that smoking has a negative effect on the mother and the baby. Stillbirth, preterm birth and malnutrition in infants are the effects of tobacco smoke on pregnant women. The adverse effects of smoking can threaten human life, the Quran prohibits all forms of actions that lead to harm and adverse effects of an action or human policy (Surah Al-Baqarah; 2: 195). This proposition becomes the basis for the prohibition of all human attitudes and actions that can threaten his survival. The teachings of the Koran require...
human life in good condition and benefits. Whatever is a part of his life must avoid evil and harm, and threaten human survival. In Surah al-Nahl verse 97 explains that everyone who does joint activities,

The Association between Diabetes Mellitus and Serum Prostate-Specific Antigen Levels

Waleed Nassar Jaffal¹, Mahir Ali Al-Talah², Alaa Al-Deen Al-Dabbagh³, Ehab Jasim Mohammad⁴

¹Ass. Professor, FICMS, College of Medicine, University of Anbar, Anbar, Iraq, ²Ass. Professor, FICMS, Department of medicine, College of Medicine, University of Anbar, Anbar, Iraq, ³Ass. Professor, FICMS, College of Medicine, Mustansiriyah University, Baghdad, Iraq, ⁴Professor, FEBU, FICMS, Head of department of Surgery, College of Medicine, Ibn Sina University of Medical and Pharmaceutical Sciences, Baghdad, Iraq

Abstract

**Background:** Diabetic patients were indicated to have an improved risk for cancers of the liver, pancreas, and colon; nevertheless, recently many studies have suggested that diabetes mellitus (DM) decreased possibility for developing the cancer of prostate in men.

**Objective:** To analyze if the levels of prostate-specific antigen (PSA) in serum of men with type two DM were low in comparison with healthy group, and to investigate the factors that could influence the PSA level in diabetic patients.

**Method:** 120 diabetic men patients were analyzed for PSA levels in the serum compared with equal number age-matched control group. The relationships between the serum PSA levels and body mass index (BMI), age, hypertension, smoking and glycosylated hemoglobin (HbA1c) were considered.

**Results:** Serum PSA levels were statistically significantly (p<0.05) lower in diabetic patients compared to healthy men. The present study demonstrated that age, BMI and high HbA1c showed independent determining factors of the PSA level in men.

**Conclusions:** Our study strongly support that DM has inverse relationship with the levels of PSA marker and more severe cases of diabetes mellitus, older age and high body mass index in diabetic patients are associated with lower levels of the serum PSA. This result confirms that diabetes mellitus is a protective factor for prostate cancer among populations.

**Keywords:** Diabetes mellitus, PSA, prostate cancer.

Introduction

Diabetes mellitus (DM) and various cancers are commonly diagnosed in the same persons(¹), which suggest that the two diseases may have common risk factors and pathogenesis. The possible links include insulin resistance, hyperinsulinemia, hyperglycemia, oxidative stress, and chronic inflammation; which are factors that have potential promoting effect on the progression of cancer in many ways(²,³).

Many studies have stated that patients with diabetes mellitus are at high risk of many types of cancers, including liver and pancreatic cancers, and the two organs have a major role in the pathogenesis of diabetes mellitus(⁴).

Different studies consistently report type two diabetes mellitus is inversely related the cancer of the prostate(⁵,⁶), but not all studies have reached to this conclusion(⁷).

The mechanisms for these paradoxical associations are not clear. Several studies reported that increased duration since diagnosis of type two DM decreases the risk of prostate cancer(⁸) and there is some suggestion that prostate cancer risk is increased in the years immediately after the diagnosis of DM(⁶,⁹).
Measuring the PSA is the most useful available tumor marker for the diagnosis of the cancer of the prostate (10). It is commonly used for screening of the cancer of the prostate cancer (11).

Although there are variable recommendations, the age of 50 years is suggested by several organizations for PSA screening (12).

**Method**

The study was conducted on 120 previously diagnosed type 2 diabetic men with age ranging from 38-70 years old and 120 age matched normal healthy control men. Patients with type 2 DM were selected from the diabetic clinic and outpatient clinics of urology with no urological disease that may affect the PSA level at Al-Ramadi teaching hospital and Al-Yarmook teaching hospital, and the controls were healthy volunteers, between October 2016 and April 2018. Type two DM was diagnosed according to the American Diabetes Association (ADA) criteria for the diagnosis of diabetes mellitus 2010 (13).

The controls should be never diagnosed with type 2 diabetes. A written consent was taken and ethical approval was obtained from Al-Anbar Medical college ethics committee.

The collection of data were based on structured questionnaires.

Men with evident prostatic disease (like prostate cancer, benign prostatic hypertrophy and prostatitis) and men with history of type 1 DM were excluded from this study.

The hemoglobin A1c (HbA1c) was used as a marker of glycemic control. Its level is used as indicator of glycemic control within the past 3 months (14). The HbA1c levels less or equal 6% was considered normal and 6.1% to 7% as high, and we used 6.1% as cutoff value, which was adopted by Bennett et al. (15) to diagnose patients with diabetes mellitus. The height and weight were measured to calculate the patient’s BMI, BMI of < 25 was considered as normal weight, BMI of >25 and <30 as overweight, and BMI of >30 as obese (16). Waist circumference was also measured.

The blood samples were used for the measurement of the PSA and HbA1c . The PSA levels were measured using Minividas Machine using its costume kit. HbA1c analyses were done (NycoCard™ HbA1c). All measurements were done at Al-Ramadi Teaching Hospital Laboratory according to the instructions of the manufacturer.

**Statistical Analysis:** ANOVA test was used to analyze the statistical differences between group means and McNemar’s test for comparison of proportions, also chi square was used for comparing categorical variables. Statistical analysis was performed using the Statistical Package for Social Sciences (SPSS version 24) software.

**Results**

The age of subjects enrolled in this study ranged from 38 to 70 years with mean of 61.59 and 60.20 year in cases and in control group respectively, there was no significant statistical difference between the age, the prevalence of smoking and family history of prostatic cancer among the two groups. Table (1).

Discussion

The cancer of the prostate is the second most frequently diagnosed cancer of men and the sixth most common cause of cancer mortality among men worldwide (17). In most Asian Countries, the incidence of cancer of the prostate has increased during the last two decades (18).

Saad et al. have suggested a mechanism for the occurrence and progression of type two DM consisting of two-parts (19).

Testosterone is varied by the status of DM and its duration and prostate cancer is the only cancer that is believed to be fueled by testosterone.

Another hypothesis adopted recently is related to microvascularization, of the prostate, where the damage to the blood vessels of the prostate, as a part of DM complications, prevents the development of prostate cancer (20).

Shi et al., demonstrated that the blood level of insulin-like growth factor-I was more in patients with prostate cancer than in controls (21).

So, in the early stage of abnormal metabolism of glucose and development of type two DM (the step of insulin resistance), the risk of the cancer of the prostate may be increased due to elevated levels of insulin and this is consistent with many studies that have examined the risk of the cancer of the prostate and duration of diabetes mellitus since the diagnosis (22) which have found an increased risk in the early stage followed by inverse association in the later stage.

Our results are largely consistent with other study (23) that found there was no significant difference by duration of DM.

However, the duration of diabetes mellitus is a parameter which is difficult to be determined because 50% of patients with type two diabetes mellitus may be undiagnosed (24), and the estimated duration of diabetes mellitus may be related to the degree of medical follow up.

It is well known that as increasing ages, the PSA level will naturally increases by about 3.2% per year (25). Richardson and Oesterling suggested age-specific reference ranges for the serum PSA level in men of different races after reviewing multiple studies (25).

In controls, our results shows that the serum PSA level was found to be significantly increased with age and it is consistent with various Asian populations based studies conducted among China, south India, Korea, Singapore, and Japan (26), while in diabetics as the age increased, the mean PSA level was decreased especially among men aged 60 and over, which similar to that reported by Ainahi et al. (27).

Despite of statistically non-significant relationship between BMI and the PSA level seen in a smaller-scale study (28), Our findings in both cases and controls are
consistent with the findings of an inverse association between BMI and the PSA levels, where there is 5% to 21% decrease in the PSA value in men with BMI more than 30 in comparison with men with normal BMI as seen in several large-scale studies(29). The relevant reduction in the PSA level might be attributable to increased volume of the plasma found in the larger men(29) or due to less androgen levels seen in the obese and insulin resistant adult males (30).

Our findings are also consistent with the results of studies that examine the association with glycemic control in patients with T2DM. Müller et al reported that the serum PSA level is 15% and 29% lower in patients with HbA1c of 6.1–6.9% and ≥7% respectively, in comparison with those with normal HbA1c (<6.1%) (31).

Ohwaki et al suggest a positive association between HbA1c and the PSA(5.7% increase in the PSA for each unit HbA1c change), which is in contrast to many studies and our current study (32).

Similar to previous studies that reported the PSA level were significantly lower in smokers in comparison to non-smokers men who are over the age of 55 (33). We found the PSA level was significantly lower as compared with never smokers in the controls. In patients with diabetes mellitus, the PSA levels were mildly lower in smokers in comparison to non-smokers, but it was statistically nonsignificant.

Among the possible explanations for lower PSA levels in patients with type 2 diabetes mellitus is hypertension (34), and this is inconsistent with our results.

Abstract

Background: Osteochondroma represents the most common benign tumor of bones and accounts for about 30-50 % of them. Poor information’s in previous studies act on demonstration of the significance of atypical histological changes as a premalignant precursor in mature osteochondroma regardless of the cap thickness. In this study, the proliferative activity of cartilaginous cap will be studied in skeletally mature patients regardless of the cap thickness to demonstrate the independent significant of histological features in predicting the malignant potential in osteochondroma.

Methodology: Cases of skeletally mature osteochondroma (78 case) were isolated and separated into sessile and pedunculated, then into G1(without suspicious histological features) and G2 (with suspicious features), and stained with Ki- 67. Data were analyzed using SPSS version 21 and p value < 0.05 was considered as significant.

Results: There was significant association between study groups and Ki 67 staining results, majority (75%) of patients with suspicious histopathological features presented with positive results of Ki 67 staining (p value < 0.001). While there was no correlation between shape of lesion and histopathological features (p value 0.662).

Conclusion: A typical histopathological features can be regarded as independent factor with the other clinical data when considering the diagnosis of grade 1 chondrosarcoma.

Keywords: Osteochondroma, proliferative marker, atypical histopathology, lesion shape, Ki 67.

