**Experimental:** A healthy blood sample was withdrawn from a healthy volunteer person. hence took 10 ml sample from health person, divided this sample to 10 test tubes in the amount of 1 ml in each test tube. all test tubes contain (intejent) to save blood from clotting. This healthy blood sample was mixed with laboratory sample this sample is a Nanomaterial with different concentration. three pulses (200, 400 and 600) The samples are shown in Figure (2) added this Nanomaterials which have different pulses to the healthy blood sample with different concentrations (2, 4 and 5)ml into the three samples at the same time. At this stage, these samples placed in a roll mixer device to mixed (Nano materials and healthy blood) together to obtain the result of this mixed by laboratory test for each mixed sample. The process took (process putting mixed materials on the roll mixer device five minutes) and then began to check a sample after another, including the healthy sample in the Mindray to get a picture of blood for each sample. Note that all samples remained on the roll mixer device during the checking process of other samples. In the results of a blood image shown in the following table with 200 pulse added to it have 2 ml of nanomaterial, gold metal to 1 ml of healthy blood, it observed a decrease in the number of units and the amount of white blood cells under the normal rate even when compared with the sample control 7.21 and also we note a decrease in all levels of granular and non-granular without the normal rates (0.611 -1.071- 0.03-0.48) for the Neu, Lym, Mon, Eos blood cell types according to order, and this is confirmed by the low percentage of these blood cells according to the rate found in the results of the tests with 200 pulses and 2 ml of nanomaterial. It is also observed a significant decrease in the number of red blood cells compared with the normal rates and with the control sample. This led to a difference in the general characteristics of the sphere and the indicator in the readings such as the size of the HCT and the average size of the red blood cell MCV, but a rise in the average hemoglobin in one MCHC is observed. It causes many diseases, such as diseases of low red blood cells and anemia. It is also noted that these laser flashes affect the amount, size and shape of the PLT, which was also read in decreasing numbers. This is a dangerous indication that causes delayed or no blood clotting in wounds or what is known as Thrombopenia. This is also illustrated by the graphs found in the results of the blood image, where a difference in the distribution of blood cells is noted, and the decrease in the numerical pyramid of red blood cells. It is noticed that the decrease in the white blood cells in the concentration of 2 ml has increased until it reached 0.42 at the concentration of 4 ml, but it returned and rose to 1.18 at 5 ml, i.e. the
increase is not a direct increase in the concentration of the nanomaterial, but it remains below the normal rates. This was also the case with RBCs, where it was 1.36 at 2 ml and 0.64 at concentration of 4 ml and then returned and decreased to 0.78 at a concentration of 5 ml of nanomaterial. The same effect was repeated on the thrombocytopenia, where it was 52 at a concentration of 2 ml, decreased sharply at a concentration of 4 ml, then increased slightly 12 at a concentration of 5 ml, but it is also below the normal rates (100-400) and indicates a significant decrease, but rather a great risk.

Results and Discussion

It has been observed that by increasing the number of laser pulses from 200 to 400 pulses when preparing the nanomaterial, gold is observed to decrease all components of blood tissue below the normal levels and further, as the level of white blood cells decreased at a concentration of 2 ml to 2.29 and at a concentration of 4 ml 1.86 and at a concentration of 5 ml to 0.37 This is due to the decrease in all types of white blood cells until some of them were completely nonexistent, which is neutrophil, and its percentage was 0% at a concentration of 5 ml of the added nanomaterial. It was also observed that the decrease became inverse, as the rates decreased with respect to white blood cells (0.37, 1.81, 2.29) at concentrations (2,4,5) ml, and successively where it was repeated with the rates of erythrocytes (0.57,1.18,1.42) in the same sequence and also with the rates Platelets (9,43,56) ml and at the same concentrations It is noted that all parameters remain below the normal ones, but they have declined to more dangerous rates.

As for the increase in the number of laser pulses to 600 pulses, an increased effect on the three main blood components, white blood cells, red blood cells and platelets, was observed. When the number of pulses increased, the WBC decrease decreased until it reached (1.15,1.27,1.98) at concentration (2, 4.5) ml, respectively, as well as with red blood cells until it reached (0.82,0.88,1.37) at the same concentrations as well as low blood platelets, where their number reached (12,15,48) at previous concentrations of nanomaterial. It is noted that the concentration of the nucleic substance is also inversely increasing as the decrease in the blood components increases with increasing the concentration of the nanomaterial. It is noted that the effect of the number of laser pulses per minute also increases the decrease in the blood components. 2.19) consecutively is unclear, and this is exactly what happened with erythrocytes (1.37, 1.42, 1.36) at the three laser pulses in a row and was repeated with platelets.

The general observation of the rates and, in general, of all components of the blood tissue has decreased in a very large and dangerous and also frightening by increasing both the concentrations of the nucleus and increasing the number of pulses of the laser per minute compared to the normal rates and with the readings of the control sample\(^{12-15}\).

**Conclusion**

It was observed when adding the gold nanomaterial to a peaceful blood sample and when taking a blood picture of each sample it was found that the general observation of the rates and in general of all components of the blood tissue has decreased very significantly and dangerous and frightening especially when increasing both the nanomaterial concentrations and increasing the number of pulses of the laser per minute Compared to normal rates and with special readings.

Molecular Detection of $bla_{OXA-51}$ in Carbapenem-resistant Acinetobacterbaumannii Isolated from Different Clinical Sources

Awad Mohammed Hameed¹, Laith Muslih Najeeb²

¹M.Sc., ²Assist Prof., Department of Biology, College of Science, University of Anbar/Iraq

Abstract

Carbapenems are the drugs of choice against serious infections caused by Gram-negative bacteria Carbapenem-resistant. Acinetobacterbaumannii (CRAB) represents one of the important causing agents of nosocomial infections especially in immunocompromised and Intensive Care Units (ICUs) patients. The aim of this work was to identify the Carbapenem-Resistant genes in Acinetobacterbaumannii isolated from Baghdad and Ramadi hospitals. Among 48 A. baumannii isolates, 33 isolates (68.75%) were resistant to imipenem and meropenem. One gene for carbapenem resistance ($bla_{OXA-51}$ like) were amplified by PCR. The presence of $bla$OXA-51-like genes in 100% of CRAB isolates indicated that the $bla$OXA-51-like genes are the predominant mechanism for imipenem resistance in our isolates.

Keywords: Acinetobacter baumannii; $bla_{OXA-51}$; Health management; genes

Introduction

Acinetobacterbaumannii is a non-fermentative, strictly aerobic, non-motile, non pigmented, catalase-positive and oxidase-negative Gram-negative coccobacillus¹. A. baumannii became clinically important pathogen due to its capability for outbreaks and resistance to most antibiotics including carbapenems². nosocomial infections has become an increasingly prevalent cause especially in immunocompromised and in Intensive Care Units (ICUs) patients in the last few years³.

Carbapenems are the drugs of choice for the treatment of serious nosocomial infections caused by A. baumannii⁴. Carbapenem resistant A. baumannii strains have been now emerged around the world. This resistance is principally caused by the production of carbapenemases⁵. Carbapenem-hydrolysing class D β–lactamases (CHDLs) are the most often reported mechanisms of carbapenem resistance in A. baumannii and four groups of CHDLs have been identified inimipenem-resistant A. baumannii, including intrinsic and chromosomally located OXA-51-like β–lactamases and acquired OXA-23-like, OXA-24-like and OXA-58-like β–lactamases⁶.

Materials and Method

Isolation and processing of samples: 48, urine, wounds, burns, blood and sputum, were collected in sterilized containers from patients attending hospitals in Baghdad and Ramadi city. These strains were isolated through a period extended from August 2019 to December 2019.

All bacterial isolates were diagnosed by conventional method such as morphological, microscopic, and biochemical tests⁷. Additionally, identification was confirmed by Vitek-2 system (Biomerieux; France).

Antibiotic susceptibility was done for two antibiotics available in themarket. Disc agar diffusion test was performed according to the Kirby–Bauer standardized antimicrobial susceptibility single disc method⁸.
An isolate was interpreted as susceptible, intermediate, or resistant to a particular antibiotic by comparison with standards inhibition zones or MIC break point according to Clinical Laboratories Standards Institute (CLSI, 2018).

**Extraction of genomic DNA:** DNA was extracted from *A. baumannii* isolates using a commercial purification system (Genomic DNA purification Kit, Promega, USA), then the DNA concentration and purity were determined.

**Traditional PCR assay:** PCR was achieved to amplify carbapenem resistance genes (oxacillinases) including: *bla* OXA-51-Like genes (which is also adopted for the identification of isolates to species level). Primers used in this study (Alpha DNA, Canada) were provided, in lyophilized form then dissolved in sterile deionized distilled water (Table I).

</tbody>
</table>

For PCR method, the initial denaturation phase for each PCR assay with primers was established on 94°C for 5 min also denaturation was 94°C for 1 min. The annealing time was 1 min and temperature was 49°C for. The extension time was 35 sec in 72°C. The final extension was done at 72°C for 7 min.

The reaction of PCR consisted of 12 μl Master mix (Bioneer, USA), 1 μl of each forward and reverse primers, 4 μl of template DNA, and 7 μl PCR grade water to a final volume 25 μl. The products of PCR were electrophoresed for 1 hr and visualized with the aid of Red Safe staining (iNtRON, Korea) and UV transilluminator documentation system.

**Result and Discussion**

During the period of August 2019 to December 2019, forty eight *Acinetobacter baumannii* were collected from Ramadi city and Baghdad. The collected isolates were from different clinical specimens (urine, wound, sputum, and burns) of in patients in this hospital. All isolates were identified by using the automated Vitek-2 system (Bio-Merieux/France) according to the manufacturer’s instructions with the using ID-GNB (Identification card - Gram Negative Bacteria).

**Antibiotic susceptibility testing:** The antibiotic susceptibility test revealed that (68.75%) carbapenem-resistant *A. baumannii* from 48 clinical strains were multidrug-resistant.

**Molecular detection of bla OXA-51 in *A. baumannii* by traditional PCR:** *A. baumannii* has successfully become a significant nosocomial pathogen because of its remarkable ability to acquire antibiotic resistance and to survive in nosocomial environments. The *bla* OXA-51-like genes were reported to be highly specific for the identification of *A. baumannii* at the species level (9). PCR product illustrate the presence of *bla* OXA-51-like genes in all 15 (100%) A. baumannii clinical isolate close to Nadeema et al (10).

Nevertheless, similar findings were reported in countries other than Iraq, such as Bulgaria, China, Brazil, Afghanistan, Korea (9), Singapore and Thailand (11). A study carried out by Hujer et al. demonstrated that 97% of A. baumannii strains (isolated from military and civilian personnelinjured in the Iraq/Kuwait region during Operations in Iraq have *bla* OXA-69-like gene (a member of *bla* OXA-51-like genes). The *bla* OXA-23-like genes present in 91.03% of IRAB which indicated its responsibility for the dominant carbapenem resistance gene in the local A. baumannii isolates.

In conclusion, this study identifies the gene responsible for the carbapenem resistance in Ramadi which is important to understand the carbapenem resistance and to suggest plans for treatment of patients in future. The high distribution of *bla* OXA-51-encoding genes presents an emerging threat in our hospital. The diversity of resistance genes is particularly worrisome due to the difficult choice of empirical antibiotic therapy in seriously ill patients and the possible contribution to increased hospital stay and associated costs.
Figure 1 : PCR amplification fragments for the detection of bla OXA-51 gene (553 bp) carbapenem-resistant \textit{Acinetobacter baumannii} strains. Lanes 1 – 15: = \textit{A. baumannii} Lane M: 100-bp DNA ladder. Amplicons were electrophoresed on agarose gel (1\%) at 70 V/cm for 1.5 h, stained with RedSafe(iNtRON, Korea), and visualized using an UV transilluminator documentation system.

Correlation between Serum Interleukin-33 Level and Uterine Fibroids

Farah Mahdi Hamza1, Nadia Mudher Al-Hilli2, Ameer KadhimAl-Humairi2

1M.B.Ch.B. Health Director of Babel, Ministry of Health, Iraq,
2Ass. Prof., Babylon University, College of Medicine, Iraq

Abstract

Introduction: Fibroid is considered the most common benign tumor of the female genital system; it has vague incidence and etiology. IL33 is thought to play a role in pathogenesis and this may open the doors to further understanding and treatment of this disease.

Aim of the study: To assess if there is any correlation between IL33 serum level and uterine fibroid and if there is correlation with tumor features such as size, site and number.

Method: We take 40 women with leiomyoma and 40 leiomyoma free women at this case control study. For both of them history and physical examination was done with diagnosis supported by US, serum is collected and IL33 level was compared between both groups.

Results: Mean age of patients is 36 years most of them are married, over-weight, para 1-3 and has history of breast-feeding. Commonest presentation is HMB about 80% the least is dyspareunia, 36.8% had history of infertility, the majority of fibroids were intramural & multiple. There was higher IL33 levels among cases.

Conclusion: there is significant correlation between IL33 serum levels and presence of uterine leiomyoma and there was significant correlation with size of fibroid while there was no correlation with the site and number of fibroid.

Keywords: Tumor; Correlation, serum interleukin-33, uterine fibroids.

Introduction

Uterine fibroids are considered an important reason of morbidity in reproductive age women and sometimes even after menopause. Many causes have been attributed to the development of these tumors, but the etiology is unknown yet. They represent the most common benign tumor of the female genital tract. Uterine leiomyoma’s are defined as a hormone responsive tumors arise from myometrium smooth muscle cells usually by neoplastic transformation of a single smooth muscle cell (monoclonal origin)1. UFs can be single or multiple but mostly multiple. Uterine fibroid is usually considered a slowly growing tumor2. Fibroids sometimes can reach to a very large size up to 30 cm3 3. Most of women with UFs are asymptomatic and undiagnosed therefore, the true incidence is underestimated. Epidemiologic data are still limited, which mainly include incidence, prevalence, risk factors, natural history & disease progression. Uterine fibroids have been considered as the most important indication for hysterectomy in the United States 4. By age of 50, fibroid incidence is estimated to be approximately 70% for whites, and over 80% for blacks; Sweden women show much lower prevalence 5. Hispanics are parallel to whites than blacks 6. While Asian women or other ethnic groups has no available screening data. Prevalence of fibroids ranges between 3.3 and 77% 5. In the United States, the financial burden of UFs is estimated to be about $5.9 billion and $34.4 billion annually 7. The incidence of change to malignant leiomyosarcoma is 0.64 per 100 000 women per year and is very uncommon in women under the age of 40 8.

Method

This is a case control study performed at department
of obstetrics and gynecology at Babylon teaching hospital for Maternity and pediatrics in the period between January 2017 and December 2018. The study involves 80 non-pregnant women; their ages range from 20 to 50 years, forty of them had ultrasound evidence of fibroid and were presented to the hospital with symptoms related to fibroid such as menorrhagia, dysmenorrhea, abdominal distention and other symptoms of fibroid. Abdominal and endovaginal ultrasound involve details of fibroids, which include number, size, and site of fibroids are all measured. The second group (40 women) were healthy women (control group) who were leiomyoma free which was confirmed by ultrasound. For both groups history and physical examination is done according to a special questionnaire designed to predict risk factors, symptoms and signs. Exclusion criteria has been set during patient selection including women with the following diseases:

- Endometriosis.
- Different types of malignancy such as breast cancer, ovarian cancer, and others.
- Scleroderma.
- Liver and lung fibrosis.
- Autoimmune or inflammatory disease.
- Infectious disease as HIV and hepatitis.
- Pregnancy.

Ultrasound was done to all of the patients and control groups by a single radiologist Dr. H. F who has 9 years of experience. After confirming diagnosis by history, physical examination and ultrasound. 5 ml of blood was collected using gel tube then allowed to clot at room temperature for about 30 minutes, sample is then centrifuged for 5 minutes at 800g, and then samples stored at -20ºC until analysis. IL33 was measured in sera by (ELISA) using an ELISA KIT according to the manufacturers recommendations (Elabscience). Statistical analysis done by SPSS 22, frequency and percentages mean and SD for all data, Fisher’s-exact test were usefor association between categorical variables, Independent t-test was used to match different for continuous data, 0.05 or less for P-value reflected as significant.

Results

Uterine fibroids represent the most common female genital tract benign tumor, it is a hormone responsive tumor; however, the exact mechanism of this disease is still unknown, and will open the doors of the future to treat this disease thus reducing the morbidity costs associated with it. Regarding the age, in this study, the patients under study are ranging from 23-50 years with a mean age of (36.92 ± 7.64), the mean age of the control group was32±7years, there was significant differences of age between cases and control group. As shown in table(1). 95% of them are married (38 women) and 5% of them are unmarred (2 women only),12 of them are of Normal BMI (18.5-24.9kg/m2) which represent 30% of patients, overweight women (BMI 25-29.9kg/m2) were 16 women (40%), while Obese women (BMI 30 or more) also were 12 (30% of patients), 2 of them (5.3%) were nulliparous apart from 2 unmarried women, 22 of them (57.9%) were para1-3, 14 of them (36.8%) were para 4 or more. 28 of them(73.7%) had history of breast feeding, 10 of patients had no history of breast feeding(26.3%), regarding abortion, 15 patient had previous abortion(39.5%) while 23 of the patients had no previous abortion (60.5%), four of them had recurrent abortion, while others had single abortion. (as shown in table 2) Clinically the following clinical manifestations are studied these include intermenstrual bleeding, heavy menstrual bleeding, abdominal pain, abdominal mass, urinary symptoms, dyspareunia and dysmenorrhea, regarding the distribution of patients according to clinical manifestations there were 22 patients had IMB which represent 55% of patients, the reminder (18 patients) had no IMB which represent 45% of the patients. there were 32 patients had HMB which represent 80% of patients, the reminder (8 patients) had no HMB which represent 20% of the patients. 27 of patients has history of abdominal pain which represent 67.5% and 13 patients had no history of abdominal pain which represent 32.5%. 12 of patients had abdominal mass by history and examination which represent 30% while 28 of patients had no abdominal mass by history and examination which represent 70%, 13 of patients had history of urinary symptoms such as frequency and urgency which represent 32.5% of patients while 27 of patients had no history of urinary symptoms which represent 67.5% of patients, 5 of the patients had history of dyspareunia which represent 12.5% while 35 of the patients had no history of dyspareunia which represent 87.5% of the patients,23 of the patients had history of dysmenorrhea which represent 57.5% while 17 of patients had no history of dysmenorrhea which represent 42.5% of the patients. (as shown in table 3). Regarding the distribution of patients according to the size, site and number of uterine fibroids 37 of the patients...
had intramural fibroids which represent 92.5% of the patients while 3 of the patients had sub serosal fibroids which represent 7.5% of the patients, 67.5% of the fibroids were multiple (n=27) while only 32.5% of the fibroids were single (n=13) (as shown in table 3). In our study, there were significant differences of age between patients with uterine fibroid and control group as in table (3). Regarding the distribution of patients according to history of infertility 14 patients had history of infertility (36.8) while 24 patients had no history of infertility (63.2) (as shown in figure 1). There was significant differences between means of IL33 (pg/ml) between patients with uterine fibroids and control group (as shown in figure 2). There was no significant association between IL33 and number and site of fibroids as demonstrated in table 4. Regarding distribution of patients with uterine fibroids according to the size there was 5% less than 40mm$^3$, 27.5% between 40-80mm$^3$ and the majority was more than 80mm$^3$

Figure (1): Distribution of patients with uterine fibroid according to history of
Infertility:

Discussion

Uterine leiomyoma is the most common neoplasm-affecting women that can cause significant morbidity and may adversely affect fertility.

In our study the mean age of patients was 36.9±7.6 and there was significant difference between the ages of cases and control group while in the study of Barbosa et al 2012 who studied the prevalence of uterine fibroids on 624 women, the mean age was (39.62±12.58) which approximate the mean in our study, while Santulli et al 10 in his sample has a mean age of 33.2±3.8 and there was no significant differences of age between the study and control groups in contrast to our study. Ezeama et al 11 study found a mean age of 35.7, which agreed with our study.

In our study married women were 95% while in Barbosa et al 9 study married women were 66.2% which doesn’t agree with our study also Ezeama et al 11 study 2012 51.5% were married which also doesn’t agree with our study. Regarding BMI in our study normal BMI was 30%, overweight women were 40%, obese women were 30% while in Barbosa study, 59.5% were of normal BMI, 27.1% were overweight (BMI 25-29.9), 10.3% were obese (BMI 30 or more) and only 3.4% were underweight.

In our study nulliparous was 5.3%, para 1-3 was 57.9% and para 4 and more was 36.8% while nulliparous women at Barbosa et al 9 study 2012 was 35.7% and Ezeama 11 study at 2012 nulliparous women were 77.7% which doesn’t agree with our study.

In our study 10.5% had history of recurrent miscarriage and 89.5% had no history of recurrent miscarriage which agree with Barbosa study has 53.5% of the sample with no history of miscarriage and 14.7% has history of miscarriage.

Regarding infertility in our study 36.8% had history of infertility whether primary or secondary and 63.2% had no history of infertility, which doesn’t agree with Barbosa study infertile women were, only 5% the other 95% were fertile.

There was no significant association between parity and uterine fibroids; there was no significant association with history of breast feeding, abortion or recurrent abortion. Only there was significant association with history of infertility whether primary or secondary.
Regarding clinical manifestation in our study the most common presenting symptom is heavy menstrual bleeding, followed by abdominal pain then dysmenorrhea, the least common symptom is dyspareunia which was only 12.5% of the patients. Ezeama et al\textsuperscript{11} found that the most common presentation is lower abdominal mass which represent 67.7% of his sample and the least one is recurrent abortion only 1%. In Ezeama et al\textsuperscript{11} study irregular vaginal bleeding was 9.7% while in our study 55%, Ezeama et al\textsuperscript{11} study found that HMB was present in 41.71% while in our study was 80%, Ezeama et al\textsuperscript{11} found that abdominal pain was present in 20.4% while in our study was present in 67.5%, Ezeama et al found that urinary symptoms was present in 8.7% while in our study urinary symptoms was present in 32.5%, Ezeama et al\textsuperscript{11} found that dysmenorrhea was present in 15.5% while in our study was present in 57.5%, lastly Ezeama et al\textsuperscript{11} found that infertility was present in 30.1 while in our study was present in 36.8%. while Barbosa\textsuperscript{9} has the following sequence of distribution of patients according to clinical manifestations, 18% of women presented with menstrual disorders such as dysmenorrhea, menorrhagia and metrorrhagia, dyspareunia was 1.1%, urinary symptoms was 1.4% and finally abdominal pain was present in 9.8% of the patients.

Regarding site of uterine fibroids we found in our study that 92.5% are intramural only the remainder were subserosal while Ezeama et al\textsuperscript{11} found that the majority were multiple 56.35% while 31% of the patients has intramural fibroids only, 5.8% has subserosal fibroids only, 7.8% has submucous fibroids only and there was a single case of intraligamentary fibroids, while, Barbosa found that 49.7% were single and 41.6% were multiple, Ezeama et al\textsuperscript{11} study 2012 found that 43.7% was single and 56.3% was multiple while in our study 67.5% was multiple and the reminder was single(32.5%) which is agreed with our study.

In this study we found a significant higher serum level of interleukin 33 in cases than controls which agreed with Santulliet al\textsuperscript{10} 2013 (the only available study) who found also that IL33 levels were higher in cases than in control.

We study the correlation of IL 33 with fibroid size, site and number. There was a positive correlation between size of fibroid & IL33 serum level, while no correlation was found between IL33 level and fibroid site and number.

**Conclusion**

There is significant correlation between IL33 serum levels and presence of uterine leiomyoma and there was significant correlation with size of fibroid while there was no correlation with the site and number of fibroid.

The Role of Foley Catheter in the Treatment of Low Grades Vesico-Ureteric Reflux (VUR)

Salam Abd Elameer Yahya¹, Bashar S. Khalaf², Iyad Hussein Ali³

¹Ass. Prof., Hammurabi College of Medicine, University of Babylon/Iraq, ²Lecturer, Hammurabi College of Medicine, University of Babylon/Iraq, ³Specialist/Babylon Health Director/Ministry of Health/Iraq

Abstract

Vesicoureteral reflux can be defined as a congenital anomalies of the lower urinary tract characterize by a defect in the vesico-ureteric valve (which is a functional valve result from the oblique intramural passage of the lower 2.5 cm. of the ureters in wall of the bladder) resulting in retrograde passage of urine into one or both ureters up to the kidneys during voiding. From March 2014 to June 2016, 60 (38 males and 22 females) children with low-grade primary VUR (10 with G1, 16 had G2 and 34 had G3) who are seeking medical advice in the urological department of Alhilla teaching and Alsadiq teaching hospitals and private clinics were included in this study. All patients evaluated by thorough medical history, complete physical examination, send for urinalysis, PCV, and ultrasonography, and confirm the diagnosis by voiding cystography. No Foley catheter put for patients with G1 VUR, while Foley catheter put for eight patients with G2 VUR (50%) and for 20 patients with G3 reflux (58.8%). Patients are fallowed for at least 1 year for any breakthrough upper or lower urinary tract infection and for the grade of reflux by frequent urinalysis and ultrasonography for any new renal scaring while voiding cystography repeat every 6 months. Conservative treatment is the first option in the treatment of low grade VUR. The use of indwelling Foley catheter in the treatment of low grade VUR remain controversy regarding its role in decreasing the back pressure on the renal parenchyma and its increasing rate of UTI. however this study reveal that the incidence of UTI occur in 6.25% of cases treated with continuous prophylactic antibiotic (CPA) alone and occur in 25% of cases treated with CPA with Foley catheter placement.

Keywords: Foley catheter, low grades, vesico-ureteric reflux (VUR).

Introduction

Vesicoureteric reflux can be defined as a congenital anomalies of the lower urinary tract characterize by a defect in the vesico-ureteric valve (which is a functional valve result from the oblique intramural passage of the lower 2.5 cm. of the ureters in wall of the bladder) resulting in retrograde passage of urine into one or both ureters up to the kidneys during voiding. The definite diagnosis and grading is best done by voiding cysotourethrogram (VCU) which can classify the condition into five grades.

The low grades VUR includes grade ¹,²,³. The treatment options for children with low grade VUR remain controversy regarding the use of long-term prophylactic antibiotic and the use of indwelling Foley catheter.⁸ Early diagnosis and use appropriate method of treatment for children with VUR increase the opportunity to prevent renal damage.³,⁹ Urinary tract infection in children with VUR increase the risk of pyelonephritis, which associated with renal scaring and damage.⁸ Many of the interventional clinical trials (controlled and randomized) which try to investigate the causal association between VUR and the frequency of febrile UTI and renal scaring are recently proved.¹⁰,AUA Guideline for Pediatric VUR establish the correlation between VUR and the frequency of febrile UTI and renal scaring in 1997.⁴,⁵,⁶ AUA Guideline state that renal scarring in children with VUR and pyelonephritis are 2.8 times greater than
the odds of scarring for children with pyelonephritis without VUR. So treatment of VUR is considered to reduce the morbidity of acute pyelonephritis and the risk of permanent renal injury, observation, continuous antibiotic prophylaxis, continuous bladder drainage by Foley catheter and surgical interventions are the main options used for treatment of children with VUR. Most of the studies which try to compare the outcomes of continuous prophylactic antibiotics versus surveillance alone in treatment of children with VUR regarding the renal scarring and damage state that renal scarring and damage occur less in children with reflux who are treated with continuous prophylactic antibiotics than those who are treated with antibiotics only when urinary tract infection occur. While other studies deny any benefit from the use of CPA over surveillance in decreasing the risk of recurrence of UTI and renal scarring. Although American Urology Association guideline in 2010 recommend that CPA is indicated during the waiting period in the conservative treatment.

Patients and Method

From March 2014 to June 2016, 60 (38 males and 22 females) children with low grade primary VUR (10 with G1, 16 had G2 and 34 had G3) who are seeking medical advice in the urological department of Alhilla teaching and Alsadiq teaching hospitals and private clinics were included in this study. Age of the patients ranging from 7 days to 6 years. All patients evaluated by thorough medical history, complete physical examination, send for urinalysis, p.c.v., and ultrasonography, and confirm the diagnosis by voiding cystography. Children with high-grade reflux and those with secondary reflux excluded from the study. Those children treated by conservative treatment, which include prophylactic antibiotics with or without Foley catheter placement. No Foley catheter put for patients with G1 VUR, while Foley catheter put for 8 patients with G2 VUR (50%) and for 20 patients with G3 reflux (58.8%). Patients followed for at least 1 year for any breakthrough upper or lower urinary tract infection and for the grade of reflux by frequent urinalysis and ultrasonography for any new renal scaring while voiding cystography repeat every 6 months. Data was collected and analyses by meta analyses with P-value of >0.05 is considered significant and of > 0.001 is considered highly significant.

Results and Discussion

1. VUR and SEX distribution: In this study, the male to female ratio is (1.7:1) as in Table 1 which seems to be near the results of most studies.

Table 1. Male to female ratio of VUR

<table>

2. The severity of VUR according to the grading: For 60 children with primary VUR who are included in the study, 10 children (16.6%) had grade 1 reflux while 16 children (26.7%) had grade 2 VUR and 34 children (56.6%) with grade 3 reflux this percentages can be presented in figure 1:

![Figure 1](image1.png)

Figure 1. Distribution of patients according to the grade of VUR
3. **The relation between VUR and UTI episodes:** For the 32 patients who are treated with prophylactic antibiotics alone without catheter placement only 2 patients had breakthrough febrile UTI (6.25%) and those 2 patients had grade 3 VUR.

For the 28 patients who are treated with prophylactic antibiotics with indwelling Foley catheter replaced every 10 days, 7 children had breakthrough febrile UTI (25%) 4 of them had grade 3 VUR and the remaining 3 children with grade 2 VUR. As showed in figure (2).

![Figure (2): The relation between the use of Foley catheter and the occurrence of UTI:](image)

4. **The relation between VUR and renal scaring:**

Renal scaring assessed by ultrasonography and for the 32 patients who are treated with prophylactic antibiotic alone, 8 of them (25%) develop new renal scars.

While for the group who treated with prophylactic antibiotics and indwelling Foley catheter, 7 out of 28 children (25%) develop new renal scars as appear in table (2).

Fisher’s Exact Test= 0.097, P-value= 0.78 (not significant).
5. Rate of resolution and/or improvement in the grade of VUR: All the 10 patient with primary VUR of grade 1, six patients (60%) has complete resolution of the reflux with in the period of follow up (about 1 year).

While of the 16 patients who had grade 2 reflux, 8 patient who treated with CPA alone, no one had complete resolution for the follow up period and only 2 patient had improvement in the grade (change to grade 1) which account 25%. While those treated, with CPA and indwelling foley catheter 2 patient had complete resolution and other 3 patients change to grade during the follow up period so the improvement rate in this group is 62.5%.

Regarding the 38 patients with grade 3 reflux, 18 patients who treated with CPA alone, only 3 patients had improvement in the VCU and change to a lower grade (27%), while 8 patients (73%) of the 20 patients who treated with CPA with indwelling catheter had improvement in VCU. Patients with grade 2 71% of them improve with Foleys while 29% improved without Foleys. There is significant association between grade of VUR and improvement with Foleys catheter. These results showed in table (3).

Discussion

The male to female ratio differ with different studies and in different communities. In this study, the male to female ratio is about (1.7:1) and this male predominance may be due to the society preference of male gender makes the families who had male child seek medical advices even with mild symptoms which not fit for female patients who are usually present late and of high grades.

Regarding the grade of VUR at time of presentation, most cases included in this study are of grade 3 (56.6%) while those of grade 2 (26.7%) and of grade 1 (16.6%) this is because most cases of primary VUR diagnose postnatal when present as UTI and most studies reveal that the risk of UTI in VUR patients increase with increase the grade of reflux which mate the results of this study.

Although most previous studies reveal that UTI is commoner in VUR patients than those without VUR, this study also show that the percentage of UTI is higher in the group treated conservatively with CPA with indwelling foley catheter (25%) than the group treated with CPA alone (6.25%) although these results are statistically insignificant with p-value of 0.7 (>0.5) and this higher percentage mostly due to the effect of foley catheter which regard as a foreign body in the bladder and increase the risk of infection.

While the study did by Mattoo TK in 2011 relate the reflux nephropathy to the occurrence of upper UTI, in this study the rate of new renal scaring identified in primary VUR patients by ultrasonography seems to be statistically insignificant between the 2 groups as it occur in 50% of patients treated with CPA alone and also in 50% of VUR patients treated by CPA with indwelling foley catheter these results may be due to the effect of foley catheter while it increase the risk of UTI and in the same time decrease the back pressure on the kidneys by decreasing the degree of dilatation of the ureters and pelvescalyceal system and this decrease in the degree of
dilatation of the ureters and pelvicalyceal system which showed in table (3) explain why the group of patients who are treated with CPA and indwelling foley catheter had higher resolution and improvement rate than the group of patients who are treated with CPA alone which seems to be statistically significant and these results are mate the results of shiraishi and Knudson. 

**Conclusion**

Conservative treatment is the first option in the treatment of vesicoureteric reflux of low grades (grades 1, 2, 3). It included good hydration, good feeding with CPA. The use of indwelling Foley catheter remain controversy and this study show that the use of indwelling Foley catheter insignificantly increase the risk of UTI and renal scaring for cases of low grades VUR while it led to higher percentage of improvement in the degree of dilatation of the ureters and pelvicalyceal system which decrease the grade of reflux and may increase the spontaneous resolution rate. Although longer period of fallow up needed to know the exact effect of indwelling Foley catheter on the resolution rate of VUR.

Clinical Comparative Study for Some Biochemical Changes in Sera of Pregnant with Iron Deficiency Anemia

Ahmed Ghitheeth Mathwar¹, Raid M.H. Al-Salih²

¹Post Graduate, ²Prof., Chemistry Department, College of Science, Thi-Qar University, Iraq

Abstract

The aim of this study was to study the evaluation of serum oxidation in pregnant women with iron deficiency anemia by measuring lipid oxidation (MDA), and antioxidant status by analogy (Ferritin). Also, Examination of erythropoietin (EPO) levels in pregnancy with iron deficiency anemia. Blood samples were obtained from (80) pregnant women with anemia divided according to the stage of pregnancy and iron deficiency as follows: 20 patients in the second third with anemia without iron deficiency, 20 patients in the second third with anemia with iron deficiency, 20 patients in the third trimester with anemia without iron deficiency, 20 patients in the third trimester have anemia with iron deficiency. In addition to (40) healthy pregnant women as a control group. Divided into two groups, 20 patients in the second trimester and 20 patients in the third trimester.

Results: The results show a presence of a significant increase in MDA and EPO in all groups of patients in Iron deficiency in comparison with control group. But, Ferritin levels showed a significant decrease in all groups of patients in Iron deficiency and Iron normal comparison with control group.

Keyword: Erythropoietin, Malondialdehyde, Ferritin, Pregnancy, Iron deficiency anemia

Introduction

Anemia is one of the most important health problems in the world. Iron deficiency anemia is the most common form of nutritional deficiency that affects both developing and developed countries. An assessment by WHO directly or indirectly attributes approximately 591,000 perinatal deaths and 115,000 maternal deaths worldwide to iron deficiency anemia¹. The South Asian countries have the highest incidence of anemia in the world. Around half of the world’s maternal deaths from anemia occur in South Asian countries, and India accounts for around 80 per cent of the deaths². Anemia affects all age ranges from childhood to adolescence to perimenopausal age. The factors for the high incidence of anemia include low iron dietary consumption, reduced iron bioavailability, phytate-rich diet, bad eating habits, frequent menstrual blood loss and increasing proportion of infections such as malaria and roundworm infestations³. Due to increased demand from the increasing fetus, the condition gets exacerbated during pregnancy. Throughout pregnancy it is recommended that prophylactic oral iron meet the increased requirement during the antenatal phase. Compliance due to associated gastrointestinal side effects such as bloating, diarrhea, heartburn, nausea, constipation and dark stools is the main issue with oral iron therapy. So, too. Oral therapy does not suffice to treat moderate to serious anemia, especially in the late second and third trimesters. Parenteral therapy provides a stronger response in these patients and can reduce the need for antenatal and postpartum blood transfusions⁴. After iron supplementation, iron deficiency anemia occurs in several pregnant women as their iron stores need to support their own increased blood volume, as well as being a source of hemoglobin for the developing baby and for placental production⁵. The intravascular hemolysis and hemoglobinuria are other less common

causes, pregnancy during Iron deficiency seems to cause long-term and permanent cognitive problems in the baby\(^6\). **Erythropoietin**, also known as EPO, is a glycoprotein hormone that controls the manufacturing of erythropoiesis, or red blood cells. It is a cytokine (protein signaling molecule) catalyst in the bone marrow for erythrocytes (red blood cells)\(^6\). The molecular weight of Human EPO is 34kDa. Also known as haematopoeitin or haemopoeitin, interstitial fibroblasts in the kidney are produced in close association with the capillary peritubular and proximal convoluted tubules. It is also formed in the liver, in perisinusoidal cells. While liver production predominates in both the fetal and perinatal periods, during adulthood renal production predominates. Other known biological functions include erythropoietin, in addition to erythropoiesis. This plays a major role in the brain’s reaction to neuronal damage, for example. The EPO also participates in the wound cure process\(^7\). The erythropoietin synthesis does not have a humoral or neural regulation. The development of erythropoietin is only dependent on the content of oxygen and is regulated by the feedback principle\(^8\).

**Malondialdehyde (MDA)** is one of the end products of peroxidation of polyunsaturated fatty acids in cells. An rise in free radicals causes MDA to become overproduced. Malondialdehyde is commonly referred to as a marker of oxidant stress in patients\(^9\).

**Ferritin**, a large iron storage protein, is essential to homeostasis of iron and participates in a wide variety of physiological and pathological processes. Ferritin is primarily used in clinical medicine as a serum measure of total body iron reserves. Serum ferritin plays a key role in both treatment and management in cases of iron deficiency and excess\(^10\).

**Design of study:** This study conducted at Women and Children Hospital in Al-Muthanna, Iraq, biochemistry laboratory at the period between 1/11/2019 and 1/4/2020. The study include (120) subjects, (80) patients with anemia (40 females second trimester divided to 20 anemia with Iron deficiency and 20 anemia non Iron deficiency, 40 female third trimester divided to 20 anemia with Iron deficiency and 20 anemia non Iron deficiency) with age range (18—40) years. While the control group, consists of (40) Healthy pregnant women divided to (20 females second trimester and 20 females third trimester).

**Collection of blood samples:** Blood samples are collected. About (5 mL) of blood samples of Pregnant women with anemia and controls are taken and allowed to clot at room temperature in empty disposable tubes and centrifuged to separate it at 3000 rotor per minute (rpm) for 10 min, the serum samples are separated and stored at (-20°C) for later measurement of biochemical parameters, unless used immediately.

**Statistical Analysis:** The statistical analysis used in this study is done using Microsoft Excel 2010, the results are expressed as mean ± standard deviations (mean ± SD) with LSD test. One way ANOVA-test is used to compare parameters in different studied groups. P-values (P ≤ 0.05) are considered statistically significant.

**Result and Discussion**

**Serume Erythropoieten concentration:** Table (2) show a significant increase in concentrations of serum EPO in patients pregnancy with anemia group in comparison with control group (P≤0.05). It was also found that there was a significant increase in 3rd groups compared to group 2nd groups, in addition to a significant increase was observed in 3rd D group compared to 3rd N, and there was also a significant increase in 2nd D group compared to 2nd N group these result agree with. Indeed, pregnancy anemia leads to increased secretion of the EPO as a response to low concentration of haemoglobin and ferritin deficiency\(^11\). The primary function of erythropoietin is an important hormone for the manufacture of red blood cells. No definitive erythropoiesis happens without it. Under hypoxic conditions, the kidney develops and secretes erythropoietin to improve red blood cell output\(^12\). Due to the physiological increase in blood volume, the increase in EPO levels is greater in the third trimester of pregnancy than in the second trimester of pregnancy. Increased renal blood flow and glomerular filtration by 30-50 percent, and since erythropoietin is of renal origin and increased oxygenation, the concentration of the EPO has been shown to increase 2-4 times\(^8\).

Serum Malondialdehyde Concentration: Table (3) show a significant increase in concentrations of serum MDA in patients pregnancy with anemia group in comparison with control group (P≤0.05). It was also found that there was a significant increase in 3d iron groups compared to group 2nd groups, in addition to a significant increase was observed in 3rd D group compared to 3rd N, and there was also a significant increase in 2nd D group compared to 2nd N these result agree with. Anemia is known to promote oxidative stress due to insufficient supply of tissue oxygen resulting in increased free radical development and very low levels of circulating red blood cells and mobile free radical scavengers that protect tissues from ROS-mediated harm(13). The increase in serum and erythrocyte fatty oxidation in pregnant women Particularly during the third trimester of pregnancy, the production of pregnancy-related oxidative therapy is obvious in pregnant women. Thus pregnancy is a physiological condition characterized by an oxidative disorder which contributes to the initiation and progression of complications related to pregnancy(14). The body's iron deficiency limits heme synthesis and reduces the production of red blood cells in the marrow that leads to anemia. Because energy Cellular metabolism is oxygen dependent, anemia has a wide range of clinical consequences. Anemia results in increased oxidative stress and increased peroxide in lipids. Can not exclude iron deficiency as an person with a normal body iron will coagulate a large portion of body iron before hemoglobin levels decrease The enzymes used in the cycle of oxidative metabolism need iron to be less than the laboratory meaning of anemia. At the same moment, This should be taken into account that iron iron is used to treat iron by mouth during pregnancy as a drug Strong oxidation and several studies have shown that iron-deficient people are more prone to this treatment than iron therapy-induced oxidative stresses. The concentration of malondialdehyde (MDA) in pregnant women with iron deficiency anaemia is higher in this study(15).

Serum Ferritin concentrations: Table (4) show a significant decrease in concentrations of serum ferritin in patients pregnancy with anemia group in comparison with control group (P≤0.05). It was also found that there was a significant increase in 3rdgroups compared to group 2nd groups, in addition to a significant decrease was observed in 3rdD group compared to 3rdN, and there was also a significant decrease in 2ndD group compared to 2ndN group these result agree with. Although concentrations of haemoglobin and ferritin are both iron deficiency markers, haemoglobin is a late marker, and may not reflect the status of tissue iron. In general, however, serum ferritin (SR) is considered the best measure of iron deficiency during pregnancy. The level falls early of iron deficiency and is not impaired by the recent ingestion of iron(16). A study of 100 women in the second and third trimester of pregnancy and anemia was shown as follows, iron deficiency anemia (Hb ≤10.5 g/dl; ferritin ≤12 ng/ml). Anemia not due to iron deficiency (Hb ≤10.5 g/dl; ferritin> 12 ng/ml)(17).

**Conclusion**

1. The levels of the hormone erythropoietin are higher in women with anemia and it increases more in women with anemia with iron deficiency.

2. The levels of lipid peroxide (MDA) markers were elevated in pregnant women with iron deficiency anemia and also elevated in pregnant women with anemia without iron deficiency.

3. Fritin levels are in iron deficiency groups below of iron normal groups.

Status of HIV/AIDS Over Ten Years in Iraq (2010-2019)

Haitham Noaman Al-Koubaisy1, Jalil Ibrahim Saleh2, Mothana Ali Khalil3, Najoh Kadhim4, Hadeer Naeem4, Nawar Sahib Khalil5

1Professor of Internal Medicine, University of Anbar, College of Medicine, Iraq, 2Assistant Professor, Al-Iraqia University, College of Medicine, Family and Community Medicine, Iraq, 3Assistant Professor of Medical Microbiology, University of Anbar, College of Medicine, Iraq, 4Specialist of Infectious and Communicable Diseases (FICMS), National HIV Center in Iraq, Ministry of Health, Iraq, 5Assistant Professor, Al-Iraqia University, College of Medicine, Family and Community Medicine, Iraq

Abstract

Despite advances, HIV/AIDS remains one of the world’s most significant health and socio-economic problems. To highlight the status situation of the HIV/AIDS in Iraq for the last ten years (2010-2019). A retrospective study of available data on new HIV cases records covering the period from 2010 to 2019. This study was conducted in Iraq from July 2018 to December 2019. We collected these data from HIV/AIDS Center in Baghdad. All the cases are diagnosed through case history, clinical examination and laboratory investigations. The cumulative annual number of new HIV cases covering the period from 2010 to 2019 was 539 cases. The trend of annual number of the cases increased with time (2010-2019). All cases are adults. The majority of new HIV cases are males (83.5%) and alive (90.2%). Sexual activity contributed the main mode of HIV transmission (74.6%) especially heterosexuals.

Keywords: HIV/AIDS, Toxicity; Status, Trend, Iraq.

Introduction

Despite advances, HIV/AIDS remains one of the world’s most significant health and socio-economic problems, particularly in low and middle-income countries including Iraq.[1]

WHO estimated that in 2018, there were about thirty eight million people living with HIV in the world. Of these two millions new HIV infections, one million AIDS-related deaths, twenty three million people were accessing antiretroviral therapy (ART), there were 36 million adults (18 million women and 16 million men) and 2 million children. Globally, in 2018, new HIV infections have been reduced by 16% since 2010 and HIV-related deaths decreased by 45% due to ART and the great efforts of national HIV/AIDS programme.[2-4] In 2014, the United Nations on HIV/AIDS (UNAIDS) declared for achieving “95-95-95” targets for ending HIV/AIDS epidemic at the end of 2030.[5-6]

In Middle East region, although the overall HIV prevalence is still low (<0.1%), but increasing in the annual number of newly identified HIV cases by 28% from 2010-2018, put this region at the top among the different regions of WHO in growing of HIV epidemic and this may be attributed to variation of socio-economic and health system.[1,7-8]

Since the detection of the first case of HIV in 1980s, Iraq is considered a country with a low HIV prevalence in general population (<0.1%) and of a low epidemic level of HIV/AIDS. In 2014, WHO and MOH/Iraq declared that our country will be free from the illness (zero) when new HIV cases were identified in 2012.[9-10] but with time we noticed many new HIV cases were detected which not correspond to the efforts of the MOH in co-ordination and corporation with WHO.

All data regarding HIV/AIDS are under strict of governmental restriction. There is no published research studying the epidemiology of HIV/AIDS in Iraq except one covering the period from 1986-2005. However, epidemiologic data are essential to plan intervention strategies and make them more successful. Therefore such data are needed to highlight the general epidemiological status and trend of the newly identified HIV/AIDS cases in Iraq for the last ten years (2010-2019).

**Materials and Method**

A retrospective study of available data on newly identified Iraqi HIV cases records covering the period from 2010-2019. This study was conducted in Iraq from the period of July 2018 to December 2019. An annual number of newly identified HIV cases had been registered at the Iraqi National AIDS Program Center (INAPC) for the last ten years (2010-2019). All cases were identified according to WHO Case definition of HIV infections through comprehensive medical history, physical examination and laboratory investigations including virologic and serologic testing represented by anti-HIV antibodies which is essential to support the clinical assessment in identification of HIV. Physical examination was used as a tool for classifying the different stages of HIV infections into asymptomatic, mild symptoms, advanced and severe symptoms.

Testing for HIV infection is available in all governmental and non-governmental hospitals and certainty private clinics and labs. HIV infection was diagnosed initially by using ELISA test as screening test, if the test is positive twice time, it should be send to Western blot for confirmation, if it is also positive, it should be send for Polymerase Chain Reaction (PCR) for viral load. Flow-cytometry CD4 count is used to complete follow up of the cases with ART which is free of charge, but it is not available in some Iraqi governorates, and then follow up is recommended by PCR every six months. All these tests are available in Central Health Laboratory in Baghdad/Iraq and also free of charge. All confirmed positive cases are registered and notified to governmental health authorities and through regional HIV/AIDS coordinators to the National HIV/AIDS Program Center.

Data collection was obtained from the records of new HIV case including age, sex, occupation, residence and province, social behavior, educational level, socio-economic status, history of possible routes of HIV transmission regarding type of sexual activity, intravenous drug injection, frequent blood transfusions, surgeries, dental operations, history of prisons, nature of sexual partners, history of condom using and history of ART.

Identification of HIV infections is based on taking mandatory HIV testing for certain groups: suspected HIV patients, contacts of sero-positive persons, blood and organ donation, imprisonment, couples who are planning to marry before marriage, travelers, staff in certain occupations, voluntary testers, illegal drug users, as well as people who have been discovered accidentally when subjected to HIV testing before undergoing surgery or performing major dental operations.

Ethical approval and permission to conduct this work was obtained from Ethical Approval Committee of Al-Anbar University in 23/February/2018, NO.24.

Statistical analysis of available data was performed using Statistical Package for Social Sciences (SPSS) Version 22. For case description; frequencies and percentages were represented in the form of tables and figures. Significance of association between various epidemiological variables was assessed using Chi-square test or Yate’s Corrected test. A P-value ≤0.05 level of significance was used as the criterion for determining statistical significance.

**Results**

A total of 539 new HIV Iraqi cases were recorded at the INAPC during the period from 2010 to 2019, of which, 486 cases are alive and the rest were dead. Their ages ranged from 16-68 years with a mean age 36.8 years. The bulk of the new HIV cases are males (83.5%). There is significant difference between both sexes (P<0.0021) (Figure 1 and table 1).

The current results show increasing in the trend of annual number of new HIV Iraqi cases (total and alive) year by year from 2010 to 2019. The distribution of the cases was ten (1.8%) in 2010, 29 (5.4%) in 2015, reaching to 157 cases (29.1%) in 2019, giving an annual HIV infection growth rate of 14.7%. The difference in the distribution of annual number of new HIV cases was statistically significant (P<0.0001) (Table 1 and Figure 2).
The distribution of HIV cases has an upward trend among both sexes across the last ten years of diagnosis (Table 1). This difference was also statistically significant (P< 0.0021). Figure 2 shows the annual AIDS-related deaths in Iraq during the period 2010-2019. The trend of the annual number of HIV-related deaths has been static (stable) for the last ten years and the annual HIV-related deaths grow at an average of 5.3%.

Table (2) shows that sexuality represents the commonest route of HIV transmission among the new HIV Iraqi cases (74.6%). Blood donation and illegal drug using accounted for 5.2%, and 0.2%, respectively; while none specify accounted 20%, this difference was also of significance (P<0.0001). The bulk of the new HIV cases reported heterosexuals in 85.1%, while 12.2% and 2.7% of the cases reported bisexuals and homosexuals, respectively, with statistically of significant (P<0.0001). (Table 2).

Discussion

Approximately, the Iraq population is 39,585,950 million, which ranks 36th in the world, with an annual population growth rate of >2%.[14] Iraq has previously been considered protective from HIV because of dominant conservative socio-cultural norms concerning behavior habits.[15]

In this study, a total number of new HIV Iraqi cases registered during the last ten years (2010-2019), is double than that reported in the same country from 1986 to 2005[11]. Thus, trend in the annual number of new HIV cases shows a progressive increasing with time and grew with an average rate of 14.7% per year. Our findings are consistent to other studies conducted in the MENA countries; meanwhile, globally, the rate was declined globally by 16% from 2010-2018.[16-19]

These findings indicate that HIV infection is endemic in Iraq and may lead to an epidemic if there is no implementation of proper and effective national plan on HIV infections. Our findings reflect a combination
of HIV patients seeking for ART which is free or from suspected HIV infection or through routinely HIV testing for certain groups and also reflects the effectiveness and activities in implementation of Iraqi National HIV/AIDS Program through performing more routinely HIV testing, counselling services; and could be the result of more acceptability and voluntary seeking of testing among Iraqi people; the more liberal life of Iraqi people after 2010 may participate in the increasing the risk of HIV transmission.

Fortunately, although the number of new HIV illness is increasing with time in Iraq, the prevalence of HIV infections still remains low (<0.1%), and incidence below 3/100,000. This may be related to the religious factor that plays directly on the socio-cultural behaviors of the people living in MENA countries. However, Iraq like other countries in the MENA region that despite of low HIV prevalence, it is considered of increasing concern.[7,16]

In the present study, sexual practices become responsible for the majority of the new HIV Iraqi cases (74.6%), largely through heterosexuals (85.1%), while blood donation was declined to 5.2%, when it was the main route of HIV transmission in the same country during the period from 1986 to 2005 (84.6%).[11] These results are consistent to others.[8,16,22] The introduction of blood screening for HBsAg and prohibition of drug abuse by public authorities in our country contributed for reducing the risk of HIV infections, but after 2010, increasing free liberal life, drug addicts and illegal sex outside the country through their travel, living abroad as refugees in many countries, all these factors collectively may increase risk of exposure to HIV.

There are some limitations in this study leading to underestimation of the true number of new HIV/AIDS cases in Iraq. Registration of data obtained in Iraq are mainly dependent on the activity of National HIV Center which depends on the Central Health Laboratory in Baghdad and other Iraqi governorates, while there are many new HIV cases diagnosed and treated outside this center and/or outside the country while they are living in Iraq. Available data on recorded new HIV cases obtained by routine surveillance does not represent the actual situation. Data collection obtained concerning sexual behavior and illegal drug injections as routes of HIV transmission are more sensitive issues, because of social stigma, so many cases reported none specify (unknown causes) which lead to information bias. There are many HIV cases not recorded because of social stigma and discrimination for both sexes but mainly for women. Another limitation is unavailability of flow cytometry CD4 count in some governorates due to the political instability especially after 2014, which acts as a barrier for studying viral load during ART courses.

**Conclusion**

Iraq still remains an area of low HIV prevalence although the trend of cumulative annual number of new HIV cases increased with time and this may lead to an epidemic/endemic. The trend of annual number of HIV-related deaths has been static for the last ten years. Most of the cases are alive and youth. The epidemiology of HIV illness has been changed with time, sexual behavior, and marital statuses are common among the HIV cases). More work is needed for HIV testing as passive and active HIV surveillance and preventive measures for the people especially the high risk groups.

Evaluation the Effect of *Blastocystis Hominis* to the Levels of Ghrelin, Growth Hormone and Lipoproteins in Sera of Patients with Gastrointestinal Manifestations in Baghdad

Wasnaa Abdulmaged Hasan¹, Aysir Saleh Mohammed Al-Samarrai²

¹Postgraduate, Department of Biology, College of Education, University of Samarra, Salah al-Din, Iraq, ²Assist. Prof. College of Applied Science, University of Samarra, Salah al-Din, Iraq

Abstract
Epidemiological study was conducted to investigate the prevalence of *Blastocystis hominis*, in Baghdad, Iraq, for the period from 1 July 2019 to 31 December 2019. The study included examination of 267 stool samples which collected from patients complained of gastrointestinal manifestations attended to Baghdad Teaching Hospital and Children Protection Teaching Hospital, in addition to examination of 30 blood samples for healthy individuals as a control group. It was found that 60 patients (22.5%) were infected with *Blastocystis hominis*. Also the study included the effect of this parasite on the levels of growth hormone (GH) and ghrelin, in addition to some biochemical parameters in the serum of the infected persons and the control group. These parameters included total serum protein (TSP), albumin, total cholesterol, triglycerides (TG), high-density lipoproteins-cholesterol (HDL-C), low-density lipoproteins-cholesterol (LDL-C), and very low-density lipoproteins (VLDL), and the results showed a significant decrease (P<0.05) in concentrations of ghrelin hormone, albumin, and HDL, while a significant increase (P<0.05) was observed in concentrations of growth hormone, total cholesterol, triglycerides, LDL-C, and VLDL.

Keywords: *Blastocystis hominis*, ghrelin, growth hormone, Lipoproteins.

Introduction
Diseases caused by intestinal parasites are one of the main public health problems around the world¹. *Blastocystis hominis* is considered as the commonest intestinal human protozoan in the world². It is an eukaryotic, single-celled, anaerobic parasite that living in the intestines of human and many animals³. Morphologically, *Blastocystis* is a highly polymorphic organism that takes several different forms during its life cycle including vacuolar, cystic, amoeboid, granular, multivacuolar, and avacuolar forms⁴, it is classified into the Stramenopiles group⁵. Prevalence rate of *B. hominis* infection in the developed countries ranging from 1.5 –10%, where as it is higher in the developing countries ranging from 30 – 60%⁶, and a recent study even showed a prevalence of 100% in a cohort of children living in a rural area of Senegal⁷. Since asymptomatic carriage by *B. hominis* is very common, its role in human health and disease remains uncertain⁸. Intensive molecular studies based on diversity within the nuclear small subunit (SSU) ribosomal RNA gene unveiled as many as 17 *Blastocystis* subtypes (STs), all of which look alike under the microscope⁹. Infection with *B. hominis* may lead to several gastrointestinal symptoms such as abdominal pain, diarrhea, nausea, vomiting, bloating, anorexia, or less commonly dermatological complaints such as urticaria and anal itching¹⁰. Intestinal parasitic infections including *B. hominis* can affect human ghrelin hormone¹¹. Ghrelin (Ghrelin Appetite Hormone) is a 28-aminoacid peptide, was discovered in the stomach as anendogenous ligand for the growth hormone Secretagogue receptor (GHS-R)¹².
Although many studies focused on the effect of intestinal parasitic infections on the growth status in human, growth hormone (GH) levels during intestinal parasitic infections have not been tested to date. Growth hormone is a peptide hormone that is secreted from the anterior pituitary, it has a central function in regulating postnatal growth and metabolism, in addition to exhibiting pleiotropic effects on various human tissues[13].

Intestinal parasitic infections have an effect on the biochemical parameters of the patients, including albumin[14], total cholesterol, triglycerides, HDL-C, LDL-C, and VLDL[11]. This study aimed to investigate the prevalence of Blastocystis hominis in Baghdad city, Iraq, and its effect on ghrelin and growth hormones in addition to some biochemical parameters in the infected patients.

Materials and Method

Study Design: A cross sectional study was performed from 1 July, 2019 to 31 of December, 2019. A total of 267 stool samples and the same number of blood samples were collected from patients complained of gastrointestinal upset, who attended to Baghdad Teaching Hospital and Children Protection Hospital. The samples collected from both sexes of different age groups (2−65 years). Information was taken from each patient based on a questionnaire form.

Microscope Examination: The collected stool samples have been brought and examined under direct microscopy after preparing double wet preparations of 0.85 % NaCl and 1% Lugol’s iodine.

Blood samples, hormonal and biochemical tests: The collected blood samples were placed in tubes containing gel and left to clot for 20 minute at room temperature and then transferred to the centrifuge (3000 rpm) for 5 minutes to obtain the serum. Serum of each patient was placed in three Ependorff tubes by using a pipette and kept in the refrigerator at (−20°C) to be used later for detection of serum levels of ghrelin and growth hormones, in addition to total serum protein (TSP), albumin, and lipid profile including total cholesterol, triglycerides (TG), HDL-C, LDL-C, and VLDL.

Statistical analysis: Results were analyzed statistically using analysis of variance test-ANOVA by using the statistical program Minitab. Averages were compared to calculations of the characteristics of the application Duncan’s Multiple Range Test by probability level P ≤ 0.05.

Results and Discussion

The current study showed that the Blastocystis hominis infection rate was 22.5%, the percentage of females infected was 56.7%, while for males was43.3%. The rate of infection in this study was consistent with many previous studies such as; 24.1% in Baghdad city, Iraq[15], and 22.15% in Al-Sulaimaniyah city, Iraq[16].

Table 1 shows the highest infection rate was with B. hominis only (single infection) by 65%, while the second group, which represented the mixed infections of B. hominis with other intestinal parasites, revealed that the highest rate was with the Entamoeba histolytica by 26.7%, while the lowest was with Giardia lamblia by 8.3%, with statistical significance (P<0.01).

</tbody>
</table>

The results of this study are consistent with the result of previous studies in Samarra city, Iraq[17], Indonesia[18], and Egypt[19].

Hormonal Parameters: Table 2 shows the results of ghrelin and growth hormones (GH) for patient samples infected with Blastocystis hominis compared to the control group. The serum levels of ghrelin hormone were found to be significantly reduced in the patients compared with the control group, the results of this study are consistent with the results of studies in Turkey[11], and Spain, which showed that there is a decrease in serum ghrelin levels in patients complaining of Helicobacter pylori infection associated with intestinal parasitic infections including B. hominis[20].

The low levels of ghrelin in people with intestinal parasitic infections, including B. hominis, may be due to inflammation of the intestinal mucosa, affecting the hormone secretion process that mainly occurs in the stomach and small intestine[21].
Studies have not been yet examined the levels of serum growth hormone during the intestinal parasitic infections, despite that the current study recorded a significant increase in levels of growth hormone in the serum of the patients infected with *Blastocystis* in comparison with the control group. The increase in levels of growth hormone in these patients may be due to the stress condition caused by the inflammatory process in repose to *Blastocystis* infection, because this hormone is one of the stress hormones[22].

**Biochemical parameters:** Table 3 shows the results of serum albumin and lipid profile including total cholesterol, triglycerides, HDL-C, LDL-C, and VLDL for patient samples infected with *Blastocystis hominis*. The serum albumin levels were found to be significantly reduced in these patients compared with the control group, the results of this study are consistent with the results of a study in Poland, which showed that there is a decrease in serum albumin levels in patients complaining of acquired immunodeficiency syndrome (AIDS) associated with *Blastocystis hominis* infection[14].

This decrease in the serum albumin levels in the infected individuals could be caused by an acute intestinal infection and diarrhea caused by the parasitic infection resulting in malnutrition and malabsorption[23].

The serum levels of total cholesterol, triglycerides, LDL-C, and VLDL were found to be significantly increased in patients with *B. hominis* infection, while HDL-C levels have been reduced in these patients compared with the control group, the results of the current study are consistent with the results of a previous study that showed an increase in serum levels of cholesterol, triglyceride, and LDL-C with reduction in serum HDL-C levels in patients with *B. hominis* infection[11], and also there is another study recorded an increase in serum cholesterol and VLDL levels with decreased serum HDL-C levels in patients with *B. hominis* infection[24].

The increase in the levels of serum lipids in patients with *B. hominis* infection may be due to the ability of this parasite to produce lipids, as some laboratory studies have shown that axenic strains of *B. hominis* appeared to be surrounded by lipid droplets inside the culture medium. It is also noted that these strains contain a spectrum of phospholipids and neutral lipids that are similar to the lipids found in the animal cells, which proves that the parasite produces the lipids by itself, and these lipids include triacylglycerol and diacylglycerol, in addition to all of the phospholipids that enter in the parasite composition[25].

Conclusion

Infection with *B. hominis* causes a highly significant increase in the serum concentrations of growth hormone, whereas causing a significant decrease in serum ghrelin concentrations and clear effect on some biochemical parameters in the infected individuals, including total cholesterol, triglycerides, LDL-C, and VLDL which appeared to be significantly increased with reducing the level of serum albumin and HDL-C levels.

Abstract

Curcumin, the active ingredient of turmeric, is well known for its broad biological effects. Exhaustive studies on curcumin conducted to revealed its antioxidant, antimicrobial, anti-inflammatory, anticarcinogenic and anti-coagulant activity. The current study was executed to investigate the effect of curcumin on histological and physiological aspects of liver, pancreas and kidney. A total one hundred fifty of chick meat of hybrids Ross 308 (1st day old) were randomly subdivided into two groups: group I (controlled), (n=75) and group II, treated birds (n=75). Group II feed with 50 mg/100kg diet of curcumin. Samples of blood were taken from 50 of chick meat per group to estimate blood parameters. Twenty five chick meat per each group were scarified after forty nine days of feeding with curcumin, the pancreas, liver & kidney were removed for histological processing. After the long-term physiological analysis of our study, results indicated the turmeric is anti-inflammatory and antioxidant properties can scavenge oxygen free radicals, alleviation of fat peroxidation by minimized the levels of liver enzymes ALT, AST and ALP at the level 0.5 of (Curcuma longa). Histologically, the results of this study revealed that employing of curcumin contribute in an improvement of the microscopical architecture of the target organs.

Keywords: Histology, physiology, Curcumin, liver, pancreas, kidney.

Introduction

Curcuma Longa Linn (Turmeric), consider as an important medical herb, Curcumin, a hydrophobic polyphenol extracted from the rhizomes part of curcuma longa, biologically and pharmacologically, curcumin has broad effects and features, in addition to curcumin, this herb contains also bisdemethoxycurcumin, demethoxycurcumin and tetrahydrocurcuminoids. A previous studies and researches provided different evidences indicated that the supplementary diet with curcumin have a potent impact on many biological aspects. Curcumin has been considered as an anti-inflammatory agent, anti-microbial, anti-carcinogenic, antioxidant in addition to its influence as a hepato and nephron-protective, suppressing of thrombosis and myocardial infarction protective.

¹³Evaluated the effects of curcumin on the Zymosan-induced arthritis (acute phase), they showed that the administration of curcumin through the oral cavity minimized the inflammatory influence of this disorder.

Numerous studies improved the anti-inflammatory activity of curcumin, it can be an effectual constituent in treatment of numerous diseases related to the inflammation with its capacity as multi-target and high pharmalogical safety. Recent studies reported the beneficial aspect of curcumin in the field of immunity, that it reinforced innate immunity and induced a large protective immunity.

Curcumin considered as a feed-additives, used in nutrition of animals in order to meliorates the
Qualitatively of food animal origin and to augment the rendering and corroborate of animals. It has also a powerful impact against diabetic cells injury that induced in both pancreas and liver of albino rats. The present study was designed to determine the effect of curcumin on the histological and physiological aspects of three important organs (liver, pancreas, and kidney) and aspects of blood parameters.

Materials and Method

Experimental Animals: This study was conducted at Agriculture College/University of Karbala, according to the criteria and rules of animal care. Total number of animals (150) Ross broiler (age: 1st day) were divided into two groups: group I: control (n=75) and group II treated animals (n=75). The sample of curcumin powder was supplied from the local market. The chick meat of control group were feeding with normal diet, while these of group II were feeding basal diet intermeshed with curcumin powder (50mg/100kg of diet). All animals of groups were chicken sheds with the same conditions (feeding libitum and water).