Introduction

Osteochondroma represents the most common benign tumor of the bony skeleton and accounts for about 30-50 % of them(1-2) some researchers regards this tumor as developmental abnormality rather than a true neoplasm. It may result from small fracture in the growth plate in skeletally immature bone and herniated through peristeal bone to form a tumor like lesion.(3-4) Pathologically, osteochondroma (also called exostosis) is composed of cartilaginous cap of hyaline type, covered with fibrous sheath that is continuous with the periosteum and it in turn covering an underlying bone and medullary cavity that is continuous with that of the parent bone.(5-6) This continuity with the underlying bone is important radiological feature in the diagnosis and it is more clear in pedunculated shape lesion than in sessile one. Development of osteochondroma in children whom treated with radiation for Wilm’s tumor due to separation and migration of physeal plate support the suggestion that osteochondroma is a tumor.
like condition\(^7,8,9\), on the other hand, presence of hereditary form of osteochondroma (hereditary multiple osteochondromatosis or called hereditary multiple exostosis HME) support the fact that osteochondroma is a true neoplasm\(^{10,11}\). HME comprise about 15 % of osteochondroma and caused by mutation in EXT1 or EXT2 genes that are located on chromosome 8 and 11 respectively\(^,12\). the most common location for osteochondroma is the metaphysis of long bones especially the lower limbs, flat bones are less commonly affected\(^,13\). this benign tumor usually affect children and adolescent and stop growing after skeletal maturity. Clinically, it may be silent or cause disfigurement, pain due to pressure on a nerve or blood vessel and fracture\(^14\), the serious complication of this neoplasm is malignant transformation, usually in form of secondary peripheral chondrosarcoma. Malignancy can complicate about 25% of HME and only 1-8 % of solitary exostosis\(^{15,16}\). At microscopy, the tumor composed of hyaline cartilage with lobulation, the chondrocytes are bland looking, evenly spaced and show ordered maturation in columns. The cartilage merges with the underlying bone that project from the bone of origin and continuous with it. Atypical histological features such as mild increased cellularity, occasional binucleation, more than one cell in the lacuna, and foci of necrosis are considered to be reactive changes in the growing cartilaginous cap and should not be overdiagnosed when the cap thickness is within usual\(^3-17\). the allowed cap thickness is up to 3 cm in children with immature skeleton and only few millimeters in skeletally mature adult\(^3-18\). Also new increased growth of exostosis in adult should raise the suspicion of malignant transformation into peripheral chondrosarcoma since osteochondroma is unusual to enlarge after maturity\(^,19\). Another features that should brought the attention is the proximal location of tumor such as around the pelvis or shoulder, grossly irregular surface, cystic changes and soft tissue invasion.

Chondrosarcoma arising in osteochondroma is usually of low grade as the trabecular bone permeation is usually absent, in addition, the cytological features may be bland with the exception of loss of columnar arrangement of the chondrocytes. This laid a hard work on the pathologist and necessitate clinico-radiological-pathological correlation for such a diagnosis\(^,19\). Eefting et al suggested a statistically significant pathological criteria that could distinguished low grade (G 1) chondrosarcoma from proximally located benign cartilaginous tumors\(^,20\). Such a histological features included increased cellularity, nuclear pleomorphism, mitosis, entrapment, mucoid changes and loss of normal cellular arrangement. These features are added to the clinical data including age of patient above 40 years, proximal location and radiological data. Few studies work on demonstration of proliferative activity of osteochondroma cartilage in children comparing with proliferative activity in premature growth plate and in adult using immunohistochemistry with Ki 67 antibodies\(^{21}\). Ki 67 is a nuclear non histone protein that is expressed in all phases of cell cycle with exception of G0\(^,22\). most articles focused on cartilage cap thickness as the main indicator of malignant transformation. However no enough previous studies act on demonstration of the significance of atypical histological changes as a premalignant precursor in mature osteochondroma regardless of the cap thickness. In this study, the proliferative activity of cartilaginous cap of osteochondroma will be studied in skeletally mature patients regardless of the cap thickness in order to demonstrate the independent significant of atypical histological features in predicting the malignant potential in osteochondroma. Also there will be a focus on the relationship between unusual histological features in osteochondroma (increased cellularity, occasional binucleation and mild pleomorphism) with shape of the lesion (sessile or pedunculated).

**Methodology**

Part of cases for study are collected from Al Hilla Teaching Hospital and Al-Hayat hospital retrospectively from the last 4 years (2015-2018). Cases with insufficient clinic-radiological data are ignored. The other part is selected prospectively from the work of orthopedic author (use of suitable longitudinal incision to expose the tumor, careful dissection with radical excision of osteochondroma from its base with the mother bone with its basal cortex to avoid recurrence). Exclusion criteria: osteochondroma from skeletally immature cases were excluded.

**Inclusion Criteria:** All skeletally mature osteochondroma regardless of cartilage cap thickness were included.

**Ethical Issues:** No patients identity or identifying photos are included in the study, so the permission of the institute, where the data are collected (including radiological and clinical information, as well as histological slides and paraffin blocks), is taken. The
The total number of collected cases was 130. Orthopedic author reviewed the radiological picture for each case and separate them into skeletally immature cases (excluded from the study) and skeletally mature cases (included), so the final number of cases was 78 case. Also the included cases were divided into sessile shape lesions and pedunculated shape lesions. All study’s cases were reviewed by two pathologists blindly from each other and without any clinical information. Cases are separated into group 1 (conventional osteochondroma with no atypical histological features) and group 2 (osteochondroma with atypical histology).

Atypical histology defined by presence of increased cellularity, binucleated chondrocytes, occasional more than one cell in the lacuna, and mild pleomorphism with absence of other features that raise the suspicion of chondrosarcoma such as irregular arrangement of chondrocytes (not in ordered columns), mitosis, marked pleomorphism, necrosis, permeation and marked myxoid changes and separation of cells into specific lobules by fibrous bands.

Cases of both groups are then stained immunohistochemically with MIB1 antibody (mouse monoclonal antibody, Dako 1:50). Three μm sections are cut, deparaffinized, rehydrated and stained with standard procedure. Heat induced antigen retrieval is used for all sections. Nuclear staining of Ki 67 was scored using the average method by manual counting of Ki67 positive cells in three representative sections for each case and calculating the average percentage of positive cells by two pathologists.

**Figure (1):** A An intra-operative picture of osteochondroma in 20 years old male show pedunculated shape tumor. B X-ray of 32 years old patient show osteochondroma in skeletally mature skeleton at lower femur and complicated by basal fracture. (our cases).

**Data Analysis:** Statistical analysis was carried out using SPSS version 21. Categorical variables were presented as frequencies and percentages. Pearson’s chi square ($X^2$) was used to find the association between categorical variables. A $p$-value of $\leq 0.05$ was considered as significant.

**Results**

**The Distribution of Patients According to Study Groups:** Figure (2) shows distribution of patients according to study groups including (group 1 osteochondroma without suspicious histo-pathological features and Group 2 osteochondroma with suspicious histo-pathological features). Majority (64.1%) of patients presented with osteochondroma without suspicious histo-pathological features.
The distribution of study groups according to Ki 67 staining results: Figure (3) shows distribution of study groups according to Ki 67 staining results including (Positive and negative). Majority (75%) of patients with osteochondroma with suspicious histopathological features had positive Ki 67 staining.

Figure (4): A osteochondroma in 25 years male with conventional histological features (group 1) show negative Ki 67 staining. B osteochondroma in 32 years old male with increased cellularity and occasional binucleation (group 2), show positive Ki 67 staining.
The Distribution of Study Groups According to Shape of Lesion: Figure (5) shows distribution of study groups according to shape of lesion including (pedunculated and sessile). More than a half of patients with osteochondroma in two groups had pedunculated shape of the lesion.

![Distribution of patients according to shape of lesion](image)

**Figure 5: Distribution of patients according to shape of lesion**

The association between study groups and study variables: Table (1) shows the association between study groups including (group 1 osteochondroma without suspicious histopathological features and Group 2 osteochondroma with suspicious histopathological features), and study variables including (Ki 67 staining results and shape of the lesion). There was significant association between study groups and Ki 67 staining results, majority (75%) of patients with suspicious histopathological features presented with positive results of Ki 67 staining (p value < 0.001), while there was no correlation between shape of lesion and histopathological features (p value 0.662).

*P value ≤ 0.05 was significant. (group 1 osteochondroma without suspicious histopathological features, Group 2 osteochondroma with suspicious histopathological features).

**Discussion**

In a large studies reported by Mayo Clinic, it had been found that (81%) of secondary chondrosarcoma arose at site of previous osteochondroma\(^{(23)}\). It has been estimated that 2/3 of these cases derived from sporadic osteochondroma. Although osteochondroma is rarely (1-2%) transformed into chondrosarcoma, its recognition is of high importance because most of these
tumors are low grade and treated by adequate excision without need for chemotherapy or radiotherapy.\textsuperscript{(24)} Huch et al performed a study on a group of solitary osteochondroma and other group of patients with multiple osteochondroma, comparing the immunohistochemical expression of Ki-67 in both groups as a marker of nuclear proliferative activity. They found that the proliferative activity in osteochondroma from patients younger than 14 years of age is similar to that in postnatal growth plate, while in individuals older than 14 years there was no significant detectable proliferative activity\textsuperscript{(21)}. So, in the current study the only skeletally mature cases are included to avoid such overlap in the results of immunohistochemical staining with Ki-67. In a study of de Andera et al, only cellular pleomorphism and mitotic activity show significant difference between osteochondroma and low grade chondrosarcoma on one hand and high grade chondrosarcoma on the other hand. While other cellular features as binucleation, necrosis, and irregular calcification was found in 72% of osteochondroma.

K.Huch et al supported the concept of increased suspicion for malignant transformation in osteochondroma of adult when Ki 67 positivity is detected.\textsuperscript{(21)}

The shape of osteochondroma (pedunculated versus sessile) was not studied previously regarding their relation to the microscopical features that raise the suspicion about malignancy (increased cellularity, frequent binucleation, nodularity and necrosis). We found that no relation between the shape of the lesion and such a histological features. However the shape of the lesion may affect the accuracy of radiological diagnosis of osteochondroma (more difficult in sessile tumors) as mentioned previously by Mark D. Murphey.\textsuperscript{(2)}

**Conclusion**

Histopathological features, when atypical, can be regarded as independent alarming factor for malignant transformation (the same as cartilage cap thickness and may precede it). There is no relation between shape of osteochondroma and risk of atypical histological features, proliferation, and hence risk of malignancy.

Effect of Tamoxifen Drug on Testes of Albino Male Rats

Amal K. Abbas¹, Aqeel H. Qasim²

¹Assistant Professor, University of Baghdad, College of Science, Biology Dept., Iraq,
²Assistant Lecturer, Ministry of Education, General Directorate of Dhi Qar Education, Al-Rifai Dept., Iraq

Abstract

This study was conducted to evaluate the negative effects of Tamoxifen (TAM) on Testis tissues and spermatogenesis. Use for this purpose forty male of mature albino rats were divided into 4 equal groups, 3 groups were administrated different doses (30, 40, 50) mg/kg b.w of TAM for 10 weeks as well as control group administrated with physiological solution (normal saline 0.9%). Histopathological examination of testes tissues in TAM groups showed histological changes that increased with the increased dose compared to control group include degeneration change were appeared as atrophy, deformity and destruction of the seminiferous tubules, congestion of blood vessels in the interstitial tissue and many seminiferous tubules. Also the results showed a significant different in the numbers of spermatogonia, primary spermatocytes and spermatiods. As noted in the results, the higher the dose, the lower the sperm production, and consequently the tissue injury increases.

Keywords: Tamoxifen, Testis, Seminiferous tubules; physiological solution; blood vessels.

Introduction

Tamoxifen is a drug used to prevent breast cancer in women and to treat breast cancer¹,². Studies are under way to use it to treat other types of cancer. It has been used in the treatment of McCune-Albert syndrome. Tamoxifen is usually taken by mouth for five years to treat breast cancer³,⁴.

Tamoxifen is used in many medical fields, the most important of which is under study, this research aim to treat male and female infertility. Females with ovarian disorders after achieving success in treating breast cancer and gynecomastia in men⁵,⁶. TAM has been used in the treatment of infertile men with idiopathic infertility, oligospermia, and nonobstructive⁷.

The testis manufactures estradiol, via enzyme aromatase. Estradiol receptors (ER), alpha (α) and beta (β) in various testicular cells that plays important roles in male reproduction such as differentiation of germ and somatic cells, spermiogenesis, spermiation, maturation, transport and motility of spermatozoa, secretory activity of efferent ductulus, scrotal testicular descent and long-term fertility. Estrogen receptors in the Leydig and Sertoli cells presumably play an important role in the paracrine regulation of spermatogenesis. The hypothalamus, pituitary, epididymis and the and Sertoli cell, Leydig cells are important components of the male reproductive system⁸,⁹.

Estrogen receptors (ER) are existent in the testis, efferent ductules and epididymis, yet, ERα is plentiful in the efferent ductule epithelium, its primary function is the regulated expression of proteins involved in fluid reabsorption¹⁰.

Tamoxifen has serious side effects, being a chronic treatment and a selective receptor for estrogen receptors) Selective estrogen receptor modulators), It is from the group of Triphenethylene¹¹. It has been proven in several experiments that tamoxifen works on estrogen receptors in the testes, accessory glands, and hypothalamic-pituitary axis after administration in adult male rats¹².

e-mail: amalk.abbas50@yahoo.com
Tamoxifen induced a decrease in testosterone hormone, ruptured the testicular seminiferous epithelium, and induced the formation of multinucleated cells in the testis\(^{13}\).

Estrogen concentrations within the testicle and semen can reach high levels due to tamoxifen, estrogen synthesis in the male reproductive in Sertoli cells but then only in Leydig cells\(^{14}\).

The aim of the study was to identify the histological damage that occurred in the testes of rats that dosed tamoxifen in different doses and to know the amount and size of histological damage, especially in the spermatic tubules and sperm cells.

**Materials and Method**

**Experimental Animal:** The experimental animals used in this study were male albino rats weighing (200 – 250 g). The animals were purchased from Pharmaceutical control of the Ministry of Health in Baghdad. Animals were given food and water *ad libitum*. Rats were maintained in a friendly environment with a 12 h/12 h light-dark cycle at room temperature (25 °C\(^{15}\)).

**Experimental Design:** A total 40 of male rats were divided at random into 4 groups of 10 animals each group and treated as following:

- **Group I (control):** Animals were administrated orally with normal saline (0.9 %) 4 times/week for 10 weeks.
- **Group II (treated):** Animals were administrated orally with TAM (30mg/kg) 4 times/week for 10 weeks.
- **Group III (treated):** Animals were administrated orally with TAM (40mg/kg) 4 times/week for 10 weeks.
- **Group IV (treated):** Animals were administrated orally with TAM (50mg/kg) 4 times/week for 10 weeks.

After anesthetizing the animal, rats were dissected, testes were excised, washed with normal saline 0.9 % (NaCl), placed in fixative solution (neutral buffered 10% formalin) for histological examination. The preparation of histological sections was performed on standard method of\(^{16}\). At last the sections were examined by light microscope under magnification power (40x,20x). Photographs were taken.

**Statistical Analysis:** Results were expressed as Mean ± standard Error of the Means (SE). The Statistical analysis system applied using one-way (ANOVA) analysis variance to verify the Least significant differences (LSD) design. All figures were drawn using the Statistical package for prism 8.1.2 (version 8.1.2, Graphpad, San Diego, CA, USA) software. The probability (p) value of less than or equal to 0.05 has been considered to be of Statistical significance.

**Results**

**Histopathological Examination:** The histopathological examination showed several changes in the testis of treated animals compared with control group (Fig.1). These changes include congestion of blood vessels in the interstitial tissue (Fig. 2).

The degenerative changes in seminiferous tubules were appeared as atrophy and deformity of seminiferous tubules with large spaces between them. Some degenerated tubules showing the capsule were empty consist of basement membrane with no germinal layers and disappearance of spermatogonia, spermatocytes, spermatids and Sertoli cells (Figure 3).

While the testis tissue in the third group (50 mg) showed more severe lesions form previous groups which include severe edema in the interstitial tissue with complete losses of spermatogenesis with vacuolation of epithelial. in addition, the seminiferous tubules appear with irregular basement membrane with absence of spermatids (Figure 4).

**Figure (1): Cross section in the testis of control animal shows normal architecture of the spermatocytes (H & E 20 X).**
Figure (2) : Microscopic section in the testis of animals treated with TAM (30 mg/kg b.w.) shows congested of Blood vessels with edema in the interstitial tissue. (H & E 20 X).

Figure (3): Histopathological section in the animal treated with TAM (40mg/kg b. w.) shows congestion of blood vessels, while many seminiferous tubules under the capsule were empty consist of basement membrane with no germinal layers (H & E 40X).

Figure (4): Histopathological section in the group (50 mg/kg b. w.) showed seminiferous tubules appears with irregular basement membrane with absence of spermatids (H & E 10X).

The count of spermatogenic cells: The count of spermatogenic cells showed significant different number of spermatogonia, primary spermatocyte, spermatids and Sertoli cells in the three groups of experiment as compared with control group (fig. 5).
Discussion

In view of the results of the current study there is a significant decrease in the number of Sertoli cells, primary spermatocytes cells and spermatogonia when treated with TAM and elevation increased as the dose multiplied increased by the level of (30, 40, 50)mg/kg compared to the control group and this is consistent with what the researchers said\(^{16, 17, 18}\).

Tamoxifen increases LH and FSH in the case of a lack of testosterone in the body responsible for sperm synthesis. LH stimulates Sertoli cells in the testicle to produce testosterone. A drug works to improve the epididymis work on the maturity of sperm and does not affect its synthesis because it has no effect inside the testicle and also works to inhibit the Pituitary gland - Adrenal gland axis (HPA axis) and thus increase each of LH, FSH to produce testosterone. But if the dose amount as in this study gradually increased to reach the highest concentration, it leads to a decrease in the production of LH due to estrogen receptors in the testicle especially Leydig cell, which reduces spermatocytes count, and thus fertility decreases down to the condition of sterility, as well as the influence of Sertoli cells (Fig. 5)\(^{19, 20, 21}\).

Estrogen synthesis in the male in Leydig cells of the adult in Sertoli cells during tests. There is a consistent presence of aromatase in Leydig cells show activity in Sertoli cells of the adult testis. Aromatase activity is a marker for Sertoli, Tamoxifen has an aromatase inhibitor effect that prevents the conversion of androgens into estrogen, which is important for the maturity and shape of sperm\(^{22}\).
The testis produces estradiol, via enzyme aromatase, and can acts locally through selectively expressed estradiol receptors (ER, (α) and (β)) in various testicular cells. It plays several important roles in male reproduction, such as differentiation of germ and somatic cells, spermiogenesis, spermatiation, maturation, transport and motility of spermatozoa, secretory activity of efferent tubules, scrotal testicular descent and long-term fertility(8,23).

The microscopic examination of histological sections of the Testes treated with TAM showed clear tissue changes can be achieved with congested Blood vessels, edema in the interstitial tissue also atrophy and deformity of seminiferous tubules with large spaces between them with incomplete spermatogenesis and vacuolation of epithelial layer as well many seminiferous tubules under the capsule were empty consist of basement membrane with no germinal layers, complete losses of spermatogenesis with vacuolation of epithelial layer in addition the seminiferous tubules appears with irregular basement membrane with absence of spermatids, destruction of the seminiferous tubules and this is consistent with previously reported results(8,22,23).

It did not match the research, which says not to change the shape and size (18).

Testes injury because of oxidative stress, through conversion to electrophiles, nucleophiles and redox-active reactants, has a direct toxic effect and causes cellular dysfunction. Oxidative stress is considered as the important factor in the development of a variety of human complications that result from over production of ROS and impairment in the biological defense system. ROS interact with the renal mitochondrial membranes producing large amounts of oxygen radicals that cause deterioration of the testis’s architecture. Oxidative stress leads to the formation of vasoactive mediators as in the bloody congestion of the testicle tissue. This further leads to the morphologic al changes(24,25).

The decreased estrogenic effect due to tamoxifen may be directly responsible for decreased testicular expression of aromatase, which in turn may be responsible for the decreased synthesis of estradiol in the testis. Estrogen acts as a regulator of the proliferation/apoptosis balance, especially in germ cells, Moreover, the decrease of testosterone secretion in tamoxifen-treated rats could worsen the effects of decreasing estrogen synthesis. Testosterone regulates some genes supporting the complex development of germ cells(26,27,28).

**Conclusion**

The results of the present study revealed that the administration of TAM with increasing doses of 20mg for a long period of time and without regularity leads to weak sperm and a few in it number and cause infertility in addition to large and evident tissue changes in the composition of the testicle and its cells.

1 Post Graduate in Department of Chemistry, College of Science for Women, University of Baghdad, Baghdad-Iraq, 2Professor, FRCP London, Consultant Transplant Nephrologist in Baghdad College of Medicine, University of Baghdad, Baghdad, Iraq, 3Assistant Professor in Department of Chemistry, College of Science for Women, University of Baghdad, Baghdad-Iraq, 4Specialist in Diagnostic Laboratory, Baghdad-Iraq

Abstract

Background: The chronic autoimmune inflammatory, systemic lupus erythematosus (SLE), is a disease that may be caused by autoantibody production, complement activation, and immune complex deposition. Several organs can be affected by this disease; lupus nephritis which considers the most complication that may be occurred. The aim of our study is to establish if that serum sVCAM-1 and IL-18 can be applied as biomarker for diagnosis of LN and CKD in patients with SLE.

Method: One hundred twenty patients from both sexes were enrolled in this study. The subjects have been divided into three groups, group one and group two represent the patient groups that include, (40) patients SLE with LN (8 male-32 female) with age range (19-44) years for the group one, (40) patients SLE without LN with age range (16-45), for the group two. The third group includes (40) healthy subjects with age range (19-62) years, which represent the control group. VCAM-1 and IL-18, were estimated by ELISA method.

Results: The results referred to present high level of VCAM-1 and IL-18 in patients group that represent a complication case of SLE in comparison with patients group without complication “without LN”. At the same time, the results showed significance increasing of VCAM-1 and IL-18 in both patients groups rather than control group. Also, this study revealed a significant correlation (p<0.01) between VCAM-1 and IL-18, but no correlation with other relevant factors.

Conclusion: The results revealed the elevation of both sVCAM-1 and IL-18 levels in patients with SLE. Furthermore, this study indicates the association between the mentioned biochemical factors and suggests being as a useful indicators for LN in patients with SLE.

Keywords: SLE, VCAM-1, IL-18, LN; Iraqi Patients.

Introduction

Complications of SLE include a wide range of disorders for numerous organs. Lupus nephritis considers the main disease that may be occurred as a result of action SLE(1). Chronic inflammation were investigated in many cases in previous our studies(2,3). The facilities of cell adhesion molecules (CAM) include adherence of leukocyte and control their movement into inflame tissues(4).

Leukocyte circulation and lymphoid cells can be adjusted and allowed to adhesion on specific tissues or inflammation sites by vascular cell adhesion molecule-1 (VCAM-1). There are three types of adhesion molecules that include: integrins selectins(5) and immunoglobulin

The supergene family (IGSF). The molecule-1 (ICAM-1) and the molecule-1 (VCAM-1) of vascular cell adhesion belong to the supergene family of immunoglobulins (IGSF), they are response for many cytokines such as IL-1 and TNF. Soluble forms of these molecules are discarding from endothelial cell surfaces and are easily measurable in serum\(^6\). At the same time, these soluble forms represent the most abundant of the circulating adhesion molecules at maximum dissimilarity levels with numerous inflammatory disorders. The highest level of these soluble adhesion molecules is found in patients with SLE and rheumatoid arthritis in comparison with healthy subjects \(^7\). On another hand, levels of sVCAM-1 have been found to associate with the activity of inflammation disease as in SLE rather than other soluble adhesion molecules. Several studies were proposed that urinary sVCAM-1 useful as a good marker for inflammatory diseases\(^8\).