Analysis of Blood (parameters): Samples of blood (3 ml) were collected from 50 birds or animals (randomly selected) into tubes contained non heparins, from the brachial vein used centrifuge at 3000 rpm for 15 minutes and the serum was kept at a hot temperature -20°C, for the purpose of conducting biochemical analyzes, which are estimated using several (kits). Alanine amino transferase and aspartate amino transferase were found out on the authority of 5. The globulin value for each sample was evaluated by throw away the albumin value from the corresponding overall protein value. The Albumin/Globulin proportion for each sample was acquired by dividing the albumin level to globulin level. Serum total protein was estimated corresponding to 7. Serum glucose was predestined as accordingly to enzymatic colorimetric analysis by 15. Serum total cholesterol was evaluated correspond to 9. Serum creatinine was implement that being the case method of Jaffe 6. So statistical analysis was performed using the complete randomized design (CRD), and t-test of inferential statistic Spss software (version 23) to determine if there is a significant difference between two groups.

Sampling of tissues and Histological Preparation: At the end of the experiment, 25 birds from each group were killed for histological investigation of pancreas, liver & kidney. The specimens of tissue (2 cm) were randomly sampled from different points of previous organs, the specimens were flushed by normal saline 10% and then fixed in Bouins solution for 24 hours. The processing of tissue including serial steps of dehydration (socked specimens were rinsed twice in 100 % alcohol), clearing in xylen, infiltrating and embedding in paraffin and then in paraffin blocks were making. The thickness of histological sections were harvested between 5 um to 7 um by microtome. Five cross sections were randomly taken from each block and were adheres on slides and then complete histological processing by staining step in routine stains of hematoxylin and eosin 4, eventually sections were examined under light microscope and photomicrograph were taken by camera of Hawawi G7.

Results

Histological Results: Histological processing and examination of liver, pancreas, and kidney was done to clarify the effects of curcumin on the normal architecture of these organs. The histological sections of liver, kidney and pancreas from control group (group I) exhibit normal texture and appearance (fig.1-A, fig.2-A, fig.3-A). The histology of liver showed typically appearance of hexagonal lobules with central vein and normal narrow regulating sinusoidal capillaries, normal hepatocytes, lining endothelium of sinusoids and kuppfer cells in addition to the presence of portal areas embedded within the parenchyma (fig.1 A,B). Whereas the results of liver of group II, in general, showed slightly improvement in histological appearance including: more regulated morphological plane and outline of hepatic cells and cords, increased of density of binucleated hepatocytes, more regular hepatic capillaries, endothelial cells that lining sinusoids and kuppfer cells in addition to the presence of portal areas embedded in the parenchyma (fig.1 A,B).

Histological processing and examination of liver, pancreas, and kidney was done to clarify the effects of curcumin on the normal architecture of these organs. The histological sections of liver, kidney and pancreas from control group (group I) exhibit normal texture and appearance (fig.1-A, fig.2-A, fig.3-A). The histology of liver showed typically appearance of hexagonal lobules with central vein and normal narrow regulating sinusoidal capillaries, normal hepatocytes, lining endothelium of sinusoids and kuppfer cells in addition to the presence of portal areas embedded within the parenchyma (fig.1 A,B). Whereas the results of liver of group II, in general, showed slightly improvement in histological appearance including: more regulated morphological plane and outline of hepatic cells and cords, increased of density of binucleated hepatocytes, more regular hepatic capillaries, endothelial cells that lining sinusoids and kuppfer cells in addition to the presence of portal areas embedded in the parenchyma (fig.1 A,B). Light microscopy of pancreas from group (I) revealed normal structure, the appearance of islets of Langerhans cells showed typical histological characteristic features (fig.2-A), and those of group II, exhibit an improvements in the components of tissue including: more regularity in the pancreatic acini and hypercellularity of pancreatic islets especially β-cells (fig. 2-B,C, D,E,F).

Fig. (2): Photomicrograph illustrated the histological structural appearance of pancreas (group I & II), IL: islets of Langerhans, AC: acini, Sp: septa, Blue star: β-cells. H & E, x: 10,40

The architecture of pancreas appear to subdivided into lobules separated by slight septa, closely filled with a purple acini. The cells of acini seems to be pyramidal in shape with rounded nuclei lie at the base of the cells (fig. 2-A).

The results of microscopical histological sections of kidney of group I showed normal appearance of renal tissue including: normal histological architecture of renal corpuscles, normal space between glomeruli and capsule and regularity of renal tubules with their epithelial lining (fig. 3-A). The results of treated group revealed developing in the size and morphology of Bouman’s corpuscles, the cuboidal and columnar epithelial that lining the renal tubules appear more developed and the space that separated the capsule from the glomeruli seems more obvious (fig. 3-A).
**Physiological Results:** Table (1) shows groups of Turmeric powder 0.5% had no significant differences in values of globulins and glucose compared with control group. On the other hand, significant differences of ALP, ALT, AST, CHOL and creatinine in Ross strain of broiler birds.

**Discussion**

The liver and kidney play an essential role in an excretion and elimination of undesirable materials away from the body, on the other hand, the pancreas considered as an important player in regulation the metabolism process of micronutrients, the current study focused on impact of curcumin on histological structure and physiological aspects of these important organs. Turmeric considered as a populist for centuries in medicines of herbs in treated of different diseases including: diabetic ulcers, anorexia, rheumatism, cough & sinusitis, the curcumin represented the chief curcuminoid components in turmeric responsibly for yellowish colour, it has been found to possess a broad spectrum of therapeutic activities including: antioxidant, anti-inflammatory, anticarcinogenic, anticoagulant, anti-mutagenic and anti-infectious effects.\(^1\)
The predictable alterations in physiology of normal investigated organs after the administration of curcumin have limited accessible informations about the histological and morphological alterations of these organs, therefore, our study conducted on these microscopical changes that expected to be take place parallel to physiological aspects.

The histological findings of liver revealed the preservation of lobular morphology with apparent improvement in the microscopical appearance of the cells and sinusoids capillaries of liver.

Beneficial effects of turmeric have been reported to be associated with stimulation of bile production in the liver of broiler chickens.

There is a recommendation for using turmeric as a feed additive for patients with fatty liver or those who had family history with hyperlipidemic.

The using of turmeric might be beneficial in preventing the fibrosis and ameliorated cirrhosis of liver throughout its anti-inflammatory effect and activity of suppression HSC establishing the hepatoprotectivity of curcumin.

Results of the present work indicated that the histological sections of pancreas for animals of group I and group II showed apparent histological alterations in their tissues that were found to be consistent with that of previous studies.

Summarized the effect of curcumin on pancreatic tissue, depending on previous studies “the pancreatic islets were found to be protected morphologically thanks to the treatment with plant extracts especially the turmeric”.

Our histological achievements of kidney; changes of glomeruli and their number; epithelium cells of glomeruli; interstitial connective tissue and lining epithelia of tubules, all of these aspects are among the reported alterations within the tissue of kidney group II. Curcumin has remarkably take part in the reduction of damage in renal morphological and histopathological characters of an inflammation, apoptosis and fibrosis, furthermore, exhibits reducing of oxidative stress.

Demonstrated that turmeric improved the function of kidney as well as microscopical alteration by alleviating the degeneration and necrosis of tubular lining epithelium, and repairing of tissue or generation of “Islets of Langerhans” in diabetes revealed the beneficial effect of homeostatis in addition to suppression the damage of liver.

Our finding shows that the groups of Turmeric powder 0.5% had no significant differences in values of globulins and glucose compared with control group. On the other hand, significant differences of ALP, ALT, AST, CHOL and creatinine in Ross strain of broiler birds.

Curcuma can scavenge oxygen free radicals like superoxide anions and hydroxyl radicals which play an important role in alleviation of fat peroxidation, by keeping the effectiveness of antioxidant enzymes (superoxide dismutase, catalase and glutathione peroxidase), that enzymes play a substantial role in organizing of lipid peroxidation. The use of Turmeric powder in poultry diets may be decrease the incidence of inflammation and damage cells of organs especially liver and kidney that may minimized the levels of liver enzymes ALT, AST and ALP. The findings of this study are in agreement with who reported the significant increase in performance parameters due to optimum antioxidant efficiency of turmeric (Curcuma longa) and Cinnamon at the level of 0.5% that catalyze protein synthesis by chicken enzymatic system.

 showed that the curcumin exhibits impact of renoprotective by inhibition accumulation of renal lipid and oxidative stress.

Recent studies suggested that curcumin encapsulated chitosan can obviously enhance effect of protection on damages in kidney and heart in diabetes.

A study has indicated that turmeric powder might have therapeutic activity such as anti-inflammatory and antioxidant properties like the anther plant, herbs, and their extract are an alternative to antibiotics.

In conclusion, the histological outcomes of this study of treated animals referred that the administration of curcumin was found to be altered and improved for different levels, the histological architecture of liver, pancreas, and kidney when compared with the control group. These finding comes compatible with that of physiological one.

Backache among Different Specialties in Dentistry (An Over World Survey)

Mohammad Munthir Abdulrazzaq
Ph.D Operative Dentistry, Al-Iraqia University, College of Dentistry, Iraq

Abstract

Aim of the Study: The purpose of this study is to determine the prevalence of backache among dentists in different countries, as well as to discover the possible correlation of this prevalence with age, gender, specialty, working posture and how to reduce this prevalence.

Materials and Method: The study was conducted among 600 dentists (359 male and 241 female). Dentists were evaluated with the special self-administered questionnaire (SAQ), for geographic distribution, prevalence of ache and its correlation to different variables in this study.

Results: The outcome of statistics showed a 44.7% incidence of backache among dentists, with the ratio of 51% of Males, and 35.3% of females, with the most incidence of presence of pain over the age of 40s.

Conclusion: Dentists worldwide demonstrate a moderate prevalence of low back pain, with the most incidence of lumber back ache by 50.4%, with correlation to specialty and working position and the geographic distribution.

Keywords: Dentist, Backache; Health care; prevalence; genders.

Introduction

Dentists are at high risk for back ache, working position, recurrent work, and long standing, can result in harm to muscles, joints, bones, ligaments, tendons, nerves, and blood vessels, which can then lead to pain(1). Back pain is the most frequent complaint, and almost all dentists worldwide have experienced this during their work(2).

As dentists use prolonged sitting and standing positions during their job, apply awkward posture and repetitive movements, many loads are exerted to the spine, it is believed that the higher muscular demand may lead to fatigue and consequently increase the risk of back pain(3,4).

In a systematic review, it was reported that the prevalence of general back pain ranges between 64% and 93%, and the most prevalent regions for pain in dentists have been shown to be the back (36.3-60.1%) (5). However, despite technical advances, dentists worldwide and particularly in the Middle East are still at higher risk of developing back pain(6,7).

Different preventive measures can be taken to minimize such pain, such as stretching before work, taking a break in the middle of the work time, performing procedures with good sitting posture, and reducing repetitive motion. However, many other factors may still be associated with this defect, the literature suggests other associated factors are age of the dentist, and type of cases handled(8,9).

Aim of the study: The purpose of this study is to investigate the risk factors, prevalence, and association of physical load and general health status with the onset of backache. Additionally, we aim to determine the dentist’s characteristics, such as age, sex, specialty, country, and working position.

Materials and Method

Study design and data collection: The sample of this study consisted of (600) dentists randomly taken from (23) countries over the world. The study was conducted electronically, and the questionnaires were filled and returned to us directly online by Google forms and data were collected directly by sheet forms.
The questionnaire (figure 1) consists of many steps: the first step is the personal information (Age, Country, Sex, Specialty including: Surgery, Prosthodontics, Periodontics, Conservative, Endodontics, Orthodontics, Oral medicine, Pedodontics, Prevention, General Practitioner). The second step consists of questions related to back pain: if the dentist complains of back pain, site of pain, if the dentist attends for treatment, if gets better after treatment. The final step is the question about position during working this includes: Standing, Sitting, and combination.

1- Age
2- Country
3- Sex
   - Male
   - Female
4- Specialty
   - Surgery
   - Prosthodontics
   - Periodontics
   - Conservative
   - Endodontics
   - Orthodontics
   - Oral medicine
   - Pedodontics
   - Prevention
   - General practitioner

5- Do you complain of back pain?
   - Yes
   - No

6- Site of pain
   - Cervical
   - Thoracic
   - Lumbar
   - Sacral

7- Do you attend for treatment?
   - Yes
   - No

8- Do you get better after treatment?
   - Yes
   - No

9- Your position during working
   - Standing
   - Sitting
   - Combination

Figure 1. The questions that were applied in the self-administrative questionnaire. (SAQ)

Data Analysis: The data were analyzed using IBM SPSS V24, and Microsoft Excel 2019. Two main statistical method are used in the questionnaire data analysis: descriptive statistics, which summarize data from a sample using frequencies and percentages and cross tabulation. Besides, Inferential statistics represented by Chi square test of association were used. To examine the degree of significance and probability values less than 0.05 were considered significantly different, (*, **, *** represent p-value less than 0.05, 0.01, and 0.001 respectively).

Results

Data analysis of this study showed that there’s average age groups as shown in table 1; in which the percentage of age group 20-29 was 11.3 and 30-39 was 41.7 and 40-49 was 29.3 and 50-59 was 16.3, and 60 years and more was 1.3 and in the same table there’s the gender distribution of: male 59.8%, and female 40.2%, and the distribution of specialties.

The frequency of the presence of pain where shown in table 2, and also the sites of pain, showing percentage of those who have pain to attend treatment, percentage of type of treatment (i.e. medicine, exercises, or combination), and further represents percentage of getting better after treatment, and finally prescribes percentage of working positions in which 10.5% standing, 46.3% sitting, and 43.2% combination type of work. Finally, the frequencies of samples between the 23 countries were shown in table 5.

<sup>a</sup>Chi square test were used, N.S, **, ***: Not significant, highly significant (P<0.01), Very high significant (P<0.001)

Then after application of statistics, we concluded that P-value of gender to complain of back pain was 0.001, that means there’s a very high significant difference, as the male have high incidence than female.

In table 3 we observe that there’s a very high relation between age groups and pain, as the pain incidence is more in age of 40s and more, also we conclude that there’s a relation between gender and site of pain. And about the relation of age groups to the site of back pain, we found a very high relation especially for cervical and sacral region. In Table 3 also shows relation of specialties to the site of back pain, there’s a very high significant relation, for example: in conservative the more incidence in lumber region, while in orthodontics in cervical. It was found that there’s a very high significant relation of age groups to the working positions, as there’s more standing position with old ages and more sitting in younger ages. Also, there’s a very high significant relation between specialties to the working positions, as shown in Table 4, for example, in surgery there’s a greater number of standing and combination position, while in endodontics there’s is obvious number of sitting positions. We observe a very significant relation of gender to the working positions, for example the number of standing is higher in males than females.

Concerning the relation of countries to the presence of back pain, Table 5 shows that there’s a very high significant relation, for example in Belgium, England, Italy, and Turkey the responses of (no pain) are higher, while in Iraq, India, and Egypt the responses of (yes there’s pain) are higher.

**Discussion**

The review of the backache of dental operator, indicates that strategies to prevent the multifactorial problem, These strategies address deficiencies in operator position, posture, flexibility, strength and ergonomics. Education and additional research are needed to promote an understanding of the complexity of the problem and to address the problem’s multifactorial nature.\(^{10}\)

In the present study, the main variable we concentrate on was the geographic distribution, in addition to other variables which includes: (age, gender, specialty, position during work), our results agreed with the results of Külcü D et Al\(^1\), were they concluded that the Working duration and posture have important influences on backache in dentistry, and also agreed with Gaowgzeh RA h et al\(^{12}\).

Our study disagreed with Jabbar T.\(^{13}\), who concluded that: Younger dentists had more symptoms than the older dentists. The female dentists had a significantly higher frequency of pain; this disagreement may be due to limitations of his study by number and method of sample selection.

Concerning the relation of back pain with the different specialties in dental field, our study agrees with the Al-Rawi N. et al \(^{14}\), who concluded that the incidence of back pain is related to specialty.

The most important factor in this study is the good number of the sample (and there demographic distribution), while other studies were done locally in some countries Shaik A. \(^{15}\), that’s why it’s not available to compare with other study from this aspect.

When we do an overall review of the studies in this field Vijay S. & Ide M.\(^{16}\), we can easily observe that: within the introduction of time, there’s a general decrease in number of dentists complaining of back pain Regina P. Ford\(^{17}\), (that’s mean comparing to nowadays results of studies), but still we need continuous and meaningful efforts for education of dental students and newly graduated dentist, to ensure good results for our profession in the future.

**Conclusion**

As a result of this study, and within its limitation, we can conclude that there’s a significant relation between back pain of dentists (and its location), with age sex, specialty, and demographic distribution, and it is important for all dentists to follow the correct principles of proper sitting and working to minimize the risk of loss of occupation due to back pain.

**Stye, Bacterial Eye Infection among the Students of the Technical Medical Institute, AL-Mansour**

Mohammed Abed Jawad¹, Taghreed Khudhur Mohammed²

¹Ass. Lecturer, Clinical Laboratory Techniques, Al-Nosor University, Baghdad, Iraq,
²Professor, Institute of Medical Technology, Al-Mansour, The Middle Technical University, Baghdad, Iraq

**Abstract**

**Background:** Eye stye is a local infection in the form of a red bump (a boil) caused by a blockage and inflammation of the sebaceous glands whose secretions help to form tears. Approximately 90-95% of the causes of “stye” is an infection with *Staphylococcus aureus*, and it is possible that malnutrition and lack of sleep contribute to the infection as well.

**Method:** The study was done at Institute of Medical Technology/al–Mansour/Baghdad from January 2018 till January of 2019. 100 conjunctiva eyes swab and Stye swab samples were collected from students suffered from eye redness and conjunctiva, which include 50 male and 50 female. The diagnoses of specimens were done by using the Analytical Profile Index System (API) for chemical tests and by culturing on enriched and selective culture media to isolate and diagnose the bacteria.

**Results:** The results showed that 57(57%) samples were positive for bacterial eye infections. The study showed high percentage of eye infection among students was due to *Staphylococcus aureus* bacteria, followed by *Staphylococcus epidermides* and *Pseudomonas aeruginosa* (61.40%, 35.08% and 3.50% respectively). Most of bacterial isolates were resistance to antibiotics.

**Conclusion:** One of the most important conclusions is to go to the doctor or pharmacist to treat eye inflammation to avoid the occurrence of eye pain, burning and redness, and not to repeat the infection. Personal and general hygiene must also be taken care of to reduce the spread of bacteria that cause eye infections among people.

**Keywords:** Bacterial conjunctivitis, *Staphylococcus aureus*, Stye, Hordeolum.

**Introduction**

Hordeolum or Stye is an acute bacterial infection that occurs in the covering of the eye or eyelid. This infection is a common condition among Iraqi school and university students, and patients are often directed to go to a university doctor or health care center for diagnosis and treatment. The patient suffers from painful eye inflammation with redness and swelling of the eyelid. Swelling may form on the outer eyelid or on the inner eyelid. This condition usually lasts one to two weeks, and is usually self-healing. It can be treated with warm compresses, massage therapy and some eye ointments¹. 

The doctor may treat a person with a stye by taking topical antibiotics, and in other cases, the removal of the stye may require surgical intervention. All age groups are affected by the infection, although there is a slight increase in the incidence rate among patients between the ages of 30 and 50 years, and with this, the infection may spread within the age groups between 5-20 years. Several researchers have found that there are no significant differences in the prevalence between populations around the world. And most patients who suffer from chronic conditions such as dermatitis, diabetes, high blood fats
(such as cholesterol) and a large number of fast foods, pickles and sugars may be the cause of the spread of infection[2]. Eye begging or humping eyes are the names for furunculosis, or stye, in Latin. It is an inflammation of the sebaceous gland on the eyelid and the sweat glands known as the mole gland[3]. The lesion appears as a small, swollen, red lump containing pus[4]. The Stye of the eye are similar to the sebaceous cyst, but it is smaller and more painful. Usually the infection is acute. Its duration is (7-10) days without treatment. The sebaceous cyst is a chronic infection and it is one of the infections that can only be treated with surgical intervention [5]. One of the most important causes of Stye infection is the bacterial infection by *Staphylococcus aureus* for the meibomian glands (the eyelid gland, which is one of the sebaceous glands located in the eyelid, its secretions prevent eyelids from sticking together) which increase concurrently with poor nutrition, lack of sleep, poor personal and general hygiene, scrubbing the eyes with contaminated hands and the use of contaminated devices such as contaminated towels[4and5]. *Staphylococcus aureus* causes severe infections between 90% and 95% compared to other bacterial species such as *Pseudomonas aeruginosa, Haemophilus influenzae* and *Chlamydia trachomatis*[6].

There are a number of research studies on stye in Iraq and most of them were in primary schools, but there is no study of a stye prevalence among students of the Medical Technical Institute/Al-Mansour. So, the aims of the current study are isolation and diagnosis of *Staphylococcus aureus, Staphylococcus epidermidis,* and *Pseudomonas aeruginosa* causing eyelid inflammation from students of the Medical Technical Institute/Al-Mansour' Baghdad.

**Materials and Method**

**Samples collection and culturing on Enriched and selective culture media:** 100 swabs (50 females and 50 males) were collected from students of the Medical Technical Institute/Al-Mansour, who suffer from Eyelid inflammation, swelling, localized eyelid pain, redness, itching, blurred vision, falling eyes and increased tear secretion. The samples collected during the period from January 2018 to January 2019. Their ages ranged between (19-25) years. All swabs were cultured in a streaking manner on the MacConkey agar, Blood agar and Chocolate agar (Oxoid™ Company, UK) and by two Petri dishes of each type of culture medium for each swab. The dishes were incubated at 37°C for 18-24 hours. The first group of plates was incubated in aerobic conditions, the second group in anaerobic conditions.

**Diagnosis of *Staphylococcus aureus***:

1. The culture characteristics were studied in the culture media, and the shape and aggregation of the bacteria were studied under light microscope using the Gram stain [7].
2. Biochemical tests (oxidase, catalase and coagulase) were performed. Mannitol fermentation using the Mannitol salt agar medium was done [8]. [bioMérieux, France] API Staphylococcus kits were used to diagnose *Staphylococcus aureus*.

**Diagnosis of *Streptococcus pyogenes***:

1. The culture characteristics were studied in the culture media, and the shape and aggregation of the bacteria were studied under light microscope using the Gram stain [7].
2. Biochemical tests were performed using the API *Streptococcus* [bioMérieux, France] to diagnose species belonging to the genus *Streptococcus*.

**Diagnosis of Enterobacteriaceae (Gram-negative bacteria):**

1. The culture characteristics were studied in the culture media, and the shape and aggregation of the bacteria were studied under light microscope using the Gram stain [7].
2. Biochemical tests were performed using the API20 [bioMérieux, France] to diagnose species belonging to the Enterobacteriaceae.

**Antibiotic sensitivity test (disc diffusion method)[8]:** Six antibiotics were used: (Cephalexin (LEX), Cefotaxime (CTX), Chloramphenicol (C), Gentamicin (GM), Tetracycline (TE), Erythromycin(E) (Hi Media Laboratories, India antibiotic discs). Antibiotic sensitivity was determined by measuring the antibacterial inhibition diameter of bacterial isolates on the Muller Hinton agar and comparing it with the index numbers established in the Committee of National Clinical Laboratory Standards (NCCLS)[9].

**Results**

100 samples were collected from students of the Medical Technical Institute/Al-Mansour who were apparently infected with eyelid inflammation and whose ages ranged between (19-25) years and for both sexes (50 females and 50 males) during the period between January 2018 until January 2019. The results showed that 57 samples gave a positive result for bacterial growth on
the enriched and selective culture media, with a range (57%, 57/100X100) of the total number of samples. Bacterial isolates were isolated and diagnosed based on [8-11]. As its cultural and phenotypic properties were studied; the shape and aggregation of bacteria under the light microscope were identified after stained with Gram stain and examined under the X 100. After that, the bacteria were diagnosed using biochemical tests. The results showed the following:

*Staphylococcus aureus* gave white colonies with beta-type hemolysis on Blood agar. Positive for coagulase and mannitol fermentation. *Staphylococcus epidermides* had white colonies without haemolysis on Blood agar, positive for catalase, and negative for coagulase and mannitol fermentation. The colonies of *Pseudomonas aeruginosa* appeared gray on blood agar, pale yellow and non-fermenting lactose sugar on MacConkey agar; positive for oxidase test and negative for urease test and indole production.

The highest percentage of eye infection among students was due to *Staphylococcus aureus* bacteria (61.40%) (Table 1) and this is close to what Al-Abidi isolated in 2006, which was 52.4% for patients suffering from eyelid inflammation in the province of Diwaniyah [12]. Likewise, an approach to the Alash study in 2015, which was 31%, and the current study did not agree with the results of the same researcher’s findings for *Staphylococcus epidermides* and *Pseudomonas aeruginosa*, as the ratio was 10 (35%) and 7 (24%), respectively [13]. The infection of *Staphylococcus epidermides* and *Pseudomonas aeruginosa* among Institute students was 35.08% and 3.50%. The results of current study also did not match the results of the researcher Al-Abidi for *Staphylococcus epidermides* and *Pseudomonas aeruginosa*, which were 7.3% and 14.6%, respectively. The researchers, Thewaini and Abed-Al sahib, concluded in 2014 [14] that the percentage of bacterial infections with eye inflammation after collecting 101 swabs from the eyes of patients who visited Al-Hussein General Hospital and the Hindia Hospital at Karbala in Iraq was 93%, distributed as follows (conjunctivitis eye 2.78 %, Ocular eyelid infections 8.13% and tear sac infections, 9.7%). The results of culturing on enriched and differential culture media showed that the percentage of *Staphylococcus aureus* in both sexes is the most common cause. As for AL-ALani and others [15], their study included isolating and diagnosing the bacteria that cause eye infection in university students who use contact lenses and eyeliner, whose ages ranged between (19-26) years at Al-Anbar University during 2009. The incidence of Staphylococci bacteria was 83.32%, and *Pseudomonas aeruginosa*, 67.16%. Also, they found that the sensitivity to antibiotics was 5.69% for Erythromycin, 52% for Gentamycin, and 8.47% for Tetracycline. While recorded the highest resistance to the antibiotic Penicillin, which was 93.6%, followed by Cephalexin with 93.6%, this may be due to the wrong and excessive use of these antibiotics by patients as well as their use of these antibiotics without consulting a specialist doctor.

The results of the current study showed that the incidence of *Staphylococcus aureus* in females was more than males, it was 55.55% and 64.10%, respectively. Whereas, the infection rate of *Staphylococcus epidermides* and *Pseudomonas aeruginosa* was almost identical for males and females (Table 2).

Table 2: Percentage of bacterial isolates from patients with eyelid inflammation according to sex

</tr>
</tbody>
</table>
The results showed sensitivity to antibiotics Cephalexin (LEX), Cefotaxime (CTX), Chloramphenicol (C), Gentamicin (GM), Tetracycline (TE), Erythromycin (E) as follows:

- **Staphylococcus aureus**: 17.14% sensitive to CTX, LEX, E and C antibiotics; And it is sensitive to 51.42% to GM antibiotic and 5.71% to TE.
- **Staphylococcus epidermidis**: 17.14% sensitive to CTX, LEX, E and C antibiotics; And it is sensitive to 51.42% to GM antibiotic and 5.71% to TE.
- **Pseudomonasaeruginosa**: The resistance rate was 100% for all antibiotics under study.

The researchers Al-Dorri and Al-jebouri[16] were found that the causes of conjunctivitis and eyes redness in Tikrit General Hospital patients in 2004 were result from **Staphylococcus aureus**, **Streptococcus pneumoniae** and **Staphylococcus epidermidis** infection in percentages 42%, 27% and 12%, respectively. Also, they were found that the isolates had the highest sensitivity to the antibiotic norfloxacin. The current study did not agree with the researchers 'study in relation to gender. The researchers found that the percentage of infection with the bacteria that cause eye inflammation was higher in men than it is in women, as it was 55% and 45%, respectively. In Babil Governorate, the researchers Abid and Ewadh[17] found that bacterial etiology of eye inflammation, eyelid and tear cyst inflammation in patients reviewing a number of Hilla hospitals in 2012 was represented by a high incidence of **Staphylococcus aureus** followed by **Escherichia coli** with a percentage of 38.06% and 2.7% Respectively. As the patients suffer from the appearance of a point tending to yellow in the middle of the eye and then it turns into pus and spreads slightly to the surrounding area.

The bacteria that cause eye inflammation can be easily transmitted from one person to another when using contaminated towels. So, hands should always be washed with water, soap, sterilizers, and wash the face frequently; in addition to not use contact lenses until they are completely cured, and not wearing glasses between people or wearing contact lenses or put contaminated eye makeup, and it is also recommended to remove makeup before bed. Azithromycin eye drops can be used after consulting a doctor or pharmacist as a topical treatment, in order to avoid some complications such as bleeding from the eyelids or when the vision is not clear. In addition, students and their supervisors in colleges and institutes should be advised to follow the aforementioned advice in order to prevent the transmission of infections among the students. Sometimes it may be necessary to keep students in their homes to avoid transmitting the infection to colleagues[18].

Abstract

Background: Good blood flow within uterine arteries and endometrium is important for implantation this study was conducted to determine the role of Doppler indices in prediction of pregnancy outcome during evaluation of ICSI women .Material and Method: It was case control study. 60 infertile women were included in the study and prepared for IVF-ET/ICSI, . All the patients underwent controlled ovarian stimulation, and evaluated by Transvaginal ultrasound and measurements performed on day oocyte retrieval and on day embryo transfer. Assessment of endometrial thickness, pattern and grade of vascularity zones, peak systolic velocity (PSV), end diastolic velocity (EDV), systolic/diastolic ratio, resistance index (RI), and pulsatility index for both uterine arteries and endometrial vessels.

Result: 30 women are pregnant and 30 women, there was significant differences at a cut value of endometrial thickness of ≥ 8 mm between pregnant and non pregnant groups(27 (90 %) versus 20 (66.7 %) with 0.015 p value at day of oocyte retrieval and (27 (90 %) versus 20 (66.7 %) with P value of 0.28 at day of embryo transfer), pregnant women are limited to zone II and III with mainly zone III while non pregnant are mainly zone II. four cases has absent endometrial vascularity at day of embryo transfer, no one of them get pregnancy, there is significant difference in day of embryo transfer regarding endometrial RI being lower in pregnant. Significant differences in uterine PSV and high significant difference in uterine EDV at embryo transfer day.

Conclusion: Endometrial thickness of 8 mm., with vascularity zone III at day of oocyte retrieval and embryo transfer are significant for positive pregnancy outcome, absent endometrial and sub endometrial vascularity at day of embryo transfer predict poor outcome of pregnancy .

Keywords: Doppler indices, uterine blood flow ,endometrial vascularity.

Introduction

In vitro Fertilization and Embryo Transfer (IVF-ET) were currently the most selective and readily available management method for treatment of infertility weather its explained or unexplained. In spite of development in this technique over the last forty years, success has been limited to 15-45 % as a result of implantation failure.(¹) implantation of human embryo only occurs in a receptive uterus at a time of functional changes of the window of implantation, during the mid secretory phase in the menstrual cycle (19-23 days)², during that time profound molecular changes occurs in the stromal component create the state of receptivity³, these changes include specialized natural killer cells recruitment, remodeling of vascular bed and decidualization of stromal fibroblast.⁴

This state of endometrial receptivity is a result although not well understood harmony between ovarian
hormones, growth factors, cytokines, and adhesion molecules\(^5\). And it reflect the end resulting effect of cooperation of the hypothalamic pituitary ovarian axis in preparing endometrium for embryo implantation. The awareness of endometrial receptivity and the presence of window of implantation has been proposed for the first time by scholarly work of Hertig and Rock in 1956\(^6\). clinically Determination of receptive endometrial remains a challenge. In clinical practice the ultrasound has a great and important role in the evaluation and treatment of subfertile women. It is a non invasive efficient and cost-effective method for assessing female reproductive organs.\(^7\)

Ultrasound assessment of endometrial morphology may reveal “readiness”, state of endometrium by endometrial blood flow, pattern and thickness, all have been used as markers for endometrial receptivity and subsequent implantation and pregnancy in IVF.\(^8\) Uterine impedance and perfusion has been linked to subsequent success of implantation\(^9\) further more abnormal uterine artery velocimetry has been associated with unexplained sub-fertility, poorer uterine receptivity to implantation, and recurrent miscarriages.\(^10\) Uterine blood flow is an important factor contributing to uterine receptivity\(^11\) and can be studied by means of two-dimensional (2D)-power color doppler (PCD) ultrasound.\(^12\) in this study ultrasound assessment of anatomical changes include, thickness, pattern and grade of vascularity in addition to assessment physiological 2 D vascular flow indices includes both endometrial and uterine vessels both at day of oocyte retrieval and day of embryo transfer, in ICSI cycle with antagonist down regulation, to determine which time of ultrasound assessment is more predictive for receptivity and pregnancy outcome.

**Subjects material and method:** This is a case control study includes 60 patient, under the age of 39 years have undergone ICSI cycle because of different causes of sub fertility in the high institute of infertility and assisted reproductive technique in Al-Nahrain university in Baghdad between September 2018-february 2019, outcome all patient has written informed consent about their acceptance for participating in this study.

**Method**

Baseline evaluation include medical history, clinical examination and baseline hormonal evaluation and basal antral follicle count by ultrasound at cycle day 2 with gonadotrohin started at a dose determined according to the age and previous cycle response, on cycle day 5 assessment for number and follicular growth rate, till three follicles reach 18 mm at that time trigger of final maturation, at that day just before oocyte retrieval time ultrasound evaluation for endometrial receptivity parameters by 2 D ultrasound using transvaginal probe (5-9 MHz, Voluson P8 GE health care ultrasound machine,) after emptying urinary bladder, by US assess endometrial thickness (the thickest distance between the outer hyper echogenic lines of endometrium. Endometrial pattern, indicating echogenicity of the endometrium relative to the nearby myometrium visualized on a longitudinal ultrasound scan, the endometrium achieves the triple line appearance during the proliferative phase of the menstrual cycle while the endometrium acquires a hyper echogenic appearance at the secretory phase of the menstrual cycle, which is due to stromal oedema. After activation of color Doppler the endometrial vascularity zones are assessed, then pulsed Doppler is activated to measure the indices which includes: peak systolic velocity, end diastolic velocity, systolic to diastolic ratio, resistance index, pulsatility index for both uterine arteries and sub-endometrial and uterine arteries. All these parameter are calculated electronically.

**Results**

**Demographic Factors:** In this case control study, during ICSI cycles 30 patients with positive clinical pregnancy outcome and 30 patients with negative clinical pregnancy outcome, there were no difference in the baseline demographic parameters. There was no significant difference in mean age BMI and type of infertility, primary or secondary between pregnant women and non pregnant women.

Women were also categorized according to causes of infertility as male factor, female factor, combined and unexplained; the difference in the distribution of women according to cause of infertility was not significant \((P = 0.129)\), as shown in figure 1.
Ultrasound assessment for endometrial receptivity at day of oocyte retrieval: There was no significant difference in mean Endometrial thickness between pregnant and non pregnant ladies. However, considering a cutoff value of 8 mm revealed that the frequency of pregnant ladies with an endometrial thickness ≥ 8 mm was significantly higher than non pregnant ladies with an endometrial thickness ≥ 8 mm, there was no significant difference in the frequency distribution of subfertile women according to endometrial pattern, trilaminar versus echogenic, between pregnant and non pregnant groups. There was significant difference in the frequency distribution of subfertile women according to vascular pattern, zone I versus II versus III versus IV, between pregnant and non pregnant groups in such a way that zone I was limited to non pregnant women, Zone II was less frequent and Zone III was more frequent in pregnant ladies, Table 1.

Discussion

The endometrial receptivity has long been linked to successful implantation\(^6\), the endometrium is the key factor in reproduction, and many methods have been used for evaluation other than ultrasound, which in non invasive and effective in monitoring controlled ovarian hyperstimulation and has many different studies with different predictors at different cycles days.

In our study, pregnant women had higher mean endometrial thickness than non pregnant at day of oocyte retrieval although this was not statistically significant. This goes with many studies which found no significant difference in the mean endometrial thickness between pregnant and non pregnant women at that day such as schild et al 2001\(^{13}\) and even a study by Kumbak et al. 2009\(^{14}\). By using a cut off value of 8 mm and more, in the current study, there was significant differences with higher number of pregnant women than non pregnant with significant effect of endometrium of 8 mm and more, on pregnancy outcome, similar to observational study by Tao Zhanget al. 2018\(^{15}\) how found a higher pregnancy rate with higher endometrial thickness. At day of embryo transfer our study at a cut of 8 mm and more give significant difference between pregnant and non pregnant groups as in a study by, Kovacs et al. \(^{16}\). On the other hand there was no significant difference with higher thickness in pregnant group, this is similar to other studies like that of kinay et al 2010\(^{17}\), Kovachev et al. at 2005\(^{18}\) suggest that assessment of endometrial volume is better in prediction of pregnancy outcome at day of embryo transfer. This controversy of endometrial thickness as predictor of pregnancy outcome is contrasted with a well known role at day of hCG administration explained in many studies as by Richter et al. 2007\(^{19}\), Traub et al. 2009 \(^{20}\), Chen et al. 2010\(^{21}\), Yu We et al. 2014 \(^{22}\) and Yuan et al. 2016 \(^{23}\).

Triple line appearance was detected in all the studied pregnant women, while most pregnant cases shows echogenic endometrium, these detected differences were statistically not significant similar result obtained from a study, by Bassil et al. 2001 \(^{24}\) while a study by Jarvela et al. 2005\(^{25}\) shows statistically significant.

Vascularity grade shows significant relation in prediction of pregnancy in our study as in many other at day of oocyte studies as Khan et al. 2016 \(^{26}\). Endometrial and uterine vascularity indices at day of oocyte retrieval has non-significant difference regarding pregnancy rate between pregnant and non-pregnant group(Bassilet
al. 2001 and Yuval et al. 1999) only in case of resistance index, as a lower mean resistance indices were found in pregnant group which was statistically significant, in a study by Elham Pourmatroud et al.

**Conclusion**

In our study, endometrial thickness of 8 mm and triple line appearance, s vascularity grade of III is correlated with good pregnancy outcome and absence of endometrial vascularity has a poor pregnancy outcome.

Abstract

Background: Epstein–Barr virus (EBV) is a ubiquitous virus and it is the first virus recognized as carcinogen, gastric cancer is one of its suspected oncogenic potentials. Also in the last few years, a role of JC polyomavirus (JCV) is suspected in gastric carcinoma. This study is carried out to determine the frequency of EBV and JCV in gastric cancer tissues.

Subjects and Method: A case-control study included 40 gastric cancer tissue samples which were categorized as intestinal- or diffuse-type, and 20 gastric tissue samples which were histologically proven normal or mild gastritis cases taken from patients suspected to have gastritis or peptic ulcer. All these tissues were subjected for DNA extraction and real-time PCR for quantification of EBV and JCV DNA copies in these tissues.

Results: Among these 40 gastric cancer tissues (15%), 6 out of 40 were EBV DNA positive, and 5 out of these 6 tissues were of diffuse type, poorly differentiated, and with lymphocytic infiltration. While none of the control tissues was positive for viral DNA, p=0.023. Moreover, 25% (10/40) of gastric cancers were positive for JCV DNA, 80% (8/10) of them were of intestinal type, and only 10% (2/20) were JCV positive among the control group with significantly higher mean viral load in cancerous tissues (P=0.028), none of the tissues had both viruses.

Conclusion: EBV could be considered one of the important risk factors for the development of gastric cancer, especially of diffused, poorly differentiated, and lymphocytic type looking like EBV-associated nasopharyngeal carcinoma. And JCV could be regarded another risk factor for the development of intestinal-type gastric carcinoma, and there is no association between these two viruses.

Keywords: EBV, JC polyomavirus, Gastric cancer, quantitative real time PCR.

Introduction

Gastric cancer is a serious health problem and it is the third leading cause of death from cancer in the world¹, it is caused by numerous environmental and genetic changes, cancer of the stomach is the fourth common types of cancer distributed worldwide and the second highest mortality rate²,³. Investigating the association between gastric cancer and viral infections especially with Epstein-Barr virus (EBV) had been established along with Helicobacter pylori (⁴).

EBV is one of the ubiquitous human herpesviruses cause lymphomas such as Burkitt’s lymphoma and Hodgkin’s lymphoma⁵, and non-lymphoid cancers such as nasopharyngeal and gastric carcinoma. Epidemiological studies on gastric adenocarcinomas revealed that EBV present in 2–16% of cases worldwide⁶-⁸. In the first of latent period; EBV expresses EBNA1 and EBER, with 40% latent membrane protein

2A (LMP2A)\textsuperscript{(9,10)}. But there is no expression of LMP1 and EBNA2, which are required for B cell transformation and immortalization\textsuperscript{(11)} that will cause transformation of gastric epithelial cells\textsuperscript{(12)}. In addition, DNA methylation of the host cell; promoter hyper-methylation of tumor-related genes and target-gene silencing by the viral micro RNAs were observed also\textsuperscript{(13-15)}.

Serological studies have indicated that approximately 90% of the world’s adult population is asymptomatic for infection with the human JC polyomavirus (JCV)\textsuperscript{(16)}. The JCV large T antigen can inactivate p53 tumor suppressor gene and members of the retinoblastoma protein (pRb) family to promote uncontrolled proliferation and immortal survival\textsuperscript{(17,18)}.

Depending on the annual Iraqi cancer registration in 2015, the incidence of gastric cancer increased through the last 5 years of registration\textsuperscript{(19)}, the present study was designed to determine the frequency of EBV and JCV in gastric cancer tissue by (qPCR) technique.

**Materials and Method**

A case-control study included forty formalin-fixed paraffin-embedded (FFPE) gastric cancer tissue samples supplied from (Al-Imamin al-Kadhmain Medical City, and Gastro-enetrology and hepatology hospital). These samples were related to patients with confirmed gastric cancer from January 2018 to August 2019. Gastric cancers were categorized as intestinal- or diffuse-type according to the Lauren criteria\textsuperscript{(20)}.

Control tissue sections included 20 FFPE gastric tissue samples which were histologically proven normal or mild gastritis cases taken from patients suspected to have gastritis or peptic ulcer. This study was approved by the IRB (institutional review board) of the College of Medicine in Al-Nahrain University (approval no. 20191023 on 13-11-2019).

**DNA Extraction:** These FFPE tissue issues were cut into thin slices and put in xylene for 10 minutes at room temperature and then washed twice in 99% ethanol. Then, samples were dried at room temperature, followed by adding digestion buffer and Proteinase K and then centrifuged at 14000 rpm for 10 minutes, the supernatant taken for DNA extraction using the QIAamp DNA mini kit (QIAGEN-Hilden-Germany) according to manufacturer instructions.

**Quantification of EBV Viral Load:** Taqman probe-based real time PCR method was used to quantify EBV DNA copies in gastric tissues using EBV Real-TM Quant (Sacace-Italy) for the detection of LMP gene in EBV genome. LMP-gene DNA amplification is detected on JOE(Yellow)/HEX/Cy3 channel; and IC glob (β-globin gene) DNA amplification is detected on FAM (Green) channel (for the total DNA extraction from cell suspension (like biopsy and autopsy material, and whole blood). The master mix for one reaction was 10 μL of PCR-mix-1, 5 μL of PCR-mix-2 buffer and 0.5 μL of hot Starttaq DNA polymerase, and then, 10 μL of DNA from samples/standards/positive or negative controls were added to the mix. Thermal protocol applied was an initial activation of hot Start Taq DNA Polymerase at 95°C for 15 min; then, forty cycles of: denaturation at 95°C for 5 sec, annealing at 60°C for 30 sec, and extension at 72°C for 15 sec, the fluorescence was detected at the annealing step in each cycle.

**Quantification of JCV Viral Load:** Gene Proof PCR kit ISIN Version kit (England) a quantitative real time-PCR kit to detect JCV DNA viral load in the biological materials was used (the target sequence was the gene overlapping the boundary between the gene encoding the VP1 and VP2 proteins).

The real time PCR instrument used was (STRATAGENE MxPro QPCR (Agilent Technologies, USA)). Thirty microliters of JCV mastermix and 10 μl of the (sample DNA, positive or negative controls, or standards) were added into the PCR tubes. Thermal protocol for Gene proof PCR kit was: a two hold steps at 37°C for 2 min, then at 95°C for 10 min, and 45 amplification cycles of 95°C for 5 sec, 60°C for 40 sec and 72°C for 20 sec. Real-time fluorescence is collected in the third step of the amplification cycles.

**Statistical Analysis:** The data of the current study were analyzed using software SPSS version 12.7.6.1. Data were classified into qualitative and quantitative. The quantitative data were also classified into parametric and nonparametric according to normality tests. Chi square and Fisher exact tests were used for association. For quantitative data mean or median difference tests were used. \(P < 0.05\) was considered to be statistically significant.

**Results**

This study included 40 gastric cancer tissues recruited from 20 (50%) males and 20 (50%) females, their mean age was 51.25±9.19. In addition to 20 control
non-cancerous gastric tissues who were comparable in age and sex. Real time QPCR analysis of the gastric cancer tissues showed 15% (6 out of 40) positive, with a mean viral load $4.6 \times 10^4 \pm 2.8 \times 10^5$ copies EBV DNA/10⁵ cells. But none of the control tissues were positive for the virus, $p=0.023$, table (1).

**Discussion**

EBV is a highly sero-prevalent virus in Iraq, which is about 80% as shown by a recent study in 2017 (21), also by real time PCR (33%) (22). EBV-associated gastric cancer (EBVaGC) has become a well-defined clinical entity (23). The current study found that 6 out of 40 (15%) of gastric cancer tissues are EBV DNA positive by quantitative real time PCR. A result that is very close to other studies that gave the range of EBVaGC of 1.7-16% among gastric carcinomas throughout the world (24). The quantification of EBV viral load by qPCR in gastric cancerous tissue highlights a high viral load associated with carcinogenesis of stomach cells. A study of Ryan, et al. showed that a cutoff value of 2000 copies for 100000 cells is considered as a threshold for determining EBV correlated to gastric cancer (25), which support the results of this study in which the mean VL was $4.6 \times 10^4 \pm 2.8 \times 10^5$ copies EBV DNA/10$^5$ cells.

This value of 15% EBV DNA in gastric cancer tissues is also associated with significant relation with diffuse type, poorly-differentiated and obvious lymphocytic infiltration. Which are also in agreement with other studies that showed EBVaGC mostly poorly differentiated adenocarcinoma, with diffuse and intense lymphocytic infiltration that is resembling EBV-associated naso-pharyngeal carcinoma (26).

Around 1.7-16% of gastric cancers have been identified as EBV-positive (24). Thus, EBVaGC is regarded the most common cancer among EBV-associated malignancies (23). In 1990, Burke et al. (27), the first who reported EBV-positive GC by PCR, and Fukayama et al. (28), found that EBVaGC result from the monoclonal proliferation of EBV-infected cells. In addition, it has been shown that EBERs have an oncogenic role by inhibiting apoptosis (28).

In the current study, JCV was detected in 25% of gastric cancerous tissues a result that is comparable to previous results (29), however, it is less than the frequency reported by other studies (30) which was more than 50%, which is probably because the target genome in our study was on VP1-VP2, while those studies target genome was the oncogene large T antigen that gave higher frequency in the cancerous tissues (30). On the other hand, JCV tissue viral load was significantly higher in the gastric cancer tissue (more than 10 times that of the none cancerous tissue) which is also in accordance with another study of JCV on gastric cancer tissues (18), and the higher frequency of JCV in intestinal type of gastric cancer also agrees with Ksiaa et al in 2010 (29) who suggested a role of JCV as a cofactor in the pathogenesis of the intestinal type of gastric carcinoma.

Abstract

The study was conducted over a hundred patients renal stone and forty apparently were taken as control group. The renal stone comprised one hundred patient aged (10-70 years) with mean ± standard deviation of (46.10± 16.30) years. The Control group includes forty apparently healthy individuals aged (20-65 years) with mean± standard deviation (30.22 + 11.36) yea . The study was conducted of the 1th period from February 2019 to the April 2019. Samples collected from outpatient Department AL- Hilla Teaching Hospital. All patients underwent full history and physical examination, including (age, sex, medical family history and the presence of stones formation frequently in the patient and other chronic diseases), Venous blood samples was collected from patients with renal stones and control subjects by using disposable (5 ml) of each patient taking (1 ml) of it and put it in tube with coagulation contain EDTA blood and leave the rest to coagulate for 10-15 minutes in Temperature of 37 ° C and then enter the rotation speed of 1800 rpm is obtained blood serum and then the serum was stored in -20 degree,

Keywords: Antioxidant; health; patients; urinary stones; blood.

Introduction

Urinary system stone is the most common cause of kidney disease and poses a remarkable health care burden on adults. Recent studies have shown that the prevalence of kidney stones is increasing, and that 1 out of every 11 Americans have kidney stones. On the other hand, global statistics have shown that the number of people with kidney stones has almost doubled in the last 15 years (1). Several factors are effective in the development of kidney stones including sex, race, age, climate, nourishment, and genetics (2,3). Recent studies have also shown that nutrition, lifestyle factors, and metabolic factors are instances of the most important factors involved in developing kidney stones (3,4). In economically advanced countries, 70% of the total kidney stones contain calcium oxalate or phosphate (5). The disease is more common among the people aged 30-60 years and, more common to men than to women (3). The formation of kidney stones is multifactorial pathogenesis, and there are several stages in the formation of stones in the renal tubes (5). Among various mechanisms for the formation of kidney stones, the damage of tubular cells and thus facilitation of the crystallization of sediment could be considered as the most possible mechanism (6,7). Numerous studies have determined that damage to tubular cells could be caused by the presence of oxalate and calcium oxalate crystals (5). However, it is known that damage to renal epithelial cells in the patients with kidney stones could be due to oxidative stress (8). Oxalate-induced membrane damage is promoted by lipid peroxidation (LPO) and oxidative stress, which is a degradative process due to the presence of reactive oxygen species (ROS) (8,9). LPO could be assayed by measurement of serum malondialdehyde (MDA) levels in the patients with renal stones. In

e-mail: alaa.h.kadhum@gmail.com
addition, various studies have reported that the vicinity of kidney epithelial cells with different crystals leads to the production of ROS (8). On the other hand, ROS through damage to and chemical changes on proteins, lipids, and carbohydrates, alter the kidney function. Association of calcium stone formation and the reduction of antioxidant levels have been suggested (10). The most common type of urinary stone found in humans worldwide is calcium oxalate (CaOx). The important risk factors of CaOx stone formation are urinary supersaturation, increased urinary stone promoters, such as calcium and oxalate, and depleted urinary stone inhibitors such as citrate and magnesium (3,5). Urinary supersaturation is a state that the concentration of solutes in urine exceeds the saturation point, causing spontaneous precipitation of solutes, with the inadequacy of stone inhibitors and urinary alkalization, calcium from a water-insoluble complex with oxalate. These crystals will aggregate and adhere to the renal tubular epithelium with the presence of urinary adhesion molecules. Regarding these, genetic susceptibility in a family with nephrolithiasis may play an important role in pathogenesis of stone formation than our current awareness. Evidence reported that stone disease occurred at a younger age and higher frequency in any population with nephrolithiasis patients in the family (11). As an antioxidant enzyme, superoxide dismutase (SOD) plays an important role in ROS removal by resisting oxidative stress and decomposing super oxide into oxygen (O2) and hydrogen peroxide (H2O2) (10).

Material and Method

One hundred patients (67 males and 33 females) in the age group ranging from 5-75 years old, admitted to Al-Hila Teaching Hospital, Urology Department from the period 1st of December 2013 till 30th of June 2013. Forty apparently healthy individuals were taken as a control group. This group comprises of 20 males their age ranging from 22-55 years, and 20 females their age ranging from 23-60 years. All tests had been performed on serum in Biochemistry department in the College of Medicine of Babylon University. Blood samples have been collected from patients and control subjects. Blood samples were withdrawn without the use of tourniquet. Both the sera from patients and controls are used for the measurements of the Serum total antioxidant.

Result

The total number of patients with renal stones was One hundred patients in the age group ranging from 5-75 years old at time of presentation, the high percentage of patients (23%) found in age group (35-45) years old. Most of antioxidants are electron donors and react with free radical to form more stable end products such as water. Thus, antioxidants can inhibit the free radical and protect against cellular damage from ROS. Concentration of Total antioxidant (TCA) was decrease in patient with kidney stone compare to control group show in the tables (1, and 2).

**Discussion**

The results showed a significant differences in age of patients with renal stones compare with those of the control group most pediatric kidney stones are predominantly composed of calcium oxalate; struvite and calcium phosphate stones are less common, Calcium oxalate stones in children are associated with high amounts of calcium, oxalate, and magnesium in acidurine(12). Urolithiasis was found to be most predominant in the age group of 31-40 years(13). Age group of early twenties to late forties is physically most active period in life. another possible mechanism may be due to increased level of serum testosterone in age group of 21-40 years, which resulted in increased production of oxalate by liver from its endogenous precursors(14). suggested that the statistically decrease in total antioxidant in kidney stone patients as compared to controls. Increased levels of TAC indicate absorption of stock organ antioxidants(15). uric acid and the induction or activation of antioxidant enzymes as an adaptation to the oxidative stress, but at a later phase of oxidative stress, the TAC falls due to depletion of antioxidants(16). In addition, high concentration of a number of metabolites, including uric acid can lead to pro-oxidant effects, introducing a further decrease of the antioxidant capacity (17).

**Conclusion**

The study showed that the serum concentration of total antioxidant (TAC) was decreased significant in patient with urinary stone when compared with control (p<0.001) in uric acid, (p<0.05) in clcium oxalate, (p<0.05) in calcium phosphate

Association of LPL Gene Variant and Serum LPL Level with Ischemic Stroke in Iraqi Population

Jaafer Mukdad Mohmmed1, Moaed E. Al-Gazally2, Mushtak A. Wtwt3

1Lecturer, College of Medicine, University of Babylon, Iraq, 2Prof., College of Medicine, University of Babylon (Works Now in Al-Ameed University), Iraq, 3Prof., College of Medicine, University of Babylon, Iraq.

Abstract

Background: Lipoprotein lipase (LPL) plays an important role in plasma lipoprotein metabolism. An increasing number of studies have suggested an association of LPL gene variants with the risk of cardiovascular and cerebrovascular diseases.

Objective: To analyze whether Hind III polymorphism of LPL gene and serum LPL level are associated with ischemic stroke in Iraqi population.

Method: Fifty ischemic stroke patients (clinical diagnosis and x-ray CT) and fifty controls were enrolled in this case–control study. The LPL Hind III polymorphism was determined by PCR-RFLP technique and LPL mass level was estimated using a sensitive sandwich enzyme-linked immunosorbent assay (ELISA).

Results: In the present research was not found any association between the Hindlll LPL gene polymorphism and acute ischemic stroke in the population studied; the allele and genotypic frequencies of the studied polymorphism was similar in cases and controls and followed the Hardy-Weinberg equilibrium. The relationship between Hind III genotypes and the LPL mass level was analyzed using ANOVA and further confirmed by Post-hoc analysis. there was no significant difference in LPL mass levels between the genotype groups H+H+, H+H-, and H-H- (p value>0.05).

Conclusions: The Hind III polymorphism of LPL is not a genetic marker for the development of ischemic stroke as well as not determinants of serum LPL level in the Iraqi sample used.

Keywords: Protein lipoprotein, lipase, ischemic stroke, polymorphism association risk.

Introduction

Cerebrovascular diseases are characterized by a neurologic deficit, due to a focal vascular lesion in the central nervous system, it includes cerebral infarction, intracranial hemorrhage and subarachnoid hemorrhage[11]. Studies have posited the lipoproteinlipase (LPL) gene as the most viable candidate for study due to its contribution to the interindividual variability in lipid levels and their consequent role in atherosclerosis, as well as to the possible correlation between hyperlipidemia and CVD[2,3]. Evidence suggests that variations in the lipoprotein lipase gene may influence stroke risk[4]. LPL has a major role in triglyceride (TG)-rich lipoprotein metabolism by catalyzing the hydrolysis of TG in chylomicrons and very low-density lipoproteins to form chylomicron and very low-density lipoprotein remnants, respectively[5,6]. The human LPL gene is located on chromosome 8p22, spans approximately 35 kb and contains 10 exons encoding a 448 amino acid mature protein[7,8]. Genetic studies have revealed almost 100 mutations and single nucleotide polymorphisms in lipoprotein lipase gene in humans[9]. A HindIII polymorphism located on intron 8 has been associated

with subtle alterations in plasma lipids in which a replacement of thymine (T) with glutamine (G) base occurs at position +495 abolishing the HindIII restriction enzyme recognition site \(^{[10]}\), and has been associated with hyperlipidemia and diabetic nephropathy\(^{[11]}\). Biochemical assessment of LPL function has also frequently been used to assess the role of LPL in atherogenesis. However, these studies are hampered by the need to administer heparin intravenously to release sufficient LPL from the endothelium to measure reliably LPL activity and LPL concentration. Because heparinization is time-consuming, not standardized, and induces bleeding risk, most investigators have only studied limited numbers of diseased and/or non-diseased individuals. Recently, the availability of a highly sensitive enzyme-linked immunosorbent assay, which can measure accurately freely circulating LPL concentration in non-heparinized serum has provided a tool to more easily assess the relationship between LPL and ischemic stroke. It was recognized that the majority of serum LPL is catalytically inactive and likely represents a mere catabolic product of catalytically active LPL that is bound to the endothelium. Also, it was demonstrated that serum LPL concentration is not associated with post-heparin LPL concentration or LPL activity \(^{[12]}\). It has been demonstrated that a reduced concentration of plasma LPL mass is associated with an increased risk of coronary artery disease\(^{[13-15]}\).

### Materials and Method

**Pre heparin LPL mass measurement:** Blood samples for LPL mass measurements were withdrawn from subjects and then put in plane tube without anticoagulants to obtain serum. The levels of LPL mass was measured by the sandwich enzyme-linked immunosorbent assay (ELISA).

**DNA isolation and genotyping:** Five ml of blood was collected in EDTA tubes. Genomic DNA was extracted from blood samples using the INTRON (korea) kit. The LPL HindIII polymorphism in intron 8 was analyzed by PCR-RFLP technique. The primers used for the amplification of the LPL gene bearing the polymorphism are Forward: 5’-TGAAGCTCAATGGAAGAGT-3’ and Reverse5’- TACAAGCAAATGACTAAA-3’. The amplification protocol involved a denaturation of the DNA segment at 94°C for 30 sec, then annealing the segment at 50°C for 30 sec and an extension segment at 72°C for 45 min, this repeated for 35 cycles and the final extension for 5 min. The amplified 715 bp PCR product was digested with HindIII restriction enzyme by incubating at 37 °C for 2 hours followed by separation of fragments on 1.5% agarose gel for one hour at 90 volt. Hind+ve allele was detected as fragments of 600 bp and 115 bp base pairs (bp) while as Hind–ve allele was detected as fragment of 715 bp.

### Results

The variables of diabetes, Hypertension and Smoking were presented with statistically significant difference.

**The levels of preheparin LPL mass in ischemic stroke patients and the control group:** Serum lipoprotein lipase level (median with interquartile range Q1 and Q3) in ischemic patients was 137.8 (83.75, 164.8) and not significantly different from that of control subjects 116.0 (80.97, 127.1) as shown in the figure 1. The Mann-Whitney U value was 723.5 and the p value was 0.10.

![Fig 1: serum lipoprotein lipase (pg/ml) among patient and control groups. median with Q1 and Q3.](image)

**Genotyping:** Polymorphisms allowed making the allele assignation in each sample for each polymorphism (Fig. 2).
Figure 2: Genotyping of HindIII polymorphisms in lipoprotein lipase gene. Restriction fragments length polymorphisms (RFLP) on 1.5% agarose gel at 90 volt/hour DNA 50 bp marker.

Lane 3,4,5,6,7,10: H+H+ genotype homozygote for presenting of 600bp and 115bp. Lane 1,8,9,11,12: H+H- genotype heterozygote for presenting of 715, 600, and 115bp. Lane 2: H-H- genotype homozygote for absence of cutting site.

Genotype and allele frequencies: The genotypes and allele frequency between the patients with ischemic stroke and the healthy subjects were in agreement with the Hardy–Weinberg equilibrium. The genotype distribution and the allele frequency for LPL gene polymorphisms are summarized in Table 1. Most frequent genotype was H'H' in ischemic patients and control subjects 29(58%), and 34(68%) respectively. H'H' in control is higher than of patients. H-H- was the lowest frequent genotype in both study population, and was in patients 3(6%) lower than of controls 6(12%). H+H- was the intermediate genotype among both patients 18(36%) and control 10(20%) and was higher in patients.

The relationship between HindIII polymorphism and pre heparin LPL level: The relationship between HindIII polymorphism and pre heparin LPL levels has been given in figure 3. In present study, no significant difference in serum LPL levels between genotype groups H+H+, H+H-, and H-H-, with mean and standard deviation 132.0 ± 78.87, 116.3 ± 35.76, 129.8 ± 52.05, respectively as shown in figure Fig(3). p value 0.622.

Discussion

To the best of our knowledge, this is the first study to evaluate the association between HindIII polymorphisms of the LPL gene and ischemic stroke in Iraqi population. Data showing no significant association between lipoprotein lipase gene polymorphism HindIII and stroke in the Iraqi simple analyzed; suggesting that this polymorphism cannot be used as genetic markers to predict risk for stroke development. A number of studies have suggested the implication of HindIII polymorphism located on intron 8 of LPL gene in the pathophysiology of cardiovascular and cerebrovascular diseases[14-15]. Recently, we have noted that HindIII variants in the LPL gene have association with atherothrombotic cerebral infarction. However, a study carried out by Xu et al. [16-17] in a Chinese population could not establish an association between HindIII polymorphism of LPL gene with atherosclerotic cerebral infarction. Study occur in 2020 demonstrate association between HindIII and coronary artery disease [18]. Thorn et al. have reported a significant association of HindIII+ve allele with severe coronary atherosclerosis[19-21]. Chen et al. reported a significant correlation between carotid artery atherosclerosis and Hind III polymorphism in White male subjects. Furthermore, meta-analysis study suggested that LPL HindIII variants were associated with a decreased risk of stroke in the Asian population, but not in the non-Asian population [22]. Another meta-analysis indicated that risk of stroke was decreased in rs320 polymorphisms in the LPL gene [23]. Munshi et al. suggests that the HindIII polymorphism of LPL is significantly associated with ischemic stroke risk[24]. However, Velásquez et al published that the HindIII polymorphism no associated with ischemic stroke in Latin America [25]. Allele frequencies for the HindIII polymorphism in our study were nearly to those found in in the dbSNP database for east Asia population and genetic studies done in different ethnic groups including (USA)[26], This may be due to LPL levels are controlled by many factors, including differential transcriptional regulation in adipose and skeletal muscle tissue, post-translational modification and translocation over the endothelium, retro-endocytosis, binding to heparan sulfate- containing proteoglycans, lipoproteins, and receptors, and hepatic clearance[27-30] in our knowledge.
no previous study has been reported to demonstrate the relationship between the ischemic stroke and this marker. The present study showed no significant differences of LPL levels among LPL genotypes, so HindIII was not be as determinant of LPL level. The genetic determinants of preheparin LPL mass and the separate relationships between LPL gene polymorphism and serum LPL mass with ischemic stroke is unknown. And also information on LPL mass is severely lacking, in particular with respect to interaction with gene polymorphism. Our data in inconsistent with that reported on 640 middle-aged Chinese, in whom LPL-HindIII and PvuII polymorphisms were found to be determinants of preheparin plasma LPL concentration, which was in turn independently modified by smoking and obesity[31].

**Conclusion**

In our study, the presence of the HindIII polymorphism of the LPL gene was not a risk factor for the development of ischemic stroke and not significantly associated with the LPL mass level as well as the LPL level not associated with increased risk of ischemic stroke.

Abstract

The swollen head syndrome is one of the most upper respiratory problems in poultry that causing high economic loss in poultry. SHS is infected of all ages mainly 4-6 weeks old with morbidity may reach to 10% and mortality about 2%. Avian metapneumovirus (aMPV) is one of the most important etiological factors that causing swollen head syndrome (SHS), (aMPV) is a member of sub family Pneumovirinae under the family Paramyxoviridae, also this family characterized by RNA non segmented negative sense genome, Ornithobacterium rhinotracheale (ORT) is one of the most important etiological factor of (SHS) is one of a contagious disease that capable to infect avian species, primarily in turkeys and chickens, causing marketable respiratory distress, decreased growth, and mortality will be depending on many factors like combination with viral infection like aMPV. Study the effect of vaccinated flocks with (ND, IB, IBD) with identification of Avian metapneumovirus (aMPV) and Ornithobacterium rhinotracheale (ORT), in middle Euphrates region in Iraq.

Keywords: Vaccine; Avian metapneumovirus; toxicity; bridles.

Introduction

Swollen head syndrome is a disease of chickens of all ages mainly 4-6 weeks old with morbidity may reach to 10% and mortality about 2%.[¹] The affected birds show depression, decrease the feed intake, nasal exudate, sneezing, coughing and conjunctivitis then many progress to facial edema which start around eye extending over the head and descending to submandibular tissues also, nervous signs may be seen like the etiology of SHS is uncertain and it is torticollis, opisthotonos, and incoordination.[²]

O. rhinotracheale is one of Gram-negative, pleomorphic rod-shaped bacterium causing upper respiratory disease in the commercial poultry industry[³], belonging to superfamily VrRNA and it is one of the family of Flavobacteriaceae also it is from the Cytophaga_lavobacterium_Bacteroides descending genetic line. ORT[⁴], first time isolated in Germany in 1981 from five-week old turkeys showing nasal discharge, facial edema and fibrinopurulent airsacculiti[⁵], and first isolation in united states was in 1989. In 1993, it was formally characterized. In 1994, after isolating and evaluating 21 strains associated with various respiratory tract infections, Ornithobacterium rhinotracheale was given its current name[⁶].

Avian metapneumovirus, also recognized as turkey rhinotracheitis, is a part of the subfamily Pneumovirinae[⁷] in the family Paramyxoviridae, induces widespread turkeys, and chicken flocks and many other bird species such as pheasants, Muscovie duck and guinea fowl.
Geese, most other ducks and potentially pigeons are suggested to be disease[8]. The infection with aMPV is characterized by an inflammation of the high respiratory tract in poultry and also considered a known risk factor for triggering swollen head syndrome (SHS) in broiler and broiler breeders also loss of egg production in layers had been reported[9], as it is well known as main etiological factor in chickens that have secondary bacterial infections complicate the development of the typical SHS by organisms like ORT[10].

Present study amide to identify the effect of vaccinated flocks with (ND, IB, IBD) with identification of Avian metapneumovirus (aMPV) and Ornithobacterium rhinotracheale (ORT), in middle Euphrates region in Iraq from typical infected flocks with swollen head syndrome.

Material and Method

The collection of samples was carried out during the period from the beginning of September 2018 till end of August 2019 on 67 poultry farms them ages ranged between (3-6) week old, three to four typical SHS cases were taken from each farm and pooling together in one it have been preserved on transport media and uploaded on FTA cards in the same time[11].

The fields that were surveyed were distributed in the middle Euphrates region and from several governorates as shown in table (1).

Table number (1) That show number of infected farms in middle Euphrates region

</tbody>
</table>

The samples were divided in to two groups the first one that put in transport media (indirect method) then carry to laboratory for culturing and detection, the second group put on FTA card (direct method)[9] to saving genetic materials for microorganism and detection by using RT-PCR, each FTA cards that have four wells each well capable to save four samples, so (2-4) samples were uploaded on each well of FTA cards.

Data statistical analytic and presentation: Data were analyzed and presented using PRISM Graphpad 8, numbers application for MAC 11, SPSS 16.0 and Microsoft exile 2010 the obtained data was checked for normal distribution by using Shapiro-Wilk test. A mixed-model analysis of variance (T-test) was used to compare the differences of mean among variable groups; the significance was tested using A mixed model (T-test) value less than 0.05 were considered statistically significant. Our data were presented as stander error mean ± (SEM).

Calculation of percentage rate: The equation for percentage calculation was used to calculate the percentage of infection and mortality rate in this study.

\[
\text{percentage} = \frac{\text{part of sample}}{\text{all sample numbers}} \times 100\%
\]

Result and Dissection

There is no vaccinated for Avian metapneumovirus & Ornithobacterium rhinotracheale in Iraq at this moment so, Therefore, the common vaccinations of broiler flocks as (ND, IB, IBD, Avian flu vaccinations) were relied upon to study their effect on the isolation rate for aMPV and ORT, the results were no significant difference between vaccinated flocks and non-vaccinated[12].

The reason due to there is no matching between the etiological local strain and commercial vaccine strain, which leads to a high probability of infection of the broilers flocks with infectious respiratory diseases or diseases that suppress the immune system, then leading to their susceptibility to infection with Avian metapneumovirus or Ornithobacterium rhinotracheale[13].

On the other hand, poor storage of vaccines and the wrong vaccination method leads to the ineffectiveness of the vaccine, which causes a high probability of infection the flocks with virus diseases to be vaccinated against it[14].

Conclusions

In infected poultry flocks that infected with ORT and aMPV were no significant different between vaccinated and no vaccinated flocks agents ND, IBD and IB this return to bad vaccination program in Iraq also due to un matching between the local strain and commercial vaccine that available in Iraq.

Ethical Clearance: The Research Ethical
Committee at scientific research by ethical approval of both MOH and MOHSER in Iraq.

Comparative Analysis of Tumor Infiltrating T Cells and Serological Markers between MIBC and NMIBC Patients

Ifad Kerim AlShibly¹ Ammad Hasan Mahmood², Fouad Qasim Jubair Al-Zayadi¹

¹Assist. Prof., College of Medicine, University of Babylon, Hilla, IRAQ.
²Prof., College of Medicine, University of Babylon, Hilla, IRAQ

Abstract
Bladder cancer is considered as that of any type of abnormal growth arising from the tissues. It has a possibility to spread other part of the body. The study aimed to evaluate counts of tumor infiltrating immune cells (CD3 & CD8) and serum soluble Fas and Fas ligand concentrations and their comparison between MIBC and NMIBC. In this cross-sectional study a total of (23) patients with bladder cancer consist of (14) males and (9) females were included, their ages ranged from (26-82) years. The patients visited urological surgery unit in Hilla Teaching Hospital during the period (December 2018 to October 2019). Tissue biopsy and 3 mL of blood were taken from each included subject for evaluation of CD3 and CD8 in bladder tumor tissues by IHC technique, and serum levels in sFas and sFasL in by ELISA technique. The results showed both CD3+ TILs and CD8+ TILs in MIBC are significantly higher than those of NMIBC (P value <0.0001 for CD3, and P value = 0.001 for CD8). Serum levels of sFas and sFasL in MIBC are not significantly different from those of NMIBC (P value >0.05). It was concluded that CD3+ TILs and CD8+TILs counts were significantly affected by the muscular invasiveness of bladder cancers, whereas both sFas and sFasL levels were not.

Keywords: Bladder, MIBC, NMIBC, TILs, sFas, sFasL; Tumor Infiltrating; health.

Introduction
Generally, the main cause of tumor incidence is genetic changes. Many years of genetic analysis showed that there are about 1000 known genes-associated cancer, categorized into three types: (1) proto oncopgenes that include in normal cells, but any mutation in this type of gene affecting the normal cell division causing abnormal cell growth (2) Tumor suppressor genes (TSGs) that responsible for normal cell growth, so the alteration in these genes may lead to uncontrolled cell growth, and (3) DNA repair genes, which involved in fixing and repairing in any alteration or damage in DNA, so the mutation in these type of genes leading to cancer occurrence. Bladder cancer is considered as that of any type of abnormal growth arising from the tissues. It has a possibility to spread other part of the body. Symptoms comprise hematuria, and painful urination (dysuria), and low back pain. The most frequent type of CA bladder is transitional cell carcinoma (TCC); other types such as squamous cell carcinoma (SCC) and adenocarcinoma are less. Most CA bladder cases are urothelial carcinomas, divided into; about 75 percent are non-muscle invasive, and 25 percent are muscle invasive. Depending on the morphology, bladder tumors can be divided into papillary, solid, and mixed types. The papillary type is most frequent, particularly in non-muscle invasive bladder cancer (NMIBC), other than muscle-invasive bladder cancers (MIBC).

Immunohistochemistry (IHC) is the most common application of immunostaining that used for the detection of solid tumors. Immunohistochemical detection of CD103+ tumor infiltrating lymphocytes can be used as potentially prediction factor in diagnosis of...
urothelial cell carcinoma (UCC) of the bladder tissue\(^5\). However, there is a study validates the performance of cell detect as a urine-based assay to identify UCC in patients with history of bladder cancer. It relies on both color and morphology to differentiate between benign and malignant cells in cytology specimens\(^6\). Generally, tumors are closely associated with immunity system. Especially functional systemic and local immunity is required for the effective responses against tumors. In addition to an active engagement with cancer cells and tumor stroma, immune cells can be affected and are often found to be dysregulated in cancer patients\(^7\). Moreover, increased T cell tumor infiltration correlated with a better prognosis in most studies\(^8\). In cases of NMIBC, increased densities of several TIL subpopulations, including cluster of differentiation CD3+, CD4+, and CD8+ T lymphocytes, were associated with worse recurrence and survival\(^9\).

The study aimed to evaluate the counts of tumor infiltrating immune cells (CD3 & CD8), and serum soluble Fas and Fas ligand concentrations and their comparison between MIBC and NMIBC.

Material and Method

In this cross-sectional study a total of (23) patients with bladder cancer consist of (14) males and (9) females were included. Their ages ranged from (26-82) years. Case information for each patient has been taken from the report of the diagnosis which were: name, sex, age, and the diagnosed tumor type. The patients visited urological surgery unit in Hilla Teaching Hospital during the period (December 2018 to October 2019).

Included & Excluded Criteria: The enrollment standards of patients in this study comprised any patient who has recent bladder tumors diagnosed histologically. Patients with normal histological results after suspicion of bladder tumor, any patient who took chemotherapy, and any case with retrospective bladder tumor have been excluded.

Ethical Approval: Patients or their sons and/or first degree relatives (father & mother) were asked permission prior to take any specimen. In addition, the study concept was accepted by the Research Ethical Committee at the College of Medicine/University of Babylon.

Samples: After patient admission, the biopsies bladder tumors were obtained from the urological surgery unit. The biopsy was preserved in plastic tube container with 10 percent neutral buffered formalin (NBF), before processing for immunohistochemical testing, using paraffin embedding technique to build formalin-fixed paraffin-embedded (FFPE) blocks. Moreover, 3mL of blood were collected from each patient for serological evaluation by ELISA technique.

Method

Sample Processing for the IHC Staining Technique:

- The thickness of tissue section was 4 μm taken from blocks of paraffin embedded tissue on positive charge slides when the cutting by microtome.
- Incubations specimen on chargeable slide (slide with tissue) for at least 2 hours at 58- 60 °C in the oven.
- At deparaffinization steps, 3 containers with Xylene on which the tissues/slides immersed for 2 minutes for each containers respectively.
- Then the tissues/slides dipped in 3 jars with alcohol (ethanol), the first jars with 30% alcohol, the second jars with 70% alcohol and the third jars with 100% alcohol, for 2 minutes at each jar respectively, this is hydration step.
- The last steps, subjected tissues/slides in container with Immuno DNA Retriever Citrate and then this Retrieval container with slide put in water bath set at 95 - 99°C for 60 minutes. then washed the tissues/ slides 5 time with wash buffer
- Then the immunohistochemical staining technique was applied (Bio SB- USA).

Evaluation: In IHC technique, the brown colored reaction in the nucleus or cytoplasm was considered a positive reaction. The intensity positive stained cells was determined by modified method through taking a pictures for three fields of each section through digital camera connected to conventional light microscope (20X power), and further image analysis was done with the Image J software (version 1.46r, National Institutes of Health, USA) for each picture to count (CD3 or CD8) cells, then the mean value was calculated that represent the cells number per field for each section\(^{10,11}\). In concerning serological markers (sFas & sFasL) were evaluated through sandwich-ELISA technique (Elabscience-USA).
Statistical Analysis: Calculation of the comparative data through Software of Statistical Package for the Social Sciences (SPSS), version 26.0, to explain the differences of study parameters between MIBC and NMIBC. Independent t-test was used for analyzing the differences. Statistically, it is considered a significant difference when P value < 0.05.

Results

In the present study, there are 23 subjects of study group were diagnosed as bladder tumors. These tumors are subdivided into: 16 (69.5%) are non-muscle-invasive bladder cancers (NMIBC); and 7 (30.5%) are muscle invasive bladder cancers (MIBC). As shown in Table (1), the mean of CD3+ TILs in MIBC patients (323.5 cells/field ±19) is highly significant (P value < 0.001) higher than those of NMIBC (170±77.4). Similarly, mean of CD8+ TILs in MIBC patients (186±61.6) is significantly (P value = 0.001) higher than those of NMIBC (64.7±29.3), Figures (1, 2). Regarding to serum soluble markers as shown in Table (2), there is no significant difference in (P value > 0.05) in means of sFas concentrations between MIBC (3251 pg/mL ±295.8) and NMIBC (3182.5 pg/mL ±351.8); also there is no significant difference (P value > 0.05) in means of Fas Lconcentrations between MIBC (474.7 pg/mL ±167) and NMIBC (374 pg/mL ±142).

### Discussion

CD3+ TILs in bladder cancers are so important regarding to its protective role\[12\]. Saeed\[13\] mentioned that CD3+ TILs quantitation in bladder carcinoma with advanced progression stages of invasion is significantly higher than others with no muscular invasion, in agreement with the current study findings. Likewise, there is an indication was reported by Sjödahl et al.,\[14\], they mentioned that the general, immunological response focusing on CD3 & CD68 in bladder cancers with no muscular invasion are weaker than that with muscle invasion. Increasing ratio of T lymphocytes in MIBC may indicate to a good prognostic aspect, like the conclusion that increasing rate of tumor infiltrating T lymphocytes has a good protective consequence \[15\]. In contrast, there is a suggestion that the intratumoral T cells in bladder cancer are mostly accounted by T regulator cells, so it leads to suppression of immune cells of anti-tumor activity\[16\].

Similarly, in our study findings of increased tumor infiltrating cytotoxic T cells quantitation in MIBC tissues suggesting the rates of phenotypic T cells differs based on the degree of bladder tumor progression. The high densities of CD8+ TILs in invasive bladder cancers may indicates to a good prognosis and give a long survival rates, in agreement with that observed in invasive urothelial carcinoma, and the better prognostic aspect is associated with high CD8+ TILs quantity \[17\]. Also, regarding to muscle-invasive urothelial carcinoma was reported that the ratio of CTLs to T reg cells is correlated with the response to neoadjuvant chemotherapy (NAC), if the tumor infiltrating T reg cells ratio is higher than CD8+ TILs leads to unresponsiveness to NAC, and the good response was observed if the CD8+ TILs ratio is higher\[18\]. In NMIBC, there is no relation between CD8+ TILs counts and prognostic aspects, and observed that CD8+ infiltration is affected by the expression of fibroblast growth factor receptor 3 (FGFR3) tumor microenvironments, and high counts CD8+ TILs were observed in NMIBC with low expression of FGFR3\[19\]. Also, Mariathasan et al., \[20\] evidenced that TGF-β has a significant role to reduce the tumor infiltrating CTLs, and showed that using of anti-TGF-β antibodies facilitate the CD8+ cells diffusion into the tumor center.

Regarding to the serum soluble Fas, the current study results may indicate to that tumor invasiveness does not affect the serum levels of Fas, in agreement with Nonomura et al., \[21\] who articulated that sFas concentrations are not associated with tumor histological stages. But, Yang et al., \[22\] disagreed with our findings by showing soluble form of Fas concentrations in urine of advanced stages of urothelial cancer are significantly higher than those with early stages, and suggest that sFas with the VEGF protein in urine may provide an improvement in treatment and diagnosis.

Despite the non-significant difference of serum levels of FasLs, the high concentrations mean of sFasL in invasive bladder cancers may be resulted from the increasing malignant cells, as evidenced that sFasL has expressed by malignant transformed cells in bladder cancers \[23\]. In contrary, Bahria-Sediki et al., \[24\] showed the serum levels of sFasL in non-invasive bladder carcinoma are higher than that in invasive bladder cancers. This disagreement may be linked to the differences in ethnicity (Asian vs European), and measurements protocols.

### Conclusion

It was concluded that CD3+ TILs and CD8+TILs counts were significantly affected by the muscular invasiveness of bladder cancers, whereas there is no differences in both sFas and sFasL levels between MIBC & NMIBC.

Prevalence of Foreign Bodies in the Ear, Nose and Throat in Alramadi City

Omar Malik Bargas1, Qays Jaafar Khalaf2, Omar Abdulqader Ajaj3

1Lecturer, Depart. Otolaryngology, College of Medicine, University of Anbar, Iraq, 2Assistant Lecturer, Depart. Otolaryngology, College of Medicine, Diyala University, Iraq, 3Lecturer, Depart. Surgery, College of Medicine, University of Anbar, Iraq

Abstract

Background: Foreign body in ENT refers to an object which settles within head orifices which includes the ear, nose, or throat.

Aim: Compare the incidence of various Foreign Bodies in the Ear, Nose and Throat and the type of anesthesia required for removal in alramadi teaching hospital.

Method: This cross-sectional study was conducted on 100 patients who presented with complaints of foreign body insertion/impactionor ingestion in ear or nose or throat in alramadi teaching hospital.

Results: These cases comprised of 64 (64%) males & 36 (36%) females having male: female ratio= 1.77: 1. Out of all patients 56 (56%) presented with ear foreign bodies, 33 patients (33%) presented with nasal cavity foreign bodies, 11 patients (11%) presented with the throat (oropharyngeal/hypopharyngeal) foreign bodies. General anesthesia was required in 8 cases (8%) while the rest removed by senior house officers under supervision by ENT specialists or Consultants without GA.

Conclusion: Foreign bodies considered an important challenge to otolaryngologist especially in children who represented the most commonly affected age.

Keywords: Foreign bodies, Ear, Nose, Throat, health.

Introduction

Foreign body in ENT refers to any exogenous object present in ear, nose or throat. These FB may enter the orifices either accidentally or intentionally due to curiosity. FB problems may involve both children and adults with the predominance of children due to their immaturity or due to imitation of adults especially in case of cotton pads which used frequently by adults. Mental retardation also considered a risk factor and encountered more in adults. Most of the FB cases presented to the ER department or ENT out clinic. In general, FB can be divided into 2 main groups, either animated or in animated FB. Regarding the animated FB, these are most commonly involving the ear where the animal enters it during sleep on the ground. Animated FB including insects, flies or cockroaches may cause severe discomfort and even otorrhagia or TM perforation. In these cases, the animal should be killed before removal and this can be done by using alcohol or olive oil then remove it by suction, syringing or use of special instruments(1). Regarding the inanimated FB these can be divided into two main groups either organic or in organic and to hygroscopic (hydrophilic) or nonhygroscopic (hydrophobic) FB(2). Organic FB usually more dangerous if left in situ for a long period.
as it may induce an inflammatory reaction, so it should be removed as soon as possible. Organic FB includes bean, chickpeas, seed or any vegetable parts. Inorganic FB includes beads, toys, button battery or jewelry. FB in the upper airway should be removed urgently to avoid aspiration into the trachea or lower respiratory tract. Button battery considered a special entity as it can cause severe tissue damage and necrosis if left in place for hours due to the chemical substances released from it. FB, in general, can be removed either by syringing, suction or instrumentation and this can be done under local or general anesthesia according to the age of patients and their compliance.

**Patients and Method**

A descriptive cross-sectional study was done in ENT department, alramadi teaching hospital from August of 2018 to March of 2019 (7 months). This study included 100 patients presented to the ENT out clinic or ER complaining of foreign body insertion, ingestion or inhalation. The data collected included (patients’ age, sex, type of foreign body and the site of impaction, method of removal). nasal examination by Killian or thudicum speculum or usage of flexible nasopharyngoscope was done for those with nasal FB. Ear examination is done by otoscope for identification of FB while those with throat FB Flexible nasopharyngoscope done and plain lateral and AP view head and neck x-ray sometimes required.

**Result**

A total of 100 cases of foreign body inserted were included in the study. About (52%) of cases were children, aged less than 10 years. Age range (2 -72) year with mean =19 year. Out of 100, 64 (64%) were males & 36(36%) were females giving male/female ratio of 1.77: 1 (figure 1). The ears were the most common site of lodgment of foreign bodies (Table 1) this occurred in 56 (56%) patients followed by the nasal cavities in 33 (33%) and then throat (oropharynx & hypopharynx) in 11(11%) patients. General anesthesia was required in 8(8%) patients (table 2)which mostly included foreign bodies in hypopharynx and larynx while the rest removed without anaesthesia . The most common foreign bodies encountered include bead 46(46%), cotton 29(29%), fishbone 11(11%)(figure 2), insect 9(9%) (figure 3), battery button 4(4%), pomegranate seed 1(1%). (table 3)
Discussion

Foreign bodies considered as an important problem that may face the otorhinolaryngologist doctor from internship level to consultant level and this may be due to the challenge of how to deal with each case. FB include a variety of objects each of them required delicate skill in removal trials of removal by untrained persons add more difficult in removal by ENT doctors as they can cause more damage to surrounding tissue or push the FB to deep location.

This study shows the prevalence of FBs according gender, age, type, site and type of anesthesia used, out of (100) cases (52%) were children aged less than 10 years this result close to outcome of (El Taher) that found (76.4%) of 1,013 cases, (Kamran M) that found (70%) of 85 cases, (Adedeji TO) that found (62.3%) of 239 patients, (Parajuli R) that found (45.71%) of 70 patients, (Ray R) that found (61.8%) of 334 cases, (Chai CK) that found (60.1%) cases of 1,084. The increased incidence in children may be due to their curiosity to explore orifices, imitation to explore orifices, imitation may be due to their eye can cause more damage to surrounding tissue or push the FB to deep locati, increased incidence of ADH syndrome and absence of observation by parents due to being busy with social media and technology.

Also we found Male predominance was noted (64%) than comparable with result of (Muhammad et al 2017) which was 46 (54%), (Adedeji et al 2016) which was 132 males (55.2%), (Ibekwe MUJU) that was 94 males (51.93%), but incomparable with (Onyeagwara Ny) that observed a slight female preponderance by 70 (53%) of 132 cases. Although the male is a predominant higher percentage in female may be due to a variety of hair and body accessories which are formed from beads and small toys which mostly observed in females with FB impaction.

The ears were the most common site of lodgment of foreign bodies this occurred in 56 (56%) patients followed by the nasal cavities in 33 (33%) and then throat (oropharynx & hypopharynx) in 11 (11%) patients this coincident with earlier findings (Adedeji et al, 2016) which were Ear foreign bodies (68.7%), followed by nasal foreign bodies (20.9%) then throat (3.7%), but disagree with (Al Hussein et al 2017) which show Swallowed FBs were the most common (53.6%), followed by aural FBs (24.68%), nasal FBs (19%), and inhaled FBs (2.6%). In another study in India on adult and children aerodigestive tract foreign bodies, the nose was the least involved site (Kamath P). This difference from our study may be due to sampling size difference. Also we found that General anesthesia was required in 8 (8%) patients which mostly included foreign bodies in hypopharynx and larynx that agree with Muhammad et al (2017) which was 16 cases (18.8%), otherwise disagree with with Al Hussein et al (2017) were the majority of FBs removed under general anesthesia 554 (54.69%) that mostly due to swallowed FBs were the most commonly encountered (544 cases- 53.7%).

In this study the most common FBs in ear were bead (27%), cotton (22%) and insect (8%) while in nose were bead (19%), cotton (7%) and battery (4%) then the throat fishbone (11%) that comparable with Taiwo et al (2016) were ear bead 25 (15.2), cotton 45 (27.4), insect 17 (10.4), while in nose bead 15 (30), cotton 0 (0), battery 1 (2). then in throat fish bone 14 (5.9).

Conclusion

FB cases should be taken seriously as most cases occur in children and usually it is not easy to deals with them, despite this, fortunately, most of these FBs can be removed under LA especially in ear and nose compared.
to pharynx and larynx where FB removal may require GA due to patient intolerance and gag reflex. Advise the parent to watch their baby while they are playing with toys is necessary.

Ultrasound Value in Diagnosis of Acute Appendicitis at Al-diwaniyah Teaching Hospital-Iraq

Shaimaa A. Kadhum Al-Zubaidi
M.D. Diagnostic Radiology/Lecturer at College of Medicine-University of Al-Qadisiyah, Iraq, Diwaniyah, Iraq

Abstract

Background: Ultrasound has been widely available and usable imaging technique help in assessment and diagnosis of various diseases. The use of ultrasound as diagnostic tool for diagnosis of appendicitis has been established, but the real value of use of ultrasound not clearly observed, the aim of our study to clarify the negativity of the predictive value of ultrasound study for acute appendicitis (NVP).

Method: Ultrasound study of the abdomen with focusing on right iliac fossa done for 100 patient clinically suspected to have acute appendicitis and a scale of one to three given for sonographic results range from negative (score 1) to confirmed appendicitis (score 3), the result compared with the CT – scan finding and specimen pathology after surgical intervention.

Result: Seventy four (74) patient were negative by ultrasound, while twenty six (26) patient has score of 3 ultrasonic features of acute appendicitis, CT scan examination with contrast adding another ten (10) patient proved to have appendicitis (i.e changing from negative to positive appendicitis by CT findings) and fifteen (15) patient with other diagnosis or discharged, so total positive cases where thirty six (36) patients whom underwent surgical intervention, from those were thirty (30) patient confirmed appendicitis by pathological result (83%), So the negative predictive value for the ultrasound diagnosis of appendicitis (NVP = 95.1%).

Conclusions: Ultrasound had an overall lower sensitivity in diagnosing appendicitis in our study, but with high specificity, however, with various studies when the appendix was not clearly identified, CT-scan assessment should be considered.

Keyword: Appendicitis, ultrasound, diagnosis of appendicitis, sonographic assessment.

Introduction

A painful abdomen is common, acute appendicitis is the commonest suspected disease and must be differentiated from other pathology\(^{(1,2,3)}\). Although, the main points for diagnosis that patient commonly present with pain around the umbilicus which radiated to right lower abdomen, with nausea, vomiting, fever, leukocytosis with neutrophilia\(^{(4)}\). Imaging studies are much helpful in diagnosis when the clinical picture are not too clear, were studies support the use of ultrasound with/without CT- scan for confirmation of acute appendicitis\(^{(1,2,3,4,5)}\). Were the sensitivity of ultrasound ranging from (67% - 88%) and specificity about (78%-100%), while the sensitivity of CT-scan about (76%-96%) and specificity about (75% - 97%)\(^{(7,8)}\). The study aiming to assess the negativity of the predictive value of ultrasound study and if can be used for screening of acute appendicitis ..\(^{(10,12)}\)

Materials and Method

Study begin in Al-diwaniyah teaching hospital in the period between October 2018 and October 2019, were
100 patients complaining of clinical features of acute appendicitis seeking the surgical and radiological in-hospital clinic has been chosen randomly and included in our study, each ultrasound study done by specialist radiologist, were superficial and convex probe used. The examination focusing on region of right iliac fossa by using graded compression technique and viewed in longitudinal and transverse images, then a score of three points we depend upon to assess the clarify the possible available radiological findings, by which:

Score 1 (normal appendix, regarded as negative result)
Score 2 (appendix can't seen or minimal secondary signs of appendicitis like peri-cecral free fluid, or increment in the peri-cecral echogenicity with thickening of the fat of the mesentery and presence of faecolith or the size range from 5-6 mm, regarded as equivocal and need further assessment).
Score 3 (clear sonographic features of appendicitis like enlarged non-compressible appendix with diameter of 7 mm or more, regarded as positive result), as shown in figure (1). CT-scan with 2 ml/kg iodine based contrast media with 5mm axial imaging protocol for abdomen used, in some cases with abdominal pain more than one day, an oral contrast has been given also.

Fig 2 Criteria for positive acute appendicitis in CT-scan are an appendix diameter of the appendix exceed six millimeter, stranding of the surrounding fat stranding, wall enhancement of the tissue of the wall, and abscess around the appendix.

We correlate the radiological finding with surgical and pathological result with definitive diagnosis.

Statistics: The accuracy of diagnosis of ultrasound study was assessed by using the positive and negative predictive value, sensitivity and specificity and their respective, negative and positive likelihood ratios. The values regarded as estimated values and 95% confidence intervals.

Results

From the 100 appendicitis diseased complainers selected for study and undergo the ultrasonic examination, 74 patients had negative ultrasound scan, and 26 have positive ultrasound scan.

Those 100 patients then undergo CT scan with contrast for the abdomen/pelvis and changing the result of 10 patient from negative to positive i.e. with CT-scan the positive became 36 patients, and 64 patients negative or had another diagnosis.

Those 36 patients underwent surgical intervention and pathological assessment, from whom 30 patient were proved to have appendicitis and 6 patient were negative by pathology, so the sensitivity of ultrasound was (75%), specificity was (92%), positive predictive value (85%), CI (46.2%–74.4%) and the negative predictive value (NPV) about (95.1%).
Discussion

Acute appendicitis suspicion is regarded as one of the mysterious cases encountered in clinical medicine, diagnosis is mainly based on clinical practice, but sometimes the case can be missed.\(^{(13,17)}\)

Radiological imaging has a vital role in the updated assessment of appendicitis, although the best radiological assessment remains unclear.\(^{(19)}\)

The ideal imaging protocol should obey the following criteria which are availability, non-expensive, reproducibility, safety, fast test, and accurate one.\(^{(18)}\)

X-ray images findings are not precise, but the presence of appendicolith is diagnostic of appendicitis, however its present in less than (5%) of acute appendicitis.\(^{(19,20)}\)

Studies that use of sonography and CT-scan in the assessment of acute appendicitis focusing on the visualization rate of the appendix with clarifying the specificity and sensitivity of the study.\(^{(1,5,14)}\)

Ultrasound examination is helpful in assessment of female, to avoid radiation to feminity organs to exclude ovarian and uterine diseases that might resemble clinical picture of acute appendicitis.\(^{(21)}\)

In the study the diseases of the ovary and uterus with pain were found in 14 patients, or another diagnosis found \(^{(22)}\).

The most criterion for the diagnosis of appendicitis by ultrasound are the identification of a non-compressible blind-ending tubular structure in the region of the right iliac fossa with an outer diameter of more than six millimeter \(^{(23)}\).

Older researches suggested that to exclude acute appendicitis, a normal appendiceal structure should be recognize \(^{(24)}\).

The sonographic visualization rate varies greatly between hospitals, from about 98% to 22%.\(^{(10)}\) In our study, negative result mean non visualization of appendix and no other signs of appendicitis, depending on these principles, the NPV was about (95.15 %), is similar to results in older studies.\(^{(10,24)}\)

The indication of use of CT-scan after ultrasound study included non-visualization, non-conclusive visualization of secondary signs of appendiceal inflammation, or negative but still with associated suspicion for acute appendicitis.\(^{(10,12,24)}\)

The positive predictive value in the study was relatively lower than others \(^{(10,11,24)}\) which could be contributed the low pretest probability of the disease in our population\(^{(22)}\).

The retrospective design added a limitation to our study, as the examinations are highly depend on the operator. However, the study was supported by the using a rigorous exclusion protocol for acute appendicitis in our hospital.\(^{(19,20,21)}\)

Our conclusion, ultrasound was found to have a high negative predictive value (95.15 %) for the exclusion of appendicitis even when the appendix can-not be seen. The role of ultrasound use in young female is supportive especially to protect their reproductive organs from radiation of other modalities, which could be done when clinical status deteriorated or still highly suggestive of acute appendicitis.\(^{(14)}\)

Association of Syndecan 4 and Osteocalcin with Application of BMP2 and BDNF in Bone Healing of Osteoporotic Rats

Lobna K Al-khafaji¹, Athraa Y Al-hijazi², Noor Natik Raheem³

¹Lecturer, Oral Histology, Department of Dentistry, El-Esraa University College, Iraq, Baghdad, ²Prof. Dr., Oral Histology and Biology, Department of Dentistry, Al-Mustaqbal University College, Iraq, Babylon, ³Ass. Lecturer, Oral Histology, College of Dentistry, Mustansiriya University, Baghdad, Iraq

Abstract

Background: Bone tissue contains multipotent stromal cells, which have the ability to differentiate into different specialized cells. Induced stem cells have been developed with various growth factors using many biomaterials, which are the most common strategies in tissue engineering. Syndecan 4 and osteocalcin expressions during healing of bone defect in osteoporotic rat, along with the application of bone morphogenic protein 2 (BMP-2) and brain-derived neurotrophic factor (BDNF), were evaluated in this study.

Method: Ten normal rats and 10 induced osteoporotic rats were used in this study. Three mm bone defects were created in the femur of each rat, one on the left side and another one on the right side. The left bone defects were left to heal spontaneously without any application, while the right ones were treated with a combination of BMP2 and BDNF. Immunohistochemical evaluation was done for positive expression of syndecan 4 and osteocalcin in bone tissue during healing periods.

Results: Application of BMP2 and BDNF for both normal and osteoporotic rats increased the expressions of syndecan 4 and osteocalcin. In addition, expression of Syndecan 4 was decreased with increment period, while Osteocalcin expression showed the reverse. Statistical analysis revealed a significant difference regarding both positive expression of Syndecan 4 and osteocalcin in the treated groups compared to their untreated counterpart.

Conclusion: Application of BMP-2 and BDNF enhances syndecan 4 and osteocalcin expressions in bone repair of osteoporotic rat.

Keywords: BMP-2, osteoporosis, bone cells, bone healing, BDNF, Syndecan 4, Osteocalcin.

Introduction

Bone healing is a physiological proliferate process resulting in new bone formation that fills the hole or the fracture site¹.². Osteoporosis is a public health problem associated with an increased risk of bone fractures and it was thought to delay or impair the regenerative response³.⁴. In bone repair of osteoporotic animals, changes in the expressions of bone sialoprotein (BSP), alkaline phosphatase, osteopontin, osteocalcin and bone morphogenetic protein (BMP) were observed. Their decreased expressions have been found to delay healing of osteoporotic bone fractures⁵.⁶.

Combination of biomaterials with BMP2 and other growth factors, was reported in many advanced bone healing studies⁷.⁸. Brain-derived neurotrophic factor (BDNF) has an influence on bone innervation, and may modulate the proliferation or differentiation of

e-mail: athraayms@yahoo.com
the developing bone cells by acting as osteogenic and angiogenic factors. Syndecan-4 considered as the best plasma membrane proteoglycan and was found on cell surfaces of fibroblasts and epithelial cells. Osteocalcin is a vitamin K-dependent, bone-specific protein and considered as specific osteoblastic bone marker. Osteocalcin expression was observed during bone healing process at the periods when intense mineralization of the bone tissue occurs.

All those factors seem to be necessary and have important roles in bone healing. And because there are few studies concerning this field, therefore, current study was conducted to study the effect of local application of BMP-2 and BDNF with the expression of Syndecan 4 and Osteocalcin in repaired bone tissue.

**Method**

**Animal Models:** Twenty female Wistar rats, weighted 0.25-0.30 kg, aged 4-5 months were used and kept in the Animal Department of National Center of Drug Control and Research, Iraq at a constant humidity and temperature of 23°C. Animal care was furnished in accordance with the National Council’s guide. After 2 weeks of acclimatization, rats were randomly allocated to 4 groups as follows, normal rats with bone defect left to heal spontaneously (group A), osteoporosis-induced rats with bone defect left to heal spontaneously (group B), normal rats with bone defect treated with application of BMP-2 and BDNF (group C), and osteoporosis-induced rats with bone defect treated with application of BMP-2 and BDNF (group D).

**Induction of Osteoporosis:** Ten rats were anesthetized by ketamine and xylazine mixture. The skin area was shaved, washed using chlorhexidine scrub and ethanol 70% and disinfected by povidone iodine. Bilateral ovariectomy was carried out by single sagittal medial laparotomy process. Then, the rats received a daily intra-muscular injection of methylprednisolone hemi succinate (MPH) at dose (1 mg/kg) for 4 consecutive weeks.

Six weeks after ovariectomy, surgical bone defect was done. The rats were anesthetized generally with a mixture of 50 mg/kg BW ketamine and 2.5 mg/kg BW xylazine. Surgical technique was performed in rat femur to prepare two 3 mm-drill-holes, 1 hole on the left femur and another hole on the right. Same surgical procedure was also performed for normal rats. The holes on left femur were considered for the A and B groups of normal/osteoporotic rats. The holes left to heal spontaneously without any application, just washed with normal saline, dried gently and sutured. Meanwhile the right holes were considered for the C and D groups. The holes were treated with a combination of 0.5 microliter BMP2 (rhBMP-2, Medtronic Sofamor Danek, TN, USA) and 1 microliter BDNF (ab9794, Abcam, UK), dried gently and sutured. Determination of effective dose for BMP2/BDNF depends on previous studies.

The animals were sacrificed by an overdose of carbon dioxide gas after surgical operation at the 7th and 14th day. Bone holes along with their surrounding bones were excised with a surgical saw right away following the euthanasia. The excess tissue were dissected and the specimens removed with a 5–10 mm margin of surrounding bone. The specimens immediately were fixed into the 10% formaldehyde solution. Then, the specimens decalcified, dehydrated, embedded in wax and sliced in serial with 4-µm thickness.

**Immunohistochemistry:** Then immunohistochemistry was performed with polyclonal anti-Syndecan-4 (ab24511, Abcam, UK) and anti-Osteocalcin (OC4-30, ab13418, Abcam) antibodies. Positive peroxidase staining produced brown color on light microscopy. The percentages of positively stained cells were counted at 5 representative fields with (X40) magnification.

Immunohistochemistry results were quantified by counting the positive cell in each 100 cells in five fields (X40) of different sections. Then the mean and scoring of positive cells was estimated for each sample. The scoring was score 0, none; score 1, <10%; score 2, 10-50%; score 3, 51-80%; and score 4, >80%.

**Statistical analysis:** All records were entered into Excel spread sheets for evaluation with the Statistical package deal for Social studies (SPSS) (Chicago, IL, united states of America). The data were analyzed using one-way ANOVA test with multiple comparisons of LSD.

**Results**

**Syndecan 4 findings:** The immuno-reaction for Syndecan 4 and Osteocalcin illustrated an increment in their expression with application of BMP2 and BDNF for both normal and osteoporotic groups. Positive expression of Syndecan 4 illustrated by osteoblast, osteocyte in
normal group while in osteoporotic group the expression mostly observed in osteoclast, inflammatory cell and mesenchymal cell (Figure 1). On other hand, minimal decrease in the scoring recorded in the 14th day period in all groups in comparison to 7th day period, which revealed mostly, score two and three. Statistic results revealed a significant different value of positive expression of Syndecan in treated groups in comparison to those untreated, in both studied periods, (Table 1).

**Osteocalcin findings:** Osteocalcin expressed by osteoblast and osteocyte in all groups but an intense brown stain observed in groups (C & D) that treated with growth factors application (Figure 2). On other hand, the expression increased with period and recorded mostly, score 2 and 3 in the 14th day period in all groups except for group B (untreated osteoporotic) that showed score 1 in both periods. Statistical analysis revealed a significant different value for positive expression of osteocalcin in treated groups in comparison to those untreated, in both periods. Groups (A & C) revealed a non-significant difference in the 14th day period, (Table 2).

LSD test
### Discussion

The present results showed an increment of the expression of both Syndecan 4 and Osteocalcin in treated groups with local application of growth factors in comparison to untreated. These results could be attributed to the cooperation of many factors related to the presence of BMP2 which enhanced many events, including the differentiation of mesenchymal stem cells (MSCs) into osteoblast and the enhancement of angiogenesis\(^{18}\). The BMPs potently record to induce osteogenic differentiation\(^{6}\) and might be involved in the chemotactic recruitment of osteoblasts during new bone formation\(^{3}\). Moreover, BDNF has an effects on vascular endothelial growth factor (VEGF) that stimulated vascularization and promote bone formation\(^{19}\). A study revealed a delay in the healing process of osteoporotic rats in comparison to that in normal rats, where they detected disturbance of new bone formation accompanied with the reduction in bone resorption\(^{6}\). Other study used MBG particles loaded with BDNF filled fracture gaps in osteoporotic mice. The study showed increase in bone formation, and reported that this growth factor (BDNF) appears as potential drug suitable to stimulate bone formation during fracture healing in osteoporosis\(^{20}\). In the present study, the application of the growth factors seem to play an effect on the activity of cells related to bone healing, specifically in the osteoporotic rats that had a defects in differentiation, vascularization and in expression of many proteins including syndecan-4 and osteocalcin\(^{21}\).

Furthermore, in the present results, the local application of combined BMP-2 and BDNF, might act as a bioactive molecules, stimulating bone cell proliferation that resulted in an increment of expression of Syndecan-4, specifically in the 7\(^{th}\) day (the time of bone apposition). Moreover, an increment of Syndecan-4 enhanced the interaction of involved cells with the extracellular matrix, anticoagulants, and other growth-factors which activate cell adhesion and cell migration, and then enhance bone healing\(^{22,23}\). A study revealed that Syndecan-4 contains binding sites for various proteins, growth factors, and cytokines. In addition, it is involved in the influence bone structure and fracture healing\(^{12}\).

Osteocalcin considered as a marker of osteoblastic activity and specific marker of bone metabolism, therefore, the present results detected the expression of osteocalcin in osteoblasts and osteocytes. These cells may play a role in the remodeling of extracellular matrices with expression of syndecan 4 during healing of the bone defect. Osteocalcin expression observed to be increased in the 14\(^{th}\) day, the period of mineralization of bone tissue during healing process\(^{24,14}\). A study observed that at seven days neo-formed trabeculae bone labelled with a small quantity of osteocalcin, while at 14 days a larger quantity of deposited trabeculae bone with higher osteocalcin values were recorded, our results were compatible with these findings\(^{25}\).

### Conclusions

Local application of BMP-2 and BDNF enhanced both the expression of syndecan-4 and osteocalcin of osteoporotic rats.

Urinary and Serum N-acetyl B-Glucosaminidase as Biomarkers of Albuminuria in Patients with Type 2 Diabetes

Ahmed Mahdi Daham¹, Raid AL-Timimi²

¹Post Graduate, ²Assist. Prof., Department of Chemistry and Biochemistry; College of Medicine, AL-Nahrain University, Iraq

Abstract

**Background:** Diabetic nephropathy is a serious kidney-related complication of type 1 diabetes and type 2 diabetes. It is also called diabetic kidney disease. About 25% of people with diabetes eventually develop kidney disease. The enzyme N-Acetyl-β-glucosaminidase (NAG) (EC: 3.2.1.30) is one of lysosomal acid hydrolases enzyme present in many body tissues with a high molecular weight (~ 140 kDa). It breaks chemical bonds of glycoside and amino sugars which form structural components in many tissues. Different pieces of cells need to be degraded and disposed of, including the cell membrane.

**Method:** By using ELISA kit, we measured urine and serum level of N-acetyl B-Glucosaminidase in 30 patients diabetes with Microalbuminuria: ACR: <30 mg/g, 30 patients diabetes with Macroalbuminuria: ACR>30 mg/g with 30 healthy volunteers enlisted as normal controls.

**Result:** Urine concentration of NAG in macro and micro- groups was comparable (13.23±1.04 ng/mL and 13.1±1.46 ng/mL, respectively) with no significant difference, while both groups showed highly significant difference compared with normo- group (5.15±2.11 ng/mL) On the other hand, serum concentration of NAG in normo- micro- and macroalbuminuria was 1.2±0.3 ng/mL, 2.5±0.58 ng/mL and 3.2±0.77 ng/mL, respectively, with highly significant differences between the three groups.

**Conclusion:** N-Acetyl-β-Glucosaminidase: the present study, diabetic nephropathy was associated with elevated urinary and serum NAG values compared to a control group. This increase in NAG was parallel to the severity of renal involvement with a characteristic increasing trend was observed among the study groups regarding albuminuria.

**Keywords:** N-Acetyl-β-Glucosaminidase, diabetes mellitus, diabetic nephropathy, ELISA.

Introduction

Diabetes mellitus is a metabolic disorder or may be described as a diverse group of diseases with different causes. Worldwide, cancer ranks second and diabetes mellitus ranks twelfth in the list of causes of death.

---

¹, It is a chronic disease that affects approximately 26.9 percent of the U.S. population aged 65 years and older. 1.9 million diabetics are diagnosed each year, in addition to 7.0 million undiagnosed and untreated. The diagnosis of diabetic patients should be based on the following: • HbA1c check with a limit of ≥ 6.5 per cent. Fasting blood Glucose (FBG) ≥ 126 mg / dL. or Glucose Tolerance Test; plasma glucose levels ≥ 200 mg / dL after two hours of consumption of 75 g glucose. Untreated diabetic patients have chronic hyperglycemia, i.e. higher than normal blood glucose levels. The cause for this is either a low level of insulin (a polypeptide hormone secreted by the pancreatic beta cell), an unusual form of insulin, or both.
Diabetic nephropathy is a diabetes-complicated kidney disease. It can occur in people with type 2 diabetes, the most common form of diabetes caused by insulin resistance, or in people with type 1 diabetes, the type that begins earlier and results from reduced insulin production. The damage to the smallest blood vessels causes diabetic nephropathy. Both kidneys start to leak proteins into the urine when small blood vessels begin to develop damage. The kidneys slowly lose their ability to remove waste products from the blood as damage to the blood vessels persists. The enzyme N-Acetyl-β-glucosaminidase (NAG) (EC: 3.2.1.30) is one of lysosomal acid hydrolases enzyme present in many body tissues with a high molecular weight (~ 140 kDa). It breaks chemical bonds of glycoside and amino sugars which form structural components in many tissues. Different pieces of cells need to be degraded and disposed of, including the cell membrane. NAG present in the lysosomes of the proximal renal tubular cells at high concentrations. There are two main isoenzymes in the kidneys of humans. Isoenzyme-A is part of an intralysosomal compartment that is excreted by exocytosis in the urine. Isoenzyme-B is associated with the lysosomal membrane and excreted during tubular damage in urine. These two enzymes vary in their heat tolerance and in acid urine stability. Because of its urine stability, its relatively large molecular mass that prevents glomerulus filtration and its involvement in high tubular lysosomal activity, elevation of urinary NAG activity has been taken as a marker for renal proximal tubular damage or more precisely loss of lysosomal integrity.

The aim of the present study was to evaluate urine and serum level of in patients with Diabetic nephropathy, and compare this group with control healthy group as well as to investigate whether it can be used as a biomarkers for detection of diabetes.

Materials and Method

Study design case control study: The present study was executed during the term from August 2019 to November 2019. This study included 60 patients with diabetic nephropathy and 30 healthy controls. Group I consist of 30 patients with Microalbuminuria: ACR: <30 mg/g Group II consist of 30 patients with Macroalbuminuria: ACR>30 mg/g Groups III Consist of 30 of matched healthy subjects were used as control ACR <20 mg/g. All samples were collected from Medical City of Baghdad Teaching Hospital. About 6 ml of blood samples were obtained from veins of patients having diabetic nephropathy and healthy control subjects. The 6 milliliters of blood were left for 15 minutes at room temperature. After coagulation, sera were separated by centrifugation at 3000 rpm. for 10 min. Sera were aspirated and divided into small aliquots for:-Immediate measurements of serum total protein, albumin, creatinine, blood urea, blood glucose, uric acid were done using appropriate method. The rest were stored at -20 C° until assayed They were measured using enzyme-linked immunosorbent assay (ELISA) kits. Ten milliliters of urine were obtained from patients and healthy children, and then collected in the plane were centrifugation at 1000x g for approximately 10 minutes.

Statistical Analysis:
- In this study the data obtained was analyzed by Microsoft excel 2010 and SPSS version 23.
- The numerical data expressed as mean ±SD.
- Student’s t-test was used to calculate individual p-value, p-value < 0.05 was considered significant.

For comparing mean of more than two groups the ANOVA was used.

Result

Demographic and Clinical Characteristics of the Study Population: The mean age of patients with normo-, micro- and macroalbuminuria was 42.3±3.25 years, 42.93±3.03 years and 44.8±4.28 years respectively with no significant difference. Similarly, there were no significant differences between the three groups in gender distribution, type of therapy and BMI. However, DM duration was significantly longer in macro (8.77±4.2 years) group than normo- group (5.63±4.96 years).

**Different small letters indicate significant differences:** Both HbA1c and FBS were significantly higher in macro group (10.22±1.72% and 177.03±24.75 mg/dL, respectively) than either normo- (7.32±1.12% and 100.73±13.89 mg/dL, respectively), or micro-group (9.18±1.79% and 163.83±21.5, respectively). In contrast, normo- group showed higher serum TSP and albumin (74.43±3.41 mg/dL and 41.97±2.04 mg/dL, respectively) than either micro- (71.5±3.01 mg/dL and 39.4±2.79 mg/dL, respectively) or macro- group (70.73±4.27 mg/dL and 39.7±3.14 mg/dL, respectively) with highly significant difference (Table 1).

**Urine and Serum Concentrations of NAG:** Urine concentration of NAG in macro and micro- groups was comparable (13.23±1.04 ng/mL and 13.1±1.46 ng/mL, respectively) with no significant difference, while both groups showed highly significant difference compared with normo- group (5.15±2.11 ng/mL) as shown in figure 3-1. On the other hand, serum concentration of NAG in normo- micro- and macroalbuminuria was 1.2±0.3 ng/mL, 2.5±0.58 ng/mL and 3.2±0.77 ng/mL, respectively, with highly significant differences between the three groups (Figure 3-2).

![Figure 1: Urine concentration of NAG](image-url)
Discussion

N-Acetyl-β-glucosaminidase: The present study, diabetic nephropathy was associated with elevated urinary and serum NAG values compared to a control group. This increase in NAG was parallel to the severity of renal involvement with a characteristic increasing trend was observed among the study groups regarding albuminuria. These results are in agreement with other studies (9) that stated that changes in urinary and serum NAG activity can reflect the activity of the disease as well as the residual functional capacity of the kidney. Our results showed that even in the absence of any clinical evidence of microvascular complications, urinary NAG excretion was invariably elevated indicating that subclinical renal tubular dysfunction may exist before the occurrence of glomerular damage. Kuzniar et al. (2006) denoted that in proteinuric glomerular diseases the increased NAG excretion can occur even in absence of morphological evidence of tubular cell damage, probably reflecting increased lysosomal activity of these cells due to the increased uptake of filtered proteins. Physiologic increases in urinary NAG for metabolizing urinary glucose and the nephrotoxic effect of glycated end products on renal proximal tubules could be possible. NAG is an enzyme involved in carbohydrate metabolism. When the proximal tubules are exposed to high urinary glucose, NAG might be secreted more in the urine, depending on urinary glucose concentrations. In addition, the peptides derived from advanced glycation end products might have a potential nephrotoxic effect on the proximal tubule, thus contributing to the occurrence of proximal tubule injury.

Conclusion

The cutoff value of urine and serum NAG high levels of NAG between groups compared with controls. This difference is useful for distinguishing between study groups.

Impact of Dyslipidemia and Body Mass Index (BMI) in Development of Osteoarthritis (OA) in Iraqi Patients

Mohammed I. Hamzah¹, Moaz Rashad Saed², Muhammed Abdul-Gabar Hamoodi Aldabagh³, Hadeel Sameer Abd Alwahab⁴

¹Assistant professor (PhD) in Clinical Chemistry, Chemistry and Biochemistry Department, College of Medicine Al-Nahrain University, Iraq, ²High Diploma in Clinical Biochemistry, General Haditha Hospital, Iraq, ³Assistant Professor (PhD) in Clinical Immunology, Medical Research Unit, Collage of Medicine, Al-Nahrain University, Iraq, ⁴Lecturer (MSc) in Analytical Chemistry, Medical Research Unit, Collage of Medicine, Al-Nahrain University, Iraq

Abstract

Objectives: Osteoarthritis is a widespread degenerative defect of the articular cartilage connected with hypertrophic bone changes. Worldwide, obesity is one of the most common risk factor for such disorder. Current study was designed to investigate effect of this factor in Iraqi OA patients. Subjects and method: Total of 75 volunteers were enrolled in this study (50 patients and 25 subjects as controls). BMI and lipid profile were measured for each subject.

Results: Our study showed significant elevations (p value< 0.05) in each of cholesterol, TG, LDL, and VLDL as well as in BMI while showed nonsignificant difference in HDL in OA patients compared to healthy individuals.

Conclusion: Obesity and disturbance of lipid profile may play substantial roll in development of OA in Iraqi patients.

Keywords: Osteoarthritis, cholesterol, TG, LDL, VLDL, HDL, BMI, Iraqi patients.

Introduction

As the most prevalent chronic, varied, and dampen arthritic disorder, osteoarthritis (OA) fundamentally effect diarthrodial joints[1-4]. Life style can be affected negatively by osteoarthritis[5]. The OA incidence ranged from 3.8-70% worldwide[6]. In Iraq, Syria, Saudi Arabia, and Yemen about 1 million people are affected by OA [7]. In man gender OA was more common than women,however in females beyond 50 are affected by OA more than man at same age[8]. Typically, OA supposed to be due to aging and obesity[9]. Accumulated studies deals with the connection of obesity and metabolic syndrome with development of OA[10-12]. Epidemiological and experimental studies propose that the biological mechanisms implicated in the progression of OA could be linked to the lipid metabolic pathway has been well studied[13-15]. On the other hand, obesity and Overweight are independently associated with elevation of OA incidence [16-18]. This condition may be due to releasing of adipokines by adipose tissue[13].

Weighted study reported that lipid disturbances may be implicated in OA pathology[19]. However, few studies have deals with the relation between OA and dyslipidemia. Current study aimed to investigate if serum lipid profile is correlated with development of OA in Iraqi community.
Subjects and Method

This study was conducted in Haditha general hospital (from July 2019 to August 2019) in Rheumatology & Rehabilitation Consultation Department). Seventy-five unrelated volunteers were enrolled in current study, 50 patients (58.2±8.1 years) from both gender proved with osteoarthritis and 25 apparently healthy (57.2±7.9 years) as control group. Body Mass Index \( [\text{BMI} = \text{weight (kg)}/\text{square height (m}^2\text{)}] \) were recorded and venous blood (after 12 hours fasting) serum were collected from each participant. Using biochemical kits, lipid profile tests (cholesterol, TG, HDL, LDL, VLDL) were done for each sample. The current study was approved by Research Ethical Committee of College of Medicine/AL-Nahrain University. All the participants were provided with written informed consent to enroll in this study.

Statistical analysis: Using software of SPSS program (version 20) collected data were analyzed. Student’s t-test was used to match means of lipid profile factors between cases and control. Concentrations of measured markers expressed as \( \text{(Mean±Standard error)} \). Significance in all tests was set at 0.05 \( (P \leq 0.05) \).

Results

The result of present study \( \text{(Mean±SD)} \) showed significant dropping \( (p \text{ value <0.001}) \) of body mass index \( \text{(BMI= kg/m}^2\text{)} \) in patients group \( (30.89±5.88) \) compared to control group \( (30.89±5.88) \) (Fig. 1).

![Body Mass Index](image)

**Figure 1:** Histogram showing body mass index in patient and control groups.

While, results \( \text{[Mean±SD(mg/dl)]} \) of lipid profile in patients with OA showed significant elevation in each of cholesterol \( (198.0±41.7, \text{p value=0.001}) \), TG \( (144.42±55.56, \text{p value=0.024}) \), LDL \( (113.84±36.44, \text{p value<0.001}) \), and VLDL \( (28.9±11.11, \text{p value= 0.024}) \) compared to levels in control group \( (162.76±30.71), (116.28±30.8), (80.83±28.9), (23.26±6.16)\) respectively. On the other hand, level of HDL \( (55.28±10.98) \) showed non-significant difference \( (p \text{ value 0.238}) \) compared to control group \( (58.68±11.55) \) (Fig. 2).
Figure 2: Histogram showing lipid profile in patients with OA and control. TG: triglycerides, HDL: high density lipoprotein-cholesterol, LDL: low density lipoprotein-cholesterol, VLDL: very low density lipoprotein-cholesterol.

Discussion

Our study showed significant elevations in each of cholesterol, TG, LDL, and VLDL as well as in BMI while HDL showed non-significant difference in OA patients compared to control group.

In massive study Garcia-Gil et al suggested that elevated levels of HDL manifest to keep against OA, also they found an opposite relationship between levels of HDL cholesterol and the incidence of OA while levels of TG showed significant tendency, moreover LDL levels showed no relation with OA[20].

In cross-sectional study by Hart et al found significant relationship between OA and elevated TC while no relation between OA and elevated concentrations of LDL, TG, or HDL [21]. Other studies reported contradictory results regarding relationships between LDL, TG, TC, and incidence of OA. Dahaghin et al showed no relation between TC/HDL ratio and OA[12].

Mechanisms of lipid metabolism may be lead to development of OA still need for massive studies. There is proof that elevated levels of HDL in the synovial fluid have significant protective action [22], vascular injury affecting the bone marrow following to the cartilage, and the toxic action of cholesterol at the joint may be contribute to the progression of OA[23].

In study to seek the incidence of dyslipidemia in OA patients Pauline et al reported that increasing of dyslipidemia was two folds with OA than without OA[24]. Moreover, in pathophysiological study carried by Visser et al suggested that correlation between metabolic syndrome (MetS) and OA may be due to effects of adipose tissues as source of proinflammatory factors as well as effects of visceral fat[25]. Coggon et al reported that there is significant positive correlation between BMI and OA, this result consent with other current study[26]. Also, Grundy and Barnett reported that obesity is associated with several deleterious changes in lipid metabolism, including high serum concentrations of total cholesterol, LDL, VLDL and TG, and reduction in serum HDL concentration[27]. In study conducted on such disease Jeppesen et al demonstrate the interaction between TG and total cholesterol or HDL[28].

In study to investigate the relation between BMI and dyslipidemia Palou et al reported the significant relationship between BMI and serum lipid profile, their results showed that in all age groups, HDL levels were significantly lower in patients who had a high BMI[29]. Furthermore, Rosenson et al showed that hypertriglyceridemia is often associated with reduced levels of HDL suggesting a possible metabolic interaction between these two lipid fractions[30].
On the other hand, Ginsberg and Stalenhoef reported that relation of fat deposition in obese individuals is associated with insulin resistance, leading to increase synthesis of TG-rich lipoproteins in the liver[31]. Other study showed that increase of TG in lipid particles changes their metabolism, TG-rich HDL particles are hydrolyzed more rapidly causing HDL level to fall [32].

Mohiti and Qujuq showed that circulating lipid profile levels appear to be one of the best biological markers of obesity and hyperleptinemia is closely associated with several risk factors related to obesity syndrome[33].

Indeed, a decrease in BMI is accompanied by significant reduction in serum lipid profile levels leading to improved lipoprotein profile [34]. Brandt et al suggested that OA is a mechanically induced disorder in which the consequences of abnormal joint mechanics provoke biological effects that are mediated biochemically through local or systemic factors [35]. Accumulated evidences support our results and revealed that OA have significant relation with dyslipidemia and obesity.

**Conclusion**

BMI and dyslipidemia may play substantial roll in development of OA in Iraqi patients.

Congenital Diaphragmatic Hernia:  
A Single Center Experience Over Seven Years

Yaser Aamer Al-Haibi, Ahmed Zbar, Abass Jaffar

M.B.Ch.B, F.I.B.M.S., Cardiothoracic and Vascular Surgeon, Lecturer College of Medicine, Al-Nahrain University, Iraq.  M.B.Ch.B, F.I.B.M.S., Pediatric Surgeon, Ass. Prof. College of Medicine, Al-Nahrain University, Iraq

Abstract

The congenital diaphragmatic hernia (CDH) is a birth defect in the fetal diaphragm allowing abdominal contents to protrude to the thoracic cavity. Presence of abdominal contents in the thoracic cavity will affect the respiratory reserve leading to respiratory symptoms mainly tachypnea. Congenital diaphragmatic hernia can be presented alone or with other congenital anomalies including cardiac, respiratory, or other anomalies. CDH can be classified as Bochdaleck, or Morgagni hernia. In 75% of cases CDH is on the left side. The aim of this study is to view the management of patients with CDH in terms of diagnosis, treatment, and survival rate. Forty-six cases were studied over seven year period from January 2012 till January 2018. They were diagnosed based on clinical examination, radiological investigations. 18 (39%) cases were 2-7 days of age. 29 (63%) of cases were presented with tachypnea. Bochdaleck’s CDH is found in 44 patients (96%). 18 patients (39%) were having pulmonary hypoplasia as an associated anomalies with CDH, such anomalies affect the pulmonary reserve by putting the child in a danger of pulmonary hypertension. Treatment was via surgical repair done by team of thoracic and pediatric surgeons. In this study, we found delaying surgical repair after stabilizing the respiratory reserve leads to good postoperative survival, this was proved by high mortality rate (8 patients 67%) in patients with less than 24 hours age. The aim of this study is to show the way of management of congenital diaphragmatic hernia in terms of diagnosis, treatment, and the survival rate.

Keywords: Congenital diaphragmatic hernia (CDH), Congenital anomalies, Bochdaleck’s CDH, Morgagni’s CDH.

Introduction

The diaphragm is the muscular structure that separate the thoracic cavity from the abdominal cavity and it is essential for the respiratory process, any birth defects in this muscular structure will lead to respiratory insufficiency due to herniation of the abdominal contents up into the thoracic cavity in a spectrum of congenital anomaly known as congenital diaphragmatic hernia. It has been found that genetic and environmental factors play a role in the pathogenesis of this anomaly; nevertheless, still pathogenesis is not well understood.(1)

Congenital diaphragmatic hernia (CDH) is a relatively common malformation in which there is failure of complete fusion of the diaphragm during the prenatal period. This leads to protrusion of abdominal organs into the thoracic cavity which can result in lung hypoplasia and respiratory failure at birth. Anatomically, CDH can be classified as postero-lateral (Bockdalek, 70–75%), anterior (Morgagni, 23-28%), or central (2-7%) defects.(2)

e-mail: yaseraamer@gmail.com
In about 75% of cases CDH can be presented in the left side leading to the possibility of herniation of the small, or large bowel, the stomach, the spleen, the left lobe of liver, or rarely the kidney. CDH on the right side can include the right lobe of the liver, the possibility of the bowel and/or the kidney. (3) CDH occurring bilaterally is a rare presentation. (4)

The classical presenting symptoms are respiratory distress in terms of tachypnea, dyspnea; reluctant for feeding; and failure to thrive. The diagnosis is clinical and radiological. Surgical correction still the treatment of choice for CDH. The survival depends primarily on the severity of pulmonary hypoplasia, and the amount of fixed pulmonary hypertension, and secondly on the severity of associated anomalies. (5)

The aim of this study is to show the way of management of congenital diaphragmatic hernia in terms of diagnosis, treatment, and the survival rate.

Patients and Method

This study was carried out prospectively including forty-six children who admitted to Al-Kadhymiya Teaching Hospital with congenital diaphragmatic hernia which were proved by imaging studies (chest x-ray, Barium meal, and chest CT-scan) over a period of seven year from January 2012 to January 2018. Nine children died preoperatively despite optimal respiratory ventilator support, they were excluded from our study. Forty-six children underwent surgical correction of congenital diaphragmatic hernia. Once patients with CDH received in our outpatient unit, full investigations underwent in terms of blood investigations, radiological studies confirming the CDH and any associated anomalies; then the planning for surgical repair is ensured. The surgery is performed by an abdominal subcostal approach, the herniated abdominal viscera are reduced, and the diaphragmatic defect is inspected for the presence of any sac that should be excised. The defect then closed by interrupted sutures in case of small ones, and synthetic patches are used to close the defects in large ones. Post operatively, child is followed up in terms of respiratory failure, and mortality.

Results

Age Distribution: The majority of cases (18 cases) 39% were in their first week of age, while only (2 cases) 4.5% were more than first year of age. As shown in the graph below.

Clinical Presentation: Clinically, (29 cases) 63% with CDH were presented having tachypnea, only (12 patients) 26% presented with cyanosis. The gastrointestinal symptoms as vomiting, constipation, and abdominal distension were in (2 patients) 4.5% only. As shown in the table below.

Chart No. (1) : Types of congenital diaphragmatic hernia.

Type of congenital diaphragmatic hernia:

- Bochdaleck’s hernia is found in 44 patients (96%), the majority (38 patients) 83% is on the right, and (6 patients) 13% are on the left. While Morgagni type of CDH is in 2 patients only (4%). As we can see below in the Pie chart.

**Associated anomalies:** There are many congenital anomalies associated to congenital diaphragmatic hernia. The most common associated anomalies are pulmonary hypoplasia (18 cases) 39%, congenital heart disease is in (11 patients) 24%. See table no. 2

Age related survival and mortality: The survival rate is found to be high in patients aged 2-7 days, while a high mortality rate is found in patients below 24 hours age. As seen below.

Graph No.(2) : Age related survival in patients with congenital diaphragmatic hernia.
Congenital diaphragmatic hernia is a birth defect, can be presented as a sole birth defect or associated with other congenital anomalies. In our study, the frequent age of presentation was in the first week of life followed by neonates of less than 24 hours age, while an age of more than one year of age was the least frequent age of presentation. Such figures in our study may be due to lack of proper referral protocol to our pediatric surgical unit. Previously, there was a belief of early surgical repair for CDH as early as possible; now with the presence of advanced respiratory and ventilatory resuscitation delaying the surgical repair increase survival rate allowing time for relaxation of pulmonary vasculature,(6) this is what found to be in our study surgical repair in older age group reflected in lower mortality rate.

In the recent study, the survival rate is found to be higher with higher age group, these results goes with Tracy E. T. et.al study.(7)

The predominant clinical presentations in our study is respiratory symptoms and signs, like Beck C, et.al study (8)

In regards to the anatomical typing of CDH, the Bochdaleck’s type was the predominant one in 44 patients (96%); out of these only 6 patients (13%) were on the left while the rest 38 patients (83%) were on the right side, these results are not the same as Le, E. D. et.al study (9) the reason for this is the limited number of our patients in a relatively short period of time.

We found that pulmonary hypoplasia is a key factor influencing the survival rate for patients by causing pulmonary hypertension, it present in 18 patients (39%), the same as Pandya KA, et.al study.(10)

There was a belief that early surgical correction is the key in managing patients with CDH, but with time it was found that respiratory stabilization is the key is ensuring high survival rate among CDH patients’. In our study the mortality rate was high among patients aged less than 24 hours (8 patients 67%), so delaying the surgery leads to high survival rate after respiratory stabilization. Its goes with other studies Fallon SC, et.al. (11) and Kumar VSH (12).

**Conclusion**

Congenital Diaphragmatic Hernia is a congenital pathology with major health problem, posing a high mortality rate if not diagnosed and managed properly. In our center, despite the limited facilities and capabilities but still have a fair experience in managing such pathologies. We recommend early prenatal diagnosis, genetic diagnosis, and proper postnatal care via the
establishment of well-established neonatal intensive care units (NICU), the availability of extracorporeal membrane oxygenation (ECMO) to provide a proper respiratory support, moreover; we need good training in the field of thoracoscopic surgery as a surgical tool in managing such pathologies.

Effects of Nutrition Education on Pregnancy Nutrition Knowledge and Practice among Pregnant Women in Baghdad City

Suhair M. Hassoon¹, Muna Abdul Kadhum Zeidan¹

¹Assist Prof. Community Health Department, College of Health and Medical Technologies, Baghdad, Middle Technical University/Iraq

Abstract

Objective: To define the effectiveness of nutrition education pregnant women during pregnancy.

Method: A cross-sectional study was conducted in medical city hospital. The sample was selected by (non-probability convenient sampling) and sample size was (150).

Results: The result detected that the middle age of the subjects was 27.40 ± 6.78 years and the 52.7% were housewife. A prevalent source of information for pregnant women about nutrition during conception is 48%. After nutrition education involvement, the ratio of pregnant women with learning on adequate nutrition during pregnancy increased from (39.78 to 74.33), while the pregnancy nutrition practice of the pregnant women increased from (50.17 to 76.89).