Dendritic cells and macrophages consider the main source to produce IL-1α, IL-B and IL-18, which belong to Interleukin-1 family cytokines. Furthermore, IL-18 involved in pathogenesis of inflammatory disease, thus, it becomes of importance in association with a wide range of inflammatory diseases especially SLE.\(^9\) Previous studies referred to that, the exogenous IL-18 mice administration increased the incidence of sickness and nephritis, while IL-18 decreased improved survival and proteinure in the mice rather than in the healthy community. Moreover, few studies were revealed that IL-18 level increase in patients with SLE. Furthermore, the association between severity disease and IL-18 was confirmed\(^10\).

**Subjects and Method**

One hundred and twenty patients from both genders who attended Baghdad Teaching Hospital/Medical City Iraq from December 2018 to May 2019 were involved in this study. The subjects have been grouped into three categories: forty SLE patients with LN (8 male-32 female) with age range (19-44) years, forty SLE patients without LN, age range (16-45) and forty healthy subjects with age range (19-62) years.

Patients with SLE (without renal involvement) were clinically diagnosed with examination markers (Antinuclear Antibody ANA. Anti-double-stranded DNA [dsDNA], C3, C4 were done by immunological method), SLE with LN (biopsy approved) patients. Using (5ml) disposable syringe between (8.30-12) AM, five ml of venous blood was taken from subjects. Four ml from the sample was transferred to the sterile plain tube enable to clotted and then centrifuged for 15 min at 3000 rpm.

Serum was dispensed in several aliquots and frozen at -20°C immediately before analyzed the immunological and biochemical markers (Urea, total protein, Creatinine, C3, C4, Anit ds DNA, ANA and h-CRP by enzymatic and immunoturbidity method). The remaining blood samples (1ml) were transferred to EDTA tubes for hematological analysis (ESR). SVCAM-1 and IL-18 analyzed in the kit use enzyme-linked immune sorbent assay (ELISA) based on biotin double antibody sandwich technology.

**Statistical Analysis:** The system-SAS (2012) software for statistical analysis was used to detect the effect of differentiating factors on the study parameters. The least significant difference – the LSD test (Analysis of Variation-ANOVA) was used to make a significant comparison between the means. To significantly compare the percentage (0.05 and 0.01 probability), the chi-square test was used. Estimation of the coefficient of correlation between variables of difference in this study.\(^11\)

**Results**

Table 1 shows mean ± SD values for age, BMI, duration of SLE, urea, creatinine, total protein, Albumin C3, C4, ANA, Anti ds DNA, ESR and h-CRP. The results showed significant differences of age for the studied groups (p>0.01), while a significant increase in the body mass index (BMI), blood urea (BU), creatinine (Cr), ANA, Anti-ds DNA, ESR and h-CRP in groups of patients (SLE with LN, SLE without LN) were observed in comparison with control. In contrast, there was a significant decrease in total protein, Albumin C3, C4 in patient groups compared to healthy subjects.

![Image of ROC curve for IL18](image)

**Figure (2): The Roc curve for IL18**

Area under the ROC curve (AUC) for the analysis includes IL18 is (0.904). The best cut-off point derived from the ROC curve shows a sensitivity of (82.5%) and specificity of (95.0%) is ≤ 1.943(ng/ml). A test value below 1.943(ng/ml) is referring to the abnormal case (disease case) and the value above 1.943(ng/ml) is representing the healthy case. As shown in figure (2), a high significance difference is (P<0.0001).
sVCAM test is considered a good marker to diagnose SLE because the area under the ROC curve (AUC) for the analysis is 0.754. The best cut-off point derived from the ROC curve shows a sensitivity of 66.2% and specificity of 77.5% is ≤ 2.232 (ng/ml). A test value below 2.232 (ng/ml) is referring to the abnormal case (disease case) and the value above 2.232 (ng/ml) is representing the healthy case. As shown in figure (3), a high significance difference is (P<0.0001).

Figure (3): The ROC curve for sVCAM

Discussion

VCAM is associated with inflammatory cell sequestration through interactions with leucocyte integrated integrin. Soluble VCAM-1 levels are raised in several autoimmune diseases, including rheumatoid arthritis and SLE (12).

Earlier studies showed the serum concentration Svcam-1 control the development of SLE disease (13). Conforming to these previous studies, it was found that absolute SVCAM-1 levels were less useful than other traditional markers such as ds DNA anti body titers C3 and C4 levels as a diagnostic tool for the identification of SLE patients due to the inherent variation of sVCAM-1 levels between individuals (14).

In past years, it was reported that sVCAM-1 level may be associated with endothelial activation. In general sVCAM and sICAM serum concentration in coronary artery disease and endothelial dysfunction-related disease are only modestly evaluated. This complies with evidence that sICAM-1 levels are nearer to systematic endothelial dysfunction than sVCAM-1 levels. sVCAM-1 level is related with those observed in patients with necrotic shock (15).

Patients with elevated SLE disease activity are among the most significant. Our observation that sVCAM-1 level are much stronger than sICAM-1, sP-selectin, sE-selectin, shows variances in the level sVCAM-1 reflect other physiological roles than endothelial activation. Furthermore, Vcam-1 has a major role at several essential steps of lymphocyte production due to its pervasive expression in minor lymphoid tissues (16).

VCAM-1 is largely expressed in bone marrow stream cells and is required for both early pre-pro B-cell production and long-lived bone marrow plasma cell retention. B-cell maturation in the mouse is caused by conditional of VCAM-1, which lead to increased circulating immature B-cell, suggesting that VCAM-1 is an important factor for homing mature B bone marrow cells (17).

It is not clear if sVCAM-1 is eliminated in the course of any the cell interactions between lymphocytes.
and DC or other stromal cells that have VCAM-1. The super family IL-1 is made up of 11 members; some are known to be pro-inflammatory, including IL-1α, IL-1β and IL-18, the most studied IL-1 superfamily members in autoimmune disease, all of whom have been involved in SLE pathogenesis.\(^{18}\)

In this research, we demonstrated that serum IL18 levels are considerably higher in patients with SLE. These results confirm previous studies that there are significantly higher IL18 levels in SLE patients than healthy control\(^{19}\).

The association of IL18 with an overall active disease (ODA) is reported in previous studies, like kidney disease and organ damage, related to other variables and also in patients with biopsy-proven LN. The association of IL-18 with active renal disease was confirmed. Similarly, in LN patients, an earlier study has shown elevated serum IL-18 levels.\(^{20}\) In other studies in both glomeruli and LN cases, it was found an increase in IL-18. IL-18 has also been proposed as a suitable marker for long term outcomes in pediatric LN. Kidney dysfunction is a significant indicaor of SLE harm development; previous results in smaller study documenting revealed the elevated IL-18 level in patients with organ damage.\(^{21}\)

Abstract

Objective: Nausea and vomiting (NVP) are among the most common symptoms during pregnancy. NVP causes emotional and psychological distress and can have a profound impact on a woman’s quality of life (QoL).

Material and Method: Vitamin D3 and Vitamin B6, Se and electrolytes (Mg⁺², K⁺) levels were determined in first and second trimesters in 120 women suffering from nausea and vomiting of pregnancy, 30 pregnant women free of symptoms, age identical between the ages of (17-45) years.

Results: Vitamin D3, Vitamin B6, K⁺, Se and Mg⁺² in the blood showed a significant decrease in all patients as compared to control group (P ≤ 0.05).

Conclusion: In patients with NVP and NP we find a significant reduction in level of Vit.D3, and decrease in level of serum Vit. B6, K⁺, Se and Mg⁺². In first trimester found a decrease in levels of Vit.D3, Vit.B6 and K⁺ more from second trimester, while in first trimester found an increase in levels Se, Mg⁺² more from second trimester.

Keywords: Pregnancy, Nausea and vomiting (NVP), First and Second trimesters, Vitamin D3, Vitamin B6, Selenium, Potassium, Magnesium.
been proposed as a cause for NVP too\(^9\). Vitamin B6 supplementation may be important for achieving adequate intake during pregnancy\(^{10}\). Selenium plays an important role in the maintenance of human health\(^{11}\). It is a vital intracellular antioxidant that prevents oxidative cellular damage\(^{12}\). The demand for selenium during pregnancy is increased to support optimal fetal growth, resulting in decreased maternal blood and tissue concentrations of selenium\(^{13}\). Electrolytes are present in the human body, and the balance of the electrolytes in bodies is essential for the normal function of the cells and organs\(^{14}\). Magnesium (Mg\(^{2+}\)) is the fourth most abundant cation in the body and the second most abundant intracellular ion\(^{15}\). Pregnancy represents a physiological situation with increased magnesium requirement\(^{16}\). An adequate magnesium intake also seems to be important for further healthy development in pregnancy\(^{17}\). Potassium (K\(^+\)) is a very important mineral to the human body for Building proteins, Break down and use carbohydrates, Building muscle, maintain normal body growth, control the electrical activity of the heart and control the acid-base balance\(^{15}\).

**Material and Method**

This study conducted at the Bent Al-Huda hospital in Thi-Qar Governorate/Iraq, biochemistry laboratory, the hormones and immunology laboratory, the specialized clinics. It included (150) subjects, the control group consisting of (30) women Symptom -free (SF) and patients (120) . About (5mL) of blood samples of NVP patients and controls. Analyzed Vitamin D3, Vitamin B6, electrolet and Se. Vitamin D3 in serum was analyzed by ELISA instrument, kits supplied by Calbiotech, USA . Serum vitamin B6 was analyzed by (ELISA) instrument, kits supplied by Elabscience, USA . Serum Mg\(^{2+}\) and K\(^+\) was analyzed by enzymatic colorimetric method by UV/VIS spectrophotometer, kits supplied by (S.A.E), Egypt. Concentrations of selenium element in serum samples were measured by flame atomic absorption device, at the college of sciences/university of Thi-Qar. **Excluded cases**: non-pregnant women, smokers, pregnant women with diabetes, preeclampsia, heart disease, patients with chronic diseases. **Statistical Analysis**: All statistical analysis was performed using SPSS, Windows version 24.0 software and Microsoft Excel 2010. the results were expressed as mean ± standard deviations (mean ± SD),and Least Significant Difference (LSD). One way analysis of variance (ANOVA) was used to compare parameters in different studied groups. P-values (P ≤ 0.05) were considered statistically significant.

**Results**

In this study, we identified the effect of NVP and NV on pregnancy womans in first and second trimesters in Vitamins (D3 and B6), Electrolytes (Mg\(^{2+}\) and K\(^+\)) and trace elements (Se). The levels of biochemical markers in pregnancy (Vit.D3,Vit B6,Se, Mg\(^{2+}\),K\(^+\)) showed a significant decrease in NVP and NP patients compared to the control group. We also identified the effect of pregnancy period (first trimester) (1st),(second trimester) (2nd) on those parameters biochemical, and the results indicate a significant decrease in the concentration of vitamin D3 (Vit.D3) in (1st) compared to (2nd) compared to the control groups .As shown a significant decrease in the concentration of (Vit.B6 and K\(^+\)) in (1st) compared to (2nd). The results showed a significant increase in the levels of (Se and Mg\(^{2+}\)) in (1st) compared to (2nd). We also identified the correlation between (V.D3) and with those parameters biochemical and the results showed positive correlation.