Conclusions: A nourishment education intervention will have a plus effect on nutritional knowledge and practice of pregnant women.

Keywords: Nutrition, Education, Knowledge, Practice, Pregnancy, Baghdad.

Introduction

A healthy and stable diet is important in the presence and during pregnancy in particular. It must supply a diet for the mother and the power of nutrients appropriate to meet the usual requirements of the mother, as well as the necessity of the growing fetus and enable mother to maintain itself essential to the health of the fetus and infant nutrients, as well as the practice of breastfeeding in the future. The main behest is to pursue a healthy, balanced diet(1).

Although most women are aware of the importance of healthy eating during pregnancy, but women may have a lack of knowledge of the specific dietary commendation may or may not enjoy the needful skills to improve dietary habits(2). One of the main causes of the problems of nutrition, lack of nutritional knowledge, leads to poor practice, causing serious damage, such as malnutrition and various non-communicable diseases(3).

Education is an important factor in health promotion. Determination of training needs is essential to achieve this goal(4). Knowledge is not demeanor, but it can be a mark factor of dietary behavior(5). Various Reports indicate that in most countries advanced, cannot receive adequate amounts of nutrients that depend on the recommended daily allowance by “(RDA)” by mothers(6).

The goals of nutrition education for pregnant women are relatively clear aiming at appropriate maternal weight gain, nutritional adequacy of the maternal
diet and affirmative infant outcomes, such as pleasant birthweight \(^7\).

Method:

The study design was conducted cross-sectional study design (comfortable taking samples) for pregnant women starting from (September 1, 2018 to March 1, 2019).

Setting of the Study: The study is conducted at medical city hospital.

The study sample: A convenient sample, purposeful sample of 150 female. The fact was collected by direct interview using special questionnaire to acquired socio-demographic information. (Age, education, occupation........ect.

Statistical Analysis Method

Descriptive statistics: The following statistical data analysis approaches were used in order to analyze and assess the results of the study:

a. Tables ( Frequencies, Percentages).
b. Mean of Score (M.S.), Standard Deviation, Relative sufficiency (RS).
c. “Chi-Square test”
d. “Binomial test”

Table (4) shows a summary statistics of nutrition practice’s items along studied (Pre and Post) periods with comparisons significant. Results of testing significant with reference of studied items, as well as scoring scales evaluated concerning effectiveness of applying educational program were reported significant differences at $P<0.01$ toward of applying program through raising practices grades of studied respondents at the post period, except the items: (Eating grain breads, cereals, or others high- complex carbohydrates and Eating meat, fish, nuts, or legumes per day), since nonsignificant differences were accounted at “$P>0.05$” and accordance with preceding results.

Table (5): Descriptive Statistics of Knowledge and Practices main domains concerning (Pre-Post) education on pregnancy women

Table (5) shows a summary statistics of nutrition knowledge and practice’s concerning main domains along studied (Pre and post) periods. Results of testing significant with reference of studied domains reported highly significant differences at “$P<0.01$” toward of applying program through raising knowledge and practices grades of studied respondents at the post period and accordance with preceding results it could be enable to confirms importance and success fulness of applying the proposed program.

Table (6): Relationships between (Women’s Knowledge) and (SDCv. and Some Reproductive) variables
Tables(6) shows significant differences at “P<0.05” were reported for studied (SDCv.) of the studied subjects and reproductive variables, except age groups, since no significant different was reported at “P>0.05” and according to preceding outcomes it could be conclude that studied of educational program registered relationships with studied subjects in light of their positive personal characteristics, such as SDCv. and reproductive variables.

**Discussion**

Nutrition health affect maternal, before and during pregnancy, the health situation for itself and the developing fetus. Pregnancy is anerious condition for improving nutritional knowledge. In current study, most pregnant women belonging to the age group 20-25 years and the findings of the current study is an agreement with the results contained in Nigeria(8), this may be because the extreme ages of reproductive years are well known about nutrition during pregnancy. And almost about (52.7%) of them were housewife the finding of the attend study isapproval with findings reported in Ethiopia(9), found a highest rate were obtained by women of unemployed.

The results of this study also showed that the proportions of mothers with appropriate feeding mother during pregnancy knowledge was 39.78%. As a result of this study, it was agreed to study in America(10) which was more than half of the women in the study and the basic knowledge necessary with regard for the benefit of pregnancy nutrition.

But this result is less than the study conducted in Malaysia(11) and Swaziland (12), reported that 67% of mothers have adequate knowledge about maternal nutrition. This can be explained through the social, economic and cultural differences of the participants in the study. In this study, most pregnant women understand that mothers who suffer from a lack of nutrition will lead to complications of the fetus The finding of the current study is agreement with findings reported in Ethiopia(13) and in India(14). It reported that the proportion of pregnant women have to know that inadequate nutrition during pregnancy can cause complications of mothers such as abortion or premature birth This may be due to the difference in the beliefs of the causal disease in areas affected by the difference in the role of knowledge of cultural and spiritual influences.

After the implementation of nutrition education in this study, the proportion of pregnant women with good knowledge of nutrition during pregnancy from 39.78% to 74.33% and good practice increases 50.17% to 76.89% this outcome agreement with the study conducted in Ethiopia(9) in America(10) & in Iran(15), the results can indicate this to the effectiveness of nutrition education to improve the nutrition information for pregnant women.

Can be higher change in nutritional knоwledge among pregnant women in this study due to the interval between the evaluation before and after the evaluation and the fact that there was one only after the evaluation of education. Was seen to know pregnant women about nutrition during pregnancy is closely important between the educational status and sources of information and the number of pregnancies and agree this result with the study conducted in Malaysia(14) and Swaziland(12) and in Ethiopia(16), has shown that women with knowledge of the nutritional better in much higher educational level and sources of information.

Number of ANC visits was associated with knowledge of pregnant women in this study this result disagreement with the study done in Kenya (17), reported that nutrition knowledge level of those attending ANC was not significantly various from those not attending ANC.
Conclusions

Nutrition education during prenatal care to grant birth attention to improve the knowing and practice of women during pregnancy. These results showed also that the level of education, occupation of mothers, do not. of pregnancy, receiving information had prenatal health center to a great relationship with knowledge.

Effects of Progesterone Hormone on the Urinary Tract Infection in Pregnant Women

Bareq A. AL Lateef¹, Israa A.A. Al Hawani², Muna Sabbar Jebra³, Naeem Rahman aljeburi⁴

¹Assist. Lect., ²Lect., ³Prof., Al-Furat Al-Awsat Technical University/51015, Babylon Technical Institute, Department of Medical Laboratories, Babylon, Iraq, ⁴Assist Prof., Hilla General Teaching Hospital Babylon/ Ministry of Health/Iraq

Abstract

Infection is the highest ratio between hospitals and visiting patients are nosocomial infection registered in hospital is the urinary tract infection (UTI). The information about the UTI causative agents and the effect of the Progesterone hormones at possibly will help to choose the right remedy. The current study aimed to discover the effect of the progesterone in pregnant women on the incidence of the UTI during pregnancy. The current study was carried out at Hilla General Teaching Hospital, Babylon, Iraq during January-October, 2019. Out of 100 urine testers poised from the outpatient women, the culture showed 15 isolates identified as Gram positive bacteria (15%), 82 isolates of Gram negative bacteria (82%) and 3 isolates of yeast (3%). The record collective pathogen isolated was Escherichia coli (48.3%), Klebsiella species (10%), Streptococcus faecalis (8%), Proteus merabilis (8%), Enterobacter cloacae (6%), Pseudomonus (5%), Acinetobacter (5%), Candida albicans (3%), Enterococcus faecium (2%), Staphylococcus aureus (2%), Streplococcus agalctiae (2%) and Staphylococcus epidermidis (1%). The progesterone hormone levels were estimated for all samples.

Keywords: Progesterone during pregnancy, UTI infection during pregnancy, urinary tract infection and age.

Introduction

Progesterone hormone produces that are synthesize and store in the brain in the different glands and during gravidity in the placenta. Throughout the latter two spans, femininity hormones¹, have a direct effect on the immune mediators levels such as (TNF-α), xanthine oxidase through periods of the multiplicative rotation². The imbalance of femininity hormones could affect the immune status of the animals³.

The main function of the progesterone is in the reproductive system, it has multiple other functions such as spasm and smooth muscle relaxation, expanding bronchi and regulates mucus⁴. It has been demonstrated that progesterone is responsible of the increase in the bladder aptitude and increase the frequency of genuine tension simultaneously through pregnancy⁵.

The urinary tract and the genital tract origin from the same embryonic tissues and distinguish during the development of the human, because of that, both systems are affected by the steroids sexual hormones through the development cycle, in the female, there are two main hormones affecting both tracts, estrogen and progesterone⁶.

(UTI) is occur when invades by microorganism one or more organizations in this tract, which combat the strong natural defenses of human body. Although, the immune emplacements, the furthermore public contaminations and container happen at whichever period of the individual life, it is responsible of approximately 8–35%of all the nosocomial contaminations⁷.
Contagions are produced by the bacteria that colonization Urinary tract as the urethra. The most predominant agent of the Uropathogenic *E. coli* UPEC, which reasons over 90% of the UTI contagions in adults. Patients suffered from recurrent infections, organizational irregularities in the urinary tract, had urethral arrangement, acquired contaminations from hospital are exposed to increased incidence of infection caused by pathogenic bacteria and other organisms.

Complex and uncomplicated Urinary tract infection is always difficult to distinguish and this distinction helps in the clinical diagnosis that helps in adopting a patient’s treatment protocol. The uncomplicated type occurs Generally in pre-menopausal healthy Women.

Multiple strains of bacteria are opportunistic and have a role in causing disease. Infections in people with weak immunity often acquire infection when visiting the hospital.

### Material and Method

1. **Sample Collection:** Samples were the urine mid-stream clean fastener samples were collected from hospitalized patients in Al-Hilla General Teaching hospital. The samples(100) were by the relevant biochemical tests according to [12].

Results blood and MacConkey agar Culture were take to mean conferring to the typical benchmarks and a progression of colony forming units/ml was reflected as substantial bacterial infections.

2. **Blood Samples:** 5ml of blood were collected bin anticoagulant free tubes was disjointed. The serum by at about 3000 (R.P.M) for 5 min by centrifuge within 2-3 hours after collection.

3. **Microscopic Investigation (Colony morphology):** The affirmative culture and identified according to their morphological properties to identify the microorganism. (Analytical profile index API-20E) was secondhand to recognize Enterobacteriaceae household and connected organisms rendering to producer’s guidelines.

4. **Progesterone ELISA Assay:** The Progesterone ELISA Assay tackle is a reasonable insusceptible enzymatic technique for quantifiable purpose of Progesterone meditation in anthropological serum or plasma. According to the ICN guide for Endocrine analysis., ICN Biomedical, Inc.pp.2:20-27[14].

### Result

1. **Identification of bacteria:** Identification of bacteria carried out by bacteriological approaches the cultivated tasters remained positive culture, only (82) nations were characterized as (18) cultures were identified as gram negative bacteria and yeast.

Among (100) cultures which showed a significant bacterial growth the distribution of the strains were *Escherichia coli* (48.0%), *Klebsiella* species (10%), *Streptococcus faecalis* (8%), *Proteus mirabilis* (8%), *Enterobacter cloacae* (6%), *Pseudomonus* (5%), *Acinetobacter* (5%), *Candida albicans* (3%), *Enterococcus faecium* (2%), *Staphylococcus aureus* (2%), *Streptococcus agalactiae* (2%) and *Staphylococcus epidermidis* (1%). as in table (1)

2. Correlations between months of pregnancy, hormone level, type of bacteria and age: The data was analyzed by using IBM SPSS software version 2.0. The p value of <0.05 stayed painstaking as substantial. The confident and destructive predictive value were calculated and the result showed no significant differences between months of pregnancy, hormone level, type of bacteria and age as showed in Table (2).

3. Frequency distribution of the progesterone hormone level: The progesterone concentration in the serum of pregnant women was determined according to the method for quantitative determination of hormone level. The result showed that the lowest concentration of the progesterone was 7.1 ng/mL, (0-20) ng/mL showed the lowest frequency, the high incidence in (21-42) ng/mL and (61-83) ng/mL and the lowest incidence was (80-100) ng/mL, with Mean=45.86 and standard division =22.145 as in figure (1).
4. **Frequency distribution of UTI infection according to the month of the pregnancy:** The result showed that the highest frequency of the UTI infections per month of pregnancy was among the group (1-3) months, (3-6) months and (6-9) months with mean=4.83 and standard division =2.23 with Cumulative Percent as revealed in Figure (2).
5. **Frequency distribution of UTI infection according to the type of microorganisms:** The bacterial growing were characterized as as Gram + and Gram negative, *Escherichia coli* recorded the uppermost percentage among all the isolates which was (48%) followed by the *Klebsiella* species (10%), *Streptococcus faecalis* (8%), *Proteus mirabilis* (8%), *Enterobacter cloacae* (6%), *Pseudomonas* (5%), *Acinetobacter* (5%), *Candida albicans* (3%), *Enterococcus faecium* (2%), *Staphylococcus aureus* (2%), *Streptococcus agalactiae* (2%) and *Staphylococcus epidermidis* (1%), with Mean=4.75 and standard division =2.973 as shown Figure (3).
Figure (3): Histogram shows frequencies between types of bacteria with Mean = 4.75 and standard Division = 2.973. 1 = Acinetobacter, 2 = Candida albicans, 3 = Escherichia coli, 4 = Enterobacter cloacae, 5 = Klebsiella pneumonia, 6 = Proteus mirabilis, 7 = Pseudomonas aeruginosa, 8 = Staphylococcus aureus, 9 = Staph. epidermidis, 10 = Streptococcus agalctiae, 11 = Strept. faecium, 12 = strept. fecalis

6. Distribution of UTI infection according to the age: The result in the contemporary revision showed that the highest occurrence of the UTI infection was among the age 20-25 years (40%), followed by 25-30 years (30%), whereas the lowest infections were in age group 15-20 and 30-35 years which was (15%) with Mean=24.75 and standard Division =5.13 9 as shown Figure (4).
Figure (4): Histogram shows frequencies of the UTI according to the age per years with Mean = 24.75 and standard Division = 5.139

Discussion

Sexes hormones have an impact on the UTI in different organisms, demonstrated that during the follicular stage the progesterone is the prevalent hormone in the adult females, which make it cause an increase in bladder oscillation in contrast to the luteal stage which is distinguished by the decrease in the bladder expand [15].

During pregnancy awake to 60% of prenatal women are suffer from anxiety incontinence indications, they suggested that the progesterone high level might be the reason for that the progesterone cause a reduction in the muscle manner of the ureters, which leads to the dilation in the ureters accompanied by a reduce and restriction in the flow of the urine the consequences of the increase in progesterone will be the urinary incontinence and urinary tract infections [16].

A pregnant and non-pregnant female share the same organisms that is Escherichia coli has been recorded in many studies as the most common pathogen in the UTI in highly rate of cases of pyelonephritis in pregnant patients Other bacteria-which may be isolated [17].

The results of present study agreed with [18] exceptsome diversion in the patients registered in the urological operation regions, anywhere the nosocomial contagions were mainly produced by K. pneumniae and P.aeruginosa [19]. P.aeruginosa is inhabit and
arrangement a biofilm that interferes with the action of the antimicrobial managers and congregation protection mechanism [20].

This product reach a decision with alternative schoolwork on urinary tract contaminations in patients with renal stones [21] in which, the maximum ratio of the UTI bacteria was according to the E. coli, followed by Proteus spp., Klebsiella pneumoniae, Pseudomonas aeruginosa, correspondingly and this outcomes drives marginally with at raining on public developed UTI which presented that E.coli was responsible of 73% of the total UTI infections, whereas K. pneumoniae 6.5%; P.aeruginosa 2.3%, Proteus spp. 2.1%[22] and, agreed with [23] that reported the record collective bacteria isolate was Escherichia coli with (57%), shadowed by Strep. fecalis(16%), Klebsiella & Pseudomonous classes (8%); Staphylococcus epidermidis (6%); Proteus classes (1.6%); Acenatobacter & Citrobacter (1.3%); Staphylococcus saprophyticus (0.4%). The sequestration percentage of urinary bacteria of the current study is dependable with the results reported in NNIS, (1997)[24], which demonstrated that Enterobacter cloacae remained triggered (9.5%), the evidence that the bacterial endotoxins and exotoxins have a direct effect on the reproductive organs and related hormones [25].

Distribution of UTI infection According to Age: UTI infection among the patients according to age group 15-20 years was (15 %), 20-25 years (40 %) and 25-30 years (30%), the lowest incidence was in 30-35 years(15%), as shown in figure(4), in addition to the practice of the diaphragm and spermicidal contraceptives which modify the ordinary vaginal vegetation and possibly will allow establishment by pathogenic bacteria[26].

Frequency Distribution of the UTI infection According to Progesteronehormone level: The progesterone was 7.1 ng/mL which was among the class group (0-20) ng/mL, the high incidence was showed in (20-40),(40-60) and (60-80) ng/mL, the lowest incidence was in (80-100) ng/mL, this might be due to the hormonal changes through the physiological cycle of women, increase subsequently ovulation and/or the duration of the luteal period. During gravidity, the progesterone levels conserved at the same luteal planes[27].

Conclusion

The current study was aimed to point the UTI combined with the progesterone level the study concluded that the hormone levels were highest in the first months of the pregnancy, also showed that the incidence of the UTI was highest in the first months of the pregnancy, linked the two parameters (hormone level and the UTI) in the first months give a clear evidence that the hormone level no affect the UTI, the most affected age was 20-25 years.

The Impact of Maternal Age on Intracytoplasmic Sperm Injection (ICSI) Outcomes in Infertile Couples

Rabab Zahir¹, Al-yasiry¹, Haythem Ali Alsayigh², Muhjah Falah Hasan³, Nawras Najah Alkafaji¹

¹Assistant Lecturer, College of Medicine, University of Babylon/Iraq, ²Assistant Prof., College of Medicine, University of Babylon/Iraq, ³Assistant Lecturer, College of Medicine, Karbala University/Iraq

Abstract

Objective: The aim of the study is to investigate the impact of maternal age on ICSI outcomes represented by the number of retrieved oocytes, number of fertilized oocytes, embryo quality and pregnancy rate in infertile couples undergoing ICSI.

Patients and Method: The study included sixty two infertile couples who underwent ICSI cycles. They divided in to two groups depending on females’ age: group Ι with age less than 35 years and group ΙΙ with age more than 35 years. Assessment of ICSI outcomes in form of retrieved oocytes number, fertilized oocytes number, quality of embryo and rate of pregnancy were done and the results were compared between both groups.

Results: The study showed that females whom their age more than 35 years produced significantly lower oocytes number with a lower fertilization rate when compared with females younger than 35 years. (the mean total number of retrieved oocytes 3.24±0.52 vs 10.84±0.81 and the mean total number of fertilized oocytes 2.29±0.26 vs 7.62±0.52, p-value =0.002 and 0.02 respectively. The total number of good quality embryos was significantly less in the females older than 35 years 1.12±0.18 vs 6.80±0.46, p-value=0.003 and the total number of bad quality embryos was significantly more 1.47±0.24 vs 0.60±0.1, p-value=0.02 when compared with females younger than 35 years. Pregnancy rate was significantly less in the older females p-value=0.0005.

Conclusion: The maternal age is one of the most important predictor of ICSI outcomes. An advanced females age has a negative impact on ICSI outcomes and females older than 35 years usually produced lower number of oocytes during oocytes’ retrieval with a lower fertilization rate. Embryos produces from those females usually of bad quality and exhibited a lower implantation potential.

Keywords: Sperm injection; Age; health; infertile couple.

Introduction

Assisted reproduction; in vitro fertilization (IVF)/ICSI is considered the final treatment modality for couples who fail to achieve pregnancy(1). ICSI is firstly used to treat infertile men and today, it becomes the most commonly applicable micromanipulator technique of all assisted cycles being used for most of infertility cases other than male factor infertility.

The international committee for assisted reproductive technologies monitoring was reported that ICSI was applied in 65% of cycles in Europe and this is highlighted in some areas of the world, ICSI is practiced in 100% of in vitro cycles(2).

It has been showed that older infertile women are at high risk of having poor ovarian reserve and producing
bad quality oocytes following traditional medical infertility treatments, which makes ICSI of a great benefit in this group. However, multiple factors tend to affect ICSI outcomes such as female age and reserve of ovaries.

The advance maternal age is defined 35 years or more at time of childbirth, it has been revealed that females’ age is one of main important factors of reproductive outcome and fertility. The chance of getting pregnancy after natural or assisted conception is highly dependent on maternal age.

The poor ovarian reserve and reduced the developmental competence of oocytes are the main reasons for age related infertility. It has been reported that advanced female age was considered one of the factors that leads to oocyte aging, which may cause atypical fertilization and abnormal development, such as arrested division, implantation failure and abortion. In addition, the aneuploidy rate has been increased in the oocytes and embryos, which are produced from old women. Women with an age of 38 years have poor outcomes and this negative impact is increased with increasing age over 40 years.

Patients and Method

All included couples were taken from the IVF clinic in Fertility Center, Al-Sader Medical City, Al-Najaf Al-Ashraf in Iraq. All of them were assessed by history, physical examination, fertility investigations at the second day of the female cycles (Estrogen (E2), follicle stimulating hormone (FSH), lutenizing hormone (LH) prolactin, trans-vaginal ultrasound (TVUS) for assessment of ovarian reserve and endometrial thickness) and male partners’ seminal fluid analysis. All couples were subjected to ICSI due to unexplained infertility. They divided into 2 groups according to female partners’ age; GI: females whom their age between 20-34 years (n=45) and GII females whom their age between 35-45 years (n=17). Female partners were subjected to controlled ovarian stimulation from cycle day two by gonadotropin releasing hormone GnRH antagonist (Cetrotide 0.25 mg*1) followed by gonadotropins stimulation (Follitrope 75 iu*2) for 7-10 days to induce development of multiple follicles. When TVUS showed 6 or more follicles of size 18 mm, Human Chorionic Gonadotropin (hCG): Pregnyl 5000 iu *2 was given to induce final maturation of oocytes and all these were under the continuous monitoring by TVUS and serum E2 assay. Ovum pick up was performed under general anesthesia and TVUS 34-36hr after hCG injection. The retrieved follicles were denuded chemically by hyaluronidase enzyme and mechanically by frequent pipetting of cumulus-oocyte complex through different size pipettes. Only metaphase II (MII) oocytes are considered mature and used for injection. Preparation of the ejaculated semen to obtain viable sperms was done concomitantly by direct swim-up from pellet (according to WHO, 2010). Injected oocytes were washed and incubated in culture media under 5% CO2 and 37°C. Normally the fertilized oocytes displayed 2 pronuclei and two polar bodies 16-18h after injection. Subsequent monitoring of the embryo quality was done based on blastomeres (number, shape and equality), nucleation and the percentage of fragmentations. The embryos were classified as good quality (grade I & II) when they have 4 cells at 48 hr or 6-8 cells 72 hr post injection, with even sized blastomeres and little or no fragmentation. Anything else were classified as bad quality embryos (grade III & IV).

Up to 3 embryos(I,II) were delivered to the uterus at day 3 after injection under TVUS guidance followed by luteal phase support by vaginal progesterone; duphaston tablets 400 mg*2, aspirin tablets 100mg *1 and folic acid tablets 5 mg*1. The pregnancy was diagnosed chemically by measuring B-hcg titer in the serum of females whom underwent embryo transfer was performed 14 day after embryo transfer(ET). Pregnancy rate calculation was done by dividing the number of females who get on the total number of females whom embryos were transferred to the uterus *100%.

Study design & Statistical analysis: The study is cross sectional, observational done prospectively. Statistical analysis was done by SPSS version 20 by measuring mean and standard deviation for the continuous data using t-test. A p-value <0.05 was significant statistically.

Results

Table (1) reveals cycle day 2 hormonal profile, duration of infertility and endometrial thickness in the studied groups, no significant differences were presented in both groups except duration of infertility which was significantly longer in the older females, p-value=0.007.
Table (1): The hormonal levels, duration of infertility and endometrial thickness among study groups.

**Discussion**

Females’ age is the main important factor affecting her fertility and her chance of getting a baby. In most women, ovarian aging will have started before any changes in their menstrual cycle; therefore, they may be at high risk of reduced fertility\(^5\). Advanced women age have been associated with high rate of maternal and obstetrical complications such as maternal death, fetal and neonatal death, maternal hypertension, prematurity and operative delivery\(^{13}\). Many authors reported that poor IVF outcomes have been associated with increasing of maternal age\(^{14}\). Some centers of IVF restrict the maternal age for IVF as 43 years\(^{10}\). Older women have poor response to controlled ovarian hyper stimulation, decreased number of retrieved oocytes, decreased number of fertilized oocytes, poor quality embryos, low implantation rate, lower pregnancy rate, higher miscarriage rate and birth defects\(^{9,11,15,16}\).

The present study showed that retrieved oocytes, fertilized oocytes, embryo quality and pregnancy chance depend primarily on maternal age. Some results were consistent with our findings\(^{16}\). Other authors reported that the outcome of IVF (retrieved oocytes number) was highest in women aged less than 30 years with poor quality embryo and lower percentage of pregnancy were observed in older women\(^{11,15,17-19}\). However, some reports, which exhibited, that there is no correlation between maternal age and pregnancy rate are still present\(^{20}\). This could be related to the facts that aging process will lead to ovulatory dysfunction, poor ovarian reserve which in turn lead to producing little number oocytes with poor developmental potential, reducing the chance of getting good quality embryos with a high implantation potential\(^{21-26}\).
**Conclusion**

The maternal age is one of the most important predictor of ICSI outcomes. An advanced female’s age has a negative impact on ICSI outcomes and females older than 35 years usually produced lower number of oocytes during oocytes’ retrieval with a lower fertilization rate. Embryos produces from those females usually of bad quality and exhibited a lower implantation potential.

The Percentage of Self-management Contribution to the Professional Adequacy of Physical Education Teachers

Maryam Ahmed Abdul Hassan¹, Nagham Salih Nemaa², Hayder Mahmood Abood²

¹Post Graduate, ²Assist. Prof., University of Babylon/College of Physical Education and Sports Science/IRAQ

Abstract

Therefore, the researchers wanted to know the nature of the relationship between self-management and the professional adequacy of teachers of physical education in order to help those interested in teacher affairs to develop appropriate plans to advance the educational process. The research aimed to identify the reality of self-management and the professional adequacy enjoyed by the members of the research sample and to identify the relationship between self-management and the professional adequacy enjoyed by the members of the research sample and the percentage of the contribution of self-management in this relationship.

The researchers used a descriptive approach to the survey method and correlations, due to its relevance and the nature of the present study. Information and data were collected from the research community and represented by physical education teachers in middle schools of the General Directorate of Education for Babil Governorate. After collecting the data and statistically processing them, the most important conclusions were reached:

1. Physical education teachers in the schools of the Babil Governorate Center enjoyed good management and high levels of professional competence in their field of work, which they assessed on the basis of their achievement.

2. There is a positive correlation between the themes of self-management and the professional competence of physical education teachers.

3. Planning is the most important aspect of the self-management scale that contributes to professional competence and the least areas of self-management contribute to professional sufficiency. The balance was for teachers of physical education.

Keywords: Self-management, professional adequacy and physical education.

Introduction

The physical education teacher is one of the prominent pillars in the educational process because it has a vital role in establishing the rules of scientific knowledge and moral values among students, so the teacher requires self-management through the teacher’s interaction with his environment and his proper training and psychological development. It occurs in an atmosphere in which the teacher is able to be able to accept himself and in this way, the teacher becomes able to improve the quality of life and improve his personality by taking advantage of his capabilities and capabilities and defining his goals accurately and working to pursue its achievement.

Therefore, faculty members should be characterized by distinct characteristics and adopt various educational method when dealing with students that stem from their professional sufficiency, which leads to providing
educational climates through which the educational process outputs can be accessed. Therefore, the researchers wanted to know the nature of the relationship between self-management and the professional adequacy of teachers of physical education in order to help those interested in teacher affairs to develop appropriate plans to advance the educational process.\(^1\)

The assessment of the adequacy of the teacher is an objective function, a tool and a scientific method aimed at making judgments about the extent to which the educational process achieves its goals and objectives. The importance of the teacher evaluation in revealing the teacher’s influence in the educational process is demonstrated. And reveal the deficiencies, if any and suggest the appropriate means and work to achieve educational goals. Educational and teaching competencies are one of the main aspects of evaluating the teacher’s professional performance and the availability of teaching competencies and the teacher’s ability to show us indicators of the possibility of an indirect evaluation of teacher preparation programs. The supervisors, educational specialists and the first teachers with field experience in highlighting the teaching competencies of the teachers and teachers of physical education for the middle school stage.\(^2\)

**Research objectives:**

1. Knowing the reality of self-management and the professional competence of the members of the research sample.

2. Knowing the relationship between self-management and the professional adequacy enjoyed by members of the research sample and the percentage of self-management’s contribution to this relationship.

**Research hypotheses:**

1. There is a statistically significant relationship between self-management and professional adequacy in the research sample.

2. There are different contribution rates for the self-management components of the professional adequacy of the research sample.

**Research fields:**

- The human field: middle school teachers to teach physical education in Babil Governorate.
- Spatial field: middle schools in Babil Governorate.

**Research methodology and field procedures**

**Research Methodology:** The researchers used a descriptive approach to the survey method and correlations, due to its relevance and the nature of the present study.

**Research community and samples:** Information and data were collected from the research community represented by physical education teachers in middle schools affiliated to the General Directorate of Education for Babil Governorate and table (1) shows that.

Field research procedures:

Validity of the paragraphs of the self-management scale for physical education teachers: In order to identify the validity of the paragraphs related to self-management in the research sample, the researchers presented a questionnaire that includes the 44 paragraphs of the above-mentioned scale. The researchers found that all paragraphs were significant under the significance level of 0.05 and the degree of freedom (1) and table (2) shows that.

Pilot study: In order to verify the scientific weight of the two scales (self-management, professional sufficiency), the exploratory experiment that took place on 11/11/2019 and the experiment was repeated on 11/11/2020 must be repeated on a sample consisting of (10) teachers studying physical education in Babylon.

Validity of the two scales (self-management, professional competence): The researchers used the validity of the content by presenting the two scales in a questionnaire to the experts and specialists. The two scales confirmed their validity.

Stability of the two measures (self-management, professional competence): The researchers conducted the pilot study on 11/11/2019 and returned it on 11/11/2020, i.e. between the experiment and 30 days in order to ensure stability. The researchers extracted the Pearson correlation coefficient, as it had a self-management scale of 0.95 and a significance level of 0.01 which is a lower level from the 0.05 level specified for accepting error, the measure of professional adequacy was Pearson’s correlation coefficient between his experiment and his experiment was repeated by 0.94 and at the significance level of 0.01 which is a level lower than the 0.05 level determined to accept the error.

Objectivity of the two scales (self-management, professional competence): The researchers put a number of repeated paragraphs in the original paragraphs
of the two scales and noted that the repeated paragraphs gave the same answers as the members of the research sample at 100%, which means that the two scales were highly objective.\(^4\)

**The main experience:** The researchers conducted the main experiment on 15/1/2020, based on the findings of the exploratory experiment from results on a sample of 145 teachers in order to tabulate the data for conducting the presentation, analysis and discussion.

**Statistical means:** The researchers used the SPSS statistic to analyze the results and the most prominent laws used were (Chi square), mean, standard deviation, Pearson correlation coefficient.

**Results and Discussions**

Through the main experiment, the researchers were able to collect and schedule data for presentation, analysis and discussion.

**Table 4. Shows the descriptive statistics indicators to measure the areas of self-management and the dimensions of performance evaluation form**

Note: The sign (**) means that the association was high and with a low error rate, i.e. less than 0.01

Table (5) shows the correlation values of the fields of self-management with the professional sufficiency of physical education teachers, which are (planning, time management, self-confidence, balance, communication) and their correlation values were in order (0.810, 0.663, 0.791, 0.619, 0.633) and by error ratios were all less of 0.05, which means that all of the correlations were of a significant and statistic characteristic. And if we notice
the percentage of the contribution of planning with vocational sufficiency was relatively high and estimated at (0.656) and this indicates that there is a high correlation between the field of planning and vocational sufficiency among teachers of physical education in middle schools in Babil province and this is what confirms that there is a vision and desire among physical education teachers behind getting on achievements within festivals, symposia and conferences and following up the developments of the educational process.  

As the pursuit according to a deliberate scientific planning to reach a good educational productivity leads to a suitable professional competence for that. As for time management, his contribution rate was (0.439), with the professional adequacy of the research sample, in keeping pace with modern scientific developments through its preparation of the scientific material and its appropriateness not Amar students and preparing it for weekly, monthly and yearly plans to study physical education and its suitability to the conditions and capabilities of the school and researchers attribute this to the commitment of teachers of physical education In middle schools in the province of Babel, study physical education to be consistent and responsive to the needs and aspirations of society and the extent of their knowledge of the scientific subject and the extent of their relevance to reality and the available capabilities.  

As for the field of self-confidence, the percentage of its contribution to professional adequacy (0.625) is relatively good, as there is a desire of physical education teachers to pay attention to the performance of their duties and commitment to preparing records for the lesson of physical education and contribute to solving obstacles facing students and contribute to creating a good state of respect And commitment within the school. As for balance, his contribution rate with professional adequacy was (0.383). Attention of the teacher by the educational institution and the development and motivation of self-management has according to plans based on scientific foundations that increase the strength and control of the physical education teacher on events and situations and this is reflected positively on career performance. Finally, with regard to the communication field, its contribution rate is (0.40) and that the evaluation process and their analysis of performance constitutes a positive step as it assesses the extent of progress and demonstrates the need for additional development and for new evaluation provisions from the viewpoint of teachers who practice the work and the result is a cause for the satisfaction of the supervisor, director and education teachers of sports, which leads to the practice of teachers not their activities more effectively.  

Conclusions  

Physical education teachers in the schools of the Babil Governorate Center enjoyed good management and high levels of professional competence in their field of work, which they assessed on the basis of their achievement. There is a positive correlation between the themes of self-management and the professional competence of physical education teachers. Planning is the most important aspect of the self-management scale that contributes to professional competence and the least areas of self-management contribute to professional sufficiency. The balance was for teachers of physical education.

Abstract

Background: Chest CT scan has a great sensitivity with rapid diagnoses of COVID-19 infection in the community. Nevertheless, the specificity of this test for diagnosis of this disease are believed to be low.

Objective: To evaluate role, effectiveness and diagnostic accuracy of chest CT scan with main imaging manifestations and hematological appearances for screening COVID-19 cases through comparing results of those with other NON-COVID-19 pneumonia.

Patients and Method: Twenty COVID–19 & 28 NON–COVID–19 pneumonia Iraqi patients in Yarmouk teaching hospital, Baghdad, Iraq from 1 march to 1 may 2020, at the beginning of the outbreak in Iraq COVID–19 had been included in current research. Confirmed COVID–19 together with NON–COVID–19 patients to be infected or not with SARS-CoV-2 using RT-PCR were included in current research. Socio-demographic, hematological and chest CT scan finding were examined to compare the variance between COVID-19 and NON-COVID-19 patients.

Result: “COVID-19” patients mean age was 62.10 ±14.308SD ranged between 35- 90 years whereas “non-COVID-19” patients mean was 61.07± 13.638 SD. There was a significant difference between WBC average number of COVID-19 compared to its average number of “NON-COVID-19” patients (P<0.001). A significant differences between Neutrophils, lymphocytes, Monocytes, Eosinophil and Basophils low counts and MCV, MCH, PDW of COVID-19 compared to its counts or levels in “NON-COVID-19” patients (P<0.001). A significantly different of CT scan Images ‘Ground glass opacity, Crazy paving alteration’, ‘Vascular dilatations, Traction Bronchiectasis alteration’, ‘Sub pleural –bands’ & Architectura) between “COVID-19” & ”NON-COVID-19 cases (P less than 0.001), whereas Consolidation was non-significant.

Conclusion: A chest CT scan might be a dependable tool for COVID-19 cases diagnosis. Hematological features that include WBC, Neutrophils, Lymphocytes, Monocytes, Eosinophil, Basophils, MCV, MCH, PDW might be substantial indications for COVID-19 appraisal.

Keywords: COVID-19, NON-COVID-19, Pneumonia, CT scan, Hematological test, case-control study.

Introduction

〈Coronavirus〉 interactive 〈disease-2019〉 (COVID-19) is a pandemic outbreak produced by 〈severe acute respiratory syndrome〉 coronavirus-2 (SARS-CoV-2). It begins suddenly in December 2019

Corresponding Author:
Mothana Ali Khalil

e-mail: mothanakhalil70@yahoo.com
in ‘Wuhan’ City, ‘China’, then spread in 213 countries characterized by a minor common cold-like sickness, to ‘severe viral-pneumonia’ might develop to ‘acute-respiratory-distress-syndrome’ that is possibly lethal\textsuperscript{1}).

RT-PCR sensitivity might be lower than 50% & certain diagnoses might be lost. Low sensitivity in ‘COVID 19’ early stage, the results of this test may take more than 24 hours, while the results of a CT scan are available immediately\textsuperscript{2}. RT-PCR test for SARS-CoV-2 viral RNA recognition is very specific but low sensitive\textsuperscript{3} as greatest of COVID-19 cases with duplication negative results. Chest CT scan lung findings are appear than clinical manifestations, which make Chest CT scan critical for runs and accurate diagnosis\textsuperscript{4}. So, CT scan might be applied as a supplementary diagnostic tool simultaneously in COVID-19 diagnosis\textsuperscript{2}.

Chest CT scans has high sensitivity with low specificity in COVID-19, so it is problematic to differentiate COVID-19 from non-COVID-19 pneumonia cases\textsuperscript{5,6}. Nevertheless, RT-PCR appear as negative results, while their CT imaging findings were abnormal as reported in certain study\textsuperscript{7,8,9,10}. Through using of chest CT scan findings with RT-PCR, the sensitivity could be reach to 99%, so chest CT scan should be used as a reference for COVID-19 diagnosis\textsuperscript{6}.

Chinese studies related to COVID-19 showed that there is a decrease in white blood cells in hospital patients, with varying degrees of decrease in lymphocytes with a relative decrease in platelets\textsuperscript{11}.

In Iraq, as far as we know, no previous study has yet compared chest CT scan and hematological investigation results between COVID-19 & non-COVID-19 viral pneumonia kinds. Thus, this study was the first research to compare chest CT scan findings & hematological features of COVID-19 & non-COVID-19 viral pneumonia kinds to know diagnostic efficacy of these tools in COVID–19 diagnosis.

Patients and Method

Prospective case-control design was used to identify the role, effectiveness and diagnostic accuracy of hematological tests with a chest CT scan for screening and rapid diagnosis of COVID-19 infections through compared the difference of Hematological tests and radiographic features results of “COVID-19” & "NON-COVID-19" viral pneumonia kinds. Twenty "COVID 19" together with pneumonia patients 28 other “NON-COVID-19” were confirmed simultaneously to be infected or not infected with SARS-CoV-2 respectively using RT-PCR & blood as a suitable specimen in Yarmouk teaching hospital, Baghdad, Iraq from 1 march to 31 April 2020, at the beginning of the outbreak in Iraq COVID-19. We analyzed the demographic, compare the pulmonary CT scan findings and hematological investigation among "COVID-19" & NON-COVID-19 Iraqi patients. Anbar medical College approved the protocol. All patients provided informed consent for participation in the study.

Statistical Analyses: Data were analyzed using IBM SPSS software version 22. The results were presented in tables as frequencies and percentages. Chi-Square test was used to compare between the variables through cross-tabulations and P-Value less than 0.05 considered a statistically significant difference

Results

Twenty COVID-19 confirmed cases with 28 chest pain non-COVID-19 cases (as a control) were enrolled in the study.

\textasciitilde‘COVID-19’ patients mean age was 62.10 ±14.308 SD ranged between 35 months and 90 years whereas ‘non COVID-19’ patients mean age was 61.07±13.638 SD, Age group had been categorized as following:

\begin{itemize}
  \item \textless= 43 (2, 10.0%);
  \item 44 – 59 (5, 25.0%);
  \item 60 – 74 (9, 45.0%);
  \item 75+ (4, 20.0%)
\end{itemize}

Fifteen (75.0%) of COVID-19 patients were identified during March and others 5 (25.0%) identified during April 2020.

A Chest CT scan of COVID–19 patients with NON–COVID–19 patients had been shown in Figure 1,2,3 and Table 3.

Ground glass was present in 17/20 patients (85.0%) in COVID-19 confirmed cases, in 9/28 patients (32.1%) in NON-COVID-19 cases. Crazy paving was present in 15/20 patients (75.0%) in COVID-19 confirmed cases and only in 2/28 patients (7.1%) in Chest pain Unconfirmed COVID-19 cases. A significant difference was observed between the COVID-19 confirmed cases and Chest pain NON- COVID-19 cases regarding the ground glass and Crazy paving alteration (P Value= 0.000) Table 3.

Vascular dilatation was present in 12/20 patients (60.0%) in COVID-19 confirmed cases and only in 2/28 patients (7.1%) in Chest pain unconfirmed COVID-19 cases. Traction Bronchiectasis was present in 11/20 patients (55.0%) in COVID-19 confirmed cases and only in 3/28 patients (10.7%) in Chest pain unconfirmed COVID-19 cases. Subpleural bands and Architectural were present in 10/20 patients (50.0%) in COVID-19 confirmed cases and only in 3/28 patients (10.7%) in Chest pain unconfirmed COVID-19 cases Significant difference was observed between the COVID-19 confirmed cases and Chest pain unconfirmed COVID-19 cases regarding the Vascular dilatation, Traction Bronchiectasisalteration and Subpleural bands and Architectural (P Value= 0.000) Table 3.

Consolidation was present only in 4/20 patients (20.0%) in COVID-19 confirmed cases and only in 15/28 patients (53.6%) in Chest pain unconfirmed COVID-19 cases, non- significant difference had been observed between the COVID–19 confirmed cases and Chest pain unconfirmed COVID–19 cases regarding the Consolidation alteration (P Value= 0.035) Table 3.

Ground –glass opacity, Crazy– paving alteration, wide Vascular– dilatation, Traction-Bronchiectasis alteration, Sub –pleural–bands & Architecture finding of Chest CT the were significantly associated with COVID-19 pneumonia, whereas Consolidation was not significantly associated with COVID-19 pneumonia (P<0.001), so chest CT scan can be documented as a preliminary diagnostic tool of COVID .

Discussion

The current research aimed to show chest CT scan findings variance among COVID–19 & non–COVID–19 patients.

Current study revealed that chest CT scans can distinguish between COVID–19 from non–COVID–19 patience with in elevation specificity with a moderate sensitivity. This results had been agreement with the result reported by Bai et al. 2020[12].

The current study indicated that 85.0% of COVID19 showed initial abnormal CT scan findings, which supports the possibility of CT scan as an assisting diagnostic tool in addition to RT-PCR for COVID19 diagnosis. Most common CT scan finding or imaging in our patients was ground–glass & two-sided peripheral spreading. Current study had been similar to previous report that showed that ground–glass was a chief chest CT scan findings in COVID–19[13].

However, It is worth noting that a small number of COVID 19 patients in our current study did not have CT scan abnormal change and this is consistent with a previous study that showed that 11.5% of patients with confirmed infection with this disease showed normal chest CT scan finding[13], so we conclude that a CT scan
finding alone is not sufficient to fully exclude reliable and confirmed diagnosis of COVID-19, especially in the early stage of the disease.

Recent study that showed consolidation imaging not characteristic for COVID-19 pneumonia, these result was disagreement with the results reported by Pan et al. and Xie et al. that exhibited imaging consolidation as a characteristics for COVID-19 pneumonia.

The current study were consistent with the findings of previous report that showed crazy-paving patterns & diffuse distribution had been characteristic for CT findings of COVID-19 pneumonia.

Results of current study also in agreement with the result reported by previous study that demonstrate chest CT scan imaging are frequently normal in initial disease phases; nevertheless, it might demonstrate bilateral-infiltrates & ground-glass opacity in initial disease phases.

Results of the hematological finding in preset study was in agreement with results of previous study the presented varying degrees of laboratory abnormalities e.g. leukopenia, leukocytosis, lymphopenia among COVID-19 & non-COVID-19 such as leukopenia, leukocytosis & lymphopenia . etc.

Laboratory findings might be applied as an supplementary diagnostic tool simultaneously with chest CT scan imaging that acts mostly on lymphocytes which decrease during COVID-19 but it still normal in non-COVID-19.

We suggested that current research on CT scan findings and imagines have highlighted the chest CT scan role in pandemic COVID-19 diagnosis. Researches with big sample size & clear chest CT scan findings or imagines from different countries are required to guide usage of this tool in the COVID-19 diagnosis.

Abstract

A study was conducted to evaluate the effect of different holding temperature before freezing on the motility, morphology and viability of chilled and frozen spermatozoa. Semen was performed from four mature bulls by electro-ejaculator. After initial evaluation and first dilution using Tris-egg yolk semen extender, four groups of diluted semen samples were kept in four different holding temperatures (4°C, 15°C, 25°C and 37°C) for 10 minutes. All semen samples were subsequently chilled in refrigerator at 4°C for at least 3 hours. Post chilling evaluation was done after second dilution with the same extender added with glycerol. The semen samples were packed into 0.25 ml straws before freezing into liquid nitrogen. Thawing of frozen semen samples were done on day 1 post cryopreservation in water maintained at 37°C for 30 seconds. Semen evaluation was conducted post thawing. The results showed that there were no significant difference among the four different holding temperatures for the post chilling and frozen-thawed sperm motility, morphology and viability. Based on the findings of this study, it can be concluded that 10 minutes holding time at different holding temperatures before freezing did not affect the quality of chilled and frozen bull spermatozoa.

Keywords: Semen, holding temperature, bull, freezing.

Introduction

The development in cryopreservation technology is able to store frozen semen for extended period of time and used for insemination. Studies have been conducted in order to improve the techniques for collecting the maximum number of viable spermatozoa from the male through preservation of the semen quality by adding suitable media, providing appropriate cooling, freezing, storage and thawing procedures[1].

Baiee et al.[2] reviewed that cryopreserved spermatozoa are susceptible to the changes of their conditions during freezing, thawing and processing, in which causing reduced fertility as compared with raw semen[3]. Spermatozoa from many species such as buck[4], boars[5], stallions[6], rams[7] and deer[8] can be maintained at 4-15°C for time periods up to 24 h, depending on their species, before cryopreservation and still have acceptable frozen-thawed sperm quality. Moreover, bull sperm held at 4°C for 4 h maintain acceptable motility (52.5%)[9]. It might be that holding time prior to cryopreservation processing can have a useful effect since it has been shown that the incubation of semen before freezing has a beneficial effect [5]. This incubation could improve resistance of spermatozoa to cold shock. Furthermore, the incubation of semen can result in a reversion of sperm capacitation processes[10]. However, documentation concerning cryopreserving bull sperm following holding in different temperature have been limited. Therefore, by manipulating different
holding temperature of the semen before cryopreservation may produce different effect to the spermatozoa in terms of viability, motility and morphology before and after freezing. Thus, the main objective of this study was to determine the effect of different holding temperatures before freezing on the quality of cryopreserved bull semen.

**Materials and Method**

**Animal:** Four sexually mature Brangus cross bulls from Taman Pertanian Universiti, Universiti Putra Malaysia cattle farm were used for semen collection. The age of the bulls were within the range of 3 to 7 years old with body weights between 300 to 400 kg. These bulls were kept semi-intensively, fed with palm kernel cake and allowed to graze freely during the day. Commercial mineral block and water were given ad libitum. The sample collection was approved by Institutional Animal Care and Use Committee (IACUC; FYP.2016/ FPV13,31).

**Experimental design:** Semen samples were divided into four groups. First group, the controlled group was kept in refrigerator at 4°C. Second group was kept in a cool water bath at 15°C inside an insulated thermal box. The third group was put in a water bath at 25°C inside an insulated thermal box. The last group of samples was put in a warm water bath at 37°C. All groups were maintained at its respective temperatures 10 minutes before chilling.

**Semen collection and fresh semen evaluation:** In day of semen collection two semen samples were collected from two bulls using an automated electro-ejaculation method; two time per week. The collection was repeated four times to get a total of sixteen semen. The semen samples were evaluated immediately based on macroscopic (volume, consistency and colour) and microscopic (spermatozoa concentration, motility, morphology and viability) characteristics. The semen sample was diluted 1 to 40 ratios with normal saline at water bath of 37°C for initial evaluation. Evaluation of spermatozoa concentration and general motility were made by using a Computer Assisted Semen Analyzer (CASA). Spermatozoa morphology at 1000× magnification and viability at 400× magnification were evaluated using eosin-nigrosin stain. A total of 200 spermatozoa were examined under a light microscope. Dead spermatozoa were stained purple and live spermatozoa were unstained. Sperm abnormality was determined by examining 200 spermatozoa for defects associated with sperm head, mid-piece and tail.

Only semen sample that achieved the standard minimum criteria can be used for the experiment (Figure 1).

![Figure 1: The initial evaluation of collected semen, A (sperm motility, viability and Morphology of sperm), B (Concentration of sperm) and C (volume of semen).](image-url)
Cryopreservation procedure

Extender preparation: Two extenders were prepared one without glycerol for chilling period and another with glycerol was added after the end of chilling period, 2.42g of Tris, 1.48g of citrate, 1g of fructose (Sigma-Aldrich) and 20 ml of fresh egg yolk were mixed with distilled water to produce 100 ml of Tris-egg yolk extender. The same components with addition of 12.8ml glycerol were mixed with distilled water to produce 100 ml of Tris-egg yolk-glycerol extender[14].

Semen dilution, packing and freezing: The semen sample was pre-diluted with Tris-egg yolk extender at water bath of 37°C. Four semen groups from each bull were kept at different holding temperature of 4, 15, 25 and 37°C respectively for 10 minutes. Then, all semen samples were transferred for chilling at temperature of 4°C and kept for more than 3 hours. After 3 hours, all the semen samples were evaluated using CASA and stain with eosin-nigrosin to determine the sperm general motility, progressive motility, viability and morphology.

The pre-diluted semen sample was then diluted with Tris-egg yolk-glycerol extender as final dilution under temperature of 4°C. The extended semen was packed into 0.25ml labelled French straws and sealed with sealing powder. Then after, the straws were subject to a slow gradual freezing process manually before they were stored in a liquid nitrogen tank following the method described by[15].

Frozen-thawed semen evaluation: After 24 hours of storage, the straws were taken out from the liquid nitrogen tank and thawed in water bath with temperature of 37°C for 30 seconds. Then, the straws were cut and the semen samples were inserted into test tubes in the water bath with temperature of 37°C. All the post thawed semen samples were also evaluated using CASA and stain with eosin-nigrosin[12].

Statistical analysis: All the data were tested for normality by using Shapiro-Wilk Test. The result of post chilling and post thawing evaluation were analysed by Kruskal-Wallis H Test using IBM SPSS Statistics 22 software (SPSS Inc., Chicago, IL, USA). Mann Whitney U Test was used to analyse the relationship between different pairs of treatment groups.

Results

From the test of normality, Shapiro-Wilk Test showed that most of the data were not normally distributed, p<0.05. Therefore, relevant non-parametric tests were selected to analyse the data from the experiment. The result of Kruskal-Wallis H Test for the post chilling evaluation revealed that there were no statistically significant difference (p>0.05) in sperm viability, sperm general motility, sperm progressive motility and sperm normal morphology between the different holding temperatures (Tables 1 and 2).

On the other hand, the result of Wilcoxon Signed Rank Test for the fresh semen evaluation and the post thawing evaluation showed that there were statistically significant differences (p < 0.05) in sperm viability, sperm general motility and sperm normal morphology. However, there was no statistically significant difference (p > 0.05) in sperm progressive motility.

From the result of Mann-Whitney U Test for the post chilling evaluation, there were no significant differences (p > 0.05) in sperm viability, sperm general motility, sperm progressive motility and sperm normal morphology between the holding temperature of 4°C and 15°C, 4°C and 25°C, 4°C and 37°C, 15°C and 25°C, 15°C and 37°C, 25°C and 37°C. Furthermore, the result of Mann-Whitney U Test for the post thawing evaluation showed that there were no significant differences (p > 0.05) in sperm viability, sperm general motility, sperm progressive motility and sperm normal morphology between the holding temperature of 4°C and 15°C, 4°C and 25°C, 4°C and 37°C, 15°C and 25°C, 15°C and 37°C, 25°C and 37°C.

### Discussion

In this study, Tris-egg yolk extender containing citrate and fructose as energy supplement to the spermatozoa were used to extend their life spans [16]. Approximately 20% of egg yolk in the extender is used as standard level for most case of bull semen cryopreservation [17]. Tris-egg yolk extender was not used as diluent during fresh semen evaluation because CASA may count the egg yolk granules from the Tris-egg yolk extender as individual sperm in which will affect the outcome.

After cooling the semen sample at 4°C in the refrigerator for more than 3 hours, Tris-egg yolk-glycerol extender was used to dilute the semen before packing for cryopreservation. Tris-egg yolk-glycerol extender gives excellent protection for sperm either frozen or unfrozen [18]. Spermatozoa are sensitive to the changes in the osmolality of the surrounding solution, in which they will lose their motility irreversibly if the osmolality is intolerable [19]. Therefore, we have to be aware of the dilution factor used to dilute the semen with extender for cryopreservation.

There were statistically significant differences in the quality of bull semen before and after cryopreservation. Cooling and freezing of spermatozoa during process of cryopreservation causes reduction of temperature of the spermatozoa and its surrounding solution. This change in temperature induces sperm plasma membrane damage which leads to a state of sperm abnormal morphology such as abnormal acrosome [13]. The damaged sperm plasma membrane allows influx of calcium ions which resulted in abnormally high amount of intracellular calcium ions in the spermatozoa. This phenomenon contributes to the premature capacitation of spermatozoa [20]. It had been reported that there was variation among individuals in the extent to which their spermatozoa are damaged by freeze-thawing [21]. This individual differences particularly for bull semen have been recorded and to cover this difference, freezing protocols were adjusted for individual bulls or packaging straws with more spermatozoa for “poor freezers”. The effect of different temperature to the quality of spermatozoa may be varies for different individuals from the same species. Therefore, the accuracy of result may be reduced due to this factor.

Conclusion

In this study, it can be concluded that different holding temperatures before freezing do not affect the quality of bull semen significantly. However, the process of cooling and freezing during cryopreservation affects the quality of bull semen significantly. Besides, more time and numbers of suitable samples should be required to improve this study. These will allow for more tests to be conducted for different parameters and more samples can be processed. Further investigation regarding the effect of different holding temperature before freezing should be done.

Maternal Hemoglobin Concentration and Pregnancy Outcome in a Sample of Iraqi Women

Elham Ali Salman¹, Israa Kamal Qasim², Taghreed Al-Haidari³

¹(M.B.Ch.B, C.A.B.O.G) Obstetrician/Department of Gynecology and Obstetrics, Al-Yarmouk Teaching Hospital, MOH; Baghdad, Iraq, ²(M.B.Ch.B, F.I.C.O.G) Obstetrician/Department of Gynecology and Obstetrics, Al-Yarmouk Teaching Hospital, MOH; Baghdad, Iraq, ³Prof. Consultant Obstetrics and Gynecology/Head of Scientific Affairs Unit, Al-Kindy College of Medicine, University of Baghdad, Iraq

Abstract

Aim of study: To analyze the maternal and perinatal outcome in varying degree of anemia and assess which level of hemoglobin concentration has best pregnancy outcome in Iraqi women.

Patients and Method: A cohort study that was conducted at Al-Elwiya Maternity Teaching Hospital during the period from 1st of Dec 2017 till end of Dec 2019. It included 500 pregnant women who were followed up in labor until delivery and their maternal and perinatal outcome were noted. Hemoglobin and MCV of each pregnant woman were measured at late second and third trimester. Hemoglobin groups were related to the maternal characteristics, delivery characteristics and pregnancy outcome. The patients underwent a complete blood count, blood film examination and hematocrit estimation.

Results: In this study, 33.4% of study participants had mild anemia and 22% of them had normal hemoglobin and MCV. Incidence of adverse perinatal outcome was 32.6% and adverse maternal outcome was 11.8%. Maternal hemoglobin and MCV levels are significantly affected by mother’s age. Hemoglobin level is also affected by parity while MCV level doesn’t. Low maternal hemoglobin was associated with increased risk of poor birth outcomes including LBW, preterm birth and adverse maternal health outcomes, including cesarean section and induction of labor.

Conclusion: Maternal anemia is strongly associated with several different types of maternal morbidity and perinatal morbidity.

Keywords: Anemia, pregnancy, hemoglobin, outcome, Iraq.

Introduction

Anemia has been a global health burden since it can affect anyone without considering age or gender group⁽¹⁾. It is an important global health problem affecting nearly 529 million women of reproductive age, including 38% of all pregnant women⁽²⁾. An average of 56% of pregnant women in developing countries are anemic⁽³⁾. Once pregnant women suffer from anemia, iron deficiency (IDA) becomes the most common cause that should be considered⁽⁴⁾. Other risk factors are unhealthy lifestyle, poor socio-economic status, malnutrition, hemoglobinopathies, age (< 20 years or > 35 years), early marriage or teenage pregnancy, decreasing period of pregnancy interval, smoking or alcohol use, history of menstrual disorder or infection and gemelli or multiple pregnancies⁽⁵⁾. According to the WHO guidelines, hemoglobin values between 10 and 10.9 g/dl are considered mild anemia, moderate anemia between 7 and 9.9 g/dl and severe anemia below 7 g/dl⁽⁶⁾.

DOI Number: 10.37506/mlu.v20i4.1929
During pregnancy, there is an increase in both red cell mass and plasma volume to accommodate the needs of the growing uterus and fetus\(^7\). The plasma volume increases more than the red cell mass does, leading to a fall in the concentration of Hb in the blood, despite an increase in the total number of red cells. This drop in Hb concentration decreases blood viscosity and is thought to enhance placental perfusion, providing better maternal-fetal gas and nutrient exchange\(^8\). In the case of IDA during pregnancy, there are several possible risks to the mother, including increased fatigue, short-term memory loss, decreased attention span and decreased performance at work, increased pressure on the cardiovascular system due to insufficient Hb and low blood oxygen saturation levels, lower resistance to infections and a reduced tolerance to significant blood loss and to surgical interventions during labor\(^9\). The presumed risks of IDA for the fetus relate to the fact that low iron levels increase the risk of reduced Hb levels and therefore oxygen, to the uterus, placenta and the fetus during development\(^10\). Moreover, iron-deficient neonates have been shown to have a statistically significant increment in both cognitive and behavioral abnormalities up to 10 years after iron repletion\(^11\). IDA, even if mild to moderate, can be associated with unfavorable obstetric outcomes, notably, premature birth, low birth weight and fetal death\(^12\). Although IDA lead to serious consequences for health and well-being, there is currently a lack of available Iraqi data on these conditions in pregnancy. The aim of the current study was to analyze the maternal and perinatal outcome in varying degree of anemia and assess which level of Hb concentration has best pregnancy outcome in Iraqi women.

**Patients and Method**

**Study design, setting:** This was a cohort study that was conducted in the Department of Obstetrics and Gynecology at Al-Elwiya Maternity Teaching Hospital during the period from 1\(^{st}\) of Dec 2017 till end of Dec 2019.

**Study Population and sample size:** The study included 500 pregnant women who were attending the Department of Obstetrics during the period of study, followed up in labor until delivery and their maternal and perinatal outcome were noted.

History and examination were performed and maternal blood sample was taken. Hb and MCV of each pregnant woman were measured at enrolment in the obstetric unit at late second and third trimester.

On the basis of hemoglobin levels and MCV performed by the method; Electronic coulter cell counter.

They were grouped into five categories based on WHO definition:

- **Group I:** normal hemoglobin Hb≥11 g/dl + Normocytic.
- **Group IIA:** mild anemia Hb, 9–10.9 g/dl + Normocytic.
- **Group IIB:** mild anemia Hb, 9–10.9 g/dl + Microcytic.
- **Group III:** moderate anemia, Hb 7–8.9 g/dl + Microcytic.
- **Group IV:** Hb, less than 7 g/dl + Microcytic.

Microcytic RBC = MCV < 84fl.

Then these Hb groups were related to the maternal characteristics (age, Parity, Gestational age at delivery, hypertensive disorders in pregnancy and preterm labor), delivery characteristics (induction of labor, caesarean section, Postpartum hemorrhage ± blood transfusion) and pregnancy outcome (Apgar Score at 5 min, birthweight, IUGR, still birth, early neonatal death and birth asphyxia). Gestational age was determined on the basis of information on menstrual history and physical examination as well as early U/S to confirm the dating.

Low birth weight was defined as less than 2500 g and babies were classified as preterm if the gestational age was less than 37 weeks and as growth restricted if below the 10\(^{th}\) percentile of the birthweight-for gestational age using completed weeks of gestation according to the WHO recommendation. Early neonatal death (death among new born infant within 7 days of life). Still birth (infants were delivered without heart rate, apnea, limp, pale and cyanosed). Patient with chronic illness were excluded from the study.

The patients underwent a complete blood count, blood film examination and hematocrit estimation.

**Statistical analysis:** The data analyzed using Statistical Package for Social Sciences (SPSS) version 25. The data presented as mean, standard deviation and ranges. Categorical data presented by frequencies and percentages. Independent t-test and Analysis of
Variance (ANOVA) (two tailed) was used to compare the continuous variables accordingly. Chi square test was used to assess the association between adverse perinatal and maternal outcomes with mother’s blood (Hb + MCV) categories. A level of P – value less than 0.05 was considered significant.

Results

In this study, 500 pregnant women were enrolled. Maternal age was ranging from 16 to 44 years with a mean of 25.6 ± 8.13 years. Most of them lived in urban area (80.4%); 57.2% were housewives; and 83.2% had less than four children. As shown in figure 1, 33.4 % of study participants had mild anemia (hypochromic, normocytic) and 22% of them had normal Hb and MCV.

![Figure 1: Distribution of the study sample according to the level of blood indices](image)

Regarding adverse perinatal outcome, the incidence was 32.6% and preterm labor was the most common (24.6%); while the incidence of adverse maternal outcome was 11.8% and cesarean section was the most common (8.2%) as shown in table (1).

**Discussion**

Anemia in pregnancy is a worldwide phenomenon particularly severe in the developing world\(^{(13)}\). In our study, the prevalence of anemia according to WHO definition is 78%. Modified definition of anemia prevalence after adjusting for MCV is 44.6%, we divide group II (9-10.9%) according to MCV into normocytic (MCV ≥ 84 fl) which is partly due to a hemodilution occurring at the late second and early third trimester and microcytic <84 fl which is probably indicates IDA. The current study showed that low maternal Hb was associated with increased risk of poor birth outcomes including LBW, preterm birth and adverse maternal health outcomes, including cesarean section and induction of labor. Our results agreed with
findings from a previous meta-analysis studies done by Xiong Xet al 2000 and by Sukrat B et al 2013 showing that low hemoglobin concentration in early pregnancy (<20 weeks gestation) was associated with preterm labor and LBW(14, 15). This is not surprising as poor placental and neonatal development in anemia due to inadequate oxygen supply to the fetus across the placentas and the oxygen supply may have a direct bearing on the development of IUGR(16,17). A study done by Malhotra M et al 2002 agreed with this study when showed that cesarean section and induction of labor were highest in severe anemia(18). These might be explained by that the duration of labor increased progressively with increasing severity of anemia in both induced and spontaneous labor. In addition to the occurrence of uterine inertia in the mothers with low Hb concentration and increased rate of operative vaginal delivery in severe anemia due to maternal exhaustion and fetal distress. We had found that the age and parity showed statistically significant difference among groups; which probably due to the effect of repeated pregnancies on the development of anemia in subsequent pregnancy as it was evident in our results that those with parity greater than four tend to have more severe anemia. Hb concentration is affected by parity, this is might be explained by that most women enter pregnancy with little or no iron reserve compounded by closely spaced pregnancies, prolonged period of lactation and blood loss by post-partum hemorrhage(19).

In conclusion, we can conclude that maternal anemia is strongly associated with several different types of maternal morbidity and perinatal morbidity. Pre and antenatal treatment of anemia has the potential to improve outcomes for affected women and their fetuses and neonates.

Abstract

Background: Tuberculosis is an infectious contagious disease caused primarily by Mycobacterium tuberculosis. The probability of developing TB disease is much higher among people with risk factors. Iraq was classified the seventh country in Middle East Asia that related to the high burden of tuberculosis. Many laboratory tests are used in diagnosis of TB. The study aimed to compare the results of AFB sputum test, sputum culture, Gene-expert automated system PCR and IGRA test for interferon Gamma in TB patients.

Aims of the Study: This study aimed to compare between efficiency of TB diagnostic tests: AFB, IGRA, IgG, IgM, Gen X pert PCR & Culture on LJ. medium used in TB. Patients attended private Clinics In Baghdad, Karch Sector, IRAQ.

Patients and Method: In a Descriptive study, one hundred fifty four (154) suspected TB patients were attending Lagash Private Clinic in Baghdad, Capital of IRAQ during the period from January 2017 to December 2019. All patients were examined by well expert physician’s senior specialist, requested clinical, chest x-ray and lab investigations AFB, IGRA, IgG, IgM, Gen X pert PCR & Culture on LJ medium were done.

Results: Patients were showing different rates of positive tests regarding their age, all patients were showing positive IGRA followed by IgM and PCR tests. While culture and AFB tests were showing the lowest rate in the studied patients sample. Gender showed no effect on the tested parameters used for TB study. We recommend depending IGRA, PCR for the rapid diagnosis of TB.

Keywords: TB, gene x pert, AFB, IGRA, TB IgM.

Introduction

Tuberculosis is an infectious contagious disease caused primarily by Mycobacterium tuberculosis. The probability of developing TB disease is much higher among people with risk factors. There is an increasing rate of the drug-resistant tuberculosis strains toward the drugs for curing of tuberculosis in large sector of risky groups, the problems of emergency multi-drug resistant TB (MDR) is major conflict in the world. TB is remaining one of the major contagious bacterial diseases around the World, in 2014, Iraq was classified the seventh in country, in Medial East Asia (MEA) that related to the high burden of tuberculosis. Symptoms of pulmonary tuberculosis which includes chest pain, cough, bloody sputum, night sweating and fever are highly observed in such cases. And about 10 % of all (PTB) seem asymptomatic. When Mycobacterium tuberculosis spreads outside the lungs producing different type of TB, the most common types of extra-pulmonary tuberculosis are pleural TB, tuberculosis meningitis, lymphatic system (especially around the neck), Urogenital tuberculosis and the bones or joints. AFB sputum test remains a faster screening diagnostic test for TB and dependent by WHO through DOTS TB control program in endemic countries. The classical cultivation method on (Lowenstein-Jensen medium) remained as a gold standard to diagnose TB.
Bacilli and to estimate the drug susceptibility DST, but this method is time-consuming (weeks to months). So many new laboratory techniques have been developed by World Health Organization (WHO) to fasten the diagnosis and detection of drug resistance of TB bacilli, these new laboratory method included phenotypic method (liquid culture) such as BacTec MGIT 960 and genotypic method (Molecular PCR Technique) by Gene Xpert system and Line Probe Assay\(^{(14-16)}\). Although microscopy and culture remain necessary for treatment monitoring, now global use of rapid molecular tests and automated cultivation systems are increasing, many countries are phasing out the use of smear microscopy for diagnostic purposes\(^{(17)}\). So this study is devoted to compare the significance of AFB, IGRA, IgG, IgM, Gene Xpert PCR & culture on LG medium in diagnosis of TB patients attending private clinics.

**Patients and Method**

In a Descriptive study, one hundred fifty four (154) suspected TB patients were attending Lagash Private Clinic in Baghdad, Capital of IRAQ during the period from January 2017 to December 2019. Considering research ethics, a written consent was done for each patient. All patients were examined by well expert physician’s senior specialist and each patient was submitted to the routine chest exam and requested clinical, chest x-ray and lab required investigations. Inclusion criteria were followed like patients with high risk for TB and patients with extra pulmonary TB were included in this study. Exclusion criteria were followed like patients with other affections like CA lung and tumors of other sites of respiratory diseases, patients with autoimmune diseases like SLE In additions to that patients with any infection causes confusion with TB are excluded in this study. Sputum specimens, Serum, blood were taken from each patient and examined as soon as possible in Lagash Private Clinical Laboratory for Clinical investigations. Each specimen was manipulated following optimal method for each technique; AFB staining technique was done for each sputum and pleural specimen as well as cultivation on LJ. Medium following\(^{(12-13)}\). Test for Interferon Gama (IGRA) ELISA test was done for each serum specimen following instructions of manufacturing company (Sigma). Gene Xpert test (PCR) Test was done for each blood specimen following instructions of the manufacturing company (Gene Xpert MTB/RIF, USA). Direct examination (AFB) test was done for each specimen following\(^{(12)}\)Guidelines for sputum examination. Data were reported and analyzed using SPSS program Version 2.

**Results and Discussion**

It is found that IGRA test showed highest ratio (40.5%) of positive result followed by PCR (30.7%) and IgG (28.8%), (Fig-1).

This was in accordance with the findings of\(^{(18)}\), this was might be attributed to the high sensitivity of IGRA test. Non-significant difference (p ≤ 0.5) was found between IGRA and PCR positive ratio (Fig-1). This was attributed to sensitivity and specificity of these tests. Low ratio of positive IgM and culture (7.8%) and
(9.8%) for each respectively, this can be explained by the fact that the peak of IgM arise in the acute reaction then undergo a decline at the same time IgG undergoes an increase and show sharp increase in chronic status\(^{(19)}\). So the low ratio of IgM was found due to the decline of this immunoglobulin in chronic disease like TB without relapse(TB Immunity\(^{(20)}\). Very low ratio(0.7%) positive AFB test was might be attributed to the low bacilli number in sputum specimens and majority of patients were treated so they were showing reduced bacilli number in their sputum specimens. AFB test requires at least 1000-2000 bacterial cells per gram of sputum to give positive results\(^{(4,12,13)}\), (Fig-1).

Regarding age group, it was found that significant difference was found between age groups in IGRA & IgG results\( (P \leq 0.0001) \) & \( (p \leq 0.017) \), patients within age group \( \geq 60 \) years old patients were showing highest ratio of IGRA & IgG positive tests results \( (51.6\%) \) & \( (48.4\%) \) for each respectively Table This was in accordance with the findings of\(^{(20-21)}\).

*Significant difference between proportions using Pearson Chi-square test at 0.05 level.

Patients within age group 40-59 years old were showing highest ratio (38.2%) of positive PCR test followed by the age group \( \geq 60 \) years (30.6%).

Patients less than 40 years old were showing the lowest positive results of the above mentioned tests (Table-1). This can be explained by the fact that increased rate of TB infection with age increase\(^{(6-21)}\) due to the potency of BCG vaccine undergo decrease with higher age so the infective rate will be higher in the age group \( \geq 60 \) year followed by 40-59 years old (Table-1). All patients showed positive IGRA and PCR tests patients were showing positive IgM (100%). Sera from TB culture positive patients were showing more positive IgM than sera from culture negative specimens, (25%) & (8.5%) for each respectively, this was in accordance with the finding of\(^{(6)}\) (Table-2).

Adult patients within the age group 46-60 years old were showing the highest rate of positive AFB and gene expert results Followed by the findings of patients within the age group 18-30 years old for AFB and Gene Expert. This was in accordance with the findings of\(^{(20)}\) in Baghdad. This is might be due to the reactivation of childhood TB among individuals within age group 45-60 years old patients\(^{(4)}\).
This indicates the early stage of infection IgG positive results were showing more IgM positive results patients (Table-2). Results of this study showed that high ratio of positive IGRA, PCR, IgM and culture results were showing higher positive IgG results,(75%, 52%,25%,20%)for each respectively(P≤00 (Table-3). Regarding IGRA test, 75.8% of positive PCR test patients were showing positive IGRA test, while 53.2% of IgG positive patients were showing positive IGRA test.

Followed by culture and IgM positive patients, 24.25 and 19.4% of them were showing IGRA test respectively (Table-3).

Regarding IGRA test, all patients with positive culture were showing positive PCR tests. This was due to the high relation between the two tests. All patients with IGRA positive results were showing positive PCR test, this means positive relation between two tests (Table-4).

The same interpretation is acceptable for Gene Expert test was the presence of adequate bacterial cells of Mycobacterium tuberculosis in sputum to show positive Gene Expert system DNA test results. Similar results were nearly obtained by Al-Ouqaili et al 2018. Who use PCR test on sputum specimens from patients in Ramadi City, west of Iraq. The study concluded that AFB and Gene Expert tests are suitable tests for the identification of TB infection in adults and children above 6 years due to easy sampling of sputum suitable for these tests. In conclusion, patients were showing different rates of positive tests regarding their age, most of patients were showing positive IGRA followed by IgM and PCR tests. While culture and AFB tests were showing the lowest rate in the studied patient sample. Gender showed no effect on the tested parameters used for TB study. We recommend use depending IGRA and PCR method for the diagnosis of TB. In the same time, dependable test depends on the age and stage of disease. Tb is endemic disease in Iraq like hydatid cyst and brucellosis.(25,26)

Incidence and Risk Factors of Neonatal Mortality at Alramadi Teaching Hospital for Maternity and Childhood: A Cross Sectional Study

Rana F. Shitran¹, Mohammed E. Atallah², Yaseen T. Sarhan³, Maysam Y. Abed⁴

¹Lecturer, Department of Pediatrics, University of Anbar/Iraq, ²Specialist, Alramadi Teaching Hospital for Maternity and Childhood/Iraq, ³Lecturer, Department of Community Medicine, University of Anbar/Iraq, ⁴Specialist, Alramadi Teaching Hospital for Maternity and Childhood/Iraq

Abstract

Objective: To estimate neonatal mortality rate and determine major risk factors that contribute to neonatal mortality at alramadi teaching hospital for maternity and childhood.

Method: A prospective cross sectional study including 3654 neonate admitted to neonatal care unit at alramadi teaching hospital for maternity and childhood. To investigate the prohibition of death neonatal we performed a logistic recession with an odds ratio estimation for the deferent of weight birth maternal education, cause of admission and place of delivery, as well as the estimate of additive and multiplicative interaction.

Results: Data reveals the The incidence of neonatal death was 9.2%. It was higher in those with birth weight below 1.5 kg this means that low birth weight have higher chance of death with OR and C.I of (3.7 & 2.18–6.07) respectively. Also mothers with low education levels have higher chance of loosing their newborn baby with OR and C.I of (2.56 & 1.06 – 4.29) respectively. Home delivery with midwife interference and sepsis also have strong association with neonatal death with OR (2.15 & 6.82) respectively.

Conclusion: This is the first study done at Neonatal care unit of alramadi teaching hospital for maternity and childhood which analyze risk factors that highly contribute to neonatal death at that hospital. Determination of risk factors of neonatal death will help medical staff to reduce it through managing the avoidable risks like sepsis and educating the society about the importance of hospital delivery.

Keywords: Mortality, neonatal, death rate, sepsis, low birth weight, home delivery, Neonatal care unit (NCU).

Introduction

The period neonatal (the first 28 days of life) considered so critical period in life possibly due to diseases threatening newborn’s life and complexity process adaptive of the newly delivered(¹-³). Universally appear that 2.8 million deaths happened in newborns in 2013, consider the 44% of deaths in under-fives (⁴). There is clue proposition,a fast comparatively drop in the universal under-5 death-rate compared to the universal newborn mortality (yearly reduction rates 4.9% vs. 2.9%) among the year 2000 and 2013(⁴).

To prevent and adequately treat the utmost very important complications of birth preterm asphyxia birth and sepsis neonatal, which account collectively for three-quarter of deaths neonatal globally(⁴). The former articles from urban Cameroon cited contagion, risks of premature delivery,congenital malformations and birth asphyxia as the large causes of the hospital
neonatal mortality\(^{(5-7)}\). The styles of neonatal death-rate are valuable index of the fineness of obstetrical and care neonatal in a special check and the estimate include the rating of the fineness of health care\(^{(8-11)}\). Infant death-rate and child death-rate are mostly considered as indicators sensitive of the status health not only of children, but all populations\(^{(12-14)}\). Very early death in newborns is any kind of newly delivered death-rate which happens during the initial 24 h following birth\(^{(15)}\). (WHO), in countries developing among 25 and 45% of neonates die within the initial 24 h after birth\(^{(16)}\). Studies from Ghana appear that universal mortality in very early newborns was 16% per 1000 deliveries\(^{(17)}\). Very early neonatal risk factors for example, prematurity, low-birthweight, infections, hypothermia, asphyxia, meconium stained and birth injury raised the hazard of very early newborn death\(^{(18)}\). Newborn size is an important indicator of infant survival and childhood mortality. Accurate and Simple method of appreciate weight of newborn that can be readily exercised, to all pregnancies and consider method important of decreasing death-rate. Many researchers appear that depressed weight of the birth is linked with rise prenatal death-rate and morbidity\(^{(19)}\). At last years techniques ultrasound improve and utilized in most obstetric and gynecology clinics in all the world\(^{(20)}\). The profile biophysical was utilized to estimate fetal well-being and to reveal gestational fetal age via measuring the diameter biparietal and crown rump length\(^{(21)}\). Other investigators need predicted intrauterine fetal weight utilize measurement ultrasonography of the fetal abdominal circumference\(^{(22)}\), most new studies have confirm the effectiveness of this measurement in normal monitoring growth fetal and in detecting growth intrauterine demise\(^{(23)}\).

### Patient and Method

A prospective cross sectional study that involve a record of neonatal deaths that occurred from birth till 28 days of life was applied at Alramadi teaching hospital for maternity and childhood. This hospital located at west of Iraq, average acceptance annual neonatal is 3654 neonates. The neonatology divided unit in to two sections; inborn and outborn units. The study in this hospital conducted because the is no annual reports for deaths neonatal at that hospital. Data were collected to attain and review data from January, 2019 to December, 2019. All newborns delivered and died within the initial 28 days following delivery from January, 2019 to December, 2019 were involved in our focus. Even referred neonates that were transferred from other health care centers to Alramadi Hospital were included. Newborns whose parents or caregivers refused the consent were excluded. All maternal and neonatal characteristics was registered and data sheet extraction. The questionnaire was designed via the researchers to write down the characteristics demographic of mothers and newborns.

- **Neonatal characteristics:** Gestational age (calculated from last menstrual period), birth weight, gender, presenting complaint findings on the examination physical (rate heart, rate respiratory, signs of distress respiratory, neurological examination, abnormal breath sounds, any congenital anomaly, cardiac murmurs, temperature, abdominal distension,) all were recorded.
- **Maternal characteristics:** age of the mother, educational level, residence and occupation.

Infections in the Neonatal was diagnosed established on the presence of clinical signs of contagion (coma, fever, unable to feed, jaundice, vomiting, hypotonia, distended belly, consciousness altered, seizure) and any of the other next criteria biological: Elevated white blood cell count >25,000/mm\(^3\), Dropping white blood cell count <5000/mm\(^3\), thrombocytes <100,000/mm\(^3\), C-reactive proteins >20 mg/l\(^{(24)}\) with documented positive blood culture of the causative microorganisms. Prematurity were acquaint established on WHO case qualifier of an age gestation less than 37 before weeks achieved\(^{(25)}\). (HIE) were established diagnosed on the Modified Sarnat-Sarnat Score\(^{(26)}\) and an Apgar score ≤ 3 at the 5th minute of life linked with central nervous system involvement signs: flaccidity, convulsions or coma\(^{(27)}\). PH analysis was not available at that time and so not included in diagnosis of HIE. The neonatal hospital death-rate rate ware acquaint as the number of deaths happening between admissible neonates through a known expressed time as a percentage\(^{(28)}\).

### Results

All results explaining in tables 1, 2, 3 and Figure 1, 2. The total number of NICU admission was 3654.

Discussion

This review which secured a number for 3654 babies, admitted to neonatal care unit at Alramadi teaching hospital for maternity and childhood.

The incidence of neonatal death in this study was 9.2% and this result disagree with Farah E. Abdifatah(29) who found a neonatal mortality rate of 5.7% in a study done in Ethiopia, our higher incidence of death may be related to the poor hospitalization care and declining facilities especially after immigration and ISIS invasion.

In our study we found that neonates weighting below 1500 gm was a significant risk factor for neonatal mortality p value was 0.008, odd’s ratio was 3.7 and this is similar to Lansky S, De Lima-Friche A, Silva A, et al and Juan C. Lona Reyes, M.D et al(30,31) who found that extreme low birth weight is a significant cause for neonatal death.
In the current study the neonatal mortality rate was significantly related to the maternal education (the illiterate mother or the mother who completed the primary school only) with a p value 0.024 odd’s ratio (2.56) and this is similar to Sandra Costa Fonseca(32) who found that the neonatal death-rate in the term was 8.09‰ and the higher in newborns of mothers with low levels of education.

Despite home deliveries were in small percentages in our study but the neonatal death were significant in home deliveries p value 0.001 odd’s ratio 2.15 and this is similar to Justice Ajaari, MSc (Med)1,2 et al.(33) and this reflected by Childbirth in institution health presented via a trained medical crew minimize maternal and neonatal death-rate and morbidity compared to births in the home.

Regarding the most common cause of admission to the NCU associated with higher mortality rate, in our study sepsis was the commonest cause of neonatal mortality p value 0.001 with odd’s ratio 6.82. This is not similar to M Hoque, S Haaq, R Islam who found that prematurity was the commonest cause of mortality in admitted neonates despite the higher percentage of admission due to sepsis.(34) This can be explained by low maternal education levels so they do not stick to the optimal sterilization ways in handling their newborns, so medical staff fails to contain the spread of infection. In addition to the old fashioned equipment and broken incubators which do not provide optimal environment to the newborns and lastly the total admission to neonatal care units exceeding its capacity due to large number of daily deliveries in that governorate, so overcrowded units is a major contributory for the spread of infection.

Abstract

The difference games are characterized by accuracy, motor and skill compatibility, as well as diversity in offensive and defensive method and method of playing, due to the development that occurred in the science of sports training, which requires coaches to keep pace with this development and through the results of the teams it was found that the method used to develop football skills are ways It does not match this development taking place in this game, which prompted the researchers to prepare special exercises using a device in order to develop the skills of passing and Suppression football, as the experimental method was used in one group, while the research sample included the industry club’s number (20). As an intentional player and after completing the field experience, the two researchers concluded that the nature of special exercises on the device is consistent with the ability of the sample, which led to the development of the skills of passing and dousing football, as well as providing an element of pleasure and joy for the players during the training unit.

Keywords: Special exercises, Flick Urban and Suppression.

Introduction

The sports field has witnessed great progress in various sports, whether in the difference or individual games, as the progress in sports and events was not a coincidence, but rather perseverance and hard work through a deep understanding of what is included in the foundations and rules of the science of sports training to raise the level of The state of training to reach the highest levels, through research and permanent access to all that is new to add new information by following modern scientific method and method, devices and various tools to reach the athlete to an advanced level in performance and that among the games and events that have attracted the attention of workers in several areas despite their modernity It is football, which has received a large share of support and encouragement.

Football is one of the different games that attract the attention of peoples and governments to the privacy that it enjoys, which is to bring pleasure, joy and pleasure to the hearts of its fans, which made it the first popular game in the world, as we note the great development taking place in the technical, physical and planning aspects of players and teams and this did not come at random but rather The result of using scientific method and proper planning in training to achieve the best level, which represents the main goal of the training process in the sports field.\textsuperscript{(1)} The handling and extinguishing skills are among the important skills in the football game, especially after the great development in the different and modern method of playing in defence and attack

and mastering my handling and extinguishing skills gives a preference to the team to excel in the matches over the competing teams, as the skills are the rule for the game although it does not perform the purpose. Without physical abilities and game plans, it remains the important element in the game and without her mastery, the team players cannot perform the duties and various play plans perfectly.

Hence the importance of research on how to develop soccer players according to the scientific foundations, by preparing exercises using a device that helps encourage players to continue training, excluding the factor of fear and failure and lack of flow of boredom and adding an element of suspense and excitement to training as well as helping to reduce effort and shortening Time, during which the coach can achieve the goals of the training unit and bring the players to a good level in mastering the skills.(2) Through the experience of the researchers in the football game, they noticed a weakness in the handling and suppression skills of the players, as well as the lack of use of devices and modern auxiliary means that help in developing these skills, since the effect of exercises in the equipment when training occurs desired developments to ensure the achievement of achieving the training goals and that through Many errors occur when performing and this may be due to the lack of use of exercises with modern equipment, which helps in developing these skills with a football.

Research objectives: Knowing the effect of the exercises related to using the device in developing the skills of handling and Suppression football for juniors.

Research hypotheses: Special exercises according to (Football Flick Urban) affect developing the skills of passing and Suppression football to the research sample.

Research methodology and field procedures

Research Methodology: It is the nature of the problem and the objectives of the research that determine the appropriate research approach. Therefore, a one-group experimental approach was used to suit the nature of the research problem.

The research sample: The research sample was chosen intentionally by the Sports Industry Club beginners, as the number of the sample population reached (20) players.

Means of gathering information and tools used in the research

Means of collecting information:
- Arab and foreign sources and references.
- Personal interviews.
- Testing and Measurement
- Data dump form.
- Devices and tools used in the research: (Football field, soccer balls, chalk, whistle (FOX), pens, training badges, tape measure).

Devices used in the research:

Football Flick Urban Device(3): It is a contemporary device with a stylish, three-dimensional and versatile design, used to develop the skills of football players, as it was designed to enable them to train individually, as it enables players to pass the ball to the height in the device and receive the ball again and at different heights and speeds and different angles to develop the handling and Suppression skills and their accuracy in controlling The ball as well as to kick the ball into the net in the device, as shown in Figure (1).

Football Flick Urban is used as an educational and training device to improve handling, Suppression, scoring and controlling ball skills, as well as providing fun and joy to players during training units in an attempt to create new skills and movements.
Figure 1. Shows the Football Flick Urban device

**Football Flick Urban:**

1. **Front slope:** It is the height located at the front of the device and consists of a convex arc. It has a smooth surface that can be adjusted to change the path and degree of difference of the return length (137 cm), width (74 cm) and height (72 cm).

2. **The back slope:** It consists of a curved corner backrest and a surface that returns to its condition Natural, which can reach (180 degrees) to change the flying ball, its length (110 cm), its width (74 cm) and height (72 cm).

3. **The network:** It is the last part of the device and is in the middle of it, which was designed to be used to pass the ball to the target, its length (48 cm), width (65 cm) and height (32 cm), as shown in Figure (2).

**Research tests:**

**Passing:**

- **Name of the test:** The ball passes about three overlapping circles drawn on the ground from a distance of (15 m).\(^{(4)}\)
- **The purpose of the test:** to measure the accuracy of the pass.
- **Tools:** (5 soccer balls), tape measure, football field, chalk, 1 person
- **Performance description:** Three concentric circles
with concentric dimensions draw their dimensions as follows: (the first circle has a diameter of 1.5 m) and the second diameter (3 m) and the third diameter (4.5 m), the starting line is determined (15 m) from the centre of the circles and the player stands behind the starting line and then He kicks the five balls in a row in the air, trying to drop them into the (smaller) circle.

- Conditions of performance: (The ball is kicked and passed in the air, not ground handling when the ball touches a joint line between two circles, the greater degree is calculated, the distance between one ball and another (50 cm)

- Recording method: (Each player has one attempt from (5) balls, the laboratory is counted (3) degrees if the ball falls in the first (the smallest) circle), the laboratory (two degrees) is counted if the ball falls in the second (middle) circle, the laboratory is calculated (a score (If the ball falls in the third circle (the largest), it is counted for the laboratory (zero) of degrees if the ball falls outside the three circles).

Control the ball:

**Test name: Ball control (suppression):**

- The purpose of the test: to measure accuracy in stopping the ball and regaining control of it alongside the foot, foot, thigh, or chest in a box (1.5 m).

- Instruments: (5 footballs), a defined area with two parallel lines, the distance between them (15m).

- Test specifications: The coach stands with the ball on line A and after giving the starting signal he throws the ball (high balls) for the player who advances from the starting line to the inside of the test are trying to stop the ball with any part of the body except the arms and then returns to the starting line Starting again and so the player repeats the five consecutive attempts.

- Conditions of performance: (If the coach misses the ball or throws it to the laboratory inappropriately, the attempt is repeated. The speed of the ball from the trainer is given to all the testers, then the correct attempt is not calculated in the following cases. “If the laboratory did not succeed in stopping the ball, if he passed any line in The area has more than one foot, if he illegally stops the ball, stands up at the football”

- Recording method: (Two grades are given in the case of putting the ball inside the box and not leaving the ball from it, one degree if the ball stands on any of the square lines and zero in the event of the ball leaving the square).

**Pilot study:** The exploratory experiment was conducted on Monday, 9/30/2019 at four o’clock in the Sports Club of Industry, on a sample of (6) players from the main research sample.

The scientific basis for the tests used: To get acquainted with the scientific bases of the tests used and after the researchers reviewed many sources from previous studies, it became clear that they were codified, as their sincerity and reliability were extracted in many studies, as well as using them on similar samples.

**Pre-test:** Pretests for the research sample were conducted on Tuesday (1/10/2019) and the soccer field and the conditions and method of testing and the assistant team were established to achieve the same conditions as possible when conducting the post-tests

Apply the main experience: The main experiment of the research sample was carried out on Thursday corresponding to (3/10/2019) and was completed on Saturday corresponding to (11/22/2019) on the members of the experimental group with two training units per week and the number of training units reached (14) units and took time Each training unit (75) minutes was divided into three sections:

1. Pre-section: 15 minutes.
2. The main section: 50 minutes.
3. The closing section: 10 minutes.

**Post-test:** The researchers intentionally conducted the post-exams after completing the training curriculum and its (14) training units on Monday corresponding (11/25/2019), taking into account all the conditions, conditions and procedures for the pretests.

Statistical means: The researchers used the appropriate statistical means to process the resulting data through pre- and post-tests via the (SPSS) system.

**Results and Discussions**

Present and discuss the results of the football handling and dousing skills in the pre and posttests.
Table 1. Shows the values of the mean, the standard deviations, the deviations of the differences from its mean, the calculated and tabulated \((t)\) value and the significance of the differences between the pre and posttests of the research sample in handling and suppression skills

\((t)\) tabulated (2.09) at the level of significance (0.05) and degree of freedom (19).

Table (1) shows the values of the mean for the pre-test of the research sample in the passing and suppression skills in the pre and posttests, as it was found that the calculated value of \((t)\) for each component under investigation, respectively. (2.09) This means that there are significant statistically significant differences between pre and posttest.

The researchers attribute the reasons for these differences to the following:

- The effect of using devices and tools to develop accuracy through the performance and repetition of special exercises in a manner that lives up to being close to the playing conditions while taking into account the change in the exercise and its multiplicity as well as the player’s rush towards the skilful performance of modern and easy to use devices that were not previously used as a Football Flick Urban device raises motivation. The player in the experience of what is new makes him perform the repetitions with confidence and desire and work towards the best and “that the player reaches the performance of the skill automatically through the permanent repetition of the performance.”

- The researchers attribute this development to the research sample to the effectiveness of skill exercises through the use of a device to develop the skills of passing and Suppression football, as the devices work to develop the capabilities of players, whether physical, motor or skill, as it expands their sensory, motor and cognitive awareness and increases the focus of their attention, “The equipment and the auxiliary tools have a distinct role in the sports field in general and in football in particular.”

- The optimal use and significant impact of the use of multipurpose teaching aids (Football Flick Urban), as these educational method added factors of influence in the player in terms of spreading the spirit of competition and fun and get rid of the boredom and monotony that exist in the traditional uses free of educational means, and “Proficiency in the use and use of teaching aids contribute to improving the processes of education and training, which leads to its contribution to teaching motor skills and mastering them to the fullest extent. The use of assistive devices and tools contributes to increasing motivation, desire and excitement in training units and increases.From the player’s ability to exercise.”

- “(9) “the necessity of using the auxiliary tools during the training process and investing all that is available from it, also stressed the need for diversification in the exercises and the tools used to keep players out of boredom and increase the suspense process.”

**Conclusion**

1. The use of skill exercises and equipment within the training curriculum in the special preparation stage has a positive and effective impact in developing ball control skills.

2. Increasing the accuracy and concentration factor of some players led to a good stage in the ball control skills.

3. The various exercises and using the devices increase the factor of excitement, suspense and competition, which led to the ease of the process of developing ball control skills among players.

The Effect of Playing Exercises According to the Training Network on the Speed of the Motor Response and the Level of Skillful Performance of Youth Soccer Players

Ahmed Obaid Rashid¹, Yagoob Yousif Ibrahim¹, Ayad Khalf Marzoog³

¹Assist. Lect. Ministry of Education/General Directorate of Anbar Education/Iraq

Abstract

The world is now witnessing a rapid development in all areas of life and the sports field, one of which has received a share of this progress and clear development and the importance of research lies in preparing play exercises that are performed according to the training network and that contribute to developing the speed of the motor response to football players, which in turn contributes to the development of The skill level of young players and the study objectives to identify the effect of these exercises on the study variables.

After testing and collecting information, the results were extracted and the most important conclusions were reached:

1. The results of the post test showed that there are statistically significant differences in the research variables.

2. The exercise exercises according to the training network have a positive effect in developing the speed of the motor response and the skill level of the research sample.

Keywords: Playing exercises, training, network and motor response.

Introduction

The world is now witnessing a rapid development in all areas of life and the sports field, one of these areas, which received a share of this progress and clear development and the outputs of the training process are evidence of the progress of the levels of players in various sporting events and football is the first popular game in the world because of its millions of practitioners Followers and fans who witnessed remarkable progress and development at the global level, which is the result of an effort by experts and specialists in the process of researching and investigating facts and knowledge and all that is new to develop and raise the level of players in this event and sees that “the greater the individual’s mastery of motor skill, The less effort exerted in performance and the more he is able to use all his thinking and attention to the various planning duties in the course of competition.”

Sports training science is one of the most important education and sports because it is closely related to all other sports sciences such as physiology, motor learning and sports rehabilitation in addition to psychology and sports training is based on modern and advanced scientific foundations when preparing exercises and training units, including the degree of intensity, size and periods of rest that are codified according to The method of training and the training phase and its appropriateness to the level of the research sample and that the codified training curriculum that is applied in an organized scientific and practical manner will produce rapid developments in
the physical, mental and skill status of athletes, which leads to achieving the goals of the training process and that the process of assessing and evaluating the success of the prepared training curriculum is measured by the extent of The development achieved by players as individuals in the activity practiced and reflected at the level of the general team and confirms that “movement develops with regular athletic training as a result of the development of the mental and intellectual level and the development of physical and motor qualities in addition to increasing what is stored in the brain from movement experiences.”

The importance of the research lies in preparing play exercises that are performed in specific areas (the training network) that contribute to developing the speed of the motor response to football players, which in turn is reflected in developing the level of skill performance of young players and this means The training of skills and plans is through close exercises What happens in the game.

Through the researchers’ pursuit of being athletic players and teachers and informing them of all the developments taking place in the field of the game, they found that there is a decline in the levels of players for skill performance and speed of motor response, which requires researchers to prepare exercises close to the atmosphere of real competition performed in specific areas (play exercises) That contributes to solving the search problem.

Research objectives:
1. Preparing exercises for playing in specific areas (the training network).
2. Knowing the effect of playing exercises according to the training network on game variables.

Hypothesis search:
1. There is a statistically significant difference by the effect of playing exercises on search variables.
2. There are statistically significant differences between the pre and posttests in the motor response speed and the skill level of the research sample.

Research fields:
- Human Field: Youth of Ramadi Football Club.
- My field: In the Ramadi Football Club.

Research methodology and procedures:

Research Methodology: Researchers have adopted the appropriate experimental approach imposed by the nature of the problem to be studied.

Community and research sample: The research population and sample were identified from the 16 Ramadi youth football players for the football season (2019-2020) and they were chosen in an intentional manner.

Research devices and tools and means of gathering information:
- Electronic hours (3) of Korean origin.
- Sony type camera (3) of Japanese origin.
- Chinese (TAKSUN) type electronic calculator.
- Legal football playing field.
- Legal soccer balls, number (18).
- Figures number (12).
- Sports shirt number (20).
- Whistle (2).
- Tape measure.
- Arab and foreign sources.
- Tests and measurements.
- Internet.
- Observation and analysis.

The tests used

Determine the football skill test:
- Test name: Football Soccer Skill Test
- Test goal: to measure soccer skill
- The necessary tools: half of the football field, an electronic stopwatch, a whistle, (4) obstacles, (6) characters, (3) flags, a tape measure, one football and one bench.
- Test description: The player starts running from the specified starting point at the corner of the penalty area that is located with the goal line, as there is a ball (10 m) from the starting point and he has to roll the ball between four contra indications to the distance between each couple (longitudinally 4 m and the width of 2 m) and then complete the rolling with the ball Until the midfield line, to meet an
upright pass from both sides and a distance of (5 m) from this upright there are four people at different distances which are respectively (1.5-1-2-1 AD) and then after the pass from the side of the last post go to the goal And after (10 m) there is a post to pass from its side and pass the ball to the Swedish tilted seat with the running line to return to the ball and kick it towards the goal.

- Recording: time is counted from the starting moment to the scoring moment and (1/10) of the second is added in the event that the player collides with one of the signs and rests on the ground.

The Nelson Test for Selective Kinetic Response⁶:

The purpose of the test: To quickly measure the ability to respond and move according to the stimulus test.

The necessary tools:

- Tennis court: a flat, barrier-free zone with a length of 20 m and a width of 2 m within which three lines plan the distance between the line and the other (6.40 m) and the length of the line in the middle (1 m).
- Electronic stopwatch, tape measure.
- Administratively testing
  - Registered/calls on names first and records test performance second.
  - Timer/Start indication with timing.
- Performance specifications: The player stands at one of the ends of the midline in the face of the timer, which stands at the end of the other end of the line and the player takes the standby position so that the midline is between the feet and then he bends his body forward slightly and the timer grabs the stopwatch with one hand and raises it to the top and then quickly moves his arm to the left or the right and at the same time the clock is running and when the player responds to the start signal he tries to run as fast as possible in the specified direction to reach the side line that is away from the middle direction a distance (6.40 m) and when the player crosses the right side line the timer stops the clock.

Test instructions:

- If the player starts in the wrong direction, the timer continues to run the clock until the player changes his direction and reaches the correct side line.
- The player is given (6) consecutive attempts between each attempt and the other (20) seconds of rest and (3) attempts on each side.
- Attempts are chosen on each side in a random and sequential manner.
- The timer must practice the starting signal in order to be able to give this signal to the arm and operate the watch at the same time.
- The player must not know the number of attempts required of him to perform it in order to reduce the player’s expectation.
- The test should start with the timer showing a signal (get ready - start) in all attempts.
- Recording method: the time for each attempt is calculated to the nearest 1/100 second.
- The test score is the average of the six attempts (total score = total attempts ÷ 6 = 0.00 Second).

Results

**Discussions**

This is what shows the extent of the effect of playing exercises according to the training network, which was applied in the training curriculum for young players to develop the speed of the motor response and skill performance in the football game, because the exercises contain the principle of excitement and suspense, which was characterized by the progression from easy to difficult and sound scientific planning, as he mentioned Training in football is characterized by planning, organization and continuity and on scientific grounds to ensure the duration of positive influence on the player’s level and its continuity as an introduction to various aspects of football as the principle of gradual increase in the level of pregnancy and the correct timing of its repetition.6

The researchers believe that the development that occurred in the research variables is due to the influence of the independent variable (exercises by playing according to the training network) and the user according to correct and studied scientific foundations that were close to their performance in the real competition atmosphere, which contributed to the development of players’ performance in the best way, in addition to the method and method of training The follower led to its positive reflection in the development of the speed of the kinetic response and its effect on the progression of the skill level of the players.7

The researchers attribute the reasons for the development of the level of skill performance and the speed of the kinetic response in the results of the post-tests to the effect of playing exercises applied in the two method of high-intensity and repeated training using the training network as well as the use of the correct repetitions of the chosen variables and correcting errors and treating them in a scientific, practical and educational manner correct and studied with giving an opportunity for players to perform The largest possible number of iterations and directing them to reach the perfect performance,8 which contributed to bringing them to a better level. And this is confirmed that developing the level of technical performance of the players by providing an opportunity to increase the number of iterations as well as giving feedback to address errors during performance and teaching motor skills leads to correct player responses and directing his motor behavior towards the correct form that It raises the level of accuracy of skill education performance,9 and this is consistent with the advantages of exercises in the designated areas help increase the speed of movement and the transition speed from one place to another without the emergence of fatigue quickly as well as developing the agility and lightness necessary to develop performance in Different skills.10

**Ethical Clearance:** The Research Ethical Committee at scientific research by ethical approval of both MOH and MOHSER in Iraq.

**Conflict of Interest:** Non

**Funding:** Self-funding

**Conclusions**

1. The results of the post test showed that there are statistically significant differences in the research variables.
2. The exercise exercises according to the training network have a positive effect in developing the speed of the motor response and the skill level of the research sample.

The Effect of the Comparative Marital Competition Method on Developing the Most Important Motor Abilities and Learning the Technical Performance of the Students’ Effective Shot Putting

Ebtighaa Mohammed Qasim¹, Rami Abdul Ameer Hassoon¹, Amjed Hashim Mohammed²

¹Lect., ²Assist. Lect., University of Kerbala/College of Physical Education and Sports Science/Iraq

Abstract

The method used in teaching the scheduled study materials do not seek to activate the role of the student in the academic stages and give her a positive character in addressing and facing educational problems that she encounters in her working life - including the effectiveness of pushing the weight, as the progress in the educational process requires the teacher to choose the best method to develop the effectiveness What is required is that teaching method have a major role in developing the skill level of learners. The more developed the teaching method used, the better the learning process and the greater the opportunity to advance the skill performance.

As for the objectives of the research, they are to identify the effect of the marital comparison method in developing the most important motor abilities and learning the technical performance of the effectiveness of pushing the weight of the students, as well as identifying the significance of the differences between the two research groups (control and experimental) in the results of the post tests in developing the most important motor abilities and learning the technical performance of the effectiveness of push Shot putting for female students. As for the research hypotheses, there are significant differences with statistical significance between the results of the pre and posttests in developing the most important abilities Kinetics and learning the technical performance of the students 'effective push.

Keywords: Comparative marital, motor abilities, health practice; and shot putting.

Introduction

The educational process is based on an important means, which is to transfer knowledge and information from the teacher to the learner in the appropriate way. An efficient teacher is the one who can diversify in the use of different method and method and provide all that is new in his field to raise the state of boredom and boredom that accompanies the learner during learning resulting from the use of one method, which may lead to the desired development, since we learned that the learner is greatly affected by the method and method that Followed by the teacher and the list on the basis of experimentation and application, so the researchers decided to use a better educational method in order to facilitate the process of learning faster and better than the educational method, which is (the method of comparative marital competition).

The field and field activities are among the activities
that have a distinguished position among other types of sports, as they include a variety of activities such as: running, jumping, jumping, throwing and mail and walking. And it is called the mother of games because it is the foundation upon which the rest of the games are built, as it develops physical characteristics, including strength, speed, elongation, agility, flexibility and others.\(^{(1)}\)

The method used in teaching the scheduled study materials do not seek to activate the role of the student in the academic stages and give her a positive character in addressing and facing educational problems that she encounters in her working life - including the effectiveness of pushing the weight,\(^{(2)}\) as the progress in the educational process requires the teacher to choose the best method to develop the effectiveness What is required is that teaching method have a major role in developing the skill level of learners. The more developed the teaching method used, the better the learning process and the greater the opportunity to advance the skill performance.\(^{(3)}\)

**Research objectives:**

1. Knowing the effect of the marital comparison method on developing the most important motor abilities and learning the technical performance of the students’ effective pushing weight.

2. Identify the significance of the differences between the two control and experimental research groups in the results of posttests in developing the most important motor abilities and learn the technical performance of the effectiveness of shot putting for students.

**Research Methodology**

The researchers used the experimental approach to fit the nature of the problem to be solved by designing the two equivalent groups with pre and post testing.

**Research community and sample:** The research community determined the third stage students in the College of Physical Education and Sports Science/University of Karbala for the academic year 2017-2018, whose number is (65) students and the sample was randomly chosen, whose number is (30) students and was divided into two groups (control - experimental) and the number of each group (15) female students and (10) female students were excluded due to their selection for the purpose of conducting the exploratory experiment.

**Research steps and field procedures:**

**Determine the most important motor abilities:**

The most important motor abilities were identified that are appropriate to the students’ weight-bearing efficacy through the researchers’ review of the sources and references and after that a questionnaire was prepared and presented to experts and specialists and the most important motor abilities that got a percentage of (70%) and above and table No. (1) were identified, this is indicated.

Determine the technical performance test for shot putting effectiveness:

**Shot putting test:** Purpose of the test: Evaluating technical performance by pushing the weight.

**Tools:** The throwing circle, which is a circle with a diameter of (2.135 meters) covered with cement in the center of the circle, there is a line that divides it into two parts and at the front of the circle there is the throwing part and fixed to the ground and is called the stop plate.

**Characterization of kinetic abilities tests**

**First: Fitness test**

The name of the test = running like a dream

The purpose of the test = (Measuring Fitness)

The tools used = (person count (4) stop hours, number (1) evaluation form)

**Second: flexibility test:**

The goal of the test: To measure the elasticity of the torso and thigh in the forward bending motions in pushing the stand.

**Tools:**

1. A scale of wood or a ruler with a length of about 20 cm divided by lines into units, each unit equal (1) cm and it is preferable that this gradient occur in a range of 10 cm.
2. A bench, chair, or table that bears the weight of the laboratory without vibration

**Third: The kinetic compatibility test between the eye and arm**

Test name: throw and receive balls on jars

The purpose of the test: to measure compatibility between the eye and the arm

The tools used: a tennis ball (1) a wall drawing a line a distance of (5) meters from the wall/evaluation form.

Method of registration: For each valid attempt, one score for the tested student is calculated and the final score is 15 degrees.

**Kinetic test between the eye-the leg**

**Test name: Numbered Circuit Test**

The purpose of the test: to measure compatibility between the eye and the leg

The tools used: stop watch number (1) draw on the ground (8) circles provided that the diameter of each of them is 60 cm and numbered from (1-8) evaluation form.

Recording method: The time spent by the student tested in the transition to the eight circles.

**The main experience:**

**Pre tests:** Pretests for the research sample were conducted on Thursday, 2/12/2017, after the implementation of two educational units within the program.
The educational units for the method of comparative conjugal competition:

- The total number of units is 8 units.
- Number of units per week (one educational unit).
- The time of the educational unit is (90) minutes.
- Time of the applied section in the main section (45 minutes)
- Exercises were used in the competitive comparison method and applied to the experimental group, as they included exercises to develop the most important abilities and test the technical performance of the effectiveness of pushing the weight of the students and to make sure that these exercises achieve the desired goal, although they came in the sources were presented to a group of experts and practitioners in this field.
- The exercises were carried out by the school of material and with the assistance of the assistant team.
- The control group is subject to the vocabulary of the educational program followed.

Post-test: The researchers conducted the post tests for the individuals of the research sample and for the control and experimental groups on Thursday, 4/2/2017. In that he followed the method he used in the pretests themselves, taking into account the same spatial, temporal and climatic conditions, the means of the tests and his tools.

The researchers believe that the implementation of the educational units prescribed for the group had an impact tangible to the members of this group, as the prepared method that led to the development of these kinetic abilities they have through their repetition and practice as practice and constant effort and repetitions are necessary in the learning and repetition process is an important and necessary factor in the process of the learner’s interaction with skill and control of his movements and checking the consistency between movements. The component of skill in continuous performance, appropriate time and continuous repetition alone from the learner’s skill development, development and mastery.\(^{5}\)

In addition, the presence of the educated in the presence of competition with the difference in performance led to the occurrence of these differences in addition to their regularity in the educational units in which they practiced a method a new one was not familiar to them,\(^{6}\) which strengthened their motivation to implement the exercises of kinetic abilities with all persistence and success and this was confirmed (in that the effort exerted on competition in order to excel is a factor considered to be at the heart of the human nature) in addition to the exercises on the kinetic abilities that worked in the course of the departments of the educational unit and by relying on the method of comparative competition,\(^{7}\) it is also an important role in the emergence of these conditions - through jogging, running and jerking exercises. Soft, arms and gaming exercises, as well as the flexibility of the muscles of the body.\(^{8}\)

The results of the technical performance test for the effectiveness of pushing the weight of the members of the research sample, where the results showed the presence of a statistically significant difference with a probability of error (0.05) and in favor of the post-test of the control group and the researchers attribute this development to the educational program followed by the lessons of the arena and field games (For weightlifting efficacy) which significantly affected the development of test results for the control group. As for the experimental group, there was a significant moral difference in favor of the post-test. The researchers attribute this difference to the effect of the conjugate comparison method applied to the experimental group, as the primary goal of all exercises is to develop the player’s ability and increase his ability to reach to a good level of performance that qualifies this level of resilience to other skills and other abilities.\(^{9}\)

Conclusions

1. The comparative, marital, competitive method has a significant and effective influence in developing the most important motor abilities and learning the technical performance of the effectiveness of shot putting.

2. The experimental group outperforms the control group in developing the most important motor abilities and learns the technical performance of shot putting effectiveness.

Abstract

Parturition in bovine consider as a stressful event to the calving cows and calves as well. In general divided into three phases. The former involves the endocrinal and mechanical arrangement of uterine and cervical tissues, embryo and birth the newborn and expulsion of the placenta. Calcium is one of the essential materials in the body which was found that subclinical hypo-calcemia can highly affect cows and about 47% of the multiparous with 25% of the heifers were affected. Forty animals were selected and divided into two equal groups, first group treated with intramuscular administrations of calcium, the remained group were injected Intramuscular normal saline. The result showed there are significant decrease in the time of parturition in group administered with calcium as compared with non-treated group.

Aim of Study: Evaluate the role of calcium on time of parturition period and some trouble shot during it.

Keywords: Calcium, Parturition, Cow; nutrition.

Introduction

Parturition in bovine is a stressful event to the calving cows and calves as well[¹]. This mechanism can alter the energy profile of offspring and dams, producing a metabolic imbalance at birth. The dilation of pelvic canal, the contractions of abdominal and uterine muscles and pain related with fetal expulsion are strongly implicated in a complex pattern of neuroendocrine regulation[²]. Parturition is generally partitioned into three phases. The former involves the endocrinal and mechanical arrangement of uterine and cervical tissues for parturition. The second stage includes bring out of the embryo and birth the newborn. The later stage includes expulsion of the placenta[³].

It was found that subclinical hypo-calcemia can highly affect cows and about 47% of the multiparous with 25% of the heifers were affected[⁴]. The subclinical hypo-calcemia elevates of non-esterified fatty acids in the plasma and destroys the immune system[⁵]. Moreover, hypo-calcemia leads to reduce reproductive performance, increase the risk of culling[⁶], female genital tract diseases and lactation production[⁷]. Therefore, calcium is the most critical electrolyte managing myometrium constrictions. The myometrium contains an intracellular pool of bound calcium put away in the sarcoplasmatic reticulum and the myometrium cells have high convergence of sarcoplasmaticreticulum[⁸]. Calcium can be mobilized from the sarcoplasmatic reticulum just as from the extracellular liquid. The insufficiency of calcium may incline the cows to dystocia[⁹] and reduce of uterine contractions resulting to the disappointment of fetal expulsion yet the immediate role of calcium in detachment of fetal membranes isn’t comprehended. Troublesome birth is a main source of calf demise at or soon after birth and prompts uterine contaminations and increasingly retained placentas[¹⁰]. Accordingly, this
research was designed to evaluate the role of calcium on time of parturition period and some trouble shot during it.

**Materials and Method**

**Animals:** The current study was approved by the Institutional Animal Care and Use Committee, University of Kufa, Iraq. A single dairy farm was conducted to do the present study. The herd consisted of 80 cows. The cows had body condition score between 3.5 and 4.5. Cows without history of retained fetal membranes (n = 40) were randomly selected and divided into two groups. All animals were healthy at the time of the study and the herd was kept under sanitary conditions throughout the study.

Cow and treatment local dairy cow utilized in the investigation were kept at a commercial farm under normal homestead conditions. Cows without history of retained fetal membranes (n = 20) were randomly divided into two equal groups. First ten cows were intramuscular administrations of calcium (20 mg/mL) mg.kg-1, the remained ten were injected Intramuscular normal saline (10 ml)and the following parameters were examined and evaluated: Time of parturition period, nature of parturition and the occurrence of retained placenta.

**Statistical analysis:** Statistical analysis of data was performed on the basis of Chi-Square Analysis using a significant level of (P<0.05). Specific group differences were determined using.

**Results**

The time of parturition period in cow treated and non-treated with calcium/hour illustrated in figure (1), the result show significant decrease (P<0.05) in the time of parturition in group treated with calcium as compared with non-treated group. While the nature of parturition normal and abnormal (birth with a veterinary intervention) and the occurrence of retained placenta clarified in figures (1 and 2) respectively, the results show no significant changes (P<0.05) between treated and non-treated with calcium.

*significant difference P<0.05 between two groups due to the value of Pearson Chi-Square (Asymptotic Significance) equal to 0.001 is less than (0.05).

*Figure (1):The time of parturition period in cow treated and non-treated with calcium/hour (h).*
*Non-significant difference P<0.05 between two groups due to the value of Pearson Chi-Square (Asymptotic Significance) equal to 0.361 is more than 0.05.

**Figure (2): Nature of parturition in cow treated and non-treated with calcium**

*Non significant difference P<0.05 between two groups due to the value of Pearson Chi-Square (Asymptotic Significance) equal to 0.361 is more than 0.05.

**Figure (3): The occurrence of retained placenta in cow treated and non-treated with calcium**
Discussion

The objective of the present study was to study the effect of calcium supplementation to pregnant cows to minimize the risk of dystocia in cows of low or high risk of retained fetal membranes.

Calcium concentrations in the circulatory system are kept up by the eating routine and calcium discharged from the skeleton. The disappointment of calcium absorption from the eating routine and skeleton result in an abrupt deduction in blood calcium concentrations. At the point when the mammary drain of plasma calcium causes hypocalcaemia extreme enough to disrupt neuromuscular function\[11\]. Due to the start of colostrum production and consequently increasing calcium demand, the nadir of serum calcium concentration occurs 12 to 24 h after parturition\[11-12\].

The results give an indication that calcium is not needed to initiate the labour while that showed decreased in time of parturition compared with non-treated group, that was agreed with\[14\], which showed the calcium oral administration of calcium is improved parturition as well as Zhang et al (2020)\[15\] showed the which Ca status is associated with energy metabolism of transition dairy cows.

The time of parturition related to the energy therefore to Cabalance which is associated with energy metabolism of transition dairy cows. In generally cows in the transition stage of parturition are susceptible to risk of negative energy balance due to lack of synchronization between appetite recovery and milk secretion while milk production related to energy balance \[16-15\]. On other hand study results showed the increased significantly in time of parturition in non-treated group compared with the treated groups.

Administration of Calcium was not affected on nature of parturition which result of study showed non-significant different between treated and non-treated group with calcium as agreed with find on similar studies\[16-17\] when used oral administration of calcium. As well as the causes of retained placenta is usually by an inflammatory state as showed by present studies\[18\] or by late gestation and labor.\[19\]

The occurrence of retained placenta did not affected which the study found that are non-significant different between treated and non-treated groups in the same time we agreed present studies \[15\] which showed calcium did not effect on the nature of parturition.

Conclusion

The administration of calcium improved parturition which decreased the period of parturition time, while that did not effect on nature of parturition and retained placenta.

Strong Evidence of Highly Pathogenic and Low Pathogenic Avian Influenza Viruses in Domestic Poultry in Iraq

Karar Mohammed Abdul-Sada

Abstract

Background: Avian influenza is very important contagious disease caused by Avian Influenza A viruses which continue to pose real threats for both human and animal. The virus subdivided into many HA and NA subtypes, some of them are highly pathogenic while others are low pathogenic for poultry.

Method: Nasal swabs or fresh tracheal swabs in case of dead birds were taken from 417 of chicken farms and flocks besides to 689 of local poultry that grew in the backyards all over Iraq to detect and identify viral subtypes.

Results: Avian influenza viruses were observed in 7.04% of commercial chicken farms and in 4.93% of local poultry that growing in the backyards at Iraq; following subtypes were recorded: H9N2, H5N1, H7N9, H5N8 and H5N2. Subtype H9N2 is the prevalent type, all infections with H5N1, H5N8 and 28.57% of H7N9 subtypes were highly pathogenic; 100% of infections with H9N2, H5N2 and 71.42% of H7N9 appeared as low pathogenic.

Conclusions: According to the author’s knowledge, the present study is first study recorded avian Influenza virus subtypes: H5N1, H7N9, H5N8 and H5N2 in domestic birds at Iraq.

Keywords: Avian Influenza Virus; Low pathogenic AIVs; Highly pathogenic AIVs.

Introduction

Avian influenza viruses (AIVs) are type A influenza viruses which considered as omnipresent pathogen that continue to pose a cosmopolitan and real threat for animal and human health, they belong to Orthomyxoviridae family; characterized by enveloped virion with single-stranded, eight segmented negative polarity RNA genome. According to their surface glycoproteins, it classified into 18 HA and 11 NA subtypes, of which about 16 HA (H1–H16) and also 9 NA (N1–N9) subtypes that circulate in birds[1,2].

Avian influenza H5 and H7 subtypes were further classified into low pathogenic avian influenza (LPAI) and highly pathogenic avian influenza (HPAI) viruses depending on certain molecular markers besides to the morbidity and mortality rates which may reach at least 70% at intravenously in vivo inoculated specific pathogen free (SPF) chickens[3].

Markedly, HPAI viruses cause severe respiratory signs concomitant with high morbidity and mortality rate in poultry farms or that grow in backyards, in a contrast manner, LPAI viruses are just induce subclinical infections or sometimes case mild respiratory disease and slight reduction in egg production ensuing low mortality rate or mild spectrum of diseases in the wild birds which are considered as the main natural reservoir of influenza A viral subtypes[4].

Infection with HPAI viruses not only cause marked effect on poultry production leading to significant economic consequences, but it also had been reported to infect human, due to the affinity of Sialic acid receptors, representing real public health problem[5].

Unfortunately, LPAI viruses of HA subtypes H5 and also H7, may mutate under vague circumstances and adversely change into HPAI variants causing severe progressive disease that conducive to high mortality rates in both domestic and wild birds[6].
Globally, HPAI viruses of the H5N1 subtype were recorded in Asia, Middle East, Europe and Africa, resulting to heavy economic losses as a result of numerous harmful epidemics affecting both domestic poultry and wild birds; More recently, three another certain HPAI H5 subtypes emerged: H5N8 and H5N6 at the years, 2014 and 2017, respectively. In addition, to new LPAI subtypes, H5N2 and H9N2 were also recorded; many studies worldwide referred to that the last subtype is the more prevalent low pathogenic avian influenza subtype in poultry [7].

Generally, few Previous studies were involved AIV in domestic chickens in Iraq but neither of them involve most common viral subtypes, while, only one orphan study of them had included local poultry in backyards [8].

Studying of HPAI and LPAI infections are crucially important to obtain an active surveillance at our country to establish a reliable ground-work, in order to pinpoint and minimize the insidious hazards of these subtypes. Therefore, this study aims to determine the incidence, temporal spreads and spatial distribution of HPIVs and LPIVs in the domestic poultry throughout Iraq.

Materials and Method

Well sophisticated team of veterinarians were participated in sample collection randomly from 417 of chicken farms and flocks all over Iraq, ten random samples were taken from live birds at different sites of each farm and flocks besides to 5-10 of dead birds. In addition to 689 of local poultry (287 of local chickens, 165 of local ducks, 132 of local turkeys and 105 of local geese) that grew in the backyards from all Iraqi provinces.

Many but not all commercial chickens were vaccinated against avian flu subtype H9N2, Newcastle disease (ND) and infectious bronchitis disease (IBD).

The study was conducted from the beginning of August 2018 to the end of September 2019, farms that designated as infected with respiratory signs were defined as flocks characterized by core clinical respiratory signs such as, sneezing, coughing, rattling, dyspnea, nasal discharges snickering, depression and/ or diarrhea or central signs nervous which concomitant with clear rising of mortality rates within at least 3 days; respiratory signs were determined after excluding all positive samples that co-infected with ND and IBD.

Special Dacron tipped swabs were aseptically used for sample collection, Nasal swab had been taken from the each bird or fresh tracheal swab in case of newly dead birds, each sample was put in sealed insulated tubes, contain viral transport medium, termed as M199 solution [0.5% (w/v) certain sterile bovine serum albumin (BSA), 26106 U/L of penicillin, 200 mg/L of streptomycin, 26106 U/L of Polymyxin B, 250 mg/L of Gentamycin and 60 mg/L of Levofloxacin hydrochloride besides to 56105 U/L from Nystatin], all these tubes were kept on ice during collection and immediately preserved in a liquids nitrogen dry shipper for shipment to our laboratory and preserved inside specific deep freezer at -70°C until use [9,10].

Samples were prepared for RNA extraction through a prepared suspensions using a High Pure Viral Nucleic Acid extraction and purification Kit (Roche, Germany), based on the manufacturer’s protocol. The RNA suspension was divided into three equivalent parts of 100 μL and each part was used for AIVs, IB and ND viruses diagnostic tests; For diagnosis of avian influenza, infectious bronchitis besides to Newcastle disease viruses, we used One-step reverse transcription real time PCR (rRT-PCR) assay, through involving following primers and probes for AIV according to [11]:

Certain amplification condition consisted of a starting first reverse-transcription initial step at 45°C for 10 minutes, followed by Thermo-Cycling of 10 minutes at 95°C hot start and then by 45 PCR cycles of denaturation at 95°C for 10 seconds, annealing and extension at 60°C for 45 seconds and 65°C for 45 seconds, respectively, as originally mentioned by [11].

All AIV positive samples were subjected again for further examination searching for most common avian influenza HA and NA types which performed through using one-step rRT-PCR kit (Enzynomics, Korea), based on recommended method through utilizing multiple sets of numerous array of forward and reverse primers and probes, which done under implementation of manufacturer’s instructions [12].

The infections were classified as HPAI or LPAI in the present study depending on the results of intravenous inoculation of a ten susceptible 4 to 8 week old SPF...
chickens with viral subtypes; the strains were considered as a highly pathogenic if they cause more than 75% mortality within 10 days, if not, they are low pathogenic, based on original method described by[13].

Statistical analysis: We use SPSS software version 26 (IBM,NY,USA) through application of Chi-square (x²), to determine parameters difference among categorical data, p-value ≤ 0.01 were considered as statistically significant.

Results

The study reveal that the percentage of infection with AIVs was 7.04% (45/639) in the commercial chicken farms that suffering from respiratory signs at the study regions; Whereas, examination of random samples from local poultry growing in the backyards demonstrate that the percentage of infection in these birds was 4.93% (34/689)(Table 1).

Further examination of all positive sample by use of specific rRT-PCR assay searching of the common AIV subtypes was recorded presence of following subtypes: H9N2, H5N1, H7N9, H5N8 and H5N2 at domestic poultry in Iraq, other viral subtypes were not observed.

The current study was reported that subtype H9N2 is the dominant type at both commercial chicken farms and local poultry that grew at backyards which came in percentages of 60.00% and 61.76%, respectively; with significant difference at level of p≤0.01 among all subtypes; Subtype H5N1 rank below in percentage of 17.77% at commercial chicken farms and 11.76% at domestic poultry that grew in the backyards; while the lowest incidence occur in H5N2 subtype at commercial chicken farms, 2.22%, in the other hand, the lowest subtype rate at local poultry was recorded with H5N8 subtype, 5.88% (Table 2).
The study revealed that all infections with H5N1, H5N8 and 28.57% (2/7) of H7N9 subtypes were highly pathogenic, whilst, 100% of infections with H9N2, H5N2 and 71.42% (5/7) of H7N9 appeared as low pathogenic pattern results shown in Fig. 1.

Discussion

Avian influenza viruses are ubiquitous pathogens imposing great human and animal health problems, conducive to heavy economic loses in poultry production besides to their risks for all mammals including man; Since about three of four consensus pandemic human influenza outbreaks during past century were ensued from a genetic re-assortment of avian influenza viruses[14].
Our study reveal that the percentage of infection with AIVs was 7.04% (45/639) in the commercial broiler chicken farms and flocks at the study regions; this infection rate was drastically lower than that found by Abdul-Sada, 2015 [8] in Iraq, who registered that AIVs were present in 63.1% (89/141) of the broiler flocks.

This remarkable variation might be attributed to involving flocks with respiratory signs only, in the last two studies, while in the current study we collected the samples randomly from commercial farms and flocks, in addition to the difference in the number of samples and numerous managements conditions of the flocks.

The examination of random samples from local poultry that growing in the backyards was pointed out that the percentage of infection in these birds was 4.93% (34/689).

The illegal stochastic trading of un-examined commercial poultry and also backyard birds into live bird markets (LBMs) is common besides to continuous exposure of these chickens to the wild birds (natural reservoir of AIVs) during their life might emphasize the elevated incidence of the virus in local chickens that grew at backyards.

Further examination of all positive sample by use of specific rRT-PCR assay searching of the common AIV subtypes was recorded presence of following subtypes: H9N2, H5N1, H7N9, H5N8 and H5N2 at domestic poultry in Iraq, other viral subtypes were not observed.

According to our knowledge, this is the first study that recorded H5N1, H7N9, H5N8 and H5N2 subtypes at the domestic poultry in Iraq.

It is clearly important to investigate the spreading and occurrence of AIVs subtypes through a consecutive and comprehensive surveillances in a periodic way at our country. The updating of the information about viral subtypes are substantially needed in everywhere at every time in order to predict or prohibit of future pandemics.

The current study explained that subtype H9N2 is the predominant type at both commercial chicken farms and local poultry that grew at backyards which came in percentages of 60.00% and 61.76%, respectively with significant difference at level of p≤0.01 among all subtypes; also it is geographically distributed more than other subtypes; Subtype H5N1 rank below in percentage of 17.77% at commercial chicken farms and 11.76% at domestic poultry that grew in the backyards. .

The domination of H9N2 subtype in this study came in alignment with majority of the studies, worldwide, like the study of Hassan et al., 2016 [15] in Egypt (nearby country) who found that this subtype is predominant and represent 41.7% from AIV subtypes followed by H5N1 in 26.7% and study of Kandeil et al., 2019 [16] which reported that H9N2 was formed 48% of all AIV in Egypt followed H5N8, 37.1%. Such scenario might be due to that this subtype is the original type in birds[6].

Contrast finding was observed by Lee et al., 2017[17] in South Korea. They Observed that H5 was the most prevalent among all AIVs subtypes and came in 23.9% of these subtypes; that might be attributed to geographical distribution, kind of assay, sample size and ornithogenic causes.

We observed that all infections with: H5N1, H5N8 and 28.57% (2/7) of H7N9 subtypes were highly pathogenic, whilst, 100% of infections with H9N2, H5N2 and 71.42% (5/7) of H7N9 appeared as low pathogenic pattern.

Interestingly, the cosmopolitan distribution of most AIVs subtypes and the pathogenic patterns of some subtypes like H5Nx and H7Nx remain unclear and vague under certain circumstances particularly regarding the shifting from low to high pathogenic forms, further global studies are required to illuminate their epidemiology and pathogenicity [4,18].

Indeed, the commercial poultry - backyards cycle at LBMs in Iraq is closely integrated that can create a good niche for subtypes spread or even re-assortment events and any breach may eminently affect poultry production and endanger public health, since its seemingly can easily pass host species barriers, so, providing of a precise and sufficient informative data concerning AIVs subtypes at our country is of crucial necessity.

Assessment of the Relationship between Obesity and Female Breast Carcinoma in Imamein Kadhumain Medical City

Anees K. Nile1, Alnahrain1, Mohammed A. Hamdawi2, AlaaMaan Nassier3

1Prof. Dr. College of Medicine/Al-Nahrain University/Iraq, 2Lec. Dr. College of Medicine/Al-Nahrain University/ Iraq, 3Specialist/Imamein Kadhumain Medical City/Ministry of Health/Iraq

Abstract

Background: Obesity, measured by body mass index (BMI), is a well-known danger feature for a widespread variation of illnesses. Yet, in breast carcinoma (B.Ca.) the link is a little discussed and differs according to different entities.

Aims: This study aimed to assess the relationship between obesity and breast cancer in premenopausal women.

Subjects and Method: This is a prospective study in which 800 women who were attending breast clinic in Al-Imamain Al-Kadhumain Medical City/Baghdad during the period from January 2016 to December 2017 were followed up for the occurrence of BCa. of these, 50 women who developed BCa during this period were selected to represent cases group. Other 50 age-matched women who did not have BCa were selected to represent control group. General obesity (BMI) and central obesity (waist circumference (WC), hip circumference (HC) and waist/hip ratio (WHR)) were measured obtained from each patients either by direct interview or from patient’s record.

Results: Demographic, reproductive and laboratory data were comparable between the two groups. Stratification of BMI revealed significantly less cases having BMI < 25 and more having BMI>30 than controls. Moreover, cases showed significantly higher mean of WC (84.12±6.22 cm) than controls (77.6±7.18 cm), Regarding hormonal receptor statuses, mean BMI (30.18± 9.21 kg/m2) was significantly higher in hormonal receptor negative cases compared to 26.31±9.1 kg/m² in estrogen and progesterone receptors positive with significant difference. Conclusions: These data shows that obesity is a possible risk factor for breast carcinoma in premenopausal women.

Keywords: Relationship, Obesity, Female Breast Carcinoma, Imamian Khdymian Medical City.

Introduction

Worldwide, breast cancer (BCa) is the most frequently occurring malignancy among women, accounting for about 18% of all female cancers [1]. In 2012, the number of new cases among women was 1.7 million (about quarter of all cancer cases), with more cases observed in the developed countries (883,000 cases in developed versus 794,000 in developing countries)[2]. In Iraq, BCa comprises for about one-third of female cancers[3]. So far, the exact causes of BCa are not fully clarified; however, many risk factors such as family history[4], life style[5], adipoprotein levels[6] and age at menarche[7] were well illustrated. On the other hand, genetic factors were subjected to massive investigations and many genetic loci have been found to strongly associate with this malignancy[8]. However, the role of many other factors, such as obesity and oral contraceptive pills remained controversial issues [9,10]. The association of obesity with the incidence of BCa is a very complicated. For better understanding of this

effect, the impact of obesity on BCa is firstly illustrated in general term and then the BCas is overlooked in premenopausal period, then each category is further specified according to estrogen and progesterone receptors [11]. Several mechanisms have been proposed for the effect of excess adipose tissue on tumorigenesis. Recently, Divella et al. proposed that the extra adipose tissue connected to the variations of the lipids focuses in the blood stream, stages of class responsive oxygen as well as to excretion of adipokines and blood stream hormones [12]. Inflammation become chronic in the adipose tissue and occur due to hypertrophy and hypoxia so cytokines secretion occur as a result of inflammation of adipose tissue, angiogenic factors excretion, macrophages M1 infiltration and resistance of insulin related to obesity and stimulus of a favorable microenvironment for tumorigenesis. Blucher and Stadler (2017) state that molecular mechanism that describes the communication between fat and BCa. Increase the fat, adipose become enlarge and increase triglycerides (TAGs) level with increase secretion adipokines and pro-inflammatory cytokines. These particles are chemoattractant for macrophages lead to lipolysis and release raised quantities of free fatty acids (FFAs). High mount of fatty acids could be a straight instrument through which adiposity may stimulate cancer development [13]. Despite the importance of BMI as an indicator for obesity, other body size indices, particularly waist circumference (WC), hip circumference (HC) and waist-to-hip ration (WHR), were profoundly found to have a role in BCa. A term of “central obesity” was used to express the ratio between WC and HC. Central obesity, or abdominal obesity, well-defined as extreme abdominal fat cover the stomach and abdomen [14] and is designated by WHR and WC. Of special importance regarding the BCa is the presence or absence of estrogen receptor and, to less extension, the progesterone receptors. This study aimed to assess the relationship between obesity and breast cancer in premenopausal women.