Discussion

Our study is the first to include a clinical study of vitamins and elements and their effect and classification of nausea and vomiting during pregnancy during the first and second trimesters of pregnant women with NP and NVP and asymptomatic pregnant women. Morning sickness is a frequent symptom in pregnancy, the pregnant woman has nausea or vomiting at various levels due to gestational hormone increase (HCG), leading to dehydration, weight loss, malnutrition, and micro-nutrient deficiency as well. Vitamin D is a well-known immunomodulatory and anti-inflammatory agent in the body(18). Pregnant women with morning sickness had a double increase in vitamin D deficiency risk versus pregnant women without morning sickness at P<0.05(19). Table (1), show a significant decrease in the concentration of serum Vit.D3 in all patient with NVP, NP in comparison with control groups. There was no significant difference in the prevalence of 25(OH) D deficiency(25(OH)D,50nmol/l)among pregnant women in the three different trimesters(20) nutrients from vitamins and supplements in addition to foods, however, revealed that the intake of many micronutrients increased substantially from the 1st to 2nd trimester(21). Vitamin D deficiency is a widespread global problem, which even can observe in the countries which get enough sunlight(22). Table (1), show a significant decrease in the concentration of serum Se in all patient with NVP, NP in comparison with control groups. In a previous study, the antioxidant activity was significantly lower in Women with NVP compared to healthy pregnant women. Some theories may explain the decreased levels of antioxidants in NVP in the study. The decreased dietary intake of most nutrients rich in antioxidants is observed in women with NVP(26). Selenium is believed to be one of the most important antioxidant nutrients in the human body, and selenoproteins have a protective effect against oxidative stress and inflammation(27). Various studies have demonstrated that during pregnancy, the whole blood and plasma selenium concentrations, and the activity of glutathione peroxidase in red cells and plasma decline in a linear fashion from the first trimester to parturition(28). The demand for selenium during pregnancy is increased to support optimal fetal growth, resulting in decreased maternal blood and tissue concentrations of selenium(13). Table (2), show a significant decrease in the concentration of serum Mg⁺² in all patient with NVP, NP in comparison with control groups. In a previous study serum Mg⁺² concentration during pregnancy was significantly lowered to a value
considered to be deficiency starting appears at the first trimester and continues to decline during the rest of pregnancy have a significant negative correlation with pregnancy duration\(^{(29)}\). The reduction of serum Mg\(^{2+}\) level during pregnancy is mainly attributed to fetal growth demand or because of nutritional status during pregnancy. Many explanations behind this reduction, it is most likely due to the fetus and placenta absorb huge amounts of nutrients particularly magnesium from the mother\(^{(30)}\). Early signs of deficiency can include loss of appetite, nausea, vomiting, fatigue, and weakness\(^{(31)}\).

Table (2), show a significant decrease in the concentration of serum K\(^+\) in all patient with NVP, NP in comparison with control groups. The concentration of (K\(^+\)) in the serum is a balance among intake, excretion, and distribution between the extra-and intracellular spaces\(^{(32)}\). A patient with Hyperemesis gravidarum (HG) frequently vomits gastric juice and, thus, the loss of hydrogen ions, sodium, chloride, and water in gastric contents leads to chloride-sensitive metabolic alkalosis, dehydration, and extracellular fluid (ECF) volume reduction\(^{(33)}\) causing elevated activity of the renin-angiotensin-aldosterone system (RAAS)\(^{(33)}\). This activated RAAS, in turn, increases the urinary excretion of potassium, compounding the hypokalaemia\(^{(34)}\).

**Conclusion**

Vitamin D is has a key role in the etiopathogenesis of nausea and vomiting pregnancy because vitamin D deficiency might lead to problems in immune regulation.

Study the Sensitivity and Specificity of Urinary Arginase in Bladder Cancer Patients in Babylon Governorate

Frhan H. Kalaf¹, Mufeed J. Ewadh², Mohammad R.J. Abood²

¹Lecturer, College of Medicine, University of Babylon, Iraq,
²Prof., College of Medicine, University of Babylon, Iraq

Abstract

Background: Urinary Arginase is an enzyme found in the urine that can be measured by ELISA. The sensitivity and specificity of this test can also be checked.

Aim: The present study aims to determine Arginase in urine in the bladder cancer patient’s the type of this study is case- controls study.

Method: The study was conducted during the period from August 2019 until February 2020. There are two groups, the first containing forty-five patients and the second forty-five control.

Results: The level of arginase in the urine of CA Bladder patients was evaluated in the two groups, the first group, G1 newly diagnosis (94.6±17.2), and second group G2 treatment and follow-up (.91.2±13.6),compared with normal patients control group (77.9±12.9).In this study, urinary arginase was significantly higher in both groups of Bladder cancer patients G1 and G2 compared to normal control group of patients (CG) P value < 0.001. In G1 (new diagnosis) urinary arginase was negligible in contrast with G2 (Treatment and follow up) P-value > 0.05. Throughout this analysis, the amount of urinary arginase increases with an increase in the cancer stage, thereby increasing cell degradation and releasing more protein molecules in the urine, such as arginase.

In Conclusion: This enzyme may serve as a useful biological urinary marker in bladder cancer while also being an indication of the progression of bladder cancer. the sensitivity of this test (92.59) and the Specificity (51.52)The sensitivity and specificity of this test should be improved in order to be used in the follow-up of patients with bladder cancer.

Keywords: Urinary Arginase, Bladder cancer, Specificity, Sensitivity.

Introduction

Bladder Cancer is the fourth most common cancer in males and the eighth in females and is the most common neoplasm of the urinary system[1]. Bladder cancer is a well-known condition that affects men more than women[2]. The definition of urothelial carcinoma is the invasion of the basement membrane or lamina propria or deeper by neoplastic cells of urothelial origin It includes one of many types of malignant growth of the urinary bladder and It characterized by abnormal cells multiply without control in the bladder[3]. Cigarette smoking is the most well-established risk factor for Bladder cancer[4]. Bladder cancer (BC) is ones of the most common cancer worldwide. It is classified in muscle invasive (MIBC) and muscle non-invasive (NMIBC) BC[5]. NMIBCs frequently recur and progress to MIBCs with a reduced survival rate and frequent distant metastasis [6]. BC detection require unpleasant and expensive cystoscopy
and biopsy, which are often accompanied by several adverse effects. Thus, there is an urgent need to develop novel diagnostic method for initial detection and surveillance in both MIBCs and NMIBCs[7]. Multiple urine-based tests approved by FDA for BC detection and surveillance are commercially available. However, at present, sensitivity, specificity and diagnostic accuracy of these urine-based assays are still suboptimal and, in the attempt to improve them, novel molecular markers as well as multiple-assays must to be translated in clinic [8].

Arginase is a ubiquitous enzyme. It is present in yeasts, bacteria, plants, Invertebrates, and Vertebrates. It acts on the final step that leads to the production of urea (urea cycle)[9]. Arginine hydrolysis to form Ornithine and urea by the action of Arginase. Ornithine will convert to proline by ornithine aminotransferase (OAT) and polyamines by the ornithine decarboxylase (ODC) pathway [10]. Arginase is a manganese metalloenzyme that hydrolyses L-arginine to urea and L-ornithine. Arginase exists in two distinct isoforms, arginase I and II, that share 60% sequence homology[11]. Although both isoforms are found throughout the body, arginase I is a cytosolic enzyme mainly localized in the liver[12]. Hepatic arginase I contributes most of the body’s total arginase activity and has a pivotal role in eliminating nitrogen formed during amino acid and nucleotide metabolism via the urea cycle [13]. More recently, arginase I expression has been demonstrated in extra-hepatic tissues including endothelial cells and vascular smooth muscle cells[14]. Arginase II is a mitochondrial enzyme with a wide distribution and is expressed in the kidney, prostate, gastrointestinal tract, and the vasculature. The role of arginase II is not completely understood, but the enzyme is assumed to be involved in the regulation of L-arginine homeostasis and production of L-ornithine for polyamine and proline synthesis for cell proliferation and development[15]. Both isoforms are expressed in the vasculature, but it appears as if the expression is both vessel and species dependent[16]. Increased arginase activity in mammals has been associated with cardiovascular and nervous system dysfunction and disease[17]. Arginase can be expressed in many various types of cells and can be stimulated by a vast variety of agents and conditions, depending on tissue and species[18].

Materials and Method

The type of this study is case- controls study, which is done in the laboratory of Biochemistry Department, College of Medicine, University of Babylon. The study was conducted during the period from August 2019 until February 2020. The entire samples collected from patients attending Al-Hila Teaching Hospital, Urology Department at Margean Hospital Department of Oncology. The patient’s group who subjected to this study were 45 patients divided into two groups depend on pathological staging: Group One (G1). Patients with this group newly diagnosis of CA bladder. This group including 19 patients in the range of age 35-76 years it is have 14 males (mean ± standard deviation 59.7 ± 10.7 years) and 5 females (mean ± standard deviation 61.0 ± 14.4 years). Group Tow (G2) This group include patients with treatment of CA bladder and Follow up after treatments. This group including 26 patients in the range of age 52-86 years it is have 20 males (mean ± standard deviation 65.4 ± 7.7 years) and 6 females (mean ± standard deviation 65.4 ± 12.1 years). Anther grouped this includes forty- five apparently healthy subjects with an age range 31-67 years there are 11 females and 34 males. None of these subjects had a history of abnormal liver function, blood dyscrasias, hematuria and with any Lwoer part of urinary infection. Ten to twenty milliliters of urine were collected from patients and healthy persons to the urine cup and then collected in the plane tube were centrifuged at 4000xg for approximately 15 minutes. The supernatant was divided in two parts of 1.ml and transferred to the Eppendrof tube and stocked at -20 C until time of use. This Arginase enzyme-linked immunosorbent assay applies a technique called a quantitative sandwich immunoassay. The microtiter plate provided in this kit has been pre-coated with monoclonal antibody specific for Arg. Standards or samples are then added to the microtiter plate wells and Arg if present, will bind to the antibody precoated wells. In order to quantitatively determine the amount of Arg present in the sample, a standardized preparation of horseradish peroxidase (HRP)-conjugated polyclonal antibody, specific for Arg are added to each well to sandwich the Arg immobilized on the plate. The microtiter plate undergoes incubation, and then the wells are thoroughly washed to remove all unbound components. Next, A and B substrate solution is added to each well. The enzyme (HRP) and substrate are allowed to react over a short incubation period. Only those wells that contain Arg and enzyme-conjugated antibody will exhibit a change in color. The enzyme-substrate reaction is terminated by the addition of a sulphuric acid solution and the color change is measured spectrophotometrically at a wavelength of 450 nm[19].
Results and Discussion

The mean ±SD age of Bladder cancer patients were (60.6±10 years). age distributions of CA Bladder patients were as follow:

According to this figure, the age distributions of CA Bladder patients in this study show a peak level in the age of 55-64 years and the least between 35-44 years age groups. The mean age of Bladder cancer in this study was 62 years, and it is near the mean age reported in a previous study done in Iraq which is 60 years [20-24].

The number of male’s patients in this study was 34 in the ages ranging between 35-80 with mean ± SD (59.7±10.7) while the female’s number was 11 in the ages ranging between 48-84 with mean ± SD (63.1±10.0). The ratio of males to females in CA Bladder patients in this study represented to 4:1 proportion. The demographic distribution of male and female in this study, the male’s patients have the greatest ratio than females, these ratios agrees with other studies done in Iraq which concluded to a similar ratio between male and female with CA bladder in his study. According to the history of Bladder cancer patients participated in this study all 30 male patient and 5 female patients was a heavy smoker for a long time. In the present study, the level of arginase in the urine of CA Bladder patients was evaluated in the two groups, the first group, G1 newly diagnosis
(94.6±17.2), and second group G2 treatment and follow-up (.91.2±13.6), compared with normal patients control group (77.9±12.9). In this study, urinary arginase was significantly higher in both groups of Bladder cancer patients G1 and G2 compared to normal control group of patients (CG) P value < 0.001. In G1 (New Diagnosis) urinary arginase was negligible in contrast with G2 (Treatment and follow up) P-value > 0.05.