**Method**

Approximately 800 women (age range 21-48 years, mean 37.43±8.9) who were attending breast clinic in Al-Imamain Al-Kadhmain Medical City/Baghdad (for early detection) during the period from January 2016 to December 2017 were followed up for the occurrence of BCa. of these, 50 women who developed BCa during this period were selected to represent cases group. Other 50 age-matched women who did not have BCa were selected to represent control group. The inclusion criteria for case were being between 20 and 48 years old with BCa was investigated by fine needle aspiration (FNA). The controls were apparently healthy women who had normal ultrasound and mammogram findings and having no evidence for cancer. The exclusion criteria are those: with genetic breast ca. and post-menopausal women. Data were collected from both cases and controls through direct interview or patients records whenever possible. Four kinds of data were collected.

1. Demographic data: age, height, weight, educational level (high, intermediate, low), smoking status (never, ex/current), dwelling (rural, urban), waist circumference and hip circumference.
2. Physiological and reproductive features: age at menarche, number of births and breast feeding.
3. Family history of BCa: first or second degree relative with BCa
4. Laboratory investigations: only for cases and included status of hormonal receptor (estrogen receptor and progesterone receptor). Cases who were not having such investigation were excluded from the study.

Statistical package for Social Sciences (SPSS version 20) was used for data analysis. Continuous variables were expressed as a mean± standard deviation (SD), while categorical variables were expressed as percentages. a P≤0.05 was considered statistically significant.

**Results**

**Demographic and Reproductive Characteristics of the Study Population:** The baseline characteristics of BCa patients and controls are shown in table 1.

Interestingly, cancer occur more in obese women and those taking contraceptives than control, although the differences did not rise to a significant level (P=0.068 and 0.296 respectively).others have no significant differences.

**Distribution of Body Mass Index:** Stratification of this index did. Women with BMI below 25 kg/m² were more frequent among controls (16, 32%) than case (7, 14%) with significant difference (P=0.03). In contrast, women with BMI over 30 kg/m² were far more frequent among cases (12, 24%) than controls (4, 8%) with significant difference (0.026) as shown in figure 1.
**Figure 1: Body mass index stratification in cases and controls**

**Waist and Hip Circumferences:** Figure 2 shows waist and hip circumferences in BCa patients and controls. For waist the circumferences were 84.12±6.22 cm and 77.6±7.18 cm respectively with significant difference (P=0.028). Likewise, BCa shows higher mean hip circumference (98.74±12.71 cm) than controls (92.17±9.14 cm); however, the difference was not significant (P=0.069).

**Figure 2: Waist and hip circumferences in breast cancer cases and controls**
Discussion

This study aimed to assess the role of obesity as a risk factor for BCa. Apart from obesity, there was no significant differences in all studied risk factors between the two groups and this will highly assist to evaluate the role of obesity in BCa. The study revealed interesting results. Below 25 kg/m², BMI showed a significant negative association with BCa, while this association was positive with BMI greater than 30 kg/m². A recent study performed by Wang et al. involving 2800 Chinese women revealed that BMI greater than 32 kg/m² was positively influence the occurrence of BCa especially in premenopausal women[11]. In another study including 183940 Japanese women, Wada et al. reported a significant positive association between BMI and premenopausal BCa[15]. Obesity considered as a danger factor for BCa[16]. Yu et al. stated that increase BMI was meaningfully connected with BCa among Asian women[17]. Renehan et al. stated that there is a relation between increase BMI and both before and after menopausal BCa in Asian-Pacific women[18] obtained almost similar result. Other studies, although have shed a light on obesity as a risk factor for BCa, but they neglected other very important factors which influence this association such as the body size indices (waist and hip circumferences), hormone receptor status and the period at which BCa occurs whether pre- or postmenopausal. Reduction in weight as Amandu et al. noticed have different percentages of BCa reduction among races. These differences in results may be attributed to many factors, the most important of which is the ethnicity, dietary life style. Furthermore, these data indicate that there are no standard values of BMI, which could be considered as risk for or protect from BCa. [19]

One of the most prominent results in the current study was that WC but not HC nor WHR is significantly associated with increased risk of BCa in premenopausal women. Compared with the other international studies, this results are in accord with that reported by Wang et al. who found that WC was positively associated with BCa among premenopausal Chinese women[10].

Stratification of BMI according to hormonal receptor statuses in the current study showed a significant difference in mean BMI between HR-negative group and ER/PR positive group. This implies two facts. The first one is that even in peremenopause woman negative for both receptors, BMI$\geq$30 kg/m² can predispose for BCa and women positive for both receptors are at increased risk of BCa even with slight obesity. The second fact is that the effect of obesity is more prominent in hormonal receptor negative women. These results are in agreement with that obtained by Munsell et al. who analyzed 16 case/control studies and reported a significant decreased in premenopausal BCa risk in obese women positive for hormonal receptors (OR=0.78, 95% CI=0.67-0.92) but not for those negative for hormonal receptors[20]. Another large study included 1149 BCa women, obesity was found to decrease risk of the disease in premenopausal women positive for hormonal receptors [21]. There is no clear explanation for this negative association between BMI and hormonal receptor statuses as risk factors for BCa in premenopausal women[22]. Renehan et al. analysed 20 cohort and case/control studies including more than 2.5 million women and 7930 premenopausal BCa and reported a 8% decreases in the incidence of this malignancy for every 5-point increase in BMI [18]. Interestingly, the reduced risk was seen in hormone receptor-positive but not hormone receptor negative. Supporting these reports are two large meta-analyses involved 6106 and 2468 premenopausal women with ER+ BCa. of note, this inverse association was restricted to white women, while null association was found in African American women[23,24]. However, this reduction in BCa with obesity was not seen in all studies. A meta-analysis of 12 population based studies[25] showed different results. i.e. increased BMI in premenopausal women was connected with an increased danger of ER+ or PR+ BCa. Furthermore, the BCa Inhibition trial, which included 5864 females, stated that obesity was significantly related with advanced premenopausal BCa. Thus, it seemed that other factors, particularly ethics, have a crucial role in formulation the association of obesity with premenopausal BCa. On the other hand, studies regarding the effect of obesity on HR- BC are vealed either positive association or no association at all. Two meta-analysis of 620 females and 1358 females with HR- BCstated 80% and 43% advanced danger for BCa in premenopausal females correspondingly[24,25], while an Indian case/control study on HR- menopausal women failed find any significant association between obesity and BCa[26].

Conclusions

These data shows that obesity is a possible risk factor for breast carcinoma and possibly has poor prognosis because of negative hormone receptor status in obese women with breast carcinoma.

Impact of Age at Starting Cysteamine Therapy on Serum Chitotriosidase in Cystinotic Iraqi Children

Zainab Ahmad¹, Shatha H.A.², Hala Sameh³

Abstract

Cystinosis is a rare autosomal recessive lysosomal storage disease with high morbidity and mortality. It is caused by mutations in the CTNS gene that encodes the cystine transporter, cystinosin, which leads to lysosomal cystine accumulation. It is the major cause of inherited Fanconi syndrome and should be suspected in young children with failure to thrive and signs of renal proximal tubular damage. The diagnosis can be missed in infants, because not all signs of renal Fanconi syndrome are present during the first months of life. Elevated white blood cell cystine content is the corner stone for the diagnosis. Since chitotriosidase (CHIT1 or chitinase-1) is mainly produced by activated macrophages both in normal and inflammatory conditions. Which suggests that cystinosis should be included in the differential diagnosis of disorders with increased plasma chitotriosidase activity. This study is aimed to investigate the impact of cystinosis on the renal function in relation to age at detection and initiation of treatment course, besides estimating serum chitotriosidase level, as a screening marker and therapeutic monitor for cystinosis disease in Iraqi children with cystinosis.

The present study is a case-control study included a samples of 30 children with nephropathic cystinosis, compared to 25 healthy control children from those attending at The Genetic Rare Diseases Center/AL-EmamAIN AL-Kadhimain teaching hospital, Baghdad-Iraq.

Our results report patients who started taking the medication (cysteamine) before two years of age were presented with significantly lower levels of cystine and chitotriosidase in addition to better renal function (higher GFR) (P-value = 0.0001). In other words, earlier treatment led to better disease control and less deterioration of renal function.

In conclusion serum chitotriosidase activity estimation might aid in monitoring therapeutic benefit of cysteamine therapy and the prognosis of the disease when WBC cystine assessment is not available.

Keywords: Cystinosis, Cysteamine, Chitotriosidase.

Introduction

Cystinosis is a rare autosomal recessive lysosomal storage disease with high morbidity and mortality. It is caused by mutations in the CTNS gene that encodes the cystine transporter, cystinosin, which leads to lysosomal cystine accumulation. Three clinical forms of cystinosis can be distinguished depending on the age at presentation and the degree of disease severity. (1) Infantile Nephropathic Form: Also known as renal Fanconi syndrome, the most frequent and most severe form of the disease. Patients are generally present before the age of 12 months with polyuria, polydipsia and failure to thrive, caused by generalized proximal tubular damage. (2) Late-Onset or Juvenile Nephropathic Form: Also known as Intermediate Cystinosis, Adolescent Form, which is characterized by the same symptoms

DOI Number: 10.37506/mlu.v20i4.1939
as infantile cystinosis, but with a disease onset mostly after the first decade of life and a slower rate of disease progression\(^2\). (3) Ocular Non-nephropathic Form of Cystinosis: Also known as Non-nephropathic adult Form, Benign Non-nephropathic Cystinosis, which is characterized by photophobia due to corneal cystine crystals deposits, while other organs remain spared\(^3\).

Early symptoms of classical nephropathic cystinosis include renal tubular Fanconi syndrome, rickets, impaired growth, hypothyroidism and photophobia\(^4\). However, cystine accumulation continued in non-renal organs, including the muscle, brain, bone marrow, liver, spleen, lymph nodes, cornea, conjunctiva, thyroid, pancreas, testes and intestines\(^5\). Consequently, the clinical course of cystinosis changed from that of a largely renal disease to that of a multisystemic disorder with significant non-renal involvement, including a distal vacuolar myopathy, decreased pulmonary function, swallowing impairment, deterioration of the central nervous system (CNS), endocrinopathies, vascular calcifications, retinal damage and other ophthalmic complications\(^6\). Definitive diagnosis is based upon a high index of suspicion because of the clinical presentation including: polyuria, thirst, failure to thrive, growth retardation, vomiting, periods of dehydration, constipation, developmental delay and rickets in some patients. Biochemically, the patients were presented with hypokalemia, hypophosphatemia, metabolic acidosis, low serum uric acid, low carnitine, and, sometimes, hyponatremia. Proteinuria can reach grams per day and consists of LMW proteins, albumin and high molecular weight proteins\(^7\) supported by slit lamp examination of the corneas showing crystals, which are generally present by 16 months of age. The detection of elevated intracellular cystine content is the cornerstone for the diagnosis\(^8\).

Nationwide birth prevalence data concerning cystinosis are only reported in few populations. However, the prevalence of cystinosis in Iraq about is 163 patients according to data collected from The Genetic Rare Diseases Center/AL-Emamain AL-Kadhimain Teaching Hospital, Baghdad-Iraq. This study was approved by the Ethics Committee of the College of pharmacy/University of Baghdad. All participants were informed about the aim and the proposed benefits of the study before obtained their agreements. Apparently healthy individuals (25) were included to serve as a control group.

Cystinotic children included in the study were those aged less than 10 years, and diagnosed to have cystinosis according to clinical symptoms of disease and eye examination; demonstrating corneal cystine crystals. Whereas the exclusion criteria were:

- Patients that have other inborn error of metabolism.
- Patients that have any endocrinopathy (DM, thyroid disorder, congenital adrenal hyperplasia).
- Patients that have other renal disorders (nephrotic syndrome, CKD, Fanconi syndrome/not related to cystinosis).

Data Collection: The patient’s information sheet included all the recorded details: anthropometric measures, medical and social history that are related to the clinical diagnosis of cystinosis patients, as summarized in table (1). The questionnaire was posed to patient parents who were diagnosed with cystinosis at the time of a regular renal care follow-up visit to the hospital.

N for patients=30, N for Control=25, SD=Standard deviations, GFR=Glomerular Filtration Rate, Normal S.Cr range is 26 to 62 µmoles/liter, Normal cystine level (Mixed leukocytes test) is less than 0.2 nm/mg protein, Normal S. Calcium range is 2.2-2.6 mmol/L, Normal BMI range is 18.5 to 24.9, Normal Chitotriosidase level is < 78.5 nmol/hr/ml.

Sample Collection and Preparation: From each participant (patient and control subjects), venous blood samples were collected after at least 6 hours from taking treatment (Cysteamine). Six milliliters was withdrawn, about (2 ml) was transferred to a tube containing Lithium Heparin and stored at (+2 to +8 °C, for several hours) to be taken it to the laboratory for separation of white blood cell (WBC) to be used for measuring cystine content by applying high performance liquid chromatography (HPLC) (12).

The other part (4 ml) of the blood sample was transferred to a plane tube and centrifuged at (3000 rpm) for 5 minutes to obtain serum, which is used for the measurement of creatinine and calcium level. The remaining aliquot of serum was kept in eppendorff tubes and frozen at (−20°C) for later analysis of serum chitotriosidase concentration. Also, urine specimens were collected using urine cups from each participant for measuring glucose in urine. Laboratory assay procedures were blinded for assays (regarding the sample was for a control or a patient) of the participants. Samples were assayed in a random order. Because, the lack of blinding could have introduced bias into the assessment of subjective outcomes such as health-related quality of life and adverse events. Additionally, it’s the first time to measure cystine level in Iraq for those patients.

Statistical analysis: The analyses were conducted using the Statistical Package for the Social Science (SPSS, version 22, IBM, New York, USA). Descriptive statistics (means, standards deviations, frequencies and percentages) of the participants (both patient and control group) were calculated. Because the variables were not normally distributed, we used non-parametric tests including Mann-Whitney (between 2 groups) tests to measure the difference in multiple measures according to participating groups (patient vs control) and different age groups. Spearman correlation was used to measure the relationships among different measures in patient group. A p-value of less than 0.05 was considered to be significant statistically.

Results

Patients & Control Demographics and Disease Characteristics: The participating patients aged
between 1.5 and 10 years (18 and 120 months) with average age of (5.4 years)(± SD 2.86)/(65.20 months) (± SD 34.27). The control group had a comparable age to patients group with average age of (5.2 years)(± SD 2.96)/(62.32 months) (±SD 35.45) and ranged between one and 10 years old (12 and 120 months). Control group included 13 male participants (52.0%) and 12 (48.0%) female. The thirty cystinotic patients, included (17 male) and (13 female) representing 56.7% and 43.3% respectively (Table -1).

Considering BMI, the patients BMI level is below normal, as compared to the control group (P-value <0.05). Meanwhile, lower weight, height, GFR and serum calcium measures were recognized compared to control group. On the other hand, the control children had significantly lower levels of serum creatinine, cystine and chitotriosidase levels compared to patients group (Table -1 & Figure-1).

The children were about two years old in average when they were diagnosed with the disease (cystinosis). The patients also had abnormally higher levels of cystine, creatinine and Chitotriosidase. In contrast, they had abnormal lower levels of serum calcium and GFR (glomerular filtration rate). In average, the treatment started after 20 months of the disease diagnosis (Table -1). Additionally, the average disease duration in patients group was about 40 months, while the average duration of the treatment was half this period (about 20 months). In other words, the patients had an average of 20 months without treatment due to unavailability of the medication (cysteamine) additionally the medication is too expensive.

The average doses as prescribed by physician were 56.67 mg/kg/day (±SD 7.581) ranging between 40mg/kg/day for newly diagnosis patient to 60mg/kg/day for the patients that had been diagnosed some time ago, the newly diagnostic patients were started at (40 mg/kg/day) to be increased over the course of 4 to 6 weeks until reaching a dose of (60 mg/kg/day), whereas the average doses frequency was 4.00 (±SD 0.695) (range 3-5 times daily).

### Figure 1: Comparison between different parameters of control and patients

Discussion

The Relationship between Age at Starting Cysteamine Therapy and Kidney Functional Outcomes in Nephropathic Cystinosis: Nephropathic cystinosis is a systemic disease that results in kidney failure at the end of the first decade of life when untreated (13) or even when treatment is initiated after 5 years of age with immediate release cysteamine therapy. In spite of cysteamine is not ordinarily able to reverse Fanconi syndrome but in some isolated cases of prenatal diagnosis who starting of cysteamine therapy through the first weeks of life averted the occurrence of the renal tubular disorder (14). The importance of early treatment was reported by Gahl among others, by estimating that for every month of treatment prior to 3 years of age, finding that 14 months’ worth of later renal function were preserved (15).

As shown in table (3) the patients were categorized into two groups: A-Children started cysteamine therapy before 2 years of age (n=13, 43.3%), B- Children started cysteamine therapy after 2 years of age (n=17, 56.7%).

GFR (glomerular filtration rate) was significantly increased in cysteamine treated patients before 2 years of age with average 82.53 (±28.46) in comparison with that started the treatment after 2 years of age had average 18.46 (±12.42). Additionally, the average WBC cystine level (a marker of disease control) in patients started the treatment before 2 years of age was 1.35 (±0.57) nmol ½ cystine/mg protein (therapeutic goal of cysteamine therapy must have average WBC cystine level < 2 nmol ½ cystine/mg protein) (16), while average WBC cystine level in patients started the treatment after 2 years of age 4.05 (±1.48) nmol ½ cystine/mg protein.

Besides that, the level of serum chitotriosidase is significantly lower than the patients who started the treatment after 2 years of age with average 176.92 (±48.24)(nmol/hr/ml), whereas those started therapy after 2 years 383.3 (±105.67) (nmol/hr/ml). Wherefore when the treatment applied before 2 years of age and with an average WBC cystine level < 2 nmol ½ cystine/ mg protein there was preservation for kidney function and limiting the renal deterioration, while after the age of two years, the glomerular filtration rate (GFR) was lowered as indicated by the increased serum creatinine which evolves to advanced CKD and hence, the serum levels of cystine and chitotriosidase were significantly increased. Data analysis of 30 child with nephropathic cystinosis shows that early treatment with cysteamine has a positive effect on the onset of renal and extrarenal complications.

A study by Cochat et al cystinotic patients reached ESRD at a mean age of 9.8 years, even though 83% had received treatment, probably due to the late introduction of cysteamine therapy (7.3 years) (17), while in the present study the average age at starting cysteamine treatment was 3.9 (ranged from 1–10) years and the patients reached ESRD at average age of less than 9.8 years, approximately 6.8 years in patients who started the treatment after 2 years of age and non-compliance to the treatment.

In conclusion serum chitotriosidase activity estimation might aid in monitoring therapeutic benefit
of cysteamine and the prognosis of the disease when WBC cystine assessment is not available, despite that chitotriosidase enzyme is not specific for this disease. However, it is believe a useful clinical screening test and a promising therapeutic monitor since a link between cystine accumulation and plasma chitotriosidase activity comes from the observation that plasma chitotriosidase activity and leukocyte cystine content ran in parallel and were both affected by the dosing regimen.

Asthma Knowledge and Behaviours among Parents of Asthmatic Children Attending Paediatric Hospitals in Mosul City

Najlaa Ibrahim Al-Sammak¹, Safwan Hashim Jame³, Ahmed Talib Ibrahim³

¹Lecturer at Family and Community Medicine Department/College of Medicine/University of Mosul, Iraq, ²Paediatric Specialist at Al-Khansaa Teaching Hospital, ³Paediatric Specialist at Ibn-Alatheer Teaching Hospital, Nineveh Health Directorate/Ministry of Health, Iraq

Abstract

Background: Asthma is a common health problem among all age groups. It disturbs all aspects of children’s life and possibly changes to chronic disease that continues for the whole patient’s life. This research focused attention on the parental knowledge and practices during and between asthmatic attacks in order to identify improper activities and improve their future performance toward their children.

Objective: This research aims to demonstrate the degree of parental knowledge and behaviours toward their children during and between asthmatic attacks in Mosul City.

Method: A case series study was conducted among 312 parents of asthmatic children that attended Al-Khansaa and Ibn-Alatheer teaching hospitals (two major paediatric hospitals in Mosul City) over a period of 6 months. A questionnaire form derived from “the Arabic version of the Chicago Community Asthma Survey Questionnaire” was distributed among the participants to evaluate their demographic characteristics, myths, knowledge, and behaviours. Various rates and proportions are used to explain these variables.

Results: This study shows that most parents got information from doctors (62.2%), their best knowledge was about the precipitating factor for asthma as dust and smoke (78%) and the symptoms of asthma as dyspnoea (84.9%), while the least information were about the mechanism of disease where 26.9% did not know the exact mechanism, and the complications of asthma as sudden death (25.3%). On the other hand, the best parental behaviour was the regular use of medications during and between attacks (88.5% and 82.7%) and the lowest ones was performing breathing exercises (around 45%).

Conclusion and Recommendation: A relatively adequate knowledge and behaviours were documented in this study; however, further education about the recent guidelines for asthma management should be offered to those parents in order to improve their offspring health and lifestyle.

Keywords: Asthma, knowledge, behaviour, Mosul.

Introduction

Asthma is one of the important chronic diseases that affect all ages and both sexes with male predominance especially among children. It has considerable health adverse outcomes in terms of morbidity and mortality worldwide (¹).

Asthma is defined as “paroxysmal or persistent attacks of dyspnoea, chest tightness, wheezing, sputum production, and cough with variable airflow limitation and airway hyper-responsiveness to endogenous and exogenous stimuli” (²). Severe asthma in children is defined by World Health Organization (WHO) as “Uncontrolled asthma which can result in risk of frequent
severe exacerbations (or death) and/or adverse reactions to medications and/or chronic morbidity (including impaired lung function or reduced lung growth in children)”(3).

The prevalence of asthma varies greatly among countries. About 300 million people have asthma worldwide and another 100 million is expected to be affected by 2025 (4). A sharp increase in the prevalence of asthma has been demonstrated in developed countries since the 60s of the past century (1); however, more than 80% of deaths happen in low and middle income countries according to WHO recent reports (5).

In Iraq, the prevalence of asthma was 22.3% among primary school children according to a study conducted in 2005 in Baghdad (6), whereas a lower rate (8.9%) was demonstrated in 2009 in another study among older age group (11-14 years) (7). Different rates were registered in earlier studies (28.4%) for 6-12 years of age in Baghdad and 15.8% for <5 children in Basra (8).

Regardless the prevalence of asthma, it still a major health problem facing children and their families, affecting their quality of life, their school performance, creativity, and recreation, in addition to the financial burden on the country. Although it is chronic disease; however, the majority of children improve by time and their signs and symptoms relieve toward adulthood. Thus, exploring parental knowledge and practices toward their children during and between asthmatic attacks is very important in order to prevent and early treat such attacks and to prevent further suffering of those children.

Aim of the study: The aim of the present work is to determine parental knowledge and behaviours toward their children’s asthmatic attacks in Mosul City.

Methodology

Administrative Agreements: To facilitate the process of data collection and for ethical considerations, administrative agreements were obtained from “Family and Community Medicine Department/College of Medicine/University of Mosul”, followed by ethical and formal agreement from “Nineveh Health Directorate”.

Study Setting: This research was conducted in Mosul city; the centre of Nineveh governorate present in the north-west area of Iraq. It is the 2nd most populated governorate in the country after the capital Baghdad, with more than three and a half million population and a natural growth rate of almost 4%. The study sample was collected from two major paediatric hospitals in this city namely Al-Khansaa maternity and paediatric teaching hospital and Ibn Alatheer paediatric teaching hospital.

Study Sample: A convenient sample was collected from both hospitals involving 312 parents of asthmatic children. Those parents were asked about their myths, knowledge and behaviour toward their kids regarding the prevention and control of asthmatic attacks.

Study Design: A descriptive case series study is the most suitable design for such type of researches that concerned with demonstrating the knowledge, practice and attitudes of individuals toward certain disease or any health problem.

Study Period: The period required for conducting this research was 6 months from July 2019 to January 2020.

Data Collection Tool: The study instrument is a questionnaire form constructed from the modified “Arabic version of the Chicago Community Asthma Survey Questionnaire” (9) which had previously used in surveys of other Arabic countries. This form was distributed among 350 parents, and the analysis was done on 312 completed formula which involved information about socio-demographic characteristics, myths and believes, knowledge items, and behaviour items of the study participants.

Outcome Measures: Various rates and proportions were calculated to explore the degree of demographic characteristics, myths and believes, knowledge and behaviours items among the parents of asthmatic children.

Results

Table 1 summarized the socio-demographic characteristics of the participants and demonstrated that most of asthmatic children were aged ≤ 5 years, males, with duration of disease ≤ 2 years, negative family history of asthma, and living in urban areas, (51.6%, 60.6%, 61.5%, 58%, and 75% respectively). Around two thirds of the mothers (63.1%) were ≤ 30 years of age, and most parents were educated (76.6% of mothers and 81.4% of fathers), although living in middle and low social classes (47.4%, and 24.7% respectively).

Table 2 revealed that in general more than half of the parents had bad believes and myths about the management of asthma and its medication. Almost 68.9% said that it is better not use inhalers for long time, another two thirds (65.4%) preferred the direct use of inhalers, and 63.8% favoured their use only during attacks. To lesser extent, 50.3% thought that inhalers can lead to dependence, and 46.5% assumed that inhalers can harmfully affect the heart.

Table 3 demonstrated parental knowledge about asthma. For the mechanism, more than half said that it is due to bronchial obstruction by inflammation and bronchial narrowing (56.7% and 56.4%). More than three quarters of parents blamed dust and smoke as the main aggravating factors for asthma (78.8% and 78.2%). Most parents knew the symptoms of asthma where 84.9% of them declared dyspnoea as the commonest symptom followed by chest tightness, cough, and wheeze (76.6%, 67.3%, and 57.7% respectively). Whereas 91.3% said that severe dyspnoea is usually present in severe attacks. Approximately, two thirds (63.5%) of parents determined sleep disturbances as the main complication of asthma in comparison with only 25.3% for sudden death. The greater proportion of the participants got their information from paediatricians and general/family physicians (44.2% and 18%).

Table 4 showed parental behaviours during and between asthmatic attacks. The majority of parents (88.5%) gave their children the necessary medications during the attacks. About two thirds rest the child, gave soft fluids, and made massage to the child (70.5%, 67.6%, and 62.8% respectively). Also, most parents gave their children regular medications and removed the aggravating factors as dust to prevent asthmatic attacks (82.7% and 81.1%), however, the least behaviour was performing regular breathing exercises (45.5%).

| Behaviors (n=312) | Number | %
---|---|---
**During asthmatic attacks**
Give the child the necessary medications | 276 | 88.5
Resting the child and reduce the movement | 220 | 70.5
Give water, juice, or herbal fluid | 211 | 67.6
Make massage to the child’s chest or back | 196 | 62.8
Ask for help | 182 | 58.3
Let the child cough to get rid the mucus | 163 | 52.2

Prevent severe exercise | 182 | 58.3
Let the child cough to remove mucus from the lung | 172 | 55.1
Regular practicing of breathing exercises | 142 | 45.5

**Discussion**

Asthma is one of the common respiratory problems facing paediatricians in their daily work worldwide. If inadequately treated, it can disturb children’s quality of life in addition to the direct and indirect economic burden on the country. Asthma can be resolved with time, and most children become free of the disease toward adult life depending on the provision of qualified care and adherence to treatment plan. Thus, adequate parental information about protective and therapeutic strategies is very important to prevent further attacks or to make them milder.
The socio-demographic characteristics of the study sample revealed that around two thirds of children (60.6%) were males, 51.6% were aged ≤5 years of age, 42% had family history of asthma, and three quarters (75%) of them were living in urban areas. Similarly, Alsamarai et al. (7) and Aljanabi et al. (10) demonstrated that most of asthmatic children were males (52% in Tikrit and 67.7% in Baghdad respectively), and 68.4% in Saudi Arabia, but most of Saudi patients (61%) were aging ≥ 5 years (11). Another national study by Jallab and Hasan found that family history of asthma was present in 52% (12), and other researchers explored comparable results of residency as Alsamarai et al. (7) and Al-Kubaisi et al. (13) with proportions of 75% and 80% respectively living in urban areas.

Most of parents in the present study were educated (76.6% for mothers and 81.4% for fathers), and around half of them (47.4%) were living in middle social class. Parallel results were demonstrated by several researchers as in Baghdad where 60.7% of mothers and 77.3% of fathers were educated and the complementary proportions were either illiterate or write only (13). In North Carolina 76% (14), and in Riyadh 85.3% of parents/guardian were educated, the latter study showed that 48% of participants lived in middle income level (11). These trivial differences in the socio-demographic characteristics between the current and other studies are expected in the light of socio-economic variations between different localities and at variable times.

More than half of parents in the present study had various misconceptions and believes about the treatment of their children, for example, 68.9% said that it is better not use inhalers for long time, 65.4% preferred to use inhaler directly, 63.8% believed that medications should be used during asthmatic attacks only, 50.3% thought that inhalers can lead to addiction, and 46.5% assumed that inhalers can affect the heart adversely. Similarly, several researches concerned with parental myths and believes were conducted at different localities such as in Riyadh where 67.5% of parents afraid from addiction effects of steroids on their children (16). Although all are Arabic areas, there are differences in the proportions of parental thoughts and believes depending on their cultural and educational backgrounds.

It is clear that most parents are more aware about the aggravating factors than the pathophysiology of asthma (17). In this study, there was a relatively moderate knowledge about the mechanism of asthma where > 56% declared that asthma is caused by either inflammatory bronchial obstruction or bronchial narrowing; and only 26.9% did not know the exact mechanism. The reverse condition was observed by Al-Binali et al. (18) in Aseer where the majority of mothers (84.4%) did not know the mechanism whereas 85.3% of parents in Riyadh agreed that airway inflammation is the main cause of asthma (11). These variations may be due to the differences in those providing information whether only mothers or both parents.

Many parents in the present study knew several aggravating factors such as dust, smoke, changes in weather, common cold etc. and the least familiarity was about the role of food (78.8%, 78.2%, 71.8%, 68.3%, and 23.4% respectively). Similarly, common cold and weather changes were the main factors and food was among the least risk factors of asthma verified by Al-Binali et al. (18) in Aseer. Whereas Dharmage and Perret (1) demonstrated dust and food as the main allergic and weather changes, exercise, and smoke as the main non-allergic triggering factors of asthma among children. These differences are expected depending on the most prevailing risk factors in each community.

The majority of parents in the current study recognized dyspnoea and chest tightness as the main symptoms of asthma (84.9% and 76.6%), while severe dyspnoea and persistent cough as the main features of severe asthma (91.3% and 74.4%). The least knowledge was about bluish discoloration of lips and nails or peripheral cyanosis (45.5%). In Khartoum, 85% of mothers explored cough and dyspnoea as the main symptoms of asthma (19), while dyspnoea, wheezing, chest tightness, and persistent cough were the main symptoms exhibited by elementary school teachers (20).

The most important complications predicted by parents in the present study were sleep disturbances (63.5%) and respiratory failure (50%). The least knowledge was about sudden death as a sequel of severe
disease (25.3%). Conversely, 77.4% of parents in Riyadh (11) and 70% of mothers in Khartoum thought that asthma can lead to death if it is severe (19). This variability may be explained as fear of parents in the current study from exhibiting death as a possible outcome of severe asthma in their kids.

Fortunately, most parents in this study received their information from several sources, but depending on their 1st answer the greater proportion said that they acquire their information from paediatricians followed by general or family physicians (44.2% and 18% respectively) just similar to information sources of caregivers in Riyadh (11).

Parental commitment with the management program is vital in controlling and preventing asthmatic attacks among their children. In the present study, most parents provided their children the necessary medications during attacks in addition to resting the children and giving them soft drinks (88.5%, 70.5%, and 67.6% respectively). The least therapeutic behaviours were making breath exercises and watching the progress of wheezes (44.6% and 40.4%). The same was demonstrated by AlOtaibi and AlAteeq (11), Albarraq (17), and Al-Binaliet al. (18) where giving medications, making massage to child’s chest, and giving homemade remedies were the main actions taken by caregivers to children during asthmatic attacks in Saudi Arabia.

On the other hand, most parents in the current study adopted several activities to prevent attacks like the regular use of medications, remove dusts and other aggravating factors …etc. (82.7%, 81.1%, and 79.8% respectively), the minimum parental practice was making regular breathing exercises for their children (45.5%). These are similar to parental practices documented by AlOtaibi and AlAteeq (11) and Al-Binaliet al. (18) researches, whereas breathing exercises was the least implemented preventive behaviour explored by Albarraq study (17). Other studies recognized limitation of child’s movement and prevention of sports as preventive strategies for childhood asthma (20,21) although practicing sports and exercises by children with controlled asthma can improve their physical capability, general health, and even can prevent asthma exacerbation. Thus, improving caregivers’ knowledge and behaviours is essential to enhance their children’s health and provide proper quality of life.

Conclusion and Recommendation

This research revealed that the best parental knowledge was in the aggravating factors and symptoms of asthma and the least ones were about the mechanism and complications of asthma, whereas the best behaviour was the regular use of medications and the worst was practicing breathing exercises. Thus, additional education about asthma is recommended to improve parental information and enrich their children’s healthy outcome.

Detection of Parvovirus B19 in B-thalassemia Major Patients by Serological and Molecular Method

Rand Rasid Abdul Sadah1, Huda Dhaher Al-marsome1

1Master Student, 2Assistant Professor, Microbiology Department, College of Medicine, Al-Nahrain University, Baghdad, Iraq

Abstract

Introduction: Because to the tropism of human parvovirus B19 to erythroid progenitor cells, infection in patients with an underlying hemolytic disorder such as Beta thalassemia major leads to suppression of erythropoiesis, referred to as reticulocytopenia, which could be life threatening. The aim of the study was to determine the rate of occurrence of parvovirus (B19) in beta thalassemia major patient by using real time-PCR, Study the correlation between B19 virus and patient’s descriptive data and the correlation between B19 viral load and IgG titer.

Method: This case-control study was done to detect the presence of parvovirus B19 DNA in plasma samples and anti-IgG ELISA of patients with beta thalassemia major. The population consisted of 75 patients with beta-thalassemia major who attended the Aban Al-balady hospital in in the City of Baghdad and 75 healthy people as a control.

Results: The prevalence of parvovirus B19 in our study population was 28 (37.3%) were positive for B19 DNA by quantitative polymerase chain reaction in which highly significant different P value (< 0.0001), Results of enzyme linked immunosorbet assays showed that IgG antibodies was positive in 16 (21.3%) compared with control group which was 7 (9.3%). According to statistical analysis the difference was in borderline between case and control group in prevalence of B19 virus. There was significant (P= 0.039) association correlation between B19 DNA and anti-IgG positivity, but were significant in WBC (P<0.0001).

Conclusion: In study, B19 infections were discovered in patients with beta thalassemia major. Screening of such risky groups will significantly reduce the incidence and prevalence of B19 infection.

Keywords: Parvovirus B19; Thalassemia; PCR, ELISA, Iraqi patients.

Introduction

Human parvovirus B19 (HPVB19) is a tiny single strand DNA virus. It is the only member of Parvoviridae family, genus Erythrovirus, known to be pathogenic to human(1).

After success access to the human host, Parvovirus B19 targets the erythroid progenitors in the bone marrow by binding to the glycosphingolipid globoside (Gb4), also recognized as blood group P antigen (2). It’s generally harmless in healthy individuals but may have a serious clinical effect in susceptible recipients such as patients with shortened red cell survival such as Sickle cell disease and BTM patients, immunocompromised patients and pregnant woman(3). HPVB19 virus may cause more severe disease, like transient aplastic crisis in patients’ suffering from chronic hemolytic disorders(4). This virus is resistant to most physicochemical factors and is mainly transmitted through respiratory secretions; however, it can be transmitted through blood and blood products(5).
The main clinical features of infection with parvovirus B19 include dermatologic manifestation, rheumatologic findings and hematologic effect\(^6\). The illness association with human parvovirus B19 evolves differently in different individuals. Some may be asymptomatic and other develop only prodromal symptoms. In some, the prodromal illness is followed by a later phase of more definable symptoms. In a few, particularly those who immunosuppressed or suffering from related illnesses which put them at high risk, the disease may become chronic and complicated with long term sequelae. In outbreak, asymptomatic infection occur in \(~20\%\) of children and adults expose to the virus\(^7\).

Beta Thalassemia major, owing to chronic hemolytic diseases with shortened half-life of RBC, are at higher risk of acquiring aplastic crisis after exposure to this virus, sudden worsening of anemia, reticulocytopenia and cessation of erythropoiesis of the bone morrow are characteristic feature of transient aplastic crisis\(^8\).

HPV B19 had a strong tropism for hemopoitic stem cell, the virus integrates in a specific site in human genome. The infected cell fail to divide, impairing the production of new RBC, reticulocytecount usually fall to as low as 0.1 to 0.5% from routine values of 6-20% in patient with hemolytic anemia disorder\(^9\).

HPV B19 infect mature erythroid progenitor, preventing further replication and maturation, the more primitive precursor are affected minimally\(^10\). There are several studies about the seroprevelance of the virus with thalassemia patients which include Kishore study in India by ELISA (IgG) that appeared 73 (81%) from 90\(^{11}\). Arabzadehstudy in Iran (Tehran) that resulted 4% from 70 by real-time PCR\(^{12}\) Mohamed study in Egypt (Fayoum) by ELISA (IgG) that presented 18.2% from 55\(^{13}\) Same 23 Tarish study in Iraq (Babylon) by ELISA (IgG) that resulted 30.4% from 46\(^{14}\).

This study was aimed to detect the occurrence of Parvovirus (B19) in Iraqi thalassemia major patients by real-time-PCR and IgG titer and Study the correlation between B19 virus and patient’s descriptive data.

**Material And Method**

This descriptive cross-sectional study was performed on 150 person, among them 75 patient with beta thalassemia major and 75 apparently healthy persons that served as control group. All patient were attended the Aban AL-balidy hospital (hereditary blood disorders center) Baghdad/Iraq during period from December 2018 to May 2019. All these individual were diagnosed as case of thalassemia major by HPLC and all relevant information was obtained from all cases using special questionnaire.

Five millimeters of venous blood were aspirated from all subjects included in the study. Blood sample divided in tow tubes, one of whole blood was collected in EDTA blood tube to get plasma for molecular part and other were allowed to clot and then centrifuged for 15 min at 3000 rpm in order to collect serum. Serum kept deeply in frozen (-20) unless worked immediately for evolution of different parameter.

HPVB19 was detected by immunological and molecular method.

In Immunological Method, Anti-HPV B19 IgG was done by using ELISA test kit (MyBioSource/ Germany). The test was done according to manufactures instructions.

In molecular method,HPVB19 DNA was extracted using a commercial genomic DNA extraction kit (Geneaid, Taiwan).

Virus copy number was for B19 determine by real-time PCR using TaqMan master mix as follows:

Pre-treatment (50°C, 2 min, 1 cycle), Initial denaturation (95°C, 10 min, 1 cycle) and annealing and extension (95 °C, 15 sec, 45 cycles) and using commercial kit (Sacace)/Italy).

SPSS version 21 was used to perform the data analysis and to calculate the descriptive statistics. Chi-Square and Fisher Exact test were used to determine the statistical significance of level of differences between patient (case) control group according to Anti-HPVB19 IgM and IgG. P value <0.05 was considered to be significant.

**Results**

The real-time PCR detection of B19 DNA revealed 28 (37.3%) positive and 47 (62.7%) negative samples out of 75 subjects and 3 (4%) positive and 72 (96%) negative samples out of 75 healthy persons as shown in Table (1). there was significant different P value (< 0.0001). Odds ratio indicate that patients with BTM had 14.3 the ability to get the infection rather than the control.

Ig G prevalence of B19 virus among participants:
The overall distribution of B19 IgG antibodies among study and control groups were shown in table (2). The highest seropositivity was noticed among study group (cases) was 16 (21.3%) compared with control group which was 7 (9.3%). According to statistical analysis the difference were in borderline between case and control group in prevalence of B19 virus. The result also indicate that thalassemia patients had 2.63 increasing in the B19 IgG antibodies than the healthy.

Frequency of WBC level within Thalassemia -B19 IgG positive patients: From the sixteen thalassemia patients positive by ELISA, 11(68.6%) had leukocytosis, 4(25%) normal leukocyte number and only one (6.2%) with leukopenia. while in negative Thalassemia patients, 34(57.6%) with normal leukocyte number, 24(40.7%) with leukocytosis and only one (1.7%) with leukopenia.

Discussion

Patients with BTM are at higher risk of acquiring aplastic crisis, sudden worsening of anemia, reticulocytopenia and cessation of erythropoiesis of the bone marrow (transient aplastic crisis) after exposure to parvovirus B19 infection\(^{(15)}\).

The present study revealed a high prevalence of the viruses in the thalassemia major patients 37% (28/75) when compared with study done in Iran by Nikoozad Et al\(^{(16)}\), in this study the rate was 20% (6/30). the difference may be due to the sample size of the. A small sample size will not provide a precise and reliable estimation of the prevalence and a larger sample size is needed to obtain a higher confidence level.

Also, our results differ from study done in Hong
Kong(17) a Thailand (5) but agree with Heegaard ET.al.(18).

Seroepidemiologic studies of several countries showed that prevalence of parvovirus B19 infection varied among countries and populations(19). Our results was lower than a study done in Babylon city/Iraq. Their result was 30.4% positive for Anti-B19 IgG(14), But result is in same rang with that reported by Fayoum study/Egypt(13) of 55 beta thalassemia major patient (Anti-B19 IgG is 18.2%).

Results obtained by Siritantkorn et al.(5) from Thailand, of 60 thalassemic major patient (Anti-B19 IgG is 38%).More or less similar rates were found by a study done in USA on patients with sickle cell disease; it showed that 30% had evidence of old PB19 infection at first testing(20).

The difference perhaps related to geographical variation in prevalence of HPVB19 infection(19).

Chronic parvovirus B19 infection was demonstrated by the presence of parvovirus B19 DNA and anti-parvovirus B19 IgG in patients’ plasma, while lacking of anti-parvovirus B19 IgM. Thalassemic patients who had parvovirus B19 DNA in their blood plasma but had no anti-parvovirus B19 IgG might be in an early phase of acute parvovirus B19 infection (21).In This search, a total of ((28)) patients were tested positive for B19 infection by using PCR and ((16)) by using ELISA techniques. The discrepancies between DNA and IgG findings refer that searching for specific IgG is a cheap and easy diagnostic tool for basic screening; but the sensitivity of the test may be very low in selected groups of objected. It is advisable that if IgG turns out to be negative, to continue searching for possible B19 infection by employing. About RBC count in this study revealed to 26 from 28 of BTM infected with B19 DNA had low RBC count and 2 were normal count this due to beta thalassemia major anemia that result from the absent synthesis of beta globin chains, leading to excess alpha chains. B-thalassemia generally presents as severe form of the disease because it produces severe anemia in their homozygous and compound heterozygous states(22). In present study apperead result Leukocytosis in BTM infected with PB19 DNA (74.3%) and anti PB19 IgG (31.4%), properly due mix infection with unknown bacteria that may be encourage PB19 infection also the Leukocytosis can use as a sign of infection with PB19.

Prevalence and Clinical Features of Ocular Adenoviral Infection among Patients Attended to Ibn-Alhaitham Teaching Eye Hospital in Baghdad, Iraq: A Molecular Study

Mohammed Abdallah Mohammed¹, MothanaAli Khalil², Rafea Allawi Fayyadh³

¹Lecturer/University of Anbar/Medical College, Department of Surgery/Iraq, ²Assist Prof./University of Anbar/Medical College, Medical Microbiology Department/Iraq, ³Assist Prof./College of Medicine, University of Fallujah/Iraq

Abstract

Background: Viral conjunctivitis is commonly caused by adenoviruses, with a rate of up to 40% of all viral causes.

Objective: To show prevalence and clinical features of ocular adenoviral infection at Ibn-Alhaitham teaching eye hospital in Baghdad, Iraq.

Patients and Method: In this cross-sectional study, eye swab samples were taken from 638 patients with clinically diagnosed infectious conjunctivitis during the period from August 2019 to February 2020. Samples were processed and tested using polymerase chain reaction (PCR) to detect adenoviral infection.

Results: Of 638 patients with infectious conjunctivitis attended to the Ibn Al-Haitham teaching ophthalmic hospital in Baghdad, 113 cases (17.7%) were confirmed to having ocular adenoviral infection with the mean age 27±8.4 years and The highest percentage of those affected in the age group 1-10-year-old (31.9%). Sixty-three were male (55.8%) and 50 were females (44.2%). non-statistically significant difference between unilateral & bilateral involvement. Of total 113 patients with ocular adenoviral infection, 50 (44.2%) patients experienced flu-like illness during or before their ocular complaint, 85 (75.2%), 28 (24.8%) showed conjunctival follicular reaction and conjunctival membrane formation respectively. Only four (3.5%) patients showed no corneal changes during their ocular infection, 39 (34.5%) patients showed mild punctate epithelial keratitis, 54 (47.8%) patients showed significant punctate epithelial keratitis and 16 (14.2 %) patients showed anterior stromal infiltrate. 64 (56.6%) patients developed lymphadenopathy.

During follow up, 13 (11.5%) of patients fully recovered within less than 14 days, 69 (61%) patients recovered in 2-4 weeks whereas 31 (27.4%) patients took longer than 4 weeks for a full recovery.

Conclusion: Results have demonstrated that adenoviruses are common causative agents for infectious conjunctivitis. PCR revealed to be more sensitive and accurate for detecting adenoviral ocular infection.

Keywords: Ocular adenoviral infection, Prevalence, clinical features, Baghdad, Iraq.

Introduction

Adenoviral ocular contagion is mainly caused by different strains of ocular adenovirus(1)(2). Conjunctivitis due to adenovirus is the world’s most common cause of red eye(3).

One of the studies at the Wells Hospital showed that conjunctivitis due to adenovirus constitutes approximately 62% of cases of clinically diagnosed infectious conjunctiva in the emergency room and this is supported by previous studies that confirm that 15
to 70% of conjunctivitis is due to this virus\(^\text{(1,3)}\). There are approximately 50 adenovirus serotypes, distributed into six groups\(^\text{(2,4,5)}\). Certain serotypes of adenovirus are associated with certain eye diseases\(^\text{(1,2)}\). The most public types of viral conjunctivitis are "epidemic-keratoconjunctivitis" (EKC) in addition to "febrile pharyngoconjunctivitis" & non-specific "follicular conjunctivitis\(^\text{(1,6)}\). EKC is frequently linked with "adenovirus serotypes" 8, 19 & 37\(^\text{(2,4,6,7,8)}\). EKC is considered as a more predominant form of "adenoviral-keratoconjunctivitis" owing to the adversarial magnitudes it might have on visual acuity\(^\text{(8)}\).

The epidemiological capacity of the adenovirus conjunctivitis has contributed to the emergence of many infections with this virus in hospitals and health care site\(^\text{(9,10,11)}\). The infection may appear in crowded places, such as schools, markets and hospitals\(^\text{(1,9)}\). The method of transmission of this virus may be through direct contact through eye secretions and the respiratory system, or by indirect means, such as dirty, contaminated tools\(^\text{(11)}\). Adenovirus may remain on non-bone surfaces for a month and is ready to cause infection through surfaces such as door handles and other surfaces\(^\text{(4,9)}\). Many people infected with adenoviruses are without clinical symptoms and this represents a major problem that contributes to the spread of the virus\(^\text{(9)}\). Ophthalmologists may unintentionally contribute to spreading the adenovirus from infected individuals who do not show clinical signs to uninfected people\(^\text{(9)}\). There is no appropriate guideline treatment plan for treating viral adenoviral conjunctivitis\(^\text{(5)}\). The spread of the adenovirus is very fast more than expected\(^\text{(9,12)}\).

**Patients and Method**

This descriptive study was conducted for a period from August 2019 to February 2020 in "Ibn Al-Haitham teaching eye hospital" in Baghdad. 638 patients with a clinical diagnosis of infectious conjunctivitis were randomly selected. Infectious conjunctivitis(conjunctival hyperemia, discharge, pain and burning) was diagnosed by an experienced ophthalmologist. Having filled the written informed consent, specimens had been scraped from "lower-palpebral conjunctiva"using cotton swab & collected by different transport media (2 ml) for PCR (distilled water). The tubes transport media had been storage at 4°C & conveyed on "cold- bag" to laboratory where they had been storage at"-70°C" till used.

Ethical approval had been obtained from Anbar medical college, Ethics Approval Committee Iraq.

**Molecular study:** The phenol chloroform method was used to purify the DNA from the eye sample and the following forward and reverse primers were used to amplify the gene for adenoviruses.

ADRJC1 "(5-GAC-ATG-ACT-TTC-GAG-G TC-GAT-CCC-ATG-GA-3)"

ADRJC-2 (3-ATG-G AC-GCG-TGG-GGA- AGA-GT C-G GC-C-5)"

"Thermal cycler"had been programmed for 1\(^\text{ST}\) initial cycle of 94°C one min, 55°C for one min & 72°C for 1min (Repeated 40 cycles). The PCR products had been "electrophoresed on a 2% "agarose gel" that contain "Ethidium bromide stain".The PCR product of unaffected eyes scraping had been used as a negative control. The bands had been visualized through ultraviolet Trans illuminator. "PCR product " had been analyzed through comparison with positive control.

Data examination had been done through using of t-test & chi-square in SPSS software (version 24, SPSS Inc., USA).

**Results**

Out of 638 patients with infectious conjunctivitis, 113 (17.7%) patients were confirmed as having an ocular adenoviral infection. Sixty-three patients were male (55.8%) and 50 patients were females (44.2%) giving a male/female ratio 1:1.1.

The range of age was from 1 year to > = 41 years. The mean age was (27±8.4 years). Most of the patients with ocular adenoviral infection presented in age group 1 – 10 year old (31.9%) followed by 11 – 20-year-old (19.5%), 19.5% were also in > = 41 years old age group, & 16.8% were in 31-40-years old age group, while remaining 12.4% were in the age group 21-30-year-old as shown in Table 1.

The study showed that 50 patients (44.2%) with ocular adenoviral infection experienced flu-like illness before or during their ocular complaint and 63 patients (55.8%) with ocular adenoviral infection didn’t have any systemic manifestation (Table 1).

Regarding the laterality, the study showed that 56(49.6%) patients with ocular adenoviral infection had unilateral ocular involvement while the other 57 (50.4) patients with ocular adenoviral infection had bilateral ocular involvement. "Non-statistically significant difference" between unilateral & bilateral ocular adenoviral infection (Table 2).

Regarding the distribution of conjunctival reaction of confirmed ocular adenoviral infection, the study showed that 85 patients (75.2%) had conjunctival follicular reaction, while only 28 (24.8%) patients showed conjunctival membrane formation in addition to conjunctival follicular reaction (Table 2).

Of 113 patients having an ocular adenoviral infection, only four (3.5%) patients showed no corneal changes during their ocular infection, 39 (34.5%) patients showed mild punctate epithelial keratitis, 54 (47.8%) patients showed significant punctate epithelial keratitis and 16 (14.2 %) patients showed anterior stromal infiltrate (Table 2).

Of the total 113 patients with ocular adenoviral infection, 64 (56.6%) patients developed lymphadenopathy (mostly preauricular, less commonly retro auricular and submandibular) during their illness, while 49 (43.4%) patients did not develop any lymphadenopathy (Table 2).

Discussions

Conjunctivitis is the most prominent eye disease where there are many viruses associated with this disease, the most important of which are (enterovirus 70 (EV70), Coxsackie A24 virus (vCA24), in addition to Denver and the last one of the most common causes of acute conjunctivitis)(12,13).

The main symptoms of ocular adenoidal surface infection that are linked with a prominent "inflammatory reaction" are red of eye, irritation, tearfulness of the eye, edema, follicular conjunctivitis, edema of the conjunctiva, hyperemia of eye, "epithelial keratitis", & most frequently the appearance of "lympho-adenopathy"(6). The adenoviral ocular infection might be fast and clinical symptoms appear only after a week of infection, which represents the incubation period(14). Mostly, the other eye may be affected by the infection within a days later, but to a much lesser degree(15). Communicability time extended from the late incubation-14 days after onset disease (16).

Studies in Japan have shown that adenovirus constitutes almost 90% of viral conjunctivitis cases. However, conjunctivitis can be due to a virus, which is mostly adenovirus, bacteria, or allergies(17) whereas, However, adenoviral conjunctivitis represents 15-75% of all cases in the world(17,18). In our study, we found that the prevalence of adenoviral ocular infection is 17.7%. The infection with adenoviruses is not related to a particular season, but it is aware of an infection rate that occurs during the summer as a result of the movement of society due to social activities such as swimming and day camps(19). Another cofactor of infection with these viruses that cause viral adenoviral conjunctivitis in urban areas is poor sanitation, in addition to overpopulation.

The discovery of a polymerase chain reaction (PCR) made it easy to use this test in the analysis of tear samples from the lower body floor in a melodramatic form, in which this test is possible to know the viral pathogen directly instead of virus isolation and this helps to reduce the prevalence of viral conjunctivitis, especially adenoviral conjunctivitis Viral where ancient studies showed that it was 18-45%(20,21) of acute conjunctivitis that had no recognizable etiology. The PCR reaction, which represents the most accurate and sensitive test in diagnosing the causes of conjunctivitis, especially viral ones, has given credence to many studies.

Adenovirus induced eye infection is a self-defined disease and yet many patients try to get treatment because of symptoms severity(7). Where treatments of such infections is the use of cold compresses, artificial tears and other comfortable measures(6). Very often antibiotic ointments, ""topical-non-steroidal anti-inflammatory drugs"" (NSAIDs) and corticosteroid ointments are used(4,6). Supportive therapy is necessary due to the lack of real "anti-adenoviral conjunctivitis" treatments(5,7,8).

Conclusion

Adenoviral ocular infection is an important cause of ocular morbidity in Iraq.

PCR is a useful test that help in diagnosis of ocular adenoviral infection, with suitable infection control depending on speedy and precise diagnosis, we can expect a real reduction in the incidence of outbreaks of community-acquired and nosocomial contagious adenoviral conjunctivitis infections.

Hepatitis B Virus Reactivation in Patients Receiving Chemotherapy and Immunosuppressive Therapy

Israa Hameed Al-shareef¹, Ghanim Aboud Jaber Al-Mola², Dakhel Ghani Omran²

¹Post graduate/College of Science for Women- University of Babylon/Iraq,
²Prof. Dr. College of Science for Women- University of Babylon/Iraq

Abstract

Hepatitis B virus (HBV) infection is a serious and common infectious disease of the liver, affecting millions of people throughout the world. The incubation period for HBV is 45-180 days, most commonly 60-90 days. Hepatitis B reactivation is the reappearance or rise of hepatitis B virus (HBV) DNA in the serum of patients with past or chronic HBV infection. Reactivation can occur in a variety of clinical settings, usually in the context of an immunosuppressed state or immunosuppressive therapy. The aim of the study is to find out the reasons that lead to reactivation of hepatitis B virus. The study conducted during the period from September 2019 to February 2020, the sample size was 135 individuals, including 85 patients and 50 control with 56.47% female and 43.53% male) blood samples. A 42 (49.41%) from patients have reactivated HBV positive results as detected by ELISA assay. A five samples at a rate of 5.88% from these are HBV reactivation by PCR technique.

Keyword: Hepatitis B virus, Reactivation, Liver function test, ELISA and PCR.

Introduction

Hepatitis B virus (HBV) is a DNA virus belonging to the Hepadnaviridae family, which includes hepatotropic viruses. The HBV virion consists of an external lipoprotein envelope and an internal protein nucleocapsid with icosahedral symmetry, containing the viral genome and the DNA polymerase. The HBV genome is partially double-stranded circular DNA molecule with four partially overlapping open reading frame encoding structural and non-structural viral proteins. It is transmitted through exposure to infectious blood, semen and other body fluids. HBV can be transmitted from infected mothers to infants at the time of birth, or from family members to infants in early childhood. Transmission may also occur through unsafe sexual intercourse, transfusions of HBV-infected blood and blood products, contaminated injections during medical procedures and sharing of needles and syringes among injecting drug users. The infection can be diagnosed 30 to 60 days after exposure; the diagnosis is usually confirmed by testing the blood for parts of the virus and for antibodies against the virus. The incubation period ranges from 45–160 days, with an average of 75 days, followed by an insidious onset of acute disease. HBV reactivation is the reappearance or rise of hepatitis B virus (HBV) DNA in the serum of patients with past or chronic HBV infection. Reactivation can occur in a variety of clinical settings, usually in the context of an immunosuppressed state or immunosuppressive therapy. HBV reactivation has been most commonly reported in patients receiving chemotherapy for hematologic malignancies and following hematopoietic stem cell transplants. An estimated 2 billion people worldwide have serological evidence of either past or present HBV infection, with around 240 million people chronically infected. The prevalence varies globally, ranging between 2% in Europe to over 10% in East Asia; in the UK it is estimated to be between 0.5-1.7%, with areas of greater ethnic diversity such as London having a higher prevalence of approximately 2.4%.

Reactivation of hepatitis B virus (HBV) is a major problem in patients receiving chemotherapy for malignant diseases or immunosuppression therapies. It has been thought that a reduction in the immune responses might result in the reactivation of HBV replication from covalently closed circular DNA (cccDNA) residing in hepatocytes. However, not only the host’s immune status, but also viral mutations have been reported to be associated with reactivation(7).

Materials and Method

The practical side of this study was conducted during the period from September 2019 to February 2020. One hundred and thirty five (135) samples were collected. Two enrolled groups of subjects were involved in this study. A eighty five (85) blood samples. The Patients were piously diagnosed with suspected liver disease by physician, included (48 females and 37 males) with an age range (14-78 years old) they were diagnosed by serological and molecular test, liver function test (LFT), complete blood count (CBC). Plasma and serum samples taken from every patients and control having thoroughly examined Fifty(50) healthy control. After laboratory tests for patients, only 42 patients were HBV positive by ELISA and PCR, using the primers designed for this study at length 482bp (RE2 5-AACCACTGAACAAATGGCAC-3), five cases appeared to have HBV reactivation.

Results and Dissection

The results of this study were shown in tables (1) and (2) five HBV reactivation risk group by PCR, only one without chemotherapy and immunosuppression therapy (renal failer) but the other four with chemotherapy and immunosuppression therapy, (A cute Leukemia, Kidney Transplantation, Lung cancer and Leukemia) two of them are normal ALT, AST, decrease in PL, and positive HBV, the four other are increase ALT, AST, decrease in PL and positive HBV. All patient are females with different age (52, 15, 40, 71, and 50) years old.

</table>

The results explained in tables 1 and 2 indicated that the patient who take chemotherapy and immunosuppression therapy with HBsAg negative and Anti-HBc positive, the patients with renal failure, acute leukemia, kidney transplantation, lung cancer leukemia are in danger (most at risk) of HBV reactivation these results consistent with previous study. Through this study it was found that patient with cancer and who have undergone an organ transplant are more likely to reactive hepatitis B virus.

HBV reactivation generally occurs in some cancer patients after chemotherapy, immunosuppressive therapy and biological modifier therapies(8). especially
when some solid tumors and leukemia patients are using hormones such as prednisolone and rituximab that emerged clinical crisis. It can also occur in some patients with autoimmune diseases, organ transplants (kidney transplants, lung transplants, heart transplants, etc.) and human immunodeficiency virus (HIV), but the most serious cases are often with bone marrow or liver transplants\(^9\). At the same time, drugs such as some tyrosine kinase inhibitors\(^10\), the serum ALT rapidly rose above the upper limit of the baseline. If the serum ALT increases by more than 5 times compared with the upper limit of normal value, which could be called hepatitis burst and if it increases by more than 10 times, it could be called deteriorating acute hepatitis. In the course of HBV reactivation, rise of the serum ALT level can be accompanied by that of HBV DNA level and sometimes the HBV DNA can increase firstly, when the HBV DNA falls back and the serum ALT level rises remarkably. Therefore, the serum ALT levels and HBV DNA levels are often used as important indicators to monitor the risk of HBV reactivation in clinical patients\(^11\).

**Conclusion**

From the present work we can concludes that reactivation of hepatitis B virus (HBV) can be occurred in patients receiving chemotherapy for malignant diseases or immunosuppression drugs. The evidence for such reactivation that the platelets count were decrease while the ALT and AST levels vary and the patient have asymptomatic HBV.

Microphages Count and Activity, a Comparison Study between Radiotherapy Technicians and other Hospital Occupational

Weam Saad Al-Hamadany

Assistant Professor Dr./Medical College/Ibn Sina University for Medical and Pharmaceutical Sciences/Baghdad/Iraq

Abstract

Radiotherapy technicians are classified as radiation occupational with continuous exposure to radiation, radiation can damage human cells including Hematopoietic cells. The present study dealt with estimation of both count and activity of peripheral microphages. A total of (23) hospital occupational were tested using peripheral Microphages count in blood film and phagocytic activity by NBT reduction test. Results showed that Test group G1 (12 technicians) recorded normal ratios of microphages count; but diminished in their activity when compared with control group G2 (11 occupational). Conclusions: there is a great association between radiation exposure dose and Microphage activity even though their counts are within normal range. And that harmful effect can increase due to synergistic effect of poor special PPE supply.

Keywords: Radiotherapy Technicians, radiation Exposure, Microphage, NBT, phagocytosis, WBCs count and PPE.

Introduction

Radiotherapy technicians are classified as persons with continuous exposure to radiation, in other word they are workers in radiation field (radiation occupational), regardless their exposure dose or time. In Iraq, the ministry of health and environment supply them with film badge to record seasonal dose of radiation exposure that they were exposed to. Moreover, a seasonal periodic checkup is applied on them and special records organized for each individual to ensure their safety. But, the management after exposure effects are poor and Biosafty equipment for personal protection (PPE) is missing\(^1\) and \(^2\).

Radiation exposure, in general, affects Microphages (Neutrophils, Basophils and Eosinophils) basically and with increase in time and dose of exposure; the effect may become more severe and may reach bone marrow upon chronic radiation exposure\(^3\).

Microphages are the first line of defense in blood stream, they represent the innate cellular immune defense against any invading microbe and they play a major role during opsonization and complement system activation and that will reflex on specific immune response assimilated by the adaptive immunity\(^4\).

Generally, all hospital workers and employees, regardless of their specification or work type, are in continuous exposure to pathogenic microbes due to their contact with patients. Hence, they need intact immune system to stay stand and response against such active and invasive pathogens in such working environment\(^5\). The present study aimed to estimate cellular innate immunity integrity in hospital occupational blood including radiotherapy technicians by evaluating the radiation effects on several parameters used.

Method and Materials

Subjects: Present study included (23) healthy volunteers, all were occupational in the Institute and
Hospital of Radiotherapy and Nuclear Medicine in Baghdad, adults of both genders, non-smokers, with no clinical symptoms of any disease, their ages ranged (49-25) with a mean (32) years. Volunteers were divided into two groups; G1: Test group included (12) Radiotherapy administration Technicians and G2: control group included (11) occupational (physicians, laboratory Technicians, directory employees and others not related to radiation exposure during work).

Samples: A total of five mL of fresh blood were collected from all subjects involved in this study, heparinized tubes were used in collection as recommended by (6) to maintain the viability and activity of microphages in collected blood samples until applying tests.

Peripheral Microphages count: Blood film technique was used in peripheral microphages counting according to (6), whereas a small drop of heparinized blood sample was used to prepare a smear for each subject’s sample and stained with Leishman’s stain (Fluka, Germany). Percentages for microphages were counted using Microscope oil immersion.

Microphages Activity Detection: Activity of peripheral Microphages was detected depending on the technique of NBT test; Nitro-Blue Tetrazolium reduction test, toxic dye was supplied by (Sigma, USA). Whereas, the participated blue Formazan particles were considered as positive result. This test was accomplished according to (3).

Statistical Analysis: Calculation of means for percentages obtained in the present study was done. Values of both counting and activity detection outcomes for both G1 and G2 were used. Then (Microsoft Word 2010 chart tool) was used to compare results.

Results
All results for G2 (control group) were found normal and accepted. Concerning peripheral microphages count; despite of the decreased values obtained for G1; the values were also accepted and within normal values, ranged (56-70%) with a mean value (63%).

While; microphage activity results for G1 showed an obvious drooping. Ratios of positive or active microphages ranged (35-64%) with a mean value (54%). Fig (1). While finding of G2 values were all normal or within normal accepted range.

Fig (1): Microphages Activity and Count Results for G1 and G2.
Discussion

Microphages are important cells in defense against any invading microbe, these cells represented by (Neutrophils, Basophils and Eosinophils) are the innate cellular defenders in human peripheral blood, and they are stand by to migrate towered any infected area in the body to eliminate infection before spreading. Phagocytosis, complement activation and opsonization are the most important processes that needed to start an immune response non-specifically to overcome any infection\(^4\).

Concerning radiation field occupational, White blood cells count (WBCs count) is one of the routine tests during the periodic checkup that applied seasonally on the radiation occupational\(^1\). But, microphages activity estimation is not included in these tests. Hence, this study dealt with detection of microphages count and activity in technicians whom in continuous exposure to radiation during work. The present study subjects included technicians that responsible of administration of radiotherapy for patients need such therapy. And due to poor management and lack of special PPE supply for those technicians; this study was accomplished to determine the effects of radiation exposure during these circumstances on the parameters included in the present study.

The outcome of microphages count showed a slight decrease in these cells ratios when compared with normal dependent range recommended by \(^5\) and the obtained percentages of G2 group (control group). Despite of the fact that the members of G2 groups were hospital occupational, but they were with no history of radiation exposure during work. These findings are supported by a similar investigation accomplished by \(^7\), they found that life style like smoking and poor sleep affect WBCs count rather than other factors estimated in workers blood. Another local study done by \(^8\), they found that the results of blood WBCs total and differential count were within normal for workers occupied in maternal and labor hospital in Karbala city and that is in agreement with the results of the present research.

Regarding microphages activity, the results revealed an obvious suppression in cells activity to reduce the NBT dye used in this test. When microphages are active and viable; they will phagocytose NBT dye and reduce it, then form the dark blue Formazan dye particles which precipitate inside the phagolysosome of microphages and cells then considered as NBT positive. The phagocytic cells consume respiratory oxidative burst to reduce this toxic dye, hence it is considered as one of the most important tests for viability estimation\(^5\).

The present study showed that radiotherapy administration technicians suffered from decreased positive Microphages for NBT test, meaning despite of the normal count of Microphages in their peripheral blood, their activity for complete phagocytosis process were diminished obviously by disability to reduce the toxic dye used in activity detection test. That can due to radiation continuous exposure which can crack microphage from the inside, even when they are still alive; they are no more active.

That opinion is depended on \(^9\), radiation exposure can accumulate inside living cells including hematopoietic cells causing inside damage and if this damage is not reparable, epically in blood cells precursors; the new cells will get the same damage. USNRC Technical Training Center\(^9\) recommended ALARA principle to overcome this problem, meaning As Low As Reasonably Achievable, avoid accumulation of radiation dose and give time for cells to repair damage is the best way to avoid such harmful consequences due to occupation exposure to radiation\(^9\).

Another study done by \(^10\), reported similar results on radiation exposure during work and decreased phagocytic activity of Neutrophils. Also the research of \(^3\) proved that irradiation can suppress neutrophils activity leading to lose function. Another consent findings were published by \(^11\) and supported the same opinion above.

Conclusions

The present study outcomes revealed that there is a great association between radiation exposure dose and Microphage activity even though their counts are within normal range. And that harmful effect can increase due to synergistic effect of poor special PPE supply.

Acknowledgment: I am grateful to the occupational in the Institute and Hospital of Radiotherapy and Nuclear Medicine in Baghdad whom donated their blood samples.

Abstract

Today technology using nanoparticle when treatment pathogenic microorganism and we focused on this here. It was found that the species of *Staphylococcus epidermidis* used in present study were sensitive to Levofloxacin. The aim of report effect (Nisin-Silver Nanoparticles) on ability of complete healing injury comparing using Nisin only . In vivo study revealed that silver nanoparticles treatment of *S. epidermidis* contaminated injured skin showed good healing process contain complete regeneration of the epithelial cells of the epidermis and good prognosis and increase of cellularity of the dermal content compared with untreated group. In conclusion, treatment of skin infected with *S.epidermidis* using silver nanoparticles at different concentration may limited the skin damage, localized the lesion to the incision site and enhance the healing process.

**Keywords:** *Staphylococcus epidermidis*, Nisin A, silver nanoparticles.

Introduction

The process of contamination of foods leading to loss of color, texture and their nutritive value and permits growth of pathogenic microbes, which deteriorates the quality of the product and makes it. Food contamination can occur with its exposure to the environment while slaughtering, food processing and packaging.(1)

Conventional food packaging aims at shelf life extension, maintenance of quality and assurance of safety of the food product. However, now a days foods ecurity is a big issue and, therefore, antimicrobial packaging system is specifically designed to control the microorganisms that adversely affect the above three goals.(2)

Antimicrobial agents have different activities on different pathogenic microorganisms due to their various diverse physiologies.(3) Silver nanoparticles (AgNPs), have strong permeability and effective broad-spectrum antibacterial properties and it used to produce a range of antibacterial therapeutic products, such as, toothpaste, gynecologic suppository and wound dressing.(4)

Thus, there is a need for “green chemistry” that comprises a clean, nontoxic and environmentally-friendly manner of nanoparticles synthesis, an alternative to conventional techniques, biological method are considered ecologically sound for the nanomaterials fabrication and safe.(5)(6)

Nisin A is a bacteriocin formed by Lactobacillus lactis. It is the most bacteriocin studied and assort as the generally recognized as safe (GRAS) in 1988 by the FDA according to low toxicity to human body (US Food and Drug Administration, 1988). It is embedded to lantibiotic class kind a liner with small amino acid peptide chain (34 amino acid residues).(7)

Bacteriocins are antimicrobial peptidesproduce
by certain bacterial strains, which are immune to them, to compete by preventing the growth of other bacteria existing in their environment. Nisin is a 35-mer bacteriocin of the lantibiotics group, whose use as a food preservative was approved by the Joint Food and Agriculture Organization.

Many reports on antibiotic extensively subclass of bacteriocins, which includes (staphylococcin C55 and NisinA) amongst others, Several type highly activity anti- clinically relevant and food-borne pathogens.

Material and Method

Media Preparation

Ready to Use Media: “The media were prepared according to instructions of the manufacturer. They were brought to boil in water to dissolve all constituents completely, then the pH was adjusted to 7.2 and sterilized by autoclaving at 121°C (15 Ib/In²) for 15min. They were incubated at 37°C for (18- 24) hrs to sterilization.”

Samples Collection: A total of 40 food samples were purchased from local markets Baghdad/Iraq October 2018 to January starting from 2019 (type of samples are: Cake without cream, Cake with cream; Arab Cheese; Kemar Arab; Raw milk (no. of samples 8 per each type to give total samples are 40)). The samples were taken after recording the labeling information (commercial name of product), then putting it in the ice box and transport to the microbiology laboratory to isolate pathogen bacteria on the same day.

Cultivation of Bacteria: Each samples put 10g or 10 ml according to type of sample then diluted in 90ml sterile enrichment peptone water and incubated at 37°C for (18- 24)hrs. Then loopful of incubated culture was cultured on were cultured first on Mannitol salt agar and MacConkey agar plates to differentiated between Gve + and Gve- bacteria.

Biochemical Analysis: The morphology and biochemical tests were conducted according to the method described by Bergey’s manual of determinative bacteriology.

Antimicrobial susceptibility testing: Bacteria gram positive and negative were detected by antibiotic disk in DDM. This method was implemented subsequently the instructions of the clinical and Laboratory Standards Institute.

Molecular assay:

DNA extraction: Genomic DNA was extracted from the detected bacterial isolates according to the protocol of Wizard Genomic DNA Purification Kit, Promega. Quantaas Fluorometer was used to detect the concentration of extracted DNA.

Well Diffusion Method: (WDA) Well diffusion method Jérôme et al., (2014) then 100 μL of the suspension was spread on the test plate (Muller Hinton Agar). And put (10 μL) of the essential oils and placed on well in agar. Plates were incubated at 37°C for 24 hours and the zone of inhibition was measured. The experiment was performed in triplicate and the average diameter of inhibition was calculated.

Preparation of Nisin A stock solution: Nisin A Figure (3-4) (Sigma Nisaplin 2/5%) was prepared by dissolving with 100mg from Nisin A powder in 10 ml HCl (0.02 N) to provide 10⁴ IU/ml (40 IU=1 g) concentration. After that the solution was passed through 0.45 filters for sterilization and was maintained at –20°C.

Preparation of Bio Extract: Fresh peel 20 gm of Lemon leaves were washed with tap water and then washed with distilled water, air dried a little and then they were finely cut and soaked in 100 ml boiling distilled water for 5-10 minutes and filtered through Whatman filter paper no. 42. This extract was used for generating Silver Nano particles.

Preparation of 1mM Silver Nitrate: Silver nitrate was brought from Lobachemie. Weigh 0.0169gm of silver nitrate and dissolve in 100mL of distilled water in amber coloured bottle.

Synthesis of Silver Nanoparticles: 3mL of prepared extract was added to 40mL of silver nitrate solution in 100mL conical flask contain lemon peel extraction Incubate at room temperature for 2- 3 hours. Control is made containing only 40 mL of silver nitrate solution. Show Figure (1)

Scanning Electron Microscope (SEM Analysis): The morphological features of synthesized silver nanoparticles from neem plant extract were studied by Scanning Electron Microscope (JSM-6480 LV). After 24Hrs. of the addition of AgNO3 the SEM slides were prepared by making a smear of the solutions on slides. A thin layer of platinum was coated to make the samples conductive. Then the samples were characterized in the SEM at an accelerating voltage of 20 KV.
Antibiotic Sensitivity Test: For inoculums, standard homogenized *Staphylococcus epidermidis* was prepared in normal saline and the suspending was diluted to $0.5 \times 10^8$ CFU ml compared with McFarland tubes.\(^{(10)}\)

Antibiotic sensitivity test for *S. epidermidis* was done by Kirby-Bauer disk diffusion method against OxacillinOX (1), Erythromycin E (15), Levofloxacin LEV (5), Cloxacillin, CX (1), Cefepime, FEP (30). The zone of inhibition were measured (mm) and compared with pretive chart a documented standard, the zone of inhibition (in mm) Clinical and Laboratory Standards Institute\(^{(16)}\).

Primers Selection: The set of primers 27F (AGAGTTTGATCTTGGCTCAG) and 1492R(TACGGTTACCTTGTTACGACTT) was used for amplification of 16s rRNA for identification of bacteria at gene level.\(^{(17)}\)

Preparation of Silver Nitrate: Silver nitrate was brought from Lobachemie. Weigh 0.0169gm of silver nitrate and dissolve in 100 ml of distilled water to obtain three concentration (25, 50 and 75mM) in ambercolored bottle.

Characterization of Silver Nanoparticles: Then synthesis of silver nanoparticles was checked in UV-Visible spectroscopy at the wavelength of 300 - 700nm.

Synthesis and optimization of Nisin-Silver nanoparticles compounds: Fifty mM of AgNO\(_3\) solution was prepared and different concentrations of Nisin Making double serial dilutions (16,32 and 64 µg/ml) in collection beaker (10 ml) to 50 mM silver nitrate solution after that was mixed with continuous stirring slowly.

Synthesis of AgNO\(_3\) at Room temperature: The solution above mentioned are incubated at 37°C (Room temperature) for 27hrs and observed the change color and checking every one day. UV-V is spectra using for the solution to monitored and measured then the flask was incubation at room temperature for another two days until the completion of the reaction.

Bacteriocin Nisin A: Bacterocin was preparation from a commercial (Nisin A obtained from Cayman Chemical Company) asaccording to\(^{(18)}\) at concentration (31.25, 62.50 and 125µg/ml).

Agar Well Diffusion Assay (AWD): Efficiency different concentration of Nisin A measurement activity was carried out by serial two-fold dilutions method by AWD.

Result and Discussion

Isolation Bacteria: The symptomatic cases are shown in Table (1), were out of 40 food samples 35(60%) isolates were identified as *S. aureus* gave positive and *E. coli* isolates reached 22. The highest percentage of isolates was present in raw milk then in cheese and cake with cream reached to respectively.

Immunological Study of Some Pathogenic Bacteria Isolated from Patients with Chronic Kidney Failure

Areej Hamad Hassan¹, Muthana Badeaa Farhan²

¹Postgraduate, College of Women Education, University of Anbar, Ramadi, IRAQ, ²Assistant Professor, College of Women Education, University of Anbar, Ramadi, IRAQ

Abstract

Renal failure is one of kidney diseases in which the kidney work in less than 15% of normal, the chronic kidney failure may develop slowly and its irreversible. Many bacterial infection can associate with kidney failure due to low immunity and insufficient kidney infiltration. This study was aimed to investigate the immunological parameters in kidney failure patients. Sixty patients with chronic renal failure reviewed to one hemodialysis center was evaluated, 50 samples with bacterial infection and 10 samples without bacteria in diuresis. The results show significant decease in IgA, IgM, IgG concentrations for patients with bacterial infection 15.24 pg/ml 60.52, 29.9, in compared with uninfected patients which show 59.1, 33.8, 18.3 pg/ml, the IgE was increased due to the presence of bacteria by 206.6pg/ml. comparing with 186.04 pg/mL in uninfected patients,also IL-1β increased significantly 72.74 pg/ml compared with controls 5.38 pg/ml and a significant decrease in complement C3 in the presence of bacteria at a concentration of 112.45 pg/ml compared with concentration of 155.4 pg/ml in healthy people. This study conclude that the immunological parameters different significantly in patients with chronic kidney failure infected with different bacterial infection in compared with uninfected patients.

Keywords: Chronic kidney failure, immunoglobulins,IL-1β,complement system

Introduction

That chronic kidney failure (Renal failure) is a deterioration in the excretory secretory function of the kidney as a result of accumulation of nitrogenous waste and harmful substances produced by various metabolic reactions¹,² as they are unable to remove the final metabolic products from the blood, which leads to a disturbance in the value balance pH and balance of bodily fluids³. Chronic kidney failure is a common disease in the modern era, especially in cases of simultaneous infection with multiple bacterial infections, where E. coli bacteria are the most common and cause urinary tract infection in patients with kidney failure followed by bacteria Others⁴. People with kidney failure have an acute systemic immunity deficiency that is responsible for around 20-30% of deaths of patients with kidney failure and those who continue with hemodialysis⁵ that may cause failure Renal to an increase in inflammatory responses, which includes a number of mechanisms that include the reaction of the immune system, which is an increase in the concentration of Proinflammatory Interleukins.⁶ Interleukins act as inflammatory indicators that stimulate or inhibit immune response cells, as the production of Interleukins is considered as a primary response of the mucous layer when Bacterial invasion, where the concentration of interleukin increases when infection occurs⁷. Most of these bacterial factors may weaken the systemic immunity of patients with chronic renal failure.

The study was aimed to Identification of some pathogenic bacteria accompanying patients with chronic renal failure from clinical samples. Study of some immunological indicators, include measurement of immunoglobulins IgG IgM, IgA, IgE and complement C3 and IL- 1β.
Materials and Method of work: 110 blood and diarrhea samples were collected at the same time from chronic kidney failure patients attending the Kidney Dialysis Unit at Ramadi General Teaching Hospital in Anbar Governorate for the period from October 2018 to August 2019 and 60 samples were divided into 50 blood and urine samples containing bacteria and 10 samples Blood and urine do not contain bacteria. The ages of patients ranged between (15-85) years and of both sexes. Also, 24 control samples were collected.

After collecting blood samples, the serum was separated in a tube by centrifugation at a speed of 3,000 rpm for 10 minutes and then the tests were done. The test was based on the Sandwich-ELISA method to conduct the examination where a specialized antibody dish was installed on the surface of the microprocessing plate, which is particularly associated with standard solutions or With serum when added to the microplate pits then washed with distilled water and read on the ELISA device with a wavelength of 450 nm.

Results

The isolation results showed 50 urine samples with positive growth of bacterial culture out of 110 samples collected from patients with chronic renal failure. The results showed that 50 samples gave bacterial growth (for both negative and positive bacteria) as in figure (1) the number of negative bacteria was (68%)The number of positive bacteria (32%).

The level of concentrations of the final rates in the measurement of immunoglobulins for patients with chronic kidney failure in the presence of bacteria when compared with patients with chronic kidney failure without bacteria and healthy people, the level of IgG in the patient sample decreased kidney failure in the presence of bacteria and the absence of bacteria compared to a sample Control. The decrease in the presence of bacteria was higher than 15.24 pg/ml, when bacteria were not found pg/ml 18.3 Comparing them with healthy subjects pg/ml 39.0. A similar decrease occurred in the serum IgM level in the patient sample with the presence of bacteria pg/ml 60.52 and lack of it pg/ml. 59.1 compared to the control sample 81.83 pg/ml and provides for a decrease in the level of Both IgG and IgM in patients with renal failure,

As for the concentration of IgA shown in Table (1), it was found that its serum concentration levels in patients with kidney failure in the presence of bacteria pg/ml 29.9 and its absence 33.8 pg/ml decreased compared to pg/ml 43.62 in the control sample. The results showed a high concentration of immunoglobulin IgE for chronic renal failure patients as shown in table (1) with bacteria 186.04 pg/ml and lack of it 206.6 pg/ml compared to healthy subjects 123.37 pg/ml where high levels of IgE in the blood were considered an indication of the disease.

Whereas, bacterial infections stimulate macrophages cells to release inflammatory media such as 1β IL-1 (18), as the results shown in Table (1) show the complement concentrations of Complement C3, an increase in patients with chronic renal failure without bacteria 155.4 pg/ml and a decrease in the presence of bacteria. 112.45 pg/ml compared to healthy subjects 147.38 pg/ml,

Discussion

The lack of growth in negative samples of bacterial culture may be attributed to the fact that the cause may be viral or from anaerobic bacteria that cannot be isolated by the usual culture method used in this study Or due to patients taking doses of antibiotics, or perhaps inappropriate use of the antibiotics that cause the disappearance of bacteria that cause urinary tract infection. The cause of the spread of negative bacteria more than positive bacteria is due to the presence of lipid polysaccharide (LPS), the main component of the outer membrane of bacteria that is negative for Gram stain. LPS helps protect bacterial cells from their surroundings (8).

The reason for the decrease in the level of immunoglobulins for patients with chronic kidney failure may be due to several reasons, including accumulated uremic toxins, which inhibit the manufacture of immunoglobulins in patients with chronic kidney failure and a decrease in the numbers of B cells B-cell, which is considered the basis for the manufacture of clopiolines in the serum of patients with chronic renal failure by inhibiting their recycling (11) and it can be known if the previous infection in the body through IgG antibodies and a recent infection through antibody type IgM (12). IgA due to decreased immunoglobulin synthesis in these patients which resulted from the patient’s malnutrition status As a result of his deterioration A decrease in IgA causes frequent infections in the urinary system, as this non-inflammatory antibody specializes in protecting the mucous membrane. Whereas, the prevalence of IgA deficiency in a uremic patient may be due to the neutralization of IgA antibodies and previous destruction leading to a decrease in the number of cells B and IgA Secreting B in a uremic patient as the decrease of this antagonist by the presence of bacteria was one of the main causes of death and disease in kidney patients, usually This is explained by the negative effects of the uremia on the immune defense, for both humoral and cellular immunity and the specific antibody response was low (13). If an increase in the concentration of clopiolines is demonstrated by the presence of bacteria in the response of the intestinal immune system to bacterial colonization by acquiring a state of a deficiency response in the blood defense process against reproductive and active readiness against pathogens, this dialogue leads to the production of large amounts of IgA (14).

The total IgE level in the blood was found to be
clinically relevant in nephrotic syndrome and this is consistent with(15), it showed that the serum IgE level was significantly higher in the renal group compared to the control group. IgE to increased risk of hypersensitivity, resulting from dialysis in patients with chronic renal failure with itching (16). The results of the current study shown in Table (1-1) showed a significant increase in the concentration of interleukin IL-bata in patients with kidney failure. Chronic presence of bacteria is higher than the absence of bacteria in patients. Chronic kidney failure and comparison with the control sample, as patients with kidney failure with bacteria reached 72.74 pg/ml. Also we note there is a rise in patients with chronic kidney failure not having bacteria pg/ml 57.43 compared to the control group 5.58 pg/ml and explained that immunodeficiency in renal failure patients is conservative. The changes in immune-dependent antibodies, as a result of these changes the proportion of immune stimuli such as interleukin and my increase in patients with renal failure to increase excretion and lack of exit from the kidneys. The lack of antibody production is a reflection of the deficiency of T-lymphocyte function(17). The reason for the high concentration in this interleukin is due to the fact that it is from the IL-1β group, as the pro-inflammatory cytokine kinases increase their production rates during cases of immunopathy and infections. And different infections. Renin in the kidneys can lead to supplemental activation. It is an effect that prevents the use of eiskirine. Because renin concentrations are higher in the renal tissues, this may explain the renal tendency of complementary diseases in the presence of complementary mutations or autoantibodies(18). These results are consistent with the researcher’s findings(19) and his group, which indicated a decrease in complement protein C3 in patients with chronic renal failure. Comparing it with the healthy people, the reason for the decrease in the complement protein in bacteria may be due to several reasons(20) including the higher loss of the complement parts by urinary tract method, an increase in its consumption of immune reactions in the circulatory system or by mucous surfaces and interference with the complement-anti-complementary substance. And the activation taking place In the complement system of patients with chronic renal failure by complications and a decrease in immune production(21).

Abstract

Introduction: Bacterial meningitis (BM) is a serious infection characterized by inflammation of the meninges, causing a high rate of acute complications in children. This research aimed to explain the effect of procalcitonin (PCT) in BM and its correlation with the others some inflammatory biomarkers.

Method: The case-control study included Fifty children who were diagnosed with suspected bacterial meningitis associated with febrile seizure according to the clinical investigation by specialized pediatrician and analysis of CSF and Forty children were enrolled as healthy control. The inflammatory biomarkers procalcitonin, Erythrocyte sedimentation rate (ESR), C-reactive protein (CRP) were estimated for each participants in addition to measurement of CBC(complete blood count) by using an automated instrument.

Results: Patients have significantly higher serum levels of PRO, CRP, ESR, total WBC count, ANC, and NLR than the control group. Elevating serum PRO and CRP levels in patients group were significantly associated with increased serum ANC levels. A significant relationship was also observed between PRO and NLR, indicating that the PRO, CRP and NLR had a suitable biomarkers in the diagnosis of BM.

Conclusion: Serum procalcitonin is more specific and sensitive inflammatory biomarkers than the NLR and CRP for the evaluation of suspected bacterial meningitis, so the recommended to use PCT assays in the early diagnosis of children with BM.

Keywords: Bacterial meningitis; biomarkers; Health; inflammatory.

Introduction

Bacterial meningitis (BM) is a serious infectious disease characterized by inflammation of the meninges, producing a high rate of morbidity and mortality in children[1]. BM could be deadly for about half of untreated cases. Even with early diagnosis and adequate treatment, more than 15% of the patients die, especially within 1-2 days of starting symptoms.[1] Furthermore, 10– 20% of the survivors are susceptible for persistent sequelae, including CNS damage, hearing loss and difficulties in learning[1]. Three primary organisms account for more than 90% of the cases of meningitis globally, which are S. pneumoniae, N. meningitides and H. influenzae type b[2].

Bacterial meningitis remains a source of mortality and morbidity in spite of new and effective antibiotics use, whereas aseptic meningitis generally has a benign course requiring only supportive care [3] Early diagnosis of BM and its differentiation from aseptic meningitis should be made to terminate the needful for antibiotic use and hospital admissions[4].
Cerebrospinal fluid (CSF) assay is a preferable for predicting of BM, together with inflammatory biomarkers such as CRP and WBC count. Furthermore, it provide enough specificity without giving a good sensitivity for the diagnosis of BM\(^5\). Also, CSF analysis requires considerable time to prepare its results and most children with CSF pleocytosis are treated with powerful antibiotics in the hospital before the CSF culture results was obtained.\(^6\) Besides atypical history, no distinctive physical examination and irresolute and low yield CSF cultures on some occasions, Sometimes CSF parameters cannot differentiate between bacterial and aseptic meningitis\(^7\) while CRP and WBC count can discriminate between bacterial and nonbacterial meningitis\(^8\). Procalcitinin (PCT) is the best candidate to supersede CRP due to its high diagnostic accuracy in different infectious pathologies, including meningitis\(^9\). Procalcitinin (PCT) is a procalcitinin peptid, is produced in C-cells of the thyroid gland in physiological conditions and released from WBC on the peripheral circulation in bacterial infections.\(^10,11\).

This study aimed to determine the diagnostic ability and using of PCT for estimating of BM and its correlation with the studied some inflammatory biomarkers (e.g., C-reactive protein, ESR, total WBC count, neutrophil/lymphocyte ratio) which are required to predict the presence of BM ifLP is contraindicated or difficult to be performed.

**Method**

The case control study was conducted from September 2018 to March 2019, at the Children Welfare Hospital, Medical City, Baghdad, Iraq. The Ethics approved the research of the University of Baghdad, Faculty of Pharmacy IEC (UBCP-RECA-562018). The information about the patients was gained from the parents of each child for study participation and undergoing the assigned investigations. Ninety children aged between 6 months to 5 years, age – sex-matched children were included in the study. Fifty of them were diagnosed with suspected bacterial meningitis according to the clinical investigation by specialized pediatrician and analysis of CSF. Forty children were enrolled as healthy control. The clinical diagnostic criteria of bacterial meningitis included fever (>38 \(^\circ\)C) with signs of meningeal irritation, bulging fontanels, unexplained irritability, disturbed level of consciousness with or without heat, complex febrile seizure, lethargy and various skin manifestations such as petechial or an erythema\(^12\).

Every child who presented with suspected meningitis underwent lumbar puncture by pediatric specialist or resident in the absence of any contra indications, to obtain CSF for Gram stain and culture, which is the most important step in the diagnosis of BM.

The samples of CSF were evaluated for simple cell analysis (pleocytosis with neutrophilia), an elevated protein, reduced concentration of CSF glucose and CSF culture for Streptococcus pneumonia, Neisseria meningitides, Haemophilus influenza. Furthermore, Blood samples were collected from each patient and healthy controls included in the study and divided into two parts, one was put in EDTA tubes for at once CBC(complete blood count) estimation using autoanalyzer instrument (Celltac-G, Nihon Kohden/ Japan) which included measurement of WBC count, absolute neutrophil count(ANC), absolute lymphocyte count (ALC) and lymphocyte counts and hemoglobin (Hb). Also, ESR was measured by using automated instruments (Vistal X20, Siemens/Italy).

The other part was allowed to clot. It centrifuged at 3500-4000 rpm for 10 minutes to obtain serum then set over pyrogen-free Eppendorf tubes to measure C-Reactive Protein) CRP by heterogeneous enzymatic immunoassay (Vitro 950 analyzer, USA), It is a latex agglutination test for qualitative examination of CRP in serum. Also frozen serum sample at - 20°C was kept until assayed of PCT using ready to use human PCT ELISA kit supplied by Mybiosource (MBS760892/USA).

The normal CSF analysis included WBC counts below 8 cells/mm3, glucose levels at (60- 80)% of the serum glucose level and protein levels between 16- 46 g/L. Abnormal CSF results were classified as bacterial profile (elevated cell count with a prevalence of neutrophil, increased protein levels and decrease glucose levels).

**Statistical analysis:** it was performed by SPSS-21. Independent t-test and one-way ANOVA were used to assess the differences between means. The receiver operation characteristic curve (ROC curve) was used to identify the validity of markers as an indicator of disease. The markers were compared according to area under curve. The analysis was performed by using MedCalc Software. \(P \leq 0.05\) is considered significant.
Results

Laboratory and demographic characteristics of patients with bacterial meningitis and control groups are listed in Table 1. Lumbar puncture was done for all patients and the results of CSF analysis include: polymorph nuclear cell (PMN cell/mm$^3$) 44.96±110.13, protein levels (g/l) 70.16±44.66, glucose levels (mg/dl) 53.16±17.94. In addition to the positive CSF cultures for patients with bacterial meningitis (15 cases of N. meningitides, 18 cases of S. pneumonia, 10 cases of H. influenza and 7 cases of E.coli). These results with clinical investigations were used as diagnostic criteria for the identification of bacterial meningitis.

Children with bacterial meningitis have significantly higher serum levels of PRO, CRP, ESR and NLR than the control group.

Discussion

A reliable marker for bacterial disease should carry out the following criteria: early prognostic diagnostic and values and should be additionally helpful for therapeutic antimicrobial decisions\[13\]. BM is a pediatric emergency with increase morbidity and mortality, so it must be diagnosed and treated immediately. But identical clinical presentation often creates it tricky to discriminate bacterial and non-bacterial etiologies in children \[14\]

CSF analysis was considered the standard for estimation of BM, together with WBC count and CRP. Also, clinical criteria, gram staining and bacterial antigen testing of CSF as well or CSF (glucose, protein, WBC and neutrophil count) used alone lack the specificity and sensitivity for the diagnosis of meningitis and can only provide clinical probability\[15,16\].

Procalcitonin has been considered to be a typical marker with the highest rigor for bacterial infections due to giving an early diagnosis, give information about the course and prognosis of the disease and rapid therapeutic decisions\[17\].

PCT have good sensitive and specific properties for diagnosis of meningitis.\[18\]. In this study, serum PCT significantly higher in children with BM than healthy control groups. This result documented with other researches where PCT concentration increased in bacterial meningitis as compare to other sources of infection with bacterial meningitis \[19-21\].

This elevation in serum PCT of BM due to the release of PCT from all differentiated cell types and parenchymal tissues throughout the body in response to elevated calcitonin gene (CALC-I gene) expression in the presence of bacterial lipopolysaccharides and cytokines associated with severe bacterial infections. PCT secretion during inflammation depends from bacterial endotoxins and inflammatory cytokines, interleukins 6 (IL-6) and tumor necrosis factor (TNF alpha)\[22\]. In contrast to this, there is a transient increase of PCT in patients with viral infection. Furthermore, a rapid response characterized by increase in serum PCT levels after a bacterial stimulus which done by giving a single endotoxin injection makes PCT level a sensitive marker for BM\[23\].

The results of this study display that the procalcitonin was more sensitive and specific inflammatory biomarkers in patients group than the CRP and ANC according to the ROC analysis, these results in agreement with other findings which observed that serum PCT level was a good biomarker for differentiation of bacterial meningitis from other causes\[5\].

Morales Casado et al. was concluded that serum PCT performs better than CRP in the detection of bacterial meningitis. Measuring the CRP released in response to inflammation and bacterial infection in BM is less sensitive and specific than measuring PCT\[24\].

Serum PCT level dramatically increased in early stage during the bacterial infection, making it more sensitive and specific than CRP as a marker of systemic bacterial infection in children. Also, increase in PCT concentrations begin from about few hours after a single endotoxin injection, peak at about 6 hours and persistant elevation for over 24 hours\[25\]. WBC count can differentiate bacterial and non-bacterial meningitis\[5\]. In this study, total WBC count was significantly higher in children with BM than the healthy control. The results of this research documented by other studies in that leukocytosis were valuable in distinguishing between bacterial and non-bacterial infections but not an independent predictor of serious bacterial infection like PCT and CRP, \[28,29\]. PCT is more worthy than CRP or and total WBC count \[25\]. The results of ROC analysis found that the PCT and ANC were more sensitive and specific biomarkers than CRP and NLR for predicting the diagnosis of BM in febrile children with seizure.

Abstract

Doxorubicin is a chemotherapeutic drug that showed a great treatment potential, unfortunately, it is not-selective to cancer cells and affects many other cells. Vitamin K-7 is available from nutritional sources and dietary supplements, it has been reported that it had many beneficial effects.

Objective: Evaluate the protective effect of vitamin K-7 against cytotoxicity and genotoxicity induced by doxorubicin.

Method: Seventy-two rats divided equally into two groups, each group divided into 6 subgroups as following

Group I: received distilled water.

Group II: received a single dose of Doxorubicin (15mg/kg).

Group III: received Vitamin K-7 (16μg/kg) for 11 successive days.

Group IV: received Vitamin K-7 (48μg/kg) for 11 successive days.

Group V: received Vitamin K-7 (16μg/kg) for 11 consecutive days before a single dose of Doxorubicin 15mg/kg on day 11.

Group VI: received Vitamin K-7 at a dose of 48 μg/kg for 11 consecutive days before a single dose of Doxorubicin 15 mg/kg at day 11.

Results: Group II caused significant reduction (P<0.05) in mitotic index associated with an elevation in the micronucleus appearance and the total chromosomal aberrations compared to those of control Group I rats; meanwhile, Groups IV and V decreased chromosomal aberration, micronucleus appearance and increase mitotic index compared to Group II rats treated with doxorubicin.

Conclusion: Vitamin K-7 has protective effects against genotoxicity and cytotoxicity induced by doxorubicin.

Keywords: Doxorubicin, Vitamin K-7, micronucleus appearance, mitotic index, chromosomal aberration.

Introduction

Doxorubicin (DOX) is an anthracycline drug that showed a great treatment potential, being regarded as one of the highly potent of the Food and Drug Administration (FDA) approved chemotherapeutic drugs(1). Such a drug can combat rapidly dividing cells and suppress disease progression. Despite its broad therapeutic effectiveness, it has been reported that the major hindering factor of DOX chemotherapy is its significant toxic effect on various organs; furthermore, early clinical assessments on DOX during phase II and III studies showed common side effects of acute vomiting and nausea, gastrointestinal (GI) problems, baldness, and disturbances to the nervous system (often causing hallucinations and light-headedness)(2). Unfortunately, DOX has been reported not to be specifically targeted only cancer cells but, it can also affect the growth of many other cell types in the body. The severity of unwanted effects and their occurrence by DOX may depend on the dosage of such a chemotherapeutic drug and the duration of its use(3).
Moreover, authors have been well documented that DOX had toxic effects mostly on the bone marrow (BM) cells(4), heart(5), liver(6), brain(7), kidney(8) and testis(9).

Vitamins are essential micronutrients that are very important for physical well-being conditions, and vitamin deficiency can have serious health consequences(10).

Vitamin K is a fat-soluble vitamin, which presents in three forms: vitamin K-1 (phylloquinone), vitamin K-2 (menaquinone), and vitamin K-3 (menadione). In general vitamin K plays essential roles in blood coagulation, regulation of calcium metabolism in tissues, cell growth and proliferation, oxidative stress (OS), inflammatory reactions, and hemostasis(11)(12).

Vitamin K-7 (menaquinone-7) is the common name for vitamin K-2 (13). Vitamin K-7 is a long-chain menaquinone that is not produced by human tissue (14). Moreover, vitamin K-7 may be produced by phylloquinone (vitamin K-1) in the colon by Escherichia coli bacteria(15). However, these menaquinones synthesized by bacteria in the gut appear to contribute minimally to overall vitamin K status(16,17). Moreover, vitamin K-7 is rapidly becoming popular as a supplement and is available as over the counter, it has also been reported that such type of vitamin K had beneficial effects like reduce the risk of osteoporosis, osteoarthritis (OA), and vascular and tissue calcification(18).

Chromosomal aberration it’s any change in either the structure of chromosome called or the number of chromosomes(19). Structural abnormalities examples are deletions, ring chromosomes acentric chromosomes or dicentric chromosome(20).

Mitotic index is a measure for the proliferation status of a cell population and defined as the ratio between the number of cells in mitosis and the total number of cells(21).

Materials and Method

Animals and Treatment Protocols: Seventy-two(72) adult Wistar Albino experimental rats of both sexes, weighing 160-250gm were used in this study; they were obtained from and maintained in the Animal House of the College of Pharmacy, University of Baghdad. The animals were maintained under normal conditions of temperature, humidity and light/dark cycle.

The experimental rats were randomly allocated into six groups, each containing 6 rats as follows:

**Group I**: Rats received 0.5ml of distilled water (D.W.) intraperitoneally (IP) injected, this group served as (negative control).

**Group II**: Rats were IP injected with a single dose of DOX (15mg/kg BW) (positive control).

**Group III**: Animals received MK-7 (16μg/kg BW/day) orally by oral gavage for 11 successive days.

**Group IV**:Animals were administered MK-7 (48μg/kg BW/day) orally by oral gavage for 11 successive days.

**Group V**: Rats received MK-7 (16μg/kg BW/day) orally by oral gavage for 11 successive days before a single IP dose of DOX 15mg/kg on day 11.

**Group VI**: Animals treated with MK-7 at a dose of 48μg/kg orally-administered once daily for 11 consecutive days before a single IP dose of DOX 15 mg/kg on day 11.

Evaluation of the mitotic index and chromosomal aberrations in bone marrow cells and spleen-cells: After 24 hours of the end of treatment, all rats were IP injected with 1mg/kg colchicine, and then two hours later, the animals were sacrificed by cervical dislocation. The BM sample of each rat was aspirated from the femur bone and spleen cells have been extracted from spleen, as previously reported elsewhere(22).

**Evaluation of the micronucleus appearance in bone marrow (BM) cells**: At the end of treatment, rats were sacrificed by cervical dislocation. Bone marrow (BM) samples were aspirated from the femur bone by using fetal calf serum and processed using for the evaluation of an appearance of micronucleus(22).

**Statistical Analysis**: All results of the study were demonstrated as Mean± Standard deviation (SD) and data input and analysis were examined by Statistical package for social sciences program version 24 (SPSS V 24) and ANOVA test was performed to compare among test groups; and (P values<0.05) were regarded as statistically significant.

Results

Table (1) showed that, Group III rats produced a non-significant difference in mitotic index compared to such index in negative control rats (P>0.05) in both BM- and spleen-cells; but at the Group IV rats, the mitotic index was significantly increased (P<0.05) compared to negative control rats in both BM- and spleen-cells. Moreover, mitotic index was significantly different when comparison was Group II, Group V and Group VI (P<0.05) in both BM- and spleen cells. Additionally, There was a significant difference (P<0.05) in the mitotic index Group V and Group VI in both BM- and spleen-cells.

*significantly different compared to distilled water ($P<0.05$).
• Values with non-identical small letters superscripts (a, b, and c) are considered significantly different when a comparison among group II, group V and group VI ($P<0.05$).
• Values with non-identical capital letters superscripts (A, and B) are considered significantly different when a comparison between group V and group VI ($P<0.05$).

Discussion

In the current study, in Group II rats caused significant reduction ($P<0.05$) in the mitotic index associated with an elevation in the micronucleus appearance in bone marrow cells and elevation in the chromosomal aberrations in both bone marrow and spleen-cells compared to those in negative control; meanwhile,(Group IV) and (Group V), decreased chromosomal aberrations, micronucleus appearance and increased mitotic index compared to those in (Group II) rats. Tables (1, 2, and 3)

A previous study showed that reactive oxygen species (ROS) cause DNA damage in cells\(^{(23, 24)}\). Moreover, mitochondria are the site of ROS production due to electrons escaping from electron transport chain and production of superoxide anion ($O_2^{-}$); moreover, DOX can drive these ROS productions through enzymes within the mitochondria, including the reduced form of nicotinamide adenine dinucleotide phosphate (NADPH) oxidase, cytochrome P-450 reductase, and xanthine oxidase (XO), can convert DOX in the form of quinone to semiquinone\(^{(25)}\), which can be regenerated back to its parental quinone readily by reacting with oxygen with the generation of $O_2^{-}$, which in turn could further be changed to other ROS\(^{(26)}\), but vitamin K can alter redox balance in cells\(^{(27)}\). In its reduced form, vitamin K hydroquinone (KH2) can protect phospholipid membranes from peroxidation by ROSuptake\(^{(28)}\). Furthermore, vitamin K inhibited\(^{(29)}\) 12-lipoygenase enzyme which preventsROS formation\(^{(29)}\); also vitamin K reduces OS by lowering levels of pro-inflammatory factors\(^{(30)}\).

Assessment of Serum Interleukin-4 and Filaggrin Protein in Patients with Atopic Dermatitis

Aseel Kasim Kareem1, Alaa Jawad Hassan1

1Department of Biology, College of Science, University of Babylon, Iraq

Abstract

The current study aimed to determine the relationship between certain immunological parameters in a topic dermatitis (AD) patients.

There was no significant differences (P≥0.05)in the level of filaggrin protein between patients and control groups regarding to the age but there was a significant differences (P≤ 0.05)in the level of IL-4 between patients and healthy subjects groups regarding to the age, also the study showed that there was no significant differences (P≥0.05) between study groups regarding the gender for above two parameters.

The data of current study support the defected skin barrier role in the AD pathogenesis, in addition the results revealed filaggrin reduced expression in atopic skin lesion and inverse correlation between filaggrin protein expression and disease severity. Add to that, the elevation of circulation interleukin IL-4 levels in AD, emphasizes the profile of systemic inflammation of this skin barrier defective dermatosis.

Keywords: IL-4; Filaggrin protein; Atopic dermatitis.

Introduction

Atopic dermatitis (AD) is the most common chronic inflammatory skin disease[1]. It starts in early infant life and remains lifelong with therapeutic difficulty especially when it is in moderate or severe form[2]. Its etiology remains poorly understood but it is believed as multifactorial with complex combination of deviation in the immune system, defective barrier function and risk of environmental factors[3,4] leading to allergens skin sensitization as a result of mutations affecting the epidermal barrier or because of an inflammation that inhibit the epidermal differentiation[5].

AD as a heterogeneous disease, activating more than one inflammatory pathway with psoriasis where IL-4 play an important role in the allergic response. IL-4 and IL-13 are involved in the promotion of isotype class switching from IgM to IgE that stimulate T cell differentiation to Th2 and B cells antigen presenting enhancement[6]. Filament aggregating protein (filaggrin) is important for cornified cell envelope (CCE) formation that is needed for effective skin barrier where it binds to and facilitates keratins (K1/10) aggregation that induce the collapse of cytoskeleton to formcornocytes[7].

Materials and Method

Patients and Control: The work was applied on 49 patients (23 males, 26 females) admitted to the Imam Sadiq Hospital & Merjan Hospital (Dermatology Advisory Unit) in Babylon Governorate and 30 healthy subjects (11 males, 20 females) without prior clinical signs as control group. All patients were initially diagnosed by specialist physician.

Blood Samples: The blood samples (5ml) were drawn from each patients and control groups by vein puncture using disposable syringes. The blood was placed in the Jell tube and kept to clot at room temperature, then centrifuged at 3000 rpm for 10 min., after that, sera samples were carefully transferred to Eppendorf tubes and preserved at -20°C untiluse.

Immunological Tests: The levels of immunological criteria IL-4 and Filaggrin, were estimated by ELISA Kit according to the manual procedures of Elabscience (USA) and Biolabs (China) respectively.

Statistical Analysis: The results were analyzed using the ANOVA-LSD-General Linear Model and SPSS (copyright 16).
Results

The results of the present study (Table 1), showed no significant differences (P ≥ 0.05) in the Filaggrin protein level between patients and control groups regarding to the age, also the study showed increase the concentration of this parameter in age category ≤ 20 years, while the low of its level represented in age category (≥ 60) years as revealed in figure (1). Whereas the results for IL-4 cytokine was show a significant differences (P ≤ 0.05) between patients and controls regarding to the age; and the study shown increases the concentration of IL-4 in age category (41-60) years, while a low concentration was demonstrated in the age group ≥ 60 years Figure (1).

Regarding to the gender the results in Table 2 and Figure (2) were showed no significant differences (P ≥ 0.05) between patients and controls in the levels of filaggrin protein and IL-4.

**Discussion**

The results of immunological criteria showed that there were no significant differences (P ≥ 0.05) in the concentration of filaggrin protein and the correlation analysis showed no correlation significant between age and gender for atopic groups compared with controls.

Filaggrin protein: Acute AD skin is associated with Th2 cytokines over expression (IL-4 and IL-13), combined with increased filaggrin expression. Therefore, whether these cytokines alter the filaggrin expression was investigated.

The current study indicated that this deficiency is partially due to the Th2 cytokines over expression that inhibit filaggrin expression that agree with[8].

Further studies need to be conducted to determine whether the early AD treatment may repair skin barrier defect. There is an association between filaggrin gene mutation and AD[9].

**Interleukin-4 (IL-4):** The results revealed a significant difference (P ≤0.05) and also a significant correlation with age between atopic and control groups.

---

**Figure 1:** The levels of filaggrin protein and IL-4 in patients with atopic dermatitis according to the age groups

**Figure 2:** The levels of filaggrin protein and IL-4 in patients with atopic dermatitis according to the gender
The present study agree with\(^{[10]}\) who indicated that acute skin lesions contain more cells that produce IL-4, IL-5 and IL-13, but not IFN-\(\gamma\) in comparison with chronic lesions where IL-4 and IL-13 are significantly decreased and increased cells expressing IL-5 and IFN-\(\gamma\)\(^{[11]}\).

IL-4 Overexpression in the epidermis, developed all marks of AD like increased inflammatory cells in the skin, pruritus, skin bacterial infection and increased IgG1 and IgE\(^{[12]}\).

The results of this study disagree with\(^{[13]}\) reported that the Th2 cells are responsible for the development of the humoral immune response and the hyperproduction of IL-4, IL-10, IL-13 in allergic diseases.

Another study showed high serum levels of cytokines in the eczematous lesions patients either acute or chronic, due to increased Th2 cells secreting IL-4 and IL-13, while high TNF serum levels in chronic lesions\(^{[14]}\).

The current study agree with the results of\(^{[15]}\) whom observed higher levels of IL-4, IL-13 and IFN-\(\gamma\) in chronic eczema.

**Conclusion**

The data of current study support the defected skin barrier role in the AD pathogenesis, in addition the results revealed filaggrin reduced expression in atopic skin lesion and inverse correlation between filaggrin protein expression and disease severity. Add to that, the elevation of circulation interleukin IL-4 levels in AD, emphasizes the profile of systemic inflammation of this skin barrier defective dermatosis.

Synthesis of New Drug Carriers of Metronidazole as Antifungal Agents

Naeemah J. Al-lami¹, Zaina Jassim², Yasmeen H. Muhamad², Mahdi jaffer²

¹Assist Prof. Department of Chemistry, College of Science, University of Baghdad/Iraq,
²Department of Chemistry, College of Science, University of Baghdad/Iraq

Abstract

New drug carriers were synthesised through etherification with sugar moiety and metronidazole drug. The synthetic pathway was started with two sugars, β-D-glucose and β-D-fructose, which were protected as peracetate and benzoate respectively, then converted to bromo sugar. The bromo sugars were subjected to coupling with metronidazole drug via Willemenson reaction to afford protected drug carriers. All prepared compounds were characterised via FT-IR, $¹$H-NMR and $¹³$C-NMR and HR-MS spectroscopy. These new carriers were tested against four types of fungi kandida yeast. Some of tested compounds showed moderate activity while the other showed weak inhibition. Interestingly, two carrier drugs showed high activity against fungi.

Keywords: Prodrug, metronidazole, nucleosides, antifungal.

Introduction

Since 1958, when Albert(1) initially coined the term prodrug and used to refer to pharmacologically compounds, the carrier-linked prodrugs are imparting some desirable properties to the drugs such as increased lipid or water solubility or site-directed delivery or decreased toxicity and prolonged or shortened action(2).

Meteronidazole, 2-methyl-5-nitroimidazole-1-ethanol (flagyl), is the most useful of a group of antiprotzoal drugs that have synthesized in several laboratories. This drug is accommodating amebicidal activity; it is valuable against both intestinal and hepatic amebiasis. It has also been explored of the use in the treatment of such other protozoal diseases as giardiasis(3-6). Because of its bactericidal action, it became an important agent for treatment of serious infections (e.g. septicemia, pneumonia and meningitis) caused by anaerobic bacteria(7-9).

Since meteronidazole is sparingly soluble in water, our target is to link meteronidazole with sugar as carrier, which called a promoiety through glycoside linkage to increase their solubility in water. The glycosidase enzyme found in colon bectria, allows hydrolysis of glycoside derivatives of drug in the colon, that is the side of action, and provides higher concentrations of active drug.(10,11)

Nucleosides, both of natural and synthetic origin have at least some biological activity.(12) Such as potential anti-viral(13) fungicidal, and anticancer agents(14,15). Nucleoside analogues play significant role in several established chemotherapies (anticancer, antiviral and antibacterial).(16-19)

A new methodology to synthesis a new modified prodrugs using two kinds of protected sugars and meteronidazole was developed in this article. The new prodrugs were examined against fungi to evaluate them as antimicrobial and antifungal agents. Expectedly, the new compounds showed higher activity against fungi.

General experimental: All chemicals were
Preparation of β-D Glucose Penta Acetate(20)

(2): β-D glucose (0.0055 mole) and (0.00975 mole) an hydrous sodium acetate were dissolved in (6mL) acetic anhydride, and then heated under reflux for 2hrs. The resulting mixture was poured on to (50mL) of ice-cold water, then filtered and recrystallized form ethanol to afford a white crystal (2) m.p: (131-132 °C); IR (thin film) cm⁻¹ 2918 (m) (CH aliphatic, stretch), 1720 (s) (C=O ester, stretch); ¹H-NMR (500 MHz, CDCl₃) δ_H 2.2 (5x 3H, s, 5CH₃), 4.2 (2H, s, CH₂), 4.6 (2 x 1H, d, 2CH), 5.1 (2 x 1H, d, 2CH), 6.21 (1H, d, CH); ¹³C-NMR (125 MHz, CDCl₃) δ_C 25 (5CH₃), 64 (CH₂), 71 (2CH), 75 (2CH), 175 (SCO); HRMS(EI⁺) found 390.2303, C₁₆H₂₂O₁₁ requires 390.2301.

General Procedure for Synthesis of 1-Bromo Acetylated Sugar(21)(3): The acetylated sugar (1) (0.38 g 0.0024 mole) was dissolved in (3 ml) of (50%) hydrogen peroxide, then was added as a catalyst. Flagyl (Metronidazole) (4.3 g, 0.1 mol) was dissolved in absolute ethanol (10 ml) and was added through dropping funnel to the stirred reaction mixture over a period of about 1 hr. The stirring is continued for 24 hr. The resulting mixture was filtered off through and the residue is washed well with chloroform. The filtrate and washings are combined together, and concentrated under reduced pressure. The residue was re-crystallized from chloroform to give brown dark powder of compound (5) in yield 75% (m.p. 197-199 °C), RF (0.75) (benzene: methanol, 6:4); IR (thin film) cm⁻¹ 2918 (m) (CH aliphatic, stretch), 1720 (s) (C=O ester, stretch), 1612 (C=N, stretch); ¹H-NMR (500 MHz, CDCl₃) δ_H 1.7 (3H, s, CH₃), 2.2 (4x 3H, s, 4CH₃), 4.2 (2H, s, CH₂), 3.6 (2H, t, CH₂O), 3.8 (2H, t, CH₂N), 4.6 (2 x 1H, d, 2CH), 5.1 (2 x 1H, d, 2CH), 6.21 (1H, d, CH), 7.5 (1H, s, CH=N); ¹³C-NMR (125 MHz, CDCl₃) δ_C 12 (CH₃), 22 (4CH₃), 65 (CH₂), 67 (CH₇), 71 (2CH), 75 (2CH), 72 (2CH), 140 (C=NO₂), 158 (CH=NO), 172 (4CO); HRMS(EI⁺) found 459.2303, C₂₀H₁₉O₁₂ requires 459.2301.

Hydrolysis of protected prodrug (6)(22): A solution of (0.0026 mole) of the blocked nucleoside analogue in (7mL) of (0.1 M) methanolic sodium methoxide was heated under reflux for 30 min. The reaction mixture was neutralized with acetic acid and concentrated to dryness. The residue was portioned between water and chloroform. The aqueous phase evaporated to dryness under vacuum to give free prodrug (6): (m.p. 197-199 °C), RF (0.75) (benzene: methanol, 6:4); IR (thin film) cm⁻¹ 2320 (s) (OH Stretch), 2918 (m) (CH aliphatic, stretch), 1612 (C=Nimidazo, stretch); ¹H-NMR (500 MHz, CDCl₃) δ_H 1.7(3H, s, CH₃), 4.4 (2H, s, CH₂), 3.5 (2H, t, CH₂O), 3.7 (2H, t, CH₂N), 4.6 (2 x 1H, d, 2CH), 5.1 (2 x 1H, d, 2CH), 6.21 (1H, d, CH), 7.5 (1H, s, CH=N); ¹³C-NMR (125 MHz, CDCl₃) δ_C 12 (CH₃), 22 (4CH₃), 65 (CH₂), 67 (CH₇), 70 (4COH), 74 (2CH), 77 (2CH), 128 (CH), 140 (C=NO₂), 158 (CH=NO), 172 (4CO); HRMS(EI⁺) found 451.2303, C₂₀H₁₉O₁₂ requires 451.2301.

Protection and Preparation of Sugar Moiety: 1,3,4,6-tetra-O-benzoyl-β-D-fructofuranose (8)(23): Benzoyl chloride (7 ml) was added dropwise to anhydrous-D-fructose (2 g, 11.11 mmol) that suspended in mixture of chloroform (30 ml) and dry pyridine (5 ml), after that the mixture was heated at 318–338 K with continuous stirring for 4 h. The mixture was poured over ice-water, and then extracted with CHCl₃ (3x15 ml). The organic layer was washed with 5% HCl solution (10 ml). The organic layer was naturalized with 5% of sodium carbonate solution (10 ml), after that the organic layer was dried over sodium sulphate and the purchased from Sigma-Aldrich unless otherwise stated. ¹H-NMR spectra were measured on a Bruker Avance 500 MHz spectrometer or on a Bruker Avance DPX 400 NMR spectrometer. ¹³C-NMR spectra were measured on a Bruker Avance 500 MHz spectrometer (Isfahan University of Technology (IUT), Iran) and Sharif University of Technology (SUT).
solvent was concentrated under vacuum to give a syrup that crystallized from absolute ethanol to afford white crystals (m.p. 394–395 K); IR (thin film) cm⁻¹ 3064 (m) (CH aromatic, stretch), 2918 (m) (CH aliphatic, stretch), 1720 (s) (C=O ester, stretch), 1655 (m) (C=O aromatic, stretch); ¹H-NMR (500 MHz, CDCl₃) δH 3.0-3.1 (2H, s, CH₂OBez), 3.3-3.4 (2H, s, 2CH), 7.3-7.4 (10H, m, 10CH aromatic), 7.8-7.9 (10H, m, 10CH aromatic); ¹³C-NMR (125 MHz, CDCl₃) δC 64 (CH₂O), 70 (2CH), 92 (2CO), 130 (8CH aromatic), 134 (8CH aromatic), 138 (4CH aromatic), 138 (4CC=O), 170 (4C=O); HRMS(EI⁺) found 612.2303, C₃₄H₂₃O₁₁ requires 612.2301.

1,3,4,6- Tetra-O-benzoyl-β-D-fructofuranosyl bromide(9)(2¹); Hydrogen bromide in glacial acetic acid (45%) (5 ml) was added to tetrabenzoyl fructofuranose 4 (2 g, 3.36 mmole), then (5 ml) of glacial acetic acid was added, the mixture was stirred for 30 min. at room temperature and left for 6 h. at room temperature, and mixture was neutralized with sodium bicarbonate solution, then extracted with chloroform (3 x 15 ml). The organic layers were dried over sodium sulphate, filtered and evaporated in vacuo to give brown syrup; IR (thin film) cm⁻¹ 3217 (broad s) (OH, stretch), 3064 (m) (CH aromatic, stretch), 2918 (m) (CH aliphatic, stretch), 1720 (s) (C=O ester, stretch), 1655 (m) (C=O aromatic, stretch); ¹H-NMR (500 MHz, CDCl₃) δH 2.1-2.3 (1H, s, CH aromatic), 4.5-4.6 (2H, s, 2CH), 7.3-7.4 (10H, m, 10CH aromatic), 7.5-7.6 (4H, m, 4CH aromatic); ¹³C-NMR (125 MHz, CDCl₃) δC 64 (CH₂O), 70 (2CH), 92 (2CO), 119 (2CH aromatic), 128 (2CH aromatic), 130 (8CH aromatic), 134 (8CH aromatic), 138 (4CC=O), 147 (2C=O aromatic), 170 (4C=O); HRMS(EI⁺) found 782.125 C₄₀H₃₆O₁₄N₃ requires 782.123.

Hydrolysis of protected prodrug(11)(2²); A solution of (0.0026mole) of the blocked prodrug 7 in (7mL) of (0.1 M) methanolic sodium methoxide was refluxed with stirring for (0.5 h). The mixture was neutralized with acetic acid and evaporated to dryness. The residue was portioned between water and chloroform. The aqueous phase evaporated to dryness under vacuum to obtain free prodrug (6). The residue was re-crystallised from chloroform to give brown dark powder in the yield 80 % (m.p. 320-333 K), Rf = 0.85 (benzene:methanol = 6:5); IR (thin film) cm⁻¹ 3225 (OH, stretch), 3070 (m) (CH aromatic, stretch), 2925 (m) (CH aliphatic, stretch), 1720 (s) (C=O ester, stretch), 1450 (m) (C=C aromatic, stretch), 7.5-7.6 (5H, m, 5CH aromatic), 7.5-7.6 (Hₛ, CH=N); ¹³C-NMR (125 MHz, CDCl₃) δC 12 (CH₃), 45 (CH₂CO), 64 (2CH₂O), 70 (2CH), 92 (2CO), 119 (2CH aromatic), 128 (2CH aromatic), 130 (8CH aromatic), 134 (8CH aromatic), 136 (4CH aromatic), 138 (4CC=O), 147 (2C=O aromatic), 170 (4C=O); HRMS(EI⁺) found 782.125 C₄₀H₃₆O₁₄N₃ requires 782.123.

Results and Discussion

To incorporate molecules containing several reactive centers, and adopt different conformation in solution like mono saccharides in a synthetic organic reaction, it is essential to block the unwanted reactive sites, and also restrict these molecules in one conformation which were required to the synthetic project successfully. β-D-glucose(1) was protected as a stable ester derivative using acetic anhydride in presence of sodium acetate afforded β - D-glucose penta acetate (2) Figure 1, then fully protected glucose treated with hydrogen bromide undergo specific displacement reaction at numeric center to give axial (α-anomer) halide, the α-halo anomer is substantially preferred,(2⁴)the short mechanism for
formation of \(\alpha\)-bromo sugar\(^3\) illustrated in Figure 2. Then, \(\alpha\)-bromo sugar\(^3\) was coupled with metronidazole (4) as nucleobase through nucleophilic substitution of hydroxyl group of metronidazole (4) on sugar bromide (3) afforded new blocked nucleoside (5) analogue, which after hydrolysed gave analogue 6 free hydroxyl groups. The FT-IR spectrum of this analogue (6) showed stretching band at 3230 cm\(^{-1}\) (stretch OH), and this was good evidence to form this compound.

The second sugar used in this article was \(\beta\)-D-fructose, which protected their hydroxyls at C-1, C-3, C-4 and C-6 leaving hydroxyl group at C-2 free for further chemical modification.\(^{26}\) In same manner, per benzoate fructose (8) was turned to \(\alpha\)-bromo sugar (9) as syrup, which coupled with metronidazole (4) as nucleobase through nucleophilic substitution of hydroxyl group of metronidazole (4) on sugar bromide (9) yielded new blocked nucleoside analogue (10), which after hydrolysis gave pro drug (11).

![Figure 1: Total synthesis of prod rug 6 and 11](image-url)
Antifungal activity of compounds 2-10: Since the metronidazole derivatives and prodrugs have been reported in the literature as antifungal [3] activity, most of these prepared compounds were examined to inhibit fungal spore germination and hyphal growth in this article. Aliquots of solutions of eight purified compounds 2, 3 and 5-10 along with compound 4 (metronidazole) were arrayed on silica TLC plates (Figure 3) and either visualized with a vanillin-$\text{H}_2\text{SO}_4$ rising reagent (left panel) or exposed to a fungal overlay bioassay (right). Antifungal activity was obvious as white zones sparkly an inhibition of spore germination and hyphal growth, only compound 4 and compounds (6,11) exhibited significant anti-fungal activity while no such activity was observed with compounds (5-7) and 3,2. The smallest amount inhibitor concentration (MIC) observed for compound 2 was 3 ng/spt, 10-fold under that necessary for compounds 6 and 11 (30 ng/spot), indicating the importance of metronidazole moiety in sugar for full antifungal activity. However, the lack of antifungal activity with compounds 5-7 suggests that sugar is not sufficient for activity.

Evaluating of Serum Electrolyte Changes in Chronic Renal Failure Pre and Post Dialysis

Wafaa H. Ajam

Ass. Lecture. Department of Pathological Analysis Techniques, Al-Mustaqbal University College/Hilla-Iraq

Abstract

Background: The kidney played a vital role in the regulation of electrolyte and acid–base balance. With progressive loss of renal function, derangements in electrolytes and acid–base balance certainly occurred and contribute to worse patient outcomes.

Objective: The aim of the present study is to assess the effect of Hemodialysis (HD) on serum electrolytes levels which compared with healthy control group; also to assess the correlation of serum electrolyte before and after hemodialysis.

Material and Method: The study done on 40 patients (25 men and 15 women) all patients with chronic kidney disease, ages of patients 25 – 65 years. All patients enter the dialysis department in Merjan teaching hospital and matched with 30 well persons as control. Results: study of comparison between patients before and after hemodialysis, significant difference in the level of serum urea and creatinine between pre and post dialysis, and significant effect of Hemodialysis on serum electrolytes particularly serum potassium levels. The pre-hemodialysis $K^+$ was 4.48± 0.83 mmol/L and post-hemodialysis $K^+$ was 3.69±0.65 mmol/L ($P<0.001$). The pre-hemodialysis $Na^+$ was 136.5±4.14 and post-hemodialysis $Na^+$ was 138.6 ±4.41 ($P = 0.36$). The pre-hemodialysis $Cl^-$ was 106.12 ± 4.02 and post-hemodialysis $Cl^-$ was 107.12 ± 4.11 ($P= 0.38$ NS).

Conclusion: There is decrease in s. urea besides creatinine level between period before and after hemodialysis. Serum $K^+$ level decreased after hemodialysis. Although serum sodium and chloride levels not significantly affected after hemodialysis.

Keywords: Chronic renal failure, hemodialysis, serum electrolytes.

Introduction

Chronic renal failure is a worldwide complication, a chief reason of high mortality rate in the developed countries. Patients are at higher risk for cardiovascular disease (CVD) and Hyperkalemia is a usually meet problem in patients with progressive renal disease[1].

Chronic renal failures induce a slow and progressive decline of kidney’s function. It is usually a consequence of complications from another serious medical condition[2].

The major causes of CRF included chronic glomerulonephritis, progressive nephritic syndrome, diabetes mellitus, chronic hypertension, polycystic kidney and chronic pyelonephritis [3].

Dialysis is a process that removes overload fluids and poisonous last part products of metabolism as urea from the plasma and corrects electrolytes balance by dialyzing the patient’s blood against fluid that contain no urea which has levels of minerals like potassium and calcium that are similar to their natural concentration in healthy blood[4].
Dialysis is based on the standard of diffusion equilibrium. In general dialyzing fluid (Dialysate) contains “Na⁺, K⁺ and HCO₃⁻ in a higher concentration than normal plasma (urea, urates, creatinine, phosphate, sulphate are absent)”. If the plasma K⁺ of patient is above normal, K⁺ diffuse out of the blood across the cellophane tubing and in to the dialyzing fluid. Also, waste products and overload of the substances diffuse in to the dialyzing fluid and removed from the body [5].

Hemodialysis is one of the useful method of treatment of hyperkalemia and uremia, also to approve sodium and serum creatinine levels in renal failure. Severe hyperkalemia occur in 10-19% of hemodialysis patients[6]. Many studies showed that a sudden change and decrease in serum K⁺ causes arrhythmia related patients undergoing dialysis[7].

Hypokalemia also arise in dialysis patients due to the exposure to low K (≤ 2 K) dialysate. Post-dialysis hypokalemia associated with serious cardiac arrhythmias and sudden cardiac deaths. And also they stated that 67% were cardiac deaths[8]. The vulnerability to hypokalemia-triggered cardiovascular trial could be related to the cardiovascular diseases, occurring in a majority of end stage renal disease patients [9].

Indialysis patients, hyponatremia is typically dilution, due to overload water or hypotonic fluid intake. Hyponatremia, when persistent, has been seen in those with impaired thirst mechanism or lack of admittance to water. Dysnatremia in chronic kidney disease (CKD) and end stage renal disease has high mortality rate [10].

The study amid to assess the changes in serum potassium, sodium and chloride in pre and post dialysis patients.

### Material and Method

A total of 40 patients were taken for this study. For them (25 males and 15 females) were End stage renal disease (ESRD), aged (25-65) year are admitted to al-dialysis unit in Merjan teaching hospital which compared with 30 healthy as control group. All patients were dialyzed three times a week and each session was at least four hours. They were dialyzed with polysulfone dialyzing membrane. The duration of dialysis ranged from 2-8 years. Subjects suffering from diabetes, acute renal failure, cardiovascular disease, hepatic disease, and any chronic or acute inflammatory illness were excluded from the study. Venous blood (5 ml) was obtained from each patient before and after dialysis. Serum then was separated by centrifugation for (10) minutes, and then divided in aliquots for measurement of serum K⁺, Na⁺, Cl⁻ as well as serum level of creatinine and urea. The control groups consisted of 30 non-hospitalized adults with no history of systemic disease (matched for age and sex).

### Result

In chronic kidney disease patients, serum Urea and Creatinine level was significantly high in pre-HD patients compared to healthy controls as shown in table No(1). The mean levels of serum sodium in pre-HD patients was lower than healthy controls as shown in table (1), also the mean Serum chloride level in pre-HD patients was higher compared to controls as shown in table (1) However, the mean level of serum K⁺ value was significantly high in pre-HD patients compared to healthy controls as shown in table No(1).

**Discussion**

The current study show that serum potassium level in post – HD patients was significantly low compared to mean serum level of pre-HD patients. Hyperkalemia reduces the resting membrane potential, slow the conduction velocity and increases the rate of repolarization. Hypokalemia on the other hand increases the resting membrane potential, and refractory period, which are potentially arrhythmogenic. The obtained result was consistent with that reported by Sreenivasulu et al. stated that mean serum potassium levels in post-HD were low compared to pre-HD Patients\(^{[11]}\). Also, The result consistent with other study\(^{[12,13,14,15]}\), observed that mean serum potassium levels in post-HD (3.69±0.65) were low compared to pre-HD Patients (4.48±0.83).

The study results show that chronic kidney disease patients has high level of serum urea is relative to the progression of the disease and is highly influenced by a catabolic state or excessive protein ingestion, leading to a higher production of other waste substances of protein catabolism, and creatinine level increase in chronic kidney disease patients that recognized by low no. of working nephrons, this lead to decrease in GFR, cause significant lowering in the renal flow of water and solutes, this result matches with the result of (Noor ul Amin.)\(^{[16]}\).

In the present study mean serum sodium levels in post-dialysis patient was slightly higher when compared to mean serum sodium levels of pre dialysis patients. Seethalakshmi reported that the mean Na\(^+\) concentration in post –hemodialysis (138.00 ±4.41) patients was high compare to prehemodialysis patients (136.87±4.14)\(^{[15]}\). A study by Naumanobserved that mean serum Na\(^+\) post-hemodialysis patients (138.00±4.41) were higher when compared to pre-hemodialysis patients (136.87±4.14)\(^{[13]}\). In chronic Hemodialysis patients, sodium (Na\(^+\)) balance largely depends on inter dialytic dietary salt intake and intra dialytic Na\(^+\) removal\(^{[17]}\). Dialysis patients appear to have a unique set point for serum sodium\(^{[18]}\). In over-all level of serum K\(^+\) after HD increase 2-4 meq/L suggesting that HD cause hyponatremia and transferrable Na\(^+\) pool is partly depleted of excess Na\(^+\)\(^{[19]}\).