Throughout this analysis, the amount of urinary arginase increases with an increase in the cancer stage, thereby increasing cell degradation and releasing more protein molecules in the urine, such as arginase. Hence, this enzyme may serve as a useful biological urinary marker in bladder cancer while also being an indication of the progression of bladder cancer. These findings of the previous research support report have showed that the amount of arginase in the different types of cancer increases as the tumor stage increases.

Figure(2): Arg in CA bladder and control groups

To extract sensitivity and specificity, Medcalc was used. Medcalc is a simple statistical program with full capabilities, as it contains all the functions and statistical tests, in addition to the lightness of the program and simple graphical interfaces from us, and also features great graphics[27]. This program was used to obtain the sensitivity and Specificity of Urinary Arginase that is managed through test schedules the results are as follows:

Conclusions

CA bladder patients in Babylon province have high urinary arginase level comparing to normal subjects. Urinary arginase can be used as CA bladder protocol during the course of follow up for CA bladder patient and may help to minimize the need for an invasive procedure or radiation imaging. Therefore, please work on improving the sensitivity and specificity to test for Urinary Arginase so that it can be used as a protocol in the follow-up of bladder cancer patients.

Aspects of Fatal Burn Injury Cases Admitted to Al–Sadiq Teaching Hospital, Babylon Province/Iraq During 2020

Elaf Mohammed Obaid\(^1\), Hasan Alwan Baiee\(^2\), Issam Salim Ismail\(^3\)

\(^1\)High Diploma Student/Family Medicine-Medical College-University of Babylon/Iraq, \(^2\)Prof. University of Babylon-Hammurabi, College of Medicine/Iraq, \(^3\)Specialist/Dr. Wasit Health Directorate/Iraq

Abstract

**Background:** Burns death both intentional and non-intentional considered among the most disastrous outcome of burn injuries.

**Objectives:** To measure the case fatality rate in hospitalized burn patients and to investigate in-hospital mortality among burn injury cases who were admitted to Al–Sadiq Teaching Hospitalburn center from the first of January to the end of June, 2020.

**Methodology:** This is an observational descriptive case series study conducted on all cases who died from burn injury among patients who were admitted to the biggest teaching hospital in Babylon Province – Iraq. Data were collected from patients themselves or their companions and from patients’ hospital records, using a pretested questionnaire designed for collection the requested information.

**Results:** The mean age ± SD (Standard Deviation) of burn death victims were 24.5±17.66 years. Young age group (15-24 years) represents the highest proportion (50%). Male to female ratio was 1:2.25. The case fatality rate was 26.6%(32/120). The majority of cases were from rural areas, 67% of suicidal burn deaths had more than 50% of burnt total body surface area. Intentional burn deaths victims had significantly severe burns (third degree burn and high-burnt surface area) as compared to accidental burn deaths. There was a statistically significant difference as regards the mode of burns between the intentional and accidental burn deaths, all intentional deaths were burnt with flame.

**Conclusions:** The case fatality rate of burn injuries was high, females outnumbered males, and suicidal burn deaths were significantly associated with severe burn as compared to the accidental ones.

**Keywords:** Intentional burn injury deaths, accidental burn deaths, Babylon, Iraq.

Introduction

According to World health Organization, fire burns were responsible for more than 300,000 deaths annually\(^(1)\). Burns still represent one of the leading cause of death in developing countries\(^(2)\).

Recently, developed countries have made good progress in lowering burn-related mortality including Self Inflicted Burn (SIB) by raising awareness, prevention, improving secondary and tertiary health care and support programs for SIB cases\(^(3)\) but SIB is still a priority public health problem in developing countries, including Iraq\(^(4)\).

Self-burn is high in Asian countries and the lowest in the United States\(^(5,6)\). This may be associated with the instability of the region, due to insecurity and the continuous arm conflicts. The rates of SIB associated burn deaths were very high 85% in Pakistan\(^(7)\), 79.6% in Iran\(^(8)\), and high 60% in Nepal\(^(9)\) while the rates of

---

Hasan Alwan Baiee  
Prof. University of Babylon-Hammurabi, College of Medicine/Iraq  
e-mail: hassanbaey@yahoo.com
deaths are low in Brazil 40%\(^{(10)}\) and Sri Lanka 27%\(^{(11)}\). SIB is generally more common among females than among males\(^{(12)}\).

The majority of burn death cases were accidental, while suicidal manner was mainly observed in females\(^{(13-21)}\).

The burden of burn in Baghdad is quite high\(^{(22)}\). The objectives of this study are to measure the case fatality rate in hospitalized burn patients and to investigate in-hospital mortality among burn injury cases.

**Methodology**

This is an observational descriptive case series study conducted on all cases who died from burn injury among patients who were admitted to Al Sadiq Teaching Hospital–Babylon Province–Iraq, this hospital is biggest general teaching hospital in Babylon province, the burn unit includes two wards for males and females. This hospital serves the population of Babylon province, which located in the south central region of Iraq and populated about two million inhabitants. The period of study started from the first of January 2020 to the end of June 2020. Data were collected from patients themselves or their companions and from patients’ hospital records, using a pretested questionnaire designed for data collection. Acceptance from the University of Babylon Ethical Committee, College of Medicine and the director of Babylon Health Directorate were taken. Informed verbal consents were obtained from the patients’ companions or their families, the confidentiality was ensured by keeping all records anonymous. Data include socio-demographic data (age, gender, level of education) types of burn and etiology of burn.

Burns can be; partial thickness burns (second degree) extend through the epidermis and into the dermis or full-thickness burns (third degree) extend through the subcutaneous fat or deeper\(^{(23,24)}\). When estimating the degree of burn in this study, only partial thickness and full thickness burns are considered, and superficial burns are excluded. The extent of burn injury determined by the total body surface area (TBSA) in which estimated according to the rule of nine \(^{(25)}\).

**Results**

A (32) dead cases included in this study out of 120 burn injured patients. The case fatality rate was (26.6%). Burn mortality higher in females than in males, OR with 95% CI (2.78; 1.16-6.72) \(P 0.019\). Death doubled in those aged >18 years old than in children aged ≤ 18 years, OR with 95% CI (3.03; 1.30-7.06) \(P 0.009\). Half of patients with 3rd degree burn injuries and mixed burn were dead, while 97% of those with 2nd. degree were cured, OR with 95% CI (30.5 6.81-136.6) \(P 0.0001\), table [1].

* Chi-Square Test

The mean age ± SD (standard deviation) of burn death victims are 24.5±17.66 years, ranged (1.5 – 83 years). Young age group (15-24 years) represents 50% of burning deaths, as shown in figure [1]. Male to female ratio 1:2.25 (P 0.013), figure [2].
Concerning the marital status, 59% of them and 15.6% are single. The majority (87%) of victims have intermediate school achievement or less, and 62% of them have not enough monthly income. Only three (9%) of victims present with past medical history, and one case (3%) present with history of mental illness. Five cases (16%) reported tobacco smoking, table [2].

The mean duration of admission to hospital was four days±2.79 SD. Findings indicated that 25%, 44% and 31% of victims hospitalized for 1 day, 2-5 days and >5 days respectively.

One-half of deaths occurred intentionally by suicide. Suicidal burn deaths patients have severe burns (3rd. and mixed degree of burn i.e. third and second degree) while most of accidental burn deaths have less severe (mixed degree patients), two of them occurred in patients with 2nd degree (P 0.051), figure [3].

Findings indicated that 63% of patients were uninvestigated for microbial infections, Pseudomonas detected in 16% of patients, negative microorganisms detected in 9% of the sample and Staphylococcus aurous detected in 6% of them.

### Discussion

The current study is undertaken to describe the characteristics of hospitalized burn deaths. The case fatality rate in this study is relatively high as compared to the results reported by other national studies conducted in Diqar, Basrah, Musol, Baghdad and Babylon governorates. The fatality rate in this study is higher than rate reported by Kandeel FS and El Mehrat et al in Menoufia University Hospital, Egypt and that reported in Jordan. But it was very much higher than that reported by Krishnan et al. from the United Kingdom who noted mortality rate 1.9%. These differences may be due to the nature of these societies as they have better health care services with higher level of public awareness, this comparison should bring the attention of health care planner in Babylon governorate to develop much better health care facilities.

Females are outnumbered among self-inflict burn victims in this study at their young age, this finding goes in line with the findings of other studies. In a qualitative study carried out by Gatea et al in Baghdad on thirty SIB women in their reproductive age they found that females who committed suicide using burn specially fire have four problems leading to this burn deaths these included; personal, social, economic and family situation of the victims. Among these, the main identified factors, family pressure, unstable families, and poor mental health. Females at home may find a fire as weapon to end their lives by burn instead of suffering in male dominated poor societies. In our study most of the victims had low level of education while Gupta et al. showed that the majority of victims had primary school level.

Most of the victims belong to low socioeconomic class this finding consistent with the finding of Vaghela et al. who reported that most of cases were in low socio economic status. The majority of victims in this study had more than 50% burnt total body surface area. The risk of death usually increased burnt surface areas as this indicates the incompatibility with life.

Suicidal burn deaths patients have severe burns (3rd, and mixed degree of burns) while most of accidental burn deaths have less severe degree of burns and the majority of cases were mainly from rural areas. These findings are consistent with the finding of other studies.

Suicidal manner was observed in half of the victims this percentage is much higher than that reported by similar study conducted in Egypt which revealed that the majority of cases were accidental burn deaths but, our finding agrees with the finding of Nath et al. in India, which revealed that the majority of deaths were suicidal in nature followed by homicidal and the least were accidental. These differences may be due to different religions, believes and cultures. The Islamic law considers suicide to be a crime act onto the self. Thus, the number of SIB may be not reported for fear of legal responsibility and social and religion rejections of this act.

This high rate of suicidal deaths mainly among women may show the tip of iceberg (underestimated) due to the above mentioned reasons and the social stigma, this denotes a real presence of high priority health and social problem of suicidal burn deaths.

### Conclusions

The case fatality rate of burn injuries was high, females outnumbered males, and suicidal burn deaths were significantly associated with high severity as compared to the accidental.

The Effect of Sports Forums within Population Centers on Physical Abilities and Results of School Table Tennis for Students

Maytham Hadi Mahdi

Assist. Lect., Ministry of Education/General Directorate of Holy Karbala Education/Iraq

Abstract

The study aimed to prepare a questionnaire for a survey of forum goers and table tennis practitioners and to identify the differences between them in terms of their physical abilities, skill performance, and results of table tennis, and the researcher used the descriptive approach in a comparative study of the reasons and the method of pre and post measurement for two groups equal to its suitability with the nature of this study, and chose a sample (415) students from the community of middle school in the holy Karbala, who are enrolled in the first semester of the academic year (2018-2019) and in an intentional way I choose (33) students from table tennis players participating in the school championship organized by the sports and scouting activity in the governorate.

They were divided into two groups, the first group included (16) students from the regions inhabited by youth forums, and the second group included (17) students from the residents of the areas where these forums did not exist, and the researcher conducted special physical tests within the main experiment of the research, then the two groups left a period (8) Weeks later, the researcher conducted the post-test and the results showed the effectiveness of the presence of forums in the housing areas and their effect on improving elements Special fitness for volleyball, as well as the training contribution in the forums showed the improvement of the skill performance of the first group by winning the school championship. It improves their physical fitness.

Keywords: Sports forums, population and physical abilities.

Introduction

Fitness is one of the most important objectives of education sports and basic components of the health of the individual to relate positively to many life areas such as growth, health, physical, mental, psychological, social, educational attainment, and other words of life that makes a person active in his community. Its importance not to the general public but also contribute effectively to the appropriate setting to perform the duties required of the individual, and because physical exercises are subject to educational and scientific foundations, they have become an area of concern for teachers and trainers at the same time, and physical fitness is divided according to its purpose into public and private physical fitness.

The physical fitness elements of the table tennis game are among the elements that must be available in the successful table football player who possesses a physical structure characterized by the speed, agility, and the superior strength of the distinctive strength, the superior strength. The kinematic dynamics of the game of ball game depends largely on the development of the elements of speed and power in addition to determining the amount of friction required between the ball and the racket that

Assist. Lect., Ministry of Education/General Directorate of Holy Karbala Education/Iraq
e-mail: aaameathm75@gmail.com
has become necessary to reach the results.\textsuperscript{1} Fast action for a short period of time that the player uses either for the purpose of quickly ending the point, or to deal with his control of the game and the style of opponent play, and so the table tennis player needs a special physical abilities that do not depend on the abilities of the support that does not support Sports belonging to the Ministry of Youth have a role in enhancing physical abilities as a result of continuous play in them and the presence of these forums near student housing, which enhances the physical abilities of the players of table tennis, so this came The study is to show the effect of playing in nearby forums on developing physical capabilities and athletic achievement if these young people have the opportunity to represent their schools in these school competitions.\textsuperscript{2}

Important and fundamental factors in the process of learning the different sports skills, are daily her constant practice, the more you practice daily workouts is getting a sense of movement or skill and can be performed better, which leads to increase performance significantly as well as upgarding the physical abilities required for the performance, and to repeat the exercise A great role in the learning of motor skills the more the student possesses a high degree of physical capabilities and technical performance, the faster the ability to learn, and the applied concept of kinetic capabilities is related to the process of receiving and coordinating.\textsuperscript{3}

Through the researcher’s work in teaching in schools and universities, he noticed the weak skill level of table football players, and after reviewing many studies in the field of table football, he found that the reason for the decline in players is the weakness of physical fitness, which in turn leads to a low level of skill, and this leads to a low level of skill, which leads to a low level the researcher pushed for this study with the aim of identifying the level of physical abilities of the Ping-Pong players and the impact of sports forums’ proximity to their schools in influencing that development that helps to stabilize the level of motor and skill performance in this game.

Research Objectives:
1. Preparing a survey questionnaire for forum goers and table tennis practitioners.
2. Identify the differences between students who attend the forums, whether or not in terms of physical abilities, skill performance, and results of table tennis.

Research Hypotheses:
- There are statistically significant differences between the results of the peripheral schools in the forums or not in the physical capabilities and the results of the matches.

Research Fields:
- The human field for middle school students
- Time range: (10/12/2018) until (1/2/2019).
- Spatial field Sports forums in the center of Karbala Governorate.

Research methodology and procedures

Research Method: The researcher used the descriptive research method in the comparative study method using the pre- and post-measurement method of two groups, which are equivalent to the suitability of the nature of this study.

Research community and sample: The research community is composed of (415) prep school students in the holy Karbala students who are enrolled in the first semester of the academic year (2018/2019) in the holy city of Karbala. The research sample was chosen intentionally, and it reached (33) students who were chosen from the research community represented by table tennis players participating in the General Directorate for Karbala Holy Education for Table Tennis, and they were divided into two groups according to the presence of their areas of residence near the group The first (16) students are residents of the areas where youth forums exist, and the second group (17) students are residents of areas where youth forums do not exist. From table (1) it is clear that there are no statistically significant differences between age, height and weight for the research community, which indicates their homogeneity, while table (2) shows the parity between the two groups, as it becomes clear from the table that there are no statistically significant differences between the two groups on the two groups. Represented by (compatibility, accuracy, flexibility, agility, reaction speed, transitional velocity, the distinctive velocity of the arms of the arms, the force distinguished by the speed of the legs) and this is evidence of the parity of the members of the two groups in the field of study in the structure level of the course.
It is evident from Table (1) that there are no statistically significant differences between age, height and weight, as the value of all torsion is between ± 3. It is clear from the table (2) no differences are statistically significant between the two groups in each of the elements of physical fitness actress (b compatibility, accuracy, flexibility, agility, speed of reaction, the transition speed, distinctive power speed of arms, distinctive force as quickly as the legs), which is evidence that the two groups have equal levels of physical fitness before starting research.

The following devices and tools:

- Dynamometers (to measure the grip force kg), Rest meter for measuring length (cm), distance measuring tape (meters), Swedish seat, adhesive characters, tennis balls, cabins, cabins, cabins Table tennis, table tennis, special table tennis balls.

Special physical tests:
- Test the numbered circuits - to measure compatibility.
- Hand aiming at overlapping rectangles - to measure accuracy.
- Bend the torso forward to stand - to measure flexibility.
- Backlash running - to measure agility.
- Ruler Nelson - to measure the reaction speed.
- Counting a meter (30 m) from a moving start - to measure the transition speed.
- Throw the medical ball (kg 3), - to measure the strength of the arms.
- Wide leap of stability - to measure the capacity of the legs.

*Significance in front of the level ≤ 0.05.
Skill performance tests:
• After reviewing the scientific references specialized in the tests in the field of table football, the following tests were chosen after they were presented to the experts:
  • Jane-die and Wayne tested to measure table tennis skill.
  • Test the transmission skill for the front strike.

Pilot study: The researcher conducted the survey study on a sample of students that reached (10) students from outside the study sample and from the study community, the researcher applied to them the tests of physical fitness elements to ensure the scientific validity of the tests, and the validity of the used tools used on the used materials.

Scientific Transactions Tests:

Validate the tests: To ensure the validity of the study tests, the researcher used the validity of the content, as he selected it after reviewing many theoretical studies and reliable sources that indicated that these tests are characterized by a high level of honesty and reliability factors. The tests selected were a group of experts on table football who agreed to achieve these tests for the desired objectives of the study.

Tests are consistent: To confirm the consistency of the tests, a sample was conducted on (10) students from the study community. The researcher used the test-retest method, and the validity was verified by extracting a correlation coefficient (correlation of 1), correlation (1 correlation), (1 correlation correlation) 0.83) Accuracy (0.79) Flexibility, (0.86) Agility, Reaction speed, (0.89), (0.85) Transition speed, Distinguished strength with speed (0.90), Rapid power for legs (0.86).

Pretests and training practice in the forums: The members of the first group practiced exercises in the forums near their areas of residence during the summer vacation and the beginning of the school year, and the second group was not able to practice these exercises because of the absence of these forums. These tests were applied to both groups, then the groups were left within a period of (8) weeks, after which the post-tests were performed.

Statistical processing: The researcher used the SPSS software for data analysis, where the mean is calculated. Standard deviation. Difference test t-test.

Results and Discussions
There were statistically significant differences at (0.05) in the physical fitness level of table tennis game among members of the first group who play the game in forums between the pre and remote measurements from the second group that did not play the game in the forums (and for the benefit of dimensional measurements 3 and the results of the group 3).

</table>

The data in Table 3 indicates the existence of statistically significant differences at the level of significance (α≤0.05). This indicates an improvement in the level of physical fitness elements of the experimental group members between the pre and post measurements, and in favor of the measurement. The data in Table (4) show the difference in significance at the level (0.05) for the physical fitness elements of the table tennis game in the ranks of the second group in the elasticity, the force distinguished by the speed of the arms, while the rest of the results showed the presence of statistically significant differences between the statistics, the measurement between the statistics Transition velocity, force distinguished by the velocity of the legs of the second group. The improvement in the level of the elements of special physical fitness among the first group members indicates the high level of the efficiency of the body systems to meet the physical burdens, which indicates the improvement of the physical characteristics of the racquet games in general and the table tennis in particular; and this is what is shown in this system. With many studies that confirmed that its training program has a positive and active role in improving the elements of physical fitness, all of which confirmed that the training program is training in training. Physical and skill for sporting activities and here the researcher would like to point out that youth forums play the role of regular training programs in promoting and raising the degree of physical fitness, whereas the second group that did not have the opportunity to practice training in forums for the lack of these forums in their areas of residence as it did not show improvement in all of the elements of fitness the physical nature of the game of backgammon, especially the one that greatly affects the performance of the game’s skills (accuracy, compatibility, speed of reaction, the characteristic strength of speed for the legs, agility) As it improves, it has elements (the speed-specific strength of the flexible arms) that may have evolved.
Performing table tennis skills during working hours or opportunities. In order to determine the preference in the results for both groups, the researcher conducted a test (t) between the dimensional measurements of both groups as shown in Table (5).

From Table (5), there are statistically significant differences at the significance level ($\alpha \leq 0.05$) in the fitness level for the game of table tennis between the two dimensional tests for the first and second groups, and for the benefit of the first group.

The researcher attributes these results to the effectiveness of youth forums in enhancing physical abilities, in which the members of this group practiced different and qualitative training for agility, speed, compatibility and accuracy, which contributed to improving the levels of these elements among the members of this group, and the compatibility of this group with indicated that the development of some special physical characteristics has a positive effect on the physical and skills level improvement. They had this opportunity, which helped them to develop each element of physical fitness for the game of table tennis, which had a great role in differentiating the first from the second, which applied general exercises and taught training skills only. pointed out that “physical preparation is considered one of the most important components of success in the performance of movement activities, which aims to develop the individual’s athletic potential and improves the level of his physical, psychological, functional and mobility abilities to meet the requirements of the aspirations and the requirements of movement.13 The development in the physical level of the members of the first group who had the opportunity of training and continuous practical practice by virtue of the presence of forums in their residential areas was also reflected in their achievement and victory in the school championship much better than the second group that did not receive training in these forums.14

**Conclusions**

1. The results showed the effectiveness of the presence of forums in residential areas and their impact on improving the fitness elements of table tennis among members of the first group close to these forums.
2. Training in these forums contributed to the improvement of the skill performance of the first group by winning the school championship.

Evaluation the Level of Hepcidin and Iron Homeostasis in Sera of Pregnant Women with Anemia in Samarra City

Hanan Nayef Mohammed¹, Rafah Razooq Hameed Al-Samarrai²

¹Post Graduate, ²Prof., Department of Chemistry, College of Education, University of Samarra, Salah al-Din/Iraq

Abstract

Cross sectional study was carried out to evaluate the level of hepcidin in sera of pregnant women with anemia. The study include 86 sample from women with reproductive age(18-35)year. Forty six sample collected from pregnant women with anemia and forty sample from healthy pregnant women as control group in 2nd and 3rd trimester, all samples were collected from Healthy center and Specialized Clinics in Samarra for the period from 14 December 2018 to 22 January 2019.

The study include the determination of Packed cell volume (P.C.V) ratiohemoglobin-Hb conc., Total Iron, total iron binding capacity-TIBC conc., Transferrin conc., Hepcidin conc., Total protein –TP conc., Albumin conc, Globulin conc., The activity of liver enzymes (Alanine aminotransferase-ALT, aspartate aminotransferase–AST and Alkaline phosphatase-ALP), the results showed that the levels of PCV ratio, Hb, total iron and hepciden significant decreased p≤0.05 in pregnant women with anemia as compared with control group, with significant p≤0.05 increase in level of TIBC, Transferrin, and the activity of AST and ALP in pregnant women with anemia as compared with control group, with no significant change p≤0.05 to the level of total protein, albumin, globulin and the activity of ALT in pregnant women with anemia as compared with control group.

Keywords: Hepcidin, anemic pregnant women, total iron, Transferrin, liver enzymes.

Introduction

Pregnancy or gestation, is the period which one or more fetal develop inside the mother’s womb, In which the unborn baby spends about 38-40 weeks in the uterus. It’s not an illness, but it’s a stressful condition in which manyphysiological and metabolic functions are altered to a considerable extent¹,². Many medical problems were increase during pregnancy due to complex interplay between lifestyle and demographic factors. This medical problems include gestational diabete, venous thromboembolism, hypertension and anemia³.

Anemia is common in pregnancy, and it’s a risk factor for infant low birth weight and iron deficiency anemia, as well as deem as one of the main risk factors for take part in 20-40% of mother deaths directly or indirectly through preeclampsia, cardiac failure, preeclampsia, puerperal sepsis, antepartum haemorrhage and postpartum haemorrhage⁴,⁵.

Mostly, anemia in pregnancy is caused to reduction of iron deficiency or folic acid deficiency or both. Folate and Iron supplementation is fixed during pregnancy to block the complications. The hemoglobin concentration in normal pregnancy, becomes diluted according to the elevate the volume of circulating blood⁶,⁵. The regulation of iron metabolism is done by Hepcidin⁷.

Hepcidin, is a peptide hormones (composed of 25 amino acids), Its a main regulator of iron metabolism⁷. It is mainly synthesized in the liver. The mechanism of the regulations for the iron metabolism is done by the inhibition the absorption of iron in the duodenum by acting mobilization of liver iron Slack⁸,⁹.
The aim of the present study is to evaluate the level of hepcidin and iron homeostasis in sera of pregnant women with anemia in Samarra city.

**Materials and Method**

**Study Design:** Cross sectional study was carried out to 86 samples from pregnant women with reproductive age (18-35) year. Forty six sample collected from pregnant women with anemia as patients group and forty sample from healthy pregnant women as control group in 2nd and 3rd trimester, all samples were collected from Specialized Clinics and Healthy center in Samarra city for the period from 14 December 2018 to 22 January 2019.

**Method:** The study include determination of blood hemoglobin-Hb concentration, packed cell volume-PCV and also determination the concentration of serum hepcidin, total iron, total iron binding capacity-TIBC, transferrin, Transferrin saturation, total protein, albumin and liver enzymes (aspartate aminotransferase –AST, Alanine aminotransferase-ALT, and Alkaline phosphatase –ALP) activity according to the standard method.

**Statistical Analysis:** The results were analyzed using the Statistical Package for the Social Sciences-SPSS using the Completely randomized design-CRD method through a t-test to analyze the variance between two groups and at a probability level (P≤ 0.05) and with this analysis, the simple linear

**Results**

The present study include determination of blood Hb concentration, PCV ratio and hepcidin, total iron, TIBC, transferrin, Transferrin saturation, total protein, albumin, globulin concentration in sera of anemic pregnant women as patient group and pregnant women without anemia as control group.

The results indicate that the Mean±SD of Hepcidin were 5.878 ± 1.699 ng/ml in sera of pregant women with anemia as patient group and 8.260 ± 1.912 ng/ml in sera of pregnant women without anemia as control group, table 1.

Table 1: Mean±SD of hepcidin, Hb, PCV, total iron, TIBC, transferrin, Transferrin saturation, total protein, albumin, globulin concentration in patients and control groups

Table 1 also showed that the Mean±SD of PCV ratio were 34.021 ± 1.939% in blood of patient group and 38.55 ± 1.205% in blood of control group, while the concentration of Hb 10.99 ± 0.627 g/dl in blood of patient group and 38.55 ± 1.205 in control group. The total iron concentration were 16.611 ± 3.479 µmol/L in sera of patient group and 12.5402 ± 0.436 µmol/L in control group, also the concentration of TIBC were 92.373 ± 14.708 µmol in patient group and 77.83 ± 13.213 µmol/L in control group. The ratio of Transferrin saturation were 18.906 ± 6.827% and 49.463 ± 16.906% in pateints and cotrol group respecivley. As well as the concentration of transferrin were 65.433± 10.061 µmol/L and 54.235±9.237 in patents and cotrol group respecivley.

The results obtained from Table 1 indicate that the level of Hepcidin,PCV,Hemoglobin, total iron, Transferrin saturation were significantly decreased at p≤0.05 in sera of pregnat women with anemia as
comparing with pregnant women without anemia as control group. While the level of TIBC and Transferrin were significantly increased at p≤0.05 in sera of patients group as copmare with control group.

Table 2 showed the Mean±SD of total protein, albumin and globulin concentration in sera of patient and control groups.

Table 2: Mean±SD of serum total protein, albumin and globulin concentration in patient and control groups.

Table 2 showed the Mean±SD for total protein concentration were 6.329 ±0.684g/dl in patient group and 6.188 ±0.586g/dl in control group, while the concentration of albumin were 4.012 ±0.780 g/dl in patient group and 4.430± 0.627g/dl in control group. The concentration of globulin were2.255 ±1.134g/dl and 1.794 ±0.954g/dl in pateints and control group respecrivley.

The results obtained from table 3 showed that the activity of ALP were significantly increased at p≤0.05 in sera of pregant women with anemia as coparing with pregnant women without anemia as control group, while the AST was significantly at p≤0.05 decreased in sera of patient group, with no significant variation for ALT between patients and control group.

Discussion

In pregnancy the concentration of hepcidin significantly reducing gradually from the 1st, to the 2nd and 3rd trimesters and reach undetectable levels, The level of hormone correlate with iron parameters during pregnancy, in which hepcidin able to provide. Maximal bioavailability. of iron for fetus and mother.
The results of the present study was agree with finding of Manolov et al.\(^{(11)}\), which indicate that the level of hepcidine significantly decreased in sera of pregnant women with anemia as compared with pregnant women without anemia and pregnant women with anemia of chronic inflammation. This study conclude that the decrease and increase in serum hepcidin concentration provides a backbone for choosing the right therapeutic process in the treatment of anemia in pregnancy. Hepcidin able to provide, maximal bioavailability of iron for fetus and mother, Because its plays an important role in regulation the concentration of iron in human body via release of iron from macrophages and repression of iron absorption from intestine\(^{(12)}\).

Wahed et al.\(^{(13)}\), found that the serum total iron significantly elevated in second and third trimester of pregnant women which take iron supplement as compared with same category of women were not take iron supplemet, other wise the TIBC also increased in groups of anemic pregnant women who take iron supplemente, or rich diet with iron.

The results of the present study were agree with the finding of Zaidan\(^{(14)}\), which found that the level of Total iron, Hb and PCV were significantly decreased, while the result of total protein, albumin and globulin significantly elevated in anemic pregnant women, this finding were disagreement with the finding of the present study, and the results of liver enzymes was agree with finding of the present study about ALT (but not AST), Which found that AST and ALT dont effect during anemic pregnant women but ALP was increased in 60% of samples for this study.

Form all the results we can conclude that the iron deficiency reduced the level of hepcidine in anemic pregnant women.

Study the Effect of the Nanomaterial of the Gold Metal Prepared by Laser Ablation Method on Healthy Human Blood

Atyaf Sarhan Farhan Alrubaie¹, Raad Shaker Alnayli²

¹Physician, ²Prof., University of AL-Qadisiyah, Department of Physics, Iraq

Abstract

The golden nanoparticles were prepared by pulse laser ablation (PLA) by the liquid phase method. Lasers (Nd: Yag) (1064nm (80mJ) wavelength) are used in different pulses (200, 400, and 600), and deionized distilled liquid water (DDDW) is used. The prepared nanomaterial was added by laser ablation and with three laser pulses to a peaceful blood sample, where the nanomaterial was added in different concentrations 2, 4, 5 ml to 1 ml of blood. A blood image was taken for each sample, where the total samples became 9 samples and compared with a sample of healthy blood. It was observed that the general observation of rates and in general of all components of blood tissues has decreased significantly and very dangerous and also frightening with increasing concentration of both nanomaterial’s and increased number of laser pulses per minute compared to normal rates and control sample readings.

Keywords: Golden nanoparticles; Lasers (Nd: Yag); blood; laser ablation.

Introduction

Blood is a connective tissue consisting of red blood cells, white blood cells, plasma and platelets, which is absolutely necessary for living organisms, there is no life without it, where blood makes up eight percent of body mass, or about five liters, blood has many functions, it will We talk in addition to talking about red blood cells and white blood cells.

Blood functions are the defense of the body by producing antibodies that fight germs, getting rid of attacking microbes, which cause many diseases and water balance in the body, which maintains the water balance in the body, by transferring excess water from the body and intestines, or expel it from During the skin as a sweat, or through the kidneys as a urine. And regulate body heat by secreting sweat to moisturize the skin, or by increasing the burning of blood sugar in order to generate energy, raise body temperature. Temporarily stop bleeding by platelets that block the bloodstream, then produce elements that help heal wounds. Substances such as oxygen, liquids, food, hormones and vitamins are delivered to all parts of the body, then returned with carbon dioxide and food waste after being converted into energy in the body with some other substances to be released into the cells. The blood components are plasma, the liquid substance in the blood, and the transparent color tends to yellow, the plasma constitutes 55% of the components of the blood, and water constitutes 90% of the blood plasma, while less than 10% of the plasma is soluble substances mostly are Proteins, in addition to vitamins and nutrients, such as glucose and amino acids. The main function of plasma is the transfusion of blood throughout the body, as well as the transport of nutrients, cellular waste products, antibodies and...
coagulation proteins and hormones. Maintaining the body’s balance. Red blood cells. The cellular components in the blood, most numerous, are produced in the bone marrow. Its size is small, circular, double concave. Their shape and flexibility help them pass through small blood vessels. Red blood cells are surrounded by a membrane consisting of fats and proteins. Red blood cells contain hemoglobin. The main red blood cells transfer oxygen from the lungs to the tissues and carry carbon dioxide and waste from the tissues to the lungs to get rid of carbon dioxide, kidneys and liver to get rid of other wastes. Platelets. Platelets are the smallest blood cells, made in the bone marrow. Their diameter ranges from 2 to 4 micrometers, ranging from 150,000-400,000 per cubic millimeter of blood, but despite the large number, they occupy a small portion of platelets that lack the nucleus and are therefore unable to divide. The lifespan of platelets ranges from seven to ten. The main function of platelets is bleeding, or wounds that stop it. White blood cells. White blood cells form within the bone marrow. By producing antibodies, most white blood cells have a lifespan of only a few hours to several days, but there are some cell types that can remain in the body for many years. Each year, the greater the number of white blood cells or the regression has medical implications, many diseased white blood cells are classified into five main types, cellular neutrophils (neutrophils) specializing in the defense against bacterial infections, especially bacterial infections and burns, strokes, And wounds. Lymphocytes form a line of defense in the body against viral infections, such as cytomegalovirus viral hepatocytes and monocytes. Monocytes rise in chronic inflammation: eosinophil’s rise in response to parasitic infections, basophils are primarily responsible for responding to allergies, histamine secretion, leading to aneurysm.