In the present study mean serum chloride level in post –HD pts was low compared to pre HD pts. A study by Kirschbaum B\(^{[14]}\) shows that mean serum chloride level in post HD patients (Mean-100) was low compare to pre HD patients (Mean-103).

**Conclusion**

There is decrease in s. urea besides creatinine level between period before and after hemodialysis, also s. K\(^+\) level decreased after hemodialysis. Although serum sodium and chloride levels not significantly affected after hemodialysis.

Retinoic Acid Teratogenicity in Mouse Embryo

Alghareeb Maha R.¹, Alani Louay M.¹, Alhadad Nedhal ².

¹Post Graduate Student, Assist. Prof., Biological Department/College of Science, University of Anbar, Iraq, ²Lect. Dr., Biological Department/Education College of Women, University of Anbar, Iraq

Abstract

The present study was designed to explore furthermore the relationship between abnormalities in mice which were used as a model to study the (NTDs) in human beings and retinoic acid. The study was conducted on the Swiss white mice, with 40 females and 10 males. Females that have the vaginal plug are isolated in separate plastic cages to study the teratogenic effect of retinoic acid in the concentration of 15, 25, 35 or 45 mg/kg live body weight which were administered intraperitonially. Also, folic acid was used with dose 35mg/kg to test the preventive effect against neural tube defects. Retinoic acid doses of 15 mg/kg, 25 mg/kg and 35 mg/kg caused different abnormalities in percent of 20% including (Small size with unclear face, NTDs), 32% including (NTDs, prolonged embryos and deformation eye and ears), 68% including (NTDs, prolonged embryos and deformation eye and ears and small size) respectively. While the dose of 45 mg/kg caused 100% reabsorption.

Keywords: Neural tube defects, Spina bifida, Exencephaly, Retinoic acid, Teratology.

Introduction

Neural tube defects are the most common congenital malformation in the central nerves system in human beings(1). The etiology is complex with environmental and other genetic factors which have significant contribution(2). There are two type of NTDs open which are common and closed. In human being the 19th day of gestation the neural plate lengthened and edges of the cranial region start to rise,forming the neural groove in the middle . The edges of folds meets and fuse . The cranial neuropore is closed on day 25 and the caudal neuropore is closed on day 27 (³).

In mice model the two types of NTDs can occur together or separately. Numerous chemical agents that may inducenueral tube defects in human beings and other experimental organism, in contrast, some agents are known as preventive agent against NTDs like folic acid. Folic acid is required for new cell growth, particularly for nucleic acid and protein synthesis. It is vital for embryos developments(4). Folate deficiency was directly related to cases of neural tube defects.Many studies have shown the supplementation of folic acid before pregnancy can reduce risk of NTDs about 70%(5). The present study was designed into two tier first to study the teratogenic effect of retinoic acid on development of neural tube in mice and the protective effect of folic acid against teratogenic effects of retinoic acid.

Material and Method

The current study was conducted on 50 Swiss white mouse,with 40 females and 10 males, average age was 8-14 weeks, and average weighted was(27 ±2) g for females and (30 ±2) g for males. Mice were obtained from the Cancer Research Center/Al- Mustansiriya University. These animals were placed in special plastic cages, with dimensions of approximately, (13×16×30) cm with sterilized water bottles. The cages are sprayed with wood shavings chips, which are replaced twice a week with care for the cleanliness and sterilization of cages(6). During the study period the environmental conditions were under control . The temperature was
maintained at 24±2 C°. During the period of the study the mice were fed the appropriate ration food with serialized water ad libitum.

Females were assigned for fertilization in a ratio of 1 male/2 females in each cage during the night hours. Next morning females were checked for presence of vaginal plug. Females that have the vaginal plug are isolated in separate plastic cages. Another group of females were assigned for folic acid treatment, females were given 0.002 mg orally on daily bases for one month before fertilization(7). Females who have not been fertilized, used again and they are re-checked for presence of vaginal plug every 12 hours. Followed by the first day of pregnancy, pregnant females were divided into two groups, RA-treated groups and RA + folic acid treated. RA-treated groups divided into 4 subgroups. In subgroup A, B, C and D, on 8th day pregnant mice were administered retinoic acid intraperitoneally in concentrations of 15 mg/kg, 25 mg/kg, 35 mg/kg or 45 mg/kg. Mice received folic acid one month before pregnancy were treated with 35 mg/kg retinoic acid on day 8th of gestation, while control received only distilled water.

The mice were killed on the 18th day of gestation by cervical dislocation. The uterine horns were opened and examined for evidence of fetal death or reabsorption. Embryos were examined externally for any abnormal embryos. For the histological study embryos fixed with natural buffer formalin for 72 hours, the embryos were washed with ethyl alcohol for 70% several times, then dehydration with ascending concentration of ethyl alcohol, clearing, infiltration, embedding in paraffin wax and cut with thickness 5mm and staining with Hematoxylin – Eocene. Finally tissue section were photographed using microscope equipped with an imaging machine.

Results and Discussion

Relationship Between Retinoic acid and Abnormalities

Neural Tube Defect: The relationship between retinoic acid and neural tube defects was highly significant ($x^2$, df, $\alpha = 0.001$) = 17.702. Injection of retinoic acid into pregnant females mice on day 8th of gestation induced defects, at the dose of 15 mg/kg, and the frequency of neural tube defects increased with increasing RA doses to 25 mg/kg and 35 mg/kg, the percentage of NTDs were 28.6% and 61.9 respectively. In all vertebrate, including humans being, the vast majority of the anterior-posterior (AP) axis malformation, which is integral to the central nervous system, is characterized by various form of spina bifida grouped under the general term of NTDs(8). This concept indicates that during neurulation, the primary defects occur, leading to neural tube malformation, NTDs could be observed at all points along the (AP), whereas the most frequently occurring position is the caudal section. Due to the teratogenic potential of retinols and the crucial role of their receptors in the development of embryos, embryopathy due to retinoic acid is intensively investigated.

Spina Bifida: There is a significant relationship between retinoic acid and spina bifida incidence ($x^2$, df, $\alpha = 0.006$) = 10.317. The result showed high incidence of spina bifida with increasing dose concentration of retinoic acid on day 8th of gestation. The result, showed a high percentage of spinabifida for dose 25 and 35 mg/kg which were 33.3% and 66.7%, respectively. While the injection with 15 mg/kg RA did not induced spina bifida.

Spina bifida defects are severe and complex disease of the central nervous system in human being and other experimental animals such as mouse and rat. The high prevalence of spina bifida in infants has been reported in mother treated with high dose of retinoic acid (9). It is still difficult to treat the neurological disorders in spite of increasing the awareness and reduced the incidence due to taken food supplement of folic acid(10).

Exencephaly: There is a significant relationship between retinoic acid and exencephaly ($x^2$, df, $\alpha = 0.19$) = 7.953, the result showed high incidence of exencephaly for dosage of retinoic acid when increased in concentration. The injection of retinoic acid with different concentration into pregnant mice on day 8th of pregnancy induced exencephaly with different percentages. The high percentage of exencephaly was at dose 25 mg/kg and 35 mg/kg, were 10.5% and 38.5%, respectively. While the injection of retinoic acid with 15 mg/kg did not induced any a anomalies.

It was hypothesized that dysraphic disorders could be caused by impairment of growth in the development and progressive elevation of neural folds. Nonetheless, several reports suggested the development deficiency and progressive with elevation of the neural folds is also caused by the negative effects on the neuroepithel(11).

Folic acid: The result showed females received 0.002 mg/day of folic acid for one month before
fertilization decrease the impact of retinoic acid effects on pregnancy. The chi-square analysis showed no relationship between retinoic acid and the incidence of NTDs, when folic acid administered one month before fertilization.

The percentage of neural tube defects within the total abnormalities, for retinoic acid was 86.7% for the treatment of retinoic acid 35mg/kg, while the NTDs were reduced to 13.3% when folic acid was administered to females mice one month before fertilization. Folic acid is an important coenzyme in the normal synthesis of purine and methionine and many other biochemical reaction including single-carbon transfer. Folic acid role is to pass one unit of carbon, which is in amino acid metabolism and nucleate acid biosynthetic purine-pyrimidine. (12) Folic acid can speed up the cells separation during neural tube closure (13).

Histological Examination

Histological Examination of Control: Histological examination sequential sections which showed differentiate the forefront of the brain and differentiate the epithelium of the brain wall into three layers. There are ependymal layer followed by mantle layer after marginal layer. As for spinal cord, it is evidently integrated in elongated central canal and differentiation of gray and white matter.

Histological Examination 15mg/kg of Retinoic acid Brain: Results of histological examination showed no change in the brain tissues (Figure1). A completes differentiation of the brain and differentiation of the brain nerve with differentiation of the brain wall into three layer, which are Ependymal layer followed by mantle layer then marginal layer which represented the white mater.

Figure (1): Histopathological photograph the normal structure of the mouse head on day 18th of gestation brain (B), skull (A)

Spinal cord: The spinal cord is elucidated with the clarity of the elongated central canal. The differentiation of the substance and the gray and white matter. This results match the results of control (Figure 2). Therefore, appearance of embryos malformation depended on the dose of retinoic acid. This results are in agreement with findings of the(14).
Histological Examination 25 mg/kg of Retinoic acid: Although the external examination of embryos showed malformation, but the histological examination did not show any significant change or any damage at concentration 25 mg/kg of retinoic acid. The embryonic histological examination is therefore identical to the control.

Histological Examination 35 mg/kg of Retinoic acid: Histological examination of embryos exposed to 35 mg/kg of retinoic acid injected on day 8th of gestation, obvious change in the tissue showed; Brain

The exam showed absence a large part of the brain, and skull bones. Three layers surrounding the brain, disappeared as well as white and gray matter with lack of skin of the skull (Figure 3).

Figure (2): Histopathological photograph of normal structure of the mouse spinal column on day 18th of gestation spinal column (A), vertebrate (B) and skin (C).

Figure (3): Histopathological photograph of incomplete of the brain (A) skull bone deformity (B).
**Spinal cord:** The exam showed defects in spinal cord (incomplete). The fluid is collected into the spinal canal resulting in expansion of the canal (Figure 4). In addition to that, there are distortion in the distribution of gray and white matter with evident of tissue necrosis.

**Histological Examination (35 mg/kg Retinoic acid + Folic acid):** The histological examination of embryos exposed to 35 mg/kg of retinoic acid showed no change in comparison with control (Figure 5). These study is in agreement with (15).
Abnormalities External: The result showed the injection of pregnant mice with retinoic acid on day 8th of gestation with 15mg/kg caused 20% abnormalities out of 20% abnormalities 66% were small size and length, with unclear face appearance, 34% showed neural tube defects, while 80% of the embryos is similar to that control group. The average weight, length body, tail are 0.79g, 18 mm and 10 mm respectively

While the study showed that injection of pregnant mice with RA on day 8th of gestation with concentration of 25mg/kg induced abnormalities of mice embryos. The percentage of abnormalities was 32%. The average weight, length body and tail were 0.74 g, 17.11mm and 9.5mm respectively, while in control were 0.89 g, 18.79mm and 10.5mm respectively. Out of total abnormalities of 32%, 40% showed spina bifida with limb deformity including 20% anencephaly, 20% prolonged embryos and deformation eye and small ears, 20% severe cured.

In addition to that mice treated with retinoic acid with concentration of 35mg/kg on day 8th of gestation induced significant abnormalities of mice embryos, the percentage of abnormalities was 68%. The average of body weight, body length and tail length were 0.7 g, 17 mm and 8.5 mm respectively, in comparison to control, were 0.89 g, 18.79 mm and 10.5mm respectively. Total abnormalities was 68%, 40% of these abnormalities were spina bifida and limbs deformity including 20% was exencephalic embryos. Prolonged embryos and deformation of eyes and small ear represent 20%, whereas trunk deformity represented 20%. Maternal treatment with a retinoic acid on day 8th of gestation in mice, results in the production of brain and spinal cord anomalies with a varying degrees of severity frameshifted.

Group Treated with 35 mg/kg of Retinoic Acid+ Folic Acid: Females were treated with folic acid in concentration of 0.002 mg/daily for one month before fertilization, and received a dose of retinoic acid of 35 mg/kg on day 8th of pregnancy showed reduced the neural tube defects. Recent clinical studies have shown that the supplementation of folic acid before conception and during the first month of pregnancy can prevent a substantial proportion of NTDs. Studies that followed these trials showed that the first occurrence of NTDs is also reduced by about 60%. In the United States in 1993 Public Health Service advised all women of child-bearing age who are qualified for becoming pregnant should take 0.4 mg/day of folic acid

In conclusions, All doses of retinoic acid caused abnormalities but the percentage increased with increasing the dose of retinoic acid. While Folic acid has inhibitory effect on the teratogenic agent (RA) when it was given to the pregnant mice one month before pregnancy.

Dipeptidyl Peptidase 4 in Women with Polycystic Ovarian Syndrome

Sura Salah Hadi1, Shyamaa Z.Nada2, Mousa Mohsin Allaq3

1Post Graduate/Department of Biochemistry/College of Medicine/University of Kerbala/Iraq, 2Asst. Prof. Dr. Department of Biochemistry/College of Medicine/University of Kerbala/Iraq, 3Asst. Prof. Dr. Department of Obstetrics and Gynecology/College of Medicine/University of Kerbala/Iraq

Abstract

Background: Polycystic ovary syndrome (PCOS) is the most prevalent reproductive endocrinopathy and currently considered to be a part of the metabolic syndrome. Women suffering from PCOS present with a group of symptoms related with menstrual disorder and androgen excess. Women with PCOS cluster risk factors associated with risk of insulin resistance, dyslipidemia, hyperandrogenemia, obesity, cardiovascular disease (CVD), infertility, and psychological disorders. Objective: The study was designed to determine the levels of DPP4 in PCOS patients and compared with control and study the correlation with biomarkers in serum of PCOS patients.

Subjects and Method: The study is case-control included 80 females and carried out from February 2019 till May 2019 for females in the reproductive age [18-45 years old], forty females were came from gynecological and obstetric hospital, in Karbala, and they all diagnosed by their physicians have polycystic ovarian syndrome and compared with forty control females [healthy females]. Plasma activity of DPP4 and biochemical variables were performed.

Results: Results obtained in this study showed that there are significant differences (p < 0.05) in serum of DPP4, SHBG, DHEA-S, LH, FSH, free testosterone and total testosterone and there is positive significant correlation between DPP4 with free testosterone, SHBG, DHEA-S, LH and total testosterone.

Conclusion: Polycystic ovarian syndrome is a higher risk of type 2 diabetic mellitus, dyslipidemia and cardiovascular diseases, Dipeptidyl peptidase 4 (DPP4) was high in PCOS patient and had positive correlation with free testosterone, total testosterone, DHEA-S, SHBG and LH.

Keyword: Polycystic, Dipeptidyl, DPP4, (PCOS).

Introduction

Polycystic ovary syndrome (PCOS) is a female endocrine disorder featuring elevated concentrations of androgen, ovulatory dysfunction1, it prevalence ranges from 9% to 18% in reproductive-aged women based on definitions and populations studied, it is associated with reproductive, (menstrual irregularity, infertility and pregnancy complications), metabolic (metabolic syndrome, type 2 diabetes (T2D) and cardiovascular disease (CVD) and psychological (anxiety and depression).2.

Dipeptidyl peptidase4 (DPP4) or (CD26), is a 110kDa glycoprotein expressed ubiquitously on the surface of different cell 3 Soluble DPP4 (sDPP4) was regarded as a novel adipokine, It is involved in the catalytic degradation of glucagon like peptide-1 [GLP-1], which suggests main function in metabolism3, GLP-1 stimulates insulin secretion and suppresses glucagon secretion, GLP-1 also controls gastric emptying, body

e-mail: haideralbadri@gmail.com
weight in relation to its impacts on glucose homeostasis. Inhibition of DPP4 results in increased concentrations of active GLP-1 and subsequent improvement of insulin release i.e. Vildagliptin increases insulin release rather than increase insulin sensitivity.

**Materials and Method**

The case control study carried out from February 2019 till May 2019 of a total number of 80 females within the reproductive age (18 to 45 years old). forty cases females out of 80 were attended from gynecological and obstetric hospital in Karbala province, and they all diagnosed by their physicians as Polycystic Ovarian Syndrome, (depending on clinical, biochemical and Rotterdam criteria), and they were compared with forty healthy control women.

**Inclusion Criteria:** All PCOS patients have already been diagnosed and the diagnosis has been confirmed by the European human reproduction society and embryology and American society for reproductive medicine criteria.

**PCOS is diagnosed if there are any two of the following:**

- Presence of PCOS on ultrasound examination.
- Menstrual disorders with an ovulation.
- Clinical or biochemical hyperandrogen.

**Exclusion Criteria:**

- All Patients with history of medical condition
- Other disorders that may affect menstrual regularity and hyperandrogenism such as thyroid dysfunction, and pituitary disease that related with hyperprolactinemia.

**Collection of Sample:** Blood specimens were collected; 5 ml venous blood samples were taking during 2nd – 5th day of the menstrual cycle (early follicular phase) for those of normal cycle. For patients with anovulation or oligomenorrhea blood sample were collected regardless of duration of the cycle. Blood samples were left for 20 minutes at room temperature. After coagulation, the serum was separated via centrifuge at (3000 run per minute) for five min., hemolysed samples were discarded. Sera were stored and frozen at - 40°C until analysis.

**Determination of Human Dipeptidyl Peptidase IV (DPP4) Principle:** This ELISA kit uses the Sandwich-ELISA principle. The micro ELISA plate provided in this kit has been pre-coated with an antibody specific to Human DPP4.

Standards or samples are added to the micro ELISA plate wells and combined with the specific antibody.

Then a biotinylated detection antibody specific for Human DPP4 and Avidin-Horseradish Peroxidase (HRP) conjugate are added successively to each micro plate well and incubated. Free components are washed away.

The substrate solution is added to each well. Only those wells that contain Human DPP4, biotinylated detection enzyme-substrate reaction is terminated by the addition of stop solution and the color turns yellow.

The optical density (OD) is measured spectrophotometrically at a wavelength of 450 nm ± 2 nm.

The OD value is proportional to the concentration of Human DPP4. You can calculate the concentration of Human DPP4 in the samples by comparing the OD of the samples to the standard curve.

**Detection range (0.31-20 ng/ml)**

**Results**

A total number of 80 women were taken with age ranged between (18-45) years and divided into 40 infertile PCOS females with and 40 healthy control females, The diagnosis depends on biochemical features (raised LH, LH/FSH ratio and/or increased testosterone, decrease FSH); clinical features include irregular menstrual cycle, hirsutism, and obesity. PCOS has been confirmed by ultrasound.

Comparison between polycystic ovary syndrome cases group and control group in the parameters measured:

The results obtained in this study showed that there is a no significant difference (P >0.05) in FSH and BMI while the results showed that there a significant difference (p< 0.05) in serum total testosterone, free testosterone, SHBG DHAES, LH and DPP4 as shown in table (1):
Table (1): Biochemical parameters in patients with polycystic ovary syndrome compared with control group.

Discussion

Polycystic ovarian syndrome (PCOS) is the most prevalent endocrinopathy of females of reproductive age. PCOS is a heterogeneous disease it impacts at 7 percent of females, According to the National Institutes of Health Office for Disease Prevention 4.

The three main prevalent factors connected with PCOS involve ovulation irregularities, enhanced concentrations of androgen, and cystic ovaries, ovulation problems and high levels of androgen happen in the majority of females with PCOS, in addition, hirsutism, menstrual irregularity, acne, and alopecia are immediately associated with high androgen levels, and the incidence of polycystic ovaries in pelvic ultrasound exceeds 70% in PCOS patients 4.

In this present study, there was a significant increase in the mean of DPP4 when compared patient with control groups at p < 0.05, this results is agreement with the result of 5.

These result indicated that a deregulation of level of DPP4 might be extra feature of the metabolic inequalities related with PCOS, Although PCOS was well defined as IR and hyperandrogen, DPP4 was not different in this group. However, a connection between DPP4 and markers of IR were found 6.

Dipeptidyl peptidase 4 inactivates both incretin hormone (GIP, GLP-1), leading to high blood glucose and insulin resistance, therefore DPP4 inhibitors are used in the treatment of type 2 diabetes several previous studies demonstrating strong association of the syndrome with IR, more than half of patients with PCOS had IR.

DPP4 inhibitors can help patients with diabetes decrease IR, reduce glycosylated hemoglobin androgen levels also correlate positively with IR in PCOS patients because hyperandrogenism induces IR by reducing insulin clearance and increasing lipoprotein lipase activity and triacylglycerol release Compensatory hyperinsulinemia in turn further aggravates hyperandrogenism SHBG lowers free androgen levels by binding free androgens to alleviate hyperandrogenism and IR 7.

The presented study indicate that serum SHBG was a significant decrease in the mean SHBG when compared patients with control group at p < 0.05.

Our results are in accordance with the previous
work done by $^{8-10}$. Who showed that hyperandrogenism carried a significant risk of hyperinsulinemia due to stimulation of ovarian androgen secretion and inhibition of hepatic SHBG production and this results agree with inverse positive correlation between DPP4 and SHBG, figure (4).

The results in table (1) show a significant increase differences in DHES when compared patients with control group compared at p < 0.001.

These results were in agreement with some previous studies$^{11-13}$

Who showed the abnormally high levels of DHEA-S occur in about 20-30% of women with PCOS.

One explanation for elevated DHEAS levels in PCOS might be found in an altered cortisol metabolism. In particular, it has been shown that the peripheral metabolism of cortisol is increased in PCOS due to the enhanced inactivation of cortisol by 5a-reductase or impaired reactivation of cortisol from cortisone by 11b-hydroxysteroid dehydrogenase type 1. This could lead to a decreased negative feedback on ACTH, resulting in increased pituitary adrenal axis activity, including androgen synthesis to maintain normal cortisol levels. Moreover, increased peripheral sulfatase activity has been observed in women with PCOS, which might increase circulating DHEAS levels.

The results of the present study showed a statistically significant positive correlation between DPP4 with DHEA-S.

The results in table (1) show a significant increase differences in total testosterone and free testosterone when compared patients with control group compared at p < 0.05.

Our results are in accordance with the previous work done by $^{14-17}$

Several Studies showed that women with diabetes had higher level of free testosterone comparing women without diabetes. therefore, reduction in the sex hormone binding globulin (SHBG) and high levels of free testosterone are accepted for the occurrence of diabetes type 2 and highlights the relationship between androgens and insulin sensitivity.

Hyperinsulinemia could result in hyperandrogenism by increasing androgen production, decreasing androgen catabolism, or increasing the tissue availability of T by decreasing serum SHBG levels $^{18}$

The results of the present study showed a statistically significant positive correlation between DPP4 with total testosterone figure (1), this is agreement with the finding of studies, and between DPP4 with free testosterone, figure (2). This is in agreement with In this study on case groups when compared with the control groups, found a significant difference in the concentrations of LH hormone p < 0.05 and no significant with FSH $^{19}$ observed that elevated LH and LH to FSH proportion, 75% of PCOS females had an increased LH concentration and 94% increased LH to FSH proportion. These finding is similar to finding of $^{20}$ indicated the plasma LH concentration for females with PCOS is increased. Similar results were found in a study done by $^{21}$ who showed that PCOS females had greater concentration of serum LH than normal females.

The data of the current study showed that there is positive significant correlations between serum DPP4 with LH, figure(3), this result agreement with 6 therefore several studies demonstrated that DPP4 inhibited androgen production by theca cells and also suggested that DPP4 inhibitors reduces pituitary luteinizing hormone and increases the production of SHBG

CT Scan Parameters as Predictor of Ureteric Stone Impaction and Ureteric Injury Post Laser Lithotripsy

Laith Amer Al-Anbary¹, Firas S. Alquraishi¹

¹Lecturer, College of Medicine, Al-Nahrain University/Iraq

Abstract

Introduction: Renal stone are little, firm deposit inside kidney, the stone consist from acid salts and minerals so the stone form in the urinary system it considered the most common reasons of sudden renal colic, Ureterorensoscopic lithotripsy (URS) for removal of stone is considered optimum procedure for patients suffer from renal stones.

Aims: To Study the relation of CT parameters in stone patients and determine which parameters are the valuable in prediction of the Surgical outcome).

Patient and Method: A prospective study conducted of 20 patients with ureteric stones, followed up in urology consultation unit, Data collected from theater room determined by surgeon were: Stone impaction, iatrogenic injury, DJ use. Data collected from CT imaging were Stone number and side, Stone site, Stone diameter, Tissue rim sign, Degree of hydronephrosis and Stone hounsfield unit.

Results: The collected data showed male (60%) predominance over females (40%) The commonest age group was 30-39 years (30%) The results showed that (70%) of stones lies in one ureter but without any correlation with surgical outcome. Regarding Stone Diameter our study showed (20%) of patients with stones >10 mm in axial image all had impacted stones. Regarding Tissue Rim sign >2.5 mm at level of stone site correlate with impaction and injury. Moderate/sever degree of hydronphrosis correlate with impaction and injury.

Conclusions: CT parameters that had strong relation to the surgical outcome in regard of stone impaction and intraoperative iatrogenic injury.

Keywords: CT scan, ureteric stone impaction, ureteric injury, post laser lithotripsy.

Introduction

Renal stone are little, firm deposit inside kidney, the stone consist from acid salts and minerals so the stone form in the urinary system it considered the most common reasons of sudden renal colic, so this type of stone affect any part of urinary system and it formulated when concentrated urine this lead to crystallization of minerals and fuse together, this concentration occur due to mild to severe dehydration. The incidence is raise to about 13% in male and 7% in female at same point. When stone pass from kidney to ureter this lead to shout acute pain but without any tissue damage but the trauma occur due to pain and lead to pass blood, clots, fragments of stone considered so painful. Site of stone inside ureter (near, middle and away) have effect on stone movement and passing. Shock-wave lithotripsy (ESWL), laparoscopic ureterolithotomy, antegrade percutaneous method are management options but the usual management is URS for remove stones. URS

e-mail: laithamer3000@gmail.com
for removal of stone is considered optimum procedure for patients suffer from renal stones. ESWL and URS are together have 80% of success rate. Stone of equal or less than 1 cm ESWL more accurate than URS in stone removal (90% vs 80%), stone of equal or more than 1 cm URS more accurate than ESWL in stone removal (68% vs of 79%). Imaging, therefore, has become an increasingly important tool in the evaluation of patients with flank pain. Before URS all patients most undergo abdominal and pelvic CT scan for evaluation urinary tract CT scan used without contrast and even so the anatomy of urinary tract well show. ¼ of patients with normal radiological findings when examine by Intravenous urography (IVU) show stones. So CT scan more reliable than IVU if there is obstruction when many films need to obtain with little radiation dose, also CT scan useful in diagnose other causes of pain especially AAA (abdominal aortic aneurysm). CT is as simple as passing X-rays through the patient and obtaining information with a detector on the other side. Owing X-rays absorption difference, different tissues seem different when the X-ray film is developed.

Patient and Method

A prospective study involving 20 cases, in the period between 10th of August 2017 to 20th of January 2018, were followed up in urology consultation unit, urology Surgical theater and CT department in Al-Imamein Al-Kadhimein medical city, after which non enhanced CT were done and taken as 1mm thickness films in same hospital by Seimens SOMATOM. The ureteroscopic procedure was done under general or regional anesthesia in lithotomy position. Astiff cystoscopy was done to find ureteric opening and progression of hydrophilic directorwire below fluoroscopic supervision into the renal pelvis or outside the level of calculus. A 6- 7.5 F semi stiff ureter scope (Karl Storz) used for lithotripsy ureter scope. Ureter scope put away to stone, we used for lithotripsy holmium laser (550um) with frequency 8-10 HZ, electrical supply 9.6-16 W AT. Stone was split and recovered and so small fragments were gone for impulsive pass. Dual J implanted when indicated or precausiously. Foley catheter was placed post operatively if needed. After consent have been taken from patient, patient been followed up and surgical parameters were taken as determined by the surgeon (impaction, DJ indication and ureteric injury). CT parameters was optained using Sante DICOM viewer v5.3. Stone site was classified as proximal ureter (above the sacroiliac joints), mid ureter (overlying the sacroiliac joints), distal ureter (below the sacroiliac joints). Stone size was defined as the maximum diameter within the plane of the axial CT section. Hydronephrosis detemrisn using “Society of Fetal Ultrasound, SFU” hydronephrosis grading system, the most common used system. A positive tissue rim sign (periureteric fatstrands) was defined as annular soft tissue attenuation (20 to 40 Hounsfield units) caused by an edematous ureteral wall surrounding the stone. Hounsfield Unit was omitted from CT parameters due to overlap of ranges and different HU in different parts of the stone. This study involved 20 patients, of them 12 were males and 8 females, their ages ranged from 16 to 69 years old, only two stones passed spontaneously and required no intervention, one ureteroscopic procedure was turned to laparotomy. Statistical analysis were used SPSS 23, mean, SD and percentage used for descriptive analysis. For analysis of variables and data we used independent T test for continuous independent data while used Fisher’s exact for categorical data. So P-value < 0.05 mean significant statistically.

Results

Prospective study involving 20 patients; 12 (60%) male 8 (40%) female, most common age group are thirties constituting 30% with mean age 42±15 years old. So (70%) of calculi in the study group lies in one ureter. In regard to stone Diameter 16 (80%) of the study group were less than 10 mm, and only 4 (20%) were equal or larger than 10 mm. Tissue rim sign surrounding stones were found to be less than 2.5 mm in the axial section in 14 (70%) of the cases and only 6 stones (30%) surrounded by more than 2.5 mm edema. Mean was 2.11 mm with standard deviation of 0.979. eleven stones (55%) were having HU less than 1300, while 45% having more than 1300 HU. Most common group associated with stones is mild (grade I, II) comprising 40% of the study group. Stone impaction is noticed in 35% while 10% passed spontaneously with no further management, 55% was not impacted but still required lithotripsy. 60% with no injury after laser lithotripsy and 40% with injury.

Results

There was no impact of age on stone impaction (P-value of 0.553). Stone impaction is not affected by the gender difference with P-value equals 1. When comparing the effect of one stone or more than one on impaction we noticed that there is no significant
correlation with P-value of 0.626, regarding effect of stone side whether in one or both ureters on impaction also was found to be insignificant with P of 0.354. number of stones found to be uncorrelated to risk of ureteral injury with p value of 1. No correlation was significant with P value of 0.62 indicate that no effect of stone site on the iatrogenic injury rate. Within population of 20 patient, 80% of them had stones <10mm in diameter of those 15% where impacted, while the other 20% of patients with stones more than 10mm all had impacted stones, P-value was 0.0072 which aided the significant correlation that state: stone diameter >10mm in axial section provide perfect toll for suggesting impaction of stone, as shown in table 1.

Table 1: Stone diameter as predictor of ureteral stone impaction.

</table>
Mild and no hydro nephrosis associated with only 5% of iatrogenic injury due to ureter scope and or lithotripsy, while those with moderate to severe hydro nephrosis (according to SFU system) associated with 35% of different levels of injuries, P value was 0.0008 which aid the state that moderate and sever degrees of hydro nephrosis associated with more iatrogenic injuries.

**Discussion**

On our study of the 20 patients the prevalence of renal stones were more common in males (60%) than females (40%), in study done in southern Punjab, Pakistan were on 1176 patients with stones prevalence in males were (74%) and in females (26%)12. The high prevalence of renal calculi in males in this study can be described by the effect of sex hormones on some other lithogenic risk factors13, with no effective correlation between gender and surgical parameters, especially stone impaction. Most common age group were 30-39, which also constitutes the majority of southern Punjab study, with mean age of 41.45±14.1113 while that of our study were 42±15 with other studies near that range, one of them were in same hospital 14, with no effect of gender on surgical parameters especially stone impaction15.

In regard of stone side the result showed that (70%) were in one ureter whether one stone or more, in a study done in the same hospital in 2006 were including 184 patients, 65.8% of them were having stones in same side16, in other study for complications of laser lithotripsy showed that there were no effect of side of stone on surgical outcome15, neither our study showed any correlation. Half (50%) of stones in our study group were in the distal ureter, fifteen percent of them were impacted ureter, 46% of patient in a study done at Thanjavur medical college and hospital having stone in distal ureter, and (37%) in proximal ureter17, other study in Netherlands showed (52.5%) in distal ureter which showed also that there is no correlation of stone location to the surgical impaction or DJ use and iatrogenic injury as our results confirmed statistically17.

Stone size smaller than 1cm were noted in (80%) in our study, and (86%) in study of Thanjavur medical college, while those larger than 1cm in diameter were only (20%) in our and (14%) in their study13, never the less, outcome of our analysis result that stone diameter has direct contribution to stone impaction and ureteric iatrogenic injury. American Urological Association/Endourological Society guild line suggest that stone >10mm will mostly require surgical intervention due to impaction19, study of Utrecht medical center concluded that the stone size doesn’t affect the surgical outcome which refute our results 15. Tissue rim sign was used in other studies as a sign for stone presence or absence, never used as predictor for outcome of lithotripsy, although its absence doesn’t exclude the presence of stone20, our results showed statistical correlation between tissue rim sign>2.5mm in diameter at the level of maximum stone diameter with stone impaction and iatrogenic injury. Degree of hydro nephrosis results in our study showed that whenever there is moderate or severe degree (grade III or IV) there will be impacted stone as well as more risk to have iatrogenic injury.

Risk of Incident Rheumatoid Arthritis Related to Anemia and Associated with CRP

Maryam Kadhim Al-Shemery

Lecturer of Medical Physiology/Department of Medical Laboratory Technique, Collage of Medical and Technique, Islamic University-54001 Najaf, Iraq

Abstract

Background and Objective: Rheumatoid arthritis (RA) is a chronic systemic inflammatory an autoimmune disease characterized by the articular and extra-articular manifestation as weight loss, fatigue, malaise, and anemia. This study aimed to find the prevalence of metabolic syndrome in its correlation with the disease activity among patients with RA in Al-Najaf province and to determine the associated risk factors this study including 75 Subjects was 50 suffering from rheumatoid arthritis and 25 subjects were healthy. Full blood count, erythrocyte sedimentation rate platelet count was determined using standard hematologic method. The result in this study exhibits there is significant decrease in (hematological characteristic) RBC number, while increase in WBC number spatially neutrophil, platelet, glucose and ESR in patients with arthritis in comparison with control. This result indicated that no significant difference (P>0.05) in the mean hematological characteristic RBC number, WBC number spatially neutrophil, platelet when compared with between Positive and negative C –reactive protein in patient with arthritis. The results revealed a significant increase (P<0.05) in mean of ESR of patients with positive C –reactive protein in compared with negative C –reactive protein in patient with arthritis.

Conclusions: Rheumatoid arthritis patients have a variety of abnormalities in hematologic characterize. RA disease can be linked with anemia of chronic inflammation, leukocytosis, and thrombocytosis. Also, in our study, we concluded that little evidence found between disease activity and anemia. ESR and C-reactive protein related to the activity of RA disease.

Keywords: Rheumatoid arthritis, anemia, ESR and C-reactive protein.

Introduction

Rheumatoid arthritis (RA) is a common immunity and inflammatory disease the studies on RA is focused on the earliest stages of the disease and has provided strong evidence that clinical signs and symptoms may be preceded by a preclincial phase during that evidence of systemic autoimmunity may be present. This disease was developed in a series of phases. The first of these phases is suggested with the presence of risk of genetic and environmental factors. In the second phase, autoimmunities such as autoantibodies and autoreactive cells were detected in the blood; also, the study predicted that the mucosal sites are the initiation site for developing that autoimmunity. So, this autoimmunity measured in the blood by serologic or another testing inpatient that characterized by an expansion of inflammation, autoimmunity, and symptoms. Finally, inflammatory arthritis that clinically detectable classified as RA.

RA is an autoimmune disease so that the immune system inpatient starts attacking itself and causes chronic inflammation when directed against the joints that lead to the releases cytokines, chemokines, complement proteins, growth factors and, matrix metalloproteinases among others. These factors not only remain the activation of the synovial cells while also induce from of new immune cells. These immune cells can destroy the extracellular matrix of cartilage and bone, causes joint deformation.

The diagnosis of RA is not constantly clear to estimation, and patients are occasionally suffering from the symptoms of disease several years before they are
diagnosed. The classification of RA requires that patients fulfill several criteria. These were already shown in 1987 and have recently been revised and explained by the American College of Rheumatology and European League Against Rheumatism, in the 2010 Rheumatoid arthritis classification criteria.(4)

Materials and Method

This study was conducted in the Al-Sader teaching hospital in ALNajaf, Serum specimens were collected from patient with rheumatoid arthritis in addition to control group.

**Study Design:** The samples tested were (75) samples divided to control group were (25) samples and (50) rheumatoid arthritis begin from the(1 to 45) years, the age of rheumatoid arthritis patients.

**Collection of Blood Sample:** Blood samples were drawn from vein by sterilized synergies with 5 milliliters. The sample put in the labeled tube. Blood was left at room temperature for 10 minutes for clotting, centrifuged 6000 rpm for 15 minutes, and then serum was separated and freezing at -80 °C until time for performed the laboratory analysis for study.

**C-reactive protein (CRP) and serological test rheumatoid factor (RF):**

Rheumatoid factor latex serological test and C – reactive protein were measured by agglutination test

**Erythrocyte sedimentation rate (ESR):** The Westergreen method was used as described by (Cheebrough,2004). When anticoagulated blood is left to stand undisturbed for 1 hour the red cells sediment gradually to the bottom of the tube leaving clear plasma on top and the distance occupied oy the supernatant plasma is determined.

**Assessment of Complete Blood Count (CBC):** Complete blood count was conducted on anticoagulant blood utilizing Mythic™ eighteen (Ringelsn co., Turk) in Haematology Laboratory.

**Statistical Analysis:** The data were statistically analyzed through SPSS package (SPSS, Version 23) at significant P<0.05. t-test was used for comparison between two groups while multivariate ANOVA has been used for the comparison among subdivided groups in the measured parameters.

RESULT:

**Hematological Characteristics of study subject:** In this study, a total of 75 cases consisting of 50 patients with Rheumatoid arthritis and control 25 were examined. As shown in table (1),The patients had ages ranging between 1 to 55 years. As illustrated in sametable, there is significant decrease in (hematological characteristic) RBC number, while increase in WBC number spatially neutrophil, platelet, glucose and ESR in patients with arthritis in comparison with control.

**Comparison of the clinical characteristics between Positive and negative C–reactive protein of study subject:** Figures (1, 2, 3 and 4), explained the general characteristics of the studied groups when compared between Positive and negative C –reactive protein in patient with arthritis. This figure indicated
that no significant difference (P>0.05) in the mean (hematological characteristic) RBC number, WBC number spatially neutrophil, platelet when compared with between Positive and negative C–reactive protein in patient with arthritis. The results revealed a significant increase (P<0.05) in mean of ESR of patients with positive C–reactive protein in compared with negative C–reactive protein in patient with arthritis.

Figure 1: Comparison of the hematological characteristics between patients with positive and negative C–reactive protein

Figure 2: Comparison of the Hb between patients with positive and negative C–reactive protein
Discussion

The result of current study showed there is significant decrease in RBC number while there is non the significant decrease in Hb mg/dl in patients with arthritis in comparison with control. The most common risk that developed in rheumatoid arthritis was Anemia which becomes less due to the newer drugs in many countries. (5) Another study suggested that rheumatologic disorders patients with hematologic abnormalities suffering from anemia of chronic disease which asymptomatic, and also iron deficiency anemia.(6,7) Though, Anemia in RA is a type of chronic disease that is often careless in clinical practice.(5) The study of Talukdar et al. (2017) was predicted that Hb is lower in patients with high activity of RA disease.(8)

The result of current study showed there is significant increase in (hematological characteristic) WBC number spatially neutrophil, platelet, and ESR in patients with arthritis in comparison with control. The current study
agreement with result of Ismail et al. (2020) study(9) which revealed that RA patients had significantly higher in the count of WBCs, Neut. cells, ESR, RF,CRP and Creatinine in comparison with HCs while levels of HDL and Hb were slightly lower in patients with RA than in the HCs.

This results supported the previous observations which speculate that the white cell counts, lymphocytes percentages, and thrombocytes have a significant increase in RA patients contrasted with controls subjects. Cascão et al.,(10) corresponded with current investigations in that the white blood cell assumes an essential role in the RA initiation. Truth be told, polymorph nuclear leukocytes are the abundant leukocytes in the patient’s synovial fluid, then in the early stage of discuses, the polymorph nuclear leukocytes indicate altogether bring downapoptosis levels (11).

While other study suggested that Anaemia was common at RA diagnosis with neutropenia and lymphopenia. This study also developed a concept that the lymphopenia and anemia linked with elevated the risk of infection in RA patient.(12)

Our outcomes additionally uncovered thrombocyte levels increased related to all patients suffering from inflammation of the rheumatoid joint. Gasparyan et al.,(13) have suggested that in RA the thrombocytosis and thrombocytes-inferred proteins inside the synovia and synovial liquid. Also, Dakhil et al.,(14) explain an increase in platelets as firmly identified with fiery markers, and suppose the main part in the pathogenesis of RA disease.

The result of present study showed that 42.85% of subject study with positive C-reactive protein (CRP) and 58.15 of subject with negative C-reactive protein. In some disease with acute infections and inflammatory process C-reactive protein (CRP) produced by the liver. In this study, the level of CRP elevated with a simultaneous raise of ESR(15). The cytokines synthesis in inflammation, particularly interleukin-1, elevate the production of CRP and decline serum albumin and transferrin synthesis.(16) Rheumatoid arthritis (RA) is a systemic inflammatory disorder in which raised C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) suggest active disease.(17)(18).

The Prevalence of Metabolic Syndrome and its Complication in Patients with the Blood Disorder

Rusul Ali AL-Masaoodi¹, Jasim M. Saleh²

¹Lecturer, ²Assist. Lecturer, Department of Medical Laboratory Technique, Collage of Medical and Technique, Islamic University-54001 Najaf, Iraq

Abstract

This study was carried out with (60) samples divided into control group (20) samples ranging from (2-29) years, (40) samples from patients with blood disorders. The age of the patients with blood disorders ranged from (2) to (29) years. The current study that divided the sample of patients by age into three categories (2-7y), (8-13y) and ≥14y, also by spleen condition to splenectomized and unsplenectomized in patients with blood disorders. This study estimated Hb, ALT, AST, and ALP levels in patients with blood and control group disorders. In this analysis the hemoglobin association with ALT, AST, was found. The current study decreased significantly (p<0.05) in Hb but significantly (p<0.05) increased in concentrations of ALT, AST, and ALP. Significant negative association (p<0.05) between Hb level and ALT, AST, was found in research. This study concluded that patients with blood disorders may have metabolic syndrome due to liver damage.

Keyword: AST, ALT, thalassemia, Sickle cell anemia, metabolic syndrome.

Introduction

Metabolic syndrome (MetS), also condition X description, Deadly quartet, Reaven’s syndrome. It is defined as an energy use and storage disorder, and finding suggests that around 20-25 percent of the world ‘s population are suffering from MetS. Persons with metabolic syndrome are at high risk of developing cardiovascular disease, stroke and disease associated with fat accumulation in the walls of the arteries. In fact, persons with MetS have twice the risk of developing heart disease or/and five times the likelihood of developing diabetes with people without the condition or/and three times the risk of suffering a heart attack or stroke.[1]

Certain meanings of Metabolic syndrome (MetS) may refer to a cluster of metabolic disorders including hypertension, central obesity, insulin resistance and atherogenic dyslipidemia. The condition has linked incremental changes of certain disorders such as atherosclerosis. MetS pathogenesis includes both genetic and acquired factors which play a role in the final inflammatory pathway leading to cardiovascular disease (CVD).[2,3]

The most significant in the production and pathogenesis of insulin resistance and the pathogenesis of type 2 diabetes (T2D) and metabolic syndrome is obesity defined as an increase mass of adipose tissue. Recent study reveals that the equilibrium between white fat, which is a significant energy storage site and brown fat, is the site of energy consumption.[4,5] At the other hand, insulin resistance and metabolic syndrome can also be associated with lipodystrophy, i.e., total or partial loss of body fat.[6]

Insulin resistance plays a major role in MetS pathogenesis as it increases circulating free fatty acids (FFA). Insulin raises muscle and liver glucose intake and reduces lipolysis and hepatic gluconeogenesis. Insulin resistance in adipose tissue inhibition insulin-mediated lipolysis inhibition, resulting in increased
circulating FFAs which further inhibit insulin’s anti-lipolytic effect.[7]

Thalassemia can be characterized as a genetic anemia caused by mutation in the hemoglobin portion of the globin and protein synthesis. In many parts of the world, this illness causes massive public health problems. In one of the globin chain, thalassemia can be separated by that the hemoglobin synthesis, leading to imbalance in the synthesis of the globin chain, unsuccessful erythropoiesis, hemolysis. The major thalassemia forms are α, β, β, π, and β. The extent of thalassemia depends on the number of genes in the alpha and beta globin chain that have been damaged.[8]

Persons with thalassemia who lack sufficient globin chain synthesis leading to their red blood cells may be abnormal and unable to carry sufficient oxygen throughout the body.[9]

β-Thalassemia was known to be the most hereditary anemic disease, arising from β globin gene mutations. β-Thalassemia-associated anemia is caused by reduced β-globin chain synthesis, increased erythrocyte degradation, and limited RBC survival.[10] This condition is linked to numerous secondary complications, such as extramedullary hematopoiesis, splenomegaly, iron overload, and blood-borne infections.[11]

Sickle cell disease (SCD) refers to a category of hereditary blood disorders that cause extreme pain, decrease the life expectancy and require extensive self-management, but are also associated with stigma and prejudice. These include abnormal forms of hemoglobin which, when deoxygenated, polymerize, or gel, making the red blood cells stiffen and elongate into a sickle or crescent shape. It disturbs circulation, starves the damaged tissue and oxygen systems and causes very intense acute pain. The spleen, a critical part of the immune system, is very vulnerable to sickling, and people with SCD are susceptible to inflammation, chronic anemia and a number of life-threatening complications.[12]

Materials and Method

This study was conducted at the Al – Zahraa Teaching Hospital in Al – Najaf province, Iraq, Thalassemia Center. In addition to the control group, serum specimens were collected from patients with blood transfusion. The samples tested were (60) samples divided into control groups, (20) samples started in (2-29) years, (40) samples were taken in patients with blood disorder. The age of patients with thalassemia began in the (2) year to age (29) year.

Cases from the study can be divided by age and splenectomy.

The collection of blood sample: The Blood samples were drawn from the vein with 5 milliliters of sterilized synergies. The sample placed in the first group of tubes, two labelled tubes, contains EDTA as anti-coagulants to avoid blood clotting to be used for physiological tests. The second group of tubes was for blood to be used to prepare serum for following biochemical and biomarkers, without an anti-coagulant as gel tubes. Blood was left to coagulate at room temperature for 10 minutes, centrifuged 6000 rpm for 10 minutes, then isolated serum and freezed at -80 oC before the laboratory analysis was performed for testing.

Hemoglobin Estimation: The hematological parameters were carried out on EDTA blood using Mythic 18 (RINGELISA N CO., Turkey) in Al-Zahraa Teaching Hospital’s Hematology Laboratory. This device is a fully automated hematology analyzer estimated total blood count (CBC) on anticoagulated blood from EDTA.

Determination of Biochemical:

Estimation of ALP-concentration: It was achieved using a system supplied by JTC Germany based on enzymatic colorimetric examination, performed with different test kit.

Estimation of AST-concentration: This was achieved by an enzymatic colorimetric test-based process, performed with a different test kit, supplied by Bio system-Spain.

Estimation of ALT-concentration: This was achieved by an enzymatic colorimetric test-based process, performed with a different test kit, supplied by Bio system-Spain

Statistical analysis: The well-known statistical method (Graph Pad prism ver. 5) was introduced, and the study of variance table one-way ANOVA (by Tukey’s multiple comparison test) was used in the calculated parameters for comparison between subdivided groups. The findings were expressed as (mean ± Error of the Stander). Comparison among Subgroups . The t-test was evaluated. Coefficients of correlation were determined to estimate the correlation between markers and parameters.
Comparison of ALT, AST and ALP in patients with blood disorders and control group: The result in table (1) shown significant increase (p<0.05) in liver function test ALT (243.9 ± 23.07), AST (50.56 ± 5.513) and (256.7 ± 23.72) in patients with blood disorders compared to control group (42.40 ± 1.477), (30.60 ± 0.9526), (25.25 ± 0.9087) respectively.

Discussion

In this study, patients with blood disorders suffer from thalassemia, sickle cell anemia, and aplastic anemia. In this study reported substantial decrease (p<0.05) in the amount of hemoglobin in patients with blood disorders compared with control group. It is in line with the Arshad et al. (2014) research, which indicated that patients with thalassemia may have decreased Hb level due to decreased erythrocyte numbers and decreased RBC index values (MCV, MCH, MCHC, HCT).[13]

Thus, in the analysis of Ashley-Koch et al. (2000), these patients suffer from anemia due to less oxygen content in the blood, exposing the irregular types of hemoglobin that polymerize, or bind, when deoxygenated, making the red blood cells stiffen and elongate into a sickle or crescent shape. It disturbs circulation, starves the damaged tissue and oxygen systems and causes very intense acute pain.[12]

In the study revealed a significant increase (p<0.05) in the concentration of ALT, AST and ALP in patients with blood disorders compared to control group, in the current study all patients receive blood transfusion, Current results agree with Zayed, (2018) who suggested that blood disorders may be causing liver tissue lesions indicated by elevation of the criteria for serum liver function.[14]

Metabolic syndrome may be correlated with the previous study demonstration of ALT, AST, and ALP, which showed increased concentration of this biochemical in patients with metabolic syndromes. Increased concentration of ALT and gamma-glutamyltransferase (GGT) has been shown to predict CVD in prospective studies. MetS has been indicated to be a risk factor for CVD, and the incidence has risen in developing countries, and associations between serum liver enzymes and MetS have received significant attention in recent years, which has shown that the rise in serum ALT and AST has been sluggish.[15,16]

Monteiro et al. (2014) revealed that serum ALP activities were significantly associated with high triglyceride and low HDL-cholesterol in men in this study, while serum ALP activities were significantly associated with abdominal obesity, high blood pressure, high plasma glucose, and high female triglyceride.[17]

Blood transfusion therapy was needed in most blood disorders such as thalassemia and sickle cell anemia, which contributed to iron overload in patients. Liver is the first iron overload site in children who are routinely transfused, and a common cause of morbidity. Iron surcharge occurs in both hepatocyte and reticuloendothelial cells. Iron-induced damage to the liver is characterized by progressive fibrosis, and ultimately cirrhosis. Liver damage in thalassemia induces low serum levels of total cholesterol, high density lipoproteins (HDL), and low density lipoproteins (LDL).[18]

Das et al. (2016), the latest study showing patients with thalassemia have hypertriglyceridemia, this may be an early atherosclerosis development that contributes to morbidity. The increase in TG concentration in these patients is related to oxidative stress and an increased risk of acute pancreatitis and cardiovascular diseases. Therefore early recognition is important. The rates decreased in our patient following a transfusion therapy.[19]

From above studies which revealed the positive correlation between metabolic syndrome and blood disorders, therefore the complication of most blood disorders is Metabolic syndrome can progressive to other diseases such as cardiovascular diseases, also suggest to use the liver function test to detect the Mets in patients with blood disorders. In the present study shown the significant negative correlation between ALT and Hb, also significant negative correlation between AST and Hb in patients with blood disorders. In thalassemia have low Hb levels which cause less supply of oxygen to tissue and leading to more anaerobic glycolysis, reason for more lactic acid levels. [20] Sucrose is a non-reducing disaccharide of glucose and fructose and is linked to various metabolic pathways of glucose and other sugars. As it is broken down into its constituents fructose and glucose and its increase in blood indicates metabolic syndrome, mostly in β-thalassemia patients glucose homeostasis is abnormal this may result in its elevation.[21]

Conclusion

The conclusion of this study, that demonstrated the patients with blood disorders can be have metabolic syndrome result from dysfunction of livers because increase the concentration of iron. the recommendation of this study is each patient with blood disorders, must made routine clinical tests for lipid profile. to avoid progressive to metabolic syndrome

Effectiveness of Health Education Intervention Regarding Family Planning Among Iraqi Women Attending Primary Health Centers In Baghdad During 2019

Lujain Anwar Alkhazrajy¹, Sarah Waleed Mizher², Alak Mohammed Alabayechi³

¹Associate Professor/Consultant Family Physician/Family and Community Medicine Department, Alkindy College of Medicine/University of Baghdad, Iraq, ²Family physician/Medical City Directorate/Baghdad Teaching Hospital/Iraq, ³MD/Baghdad teaching Hospital/Ministry of health/Iraq

Abstract

Background: Family planning has become a major strategy of population control both at the national and global level.

Objectives: To examine the impact of health education intervention regarding family planning on knowledge among pregnant Iraqi women.

Methodology: A quasi-experimental study was conducted at three primary health care centers in Baghdad with sample size of 90 female who were chosen by convenient sampling technique, with 2 groups: 60 lady in control group and 30 lady in intervention group. Along seven months duration, data were collected using a questionnaire which was adopted from many literatures with modifications, Chi-square and Fisher Exact test was used to test association of variables with a P. value <0.05 considered statistically significant.

Results: The age of the studied ranged between (26-35 years). The level of education for both groups was college and above degrees, (55%), with negative history of consanguinity, the control group had poor knowledge about family planning, the intervention group showed higher knowledge score than the control after the intervention. While no significant association was found between knowledge score of the participants of the whole studied sample and its socio-demographic variables.

Conclusions: Married women with highest number of children having more information about family planning than single women. Health education significantly increases the knowledge of women about all types of family planning and improves attitudes towards family planning and their usage.

Keyword: Health education, family planning, primary care.

Introduction

Global community has decided that the exact to health involves the right to regulate one’s health and body include sexual choice (1). Family planning has become a major strategy of population control both at the national and global level (2). Big families and quickly breed in inhabitants hold back progress at both the home and state portion, even so family scheduling systems are obtainable, females not take it due to economic limitations, individual opinions and antagonism from family associations or fears about the specious contrasting properties on well-being or upcoming fertility. The family planning programs helped pave the way for much subsequent health, social, and economic programs, they helped establish the feasibility and legitimacy of mounting large-scale interventions (3).

e-mail: lujainalkhazrajy@kmc.uobaghdad.edu.iq
Definition of Health Education: Health professionals and others impart information to patients that will improve their health status or alter their health behavior by a process. Iraqi family planning Organization was established in 1971, and Iraqi ministry of health initiated family planning program at 1974-1981, but till now Iraq have unmet need for family planning as the official united nation site for the millennium development. The solutions to active and supportable family-planning sequencers are fine recognized: high quality governmental assurance, a wide-ranging union of support from choice collections; sufficient finance; reduced families members and modern contraceptives done by mass broadcasting etc.; and creation a variety of procedures obtainable through medical services, public selling, and outreach facility. Accessible evaluations refer that admission to PHC in Iraq is insufficient, the level of perceived quality is low, the level of physical organisation is not well demand and wants chief cares, purpose is obviously incomplete, low level of drug supply, and not always the crucial facilities found. PHC schedules reinforces the MOH exertions with concentration on family training perfect of deal transfer, and promotions MOH in the Conclusion of Well-being Info Arrangement and Human Incomes for Well-being strategies. Aim of the study to examine the impact of health education intervention on family planning on knowledge about family planning among Iraqi women.

Method

Experimental Study, 90 female was conducted from the 1st Dec. 2018 to the End of July 2019 at three primary health care centers of family medicine in Baghdad at Alrusafa health Directorate (AI-Mustanseria, Alselaihk 1st, Al- Alselaihk 2nd PHCCs). 90 women with two groups: 60 woman in control group and 30 woman in intervention group. Inclusion Criteria: all Iraqi females attending PHC centers at child bearing age (14-45). Exclusion Criteria: any female who did not meet the above mentioned inclusion criteria automatically excluded from the study. Direct interview and specially designed questionnaire that derived from previous literatures, with some modifications that was done by the researches and validated by three experts of family and community medicine. General Sociodemographic Data: sector, PHC name, age, marital status, number of children, breast-feeding or not, educational level, occupation, consanguinity with the husband. Knowledge Section: consists of 33 questionnaire divided into 3 parts; part 1: definition of family planning (male and female types, mechanical and hormonal types), part 2: involved family planning types specifically used by female, part 3: involved family planning types specifically used by male including these questions varies between multiple choice or tabulated pattern consist of (yes, no, i don’t know) to assess people knowledge about family planning. To assess the knowledge, scoring system used were each correct answer scored as 1, incorrect answer or “I Don’t Know” scored as 0 as follows: ≤ 16 = Poor, 17-25 = Fair, 26-33 = Good.

Statistical Analysis: Done by using (SPSS) V.23 descriptive statistics used, t-test used to check if there was any difference in sociodemographic characteristics between control group and intervention group. Chi – Square and Fisher Exact Test used to test association of variables with. P- Value < 0.05 considered statistically significant; also, ANOVA test used for comparison of knowledge score for the study sample groups.

Results

The study was conducted on 90 participants, of them 30 participants were assigned as intervention group and 60 were assigned as control group more than half of the studied sample had age that ranged between (26-35 years), nearly all the studied sample had less than five children most of the participants were married. The highest level of education for both groups was college and above degrees, were it reaches nearly 55% while illiterate participant form about (3.3%) as shown in (table 1). Regarding occupation, 56% of the intervention group were housewives while 51% of the control group were employee. Nearly 85% of the whole sample did not breast fed their children, with negative history of consanguinity (table 1). In the current study, it was found that the control group had poor knowledge about family planning (45%) shown in (fig1). There was no significant variation between the two groups regarding the demographic variables of the study, as shown in table (2) . The study showed that there was no significant association between knowledge score of the participants of the completely studied sample and its Sociodemographic variables, as shown in table (3). There was a statistically significant difference between percentages of means of the three groups. Were the interference group showed advanced knowledge score than the control after the intervention? (Table 4). There was significant difference for the intervention group regarding knowledge about family planning before (59.39 %) and after (93.1 %) intervention (table 1).

Discussion

Family planning is one of the greatest development and public health favorable outcome of the past 50 years. It has transformed and saved the lives of millions of children and women, it has helped to slow down population growth, and it has hold up families to break the cycle of poverty (10). The study revealed that Iraqi women had poor knowledge level about family planning, as less than half of them answered correctly regarding questions related family planning method, but the reviled level is still higher than that of the study done in Erbil on two groups the Score of knowledge in 2 groups G1 7.7% and G2 14.0% G2(8). Similar studies were conducted in Australia (9) also a low level of knowledge and in Egypt (10) showed that about EC most of the study subjects (75.5%) lack the knowledge about EC method, on the other hand other studies were in consistent with our results, like the study done in Sudan (2016) were highly score of knowledge level about family planning 91.3% (11), also the study done in Nigeria from (2003-2013) the knowledge level highly proportion 75% (12). Association between knowledge of the Iraqi Women Regarding family planning and their socio demographic data: there was no significant association between age and knowledge of participants regarding family planning in our study, while in a study done in Northeast Ethiopia showed that, the age of the participants had an association with practicing family planning (13). There was no significant association between Marital status and knowledge of participants regarding family planning in our study, while in a study done in Afghanistan that showed the participants who had job knew more about family planning method than who did not have a job (15). No significant association between the knowledge and educational level of participants, this was in consistent with the study done in Mosul were there increase percentage of knowledge about unmet need from illiterate 34% to high education group 60% (16). And also study done in Ethiopia (17) and Egypt (18) and Baghdad city (19) were the educational level of the mother and her husband has been identified with a highly significant relation to increase knowledge of the use of FP also another study done in Saudi (20) and Ghana (21). No significant association between breast-feeding and knowledge of participants regarding family planning in our study. Similar to our study done in chufa their knowledge about breast-feeding was a non-significant and poor knowledge about breast-feeding (22). In Our study, the knowledge scores of the intervention group were higher than control group, and the significant statistical difference between the groups. By using, the interference program that promoted health education about family planning in our study the score of health education was (59.39%-93.13%) For pre and post intervention, respectively these results were similar to research studies done in Nigeria increase knowledge in intervention group (36.6%-44.6%) in pre and post intervention groups respectively (23).

Conclusion

Married women with highest number of children having more information about family planning than single women do. Health education significantly increases the knowledge of women about all types of Family planning and improves attitudes towards family planning and their usage.

The Correlation of Epicardial Fat Thickness with Ischemic Heart Disease among Patients Consulting Merjan Medical City in Babil

Hassan Salim Aljumaily¹, Abdulhamza Rajooj Hmood²

¹Ass. Prof., College of Medicine, Babylon University/Iraq, ²Ass. Prof., College of Medicine, Karbala University/Iraq

Abstract

Introduction: Epicardial fat thickness (EFT) is regarded as marker of cardiovascular risk.

Aim of Study: To show if there is correlation between EFT with ischemia and its correlation with other variable as age, sex, hypertension, Diabetes, smoking and Body mass index.

Patients and Method: We studied 100 patients who consulting merjan medical city in Babylon province for the period from December 2017 to May 2018. Transthoracic echocardiography was done for all patients; we measure wall motion score and EFT. 50 patients had ischemic heart disease (IHD). EFT measured at free wall of RV at end systole both group from short axis view and long axis view and wall motion score also measured according to this formula.

Results: Mean age was (58.67±13.3), 50% had hypertension, 45% had diabetes .74 patient were male 37% are smoker regarding body mass index, 31.87% are obese, 31.87% over weight 36.2% are normal body mass index. PT with no IHD had normal wall motion score 16/16 While IHD group PT had higher than 16-wall motion score. EFT had significant correlation with high ischemic score, EFT was higher among smoker patients(p value 0.001) and diabetic patients(p value 0.005) and hypertensive patients (p value 0.002). Patients with increasing BMI had higher EFT(p value 0.001).

Conclusions: This study concludes that patients with higher EFT had higher ischemic score, so it is arisk factor of IHD. EFT more than 5.5 in male and 5.7 in female associated with ischemia. Epicardial fat increase with higher BMI and more in smoker,HT and diabetic patients.

Keyword: Epicardial fat thickness, ischemic heart disease, echocardiography.

Introduction

EFT has been designated as a risk factor for CAD(1) and predictor for the presence of cardiovascular insults(2), its site between visceral pericardium and the myocardium. Studies show that epicardial fat immediately surrounds the coronary arteries it postulated that it produce substances that act as an endocrine organ secreting hormones like bio active chemokines and adipokines(3) which predispose to coronary artery disease consequently EFT may have significant role as risk factor in patients presenting with chest pain. EFT can be calculated by TTE, cardiac (CT), and cardiac MRI. Assessment by TTE has come to the front because of many benefits, like availability, lesscost; there is no exposure to radiation. EFT illustrated by TTE is the echo-lucent area between the visceral pericardium and myocardium of the right ventricle appear above the right ventricular free wall as a thick line(4,5). While assessing epicardial fat (EPF), necessary to differentiate it from pericardial adiposetissue, both emerge from different embryonic sites, their local circulation and bimolecular...
characteristics are different\(^6\). Anterior to EPF and parietal sheet, there is pericardial tissue (hypoechoic zone)\(^7\). EPF not interfere with cardiac cycle so it can simply separation. EFT have transparent and spotted appearance on Echo and Pericardial effusion highly hypoechoic\(^8\). Difference studies about EFT thickness\(^9\) stated that EFT width designed throughout end – systole it is (1-22.6) mm, mean is 6.5 mm in females, 9.5 mm in male\(^7\). The concept is that EFT play a role in the incident of ischemic heart disease through correlation with other risk factors and by direct paracrine and other endocrine effects. This theory was suspected many years ago illustrating there is no atherosclerosis inside myocardial only\(^10\). Coronary arteries with no EFT detached from it by abridge of myocardial tissue that save from progress of atherosclerosis. Loss adipose tissue in myocardium consider important protection mechanism against atherosclerosis in intramural coronary artery while epicardial coronary arteries have adipose tissue so it more likely to have atherosclerosis. EFT give feature of atherosclerosis by discharge of bioactive molecules and specialmechanical factor in coronary arteries\(^11\). Because of its intrinsic compressibility epicardial fat suggested to play significant role in the vessel wall expansion called positive remodeling. Coronary injuries, which are bounded by the epicardial fat, have expanded more than injuries bounded by the myocardium\(^12\).

### Method

A cross sectional study 100 patient were studied whom consulting merjan medical city in Babylon province for the period from December 2017 to May 2018. Half of patients had IHD. Medical history of HT, D.M, gender and smoking obtained and their age recorded. Blood pressure was measured by mercurial sphygmomanometer hypertension when SBP\(\geq 140\) mmHg, DBP\(\leq 90\) mmHg or need for anti-hypertensive drugs, body mass index was calculated as BW in kilogram divided by height squared\(^13\). DM according to criteria of American diabetic association as FBG >126 mg (\(>7\) mmol/dl) or patient with classical symptom of hyperglycemia with random plasma glucose > 200 mg /dl or (\(>11.1\) mol/dl)\(^14\). Lipid profile not assessed because most patient with ischemic heart disease on lipid lowering age.

**Echo Measurement:** TTE were performed with GE vivid E9 echo devise instrument according to standard technique with patient in left lateral side to measured EFT on RV free wall from parasternal long and short axis view we assess the finding three time and we take the mean. this assessment obtained under supervision of two cardiologist. We prefer to measure at end systole because compression of EPF occur during diastole. Also by echocardiography, we assess wall motion abnormal wall motion that can be classified as (2-1).

Fig: 3: Epicardial fat of Ischemic and non-ischemic heart disease according to gender: Female patients with ischemia had higher pericardial fat thickness than male patients.

**Discussion**

In the current study, we discuss correlation of EF with the IHD and EFT & its association with other risk factors for IHD such as HT, DM, BMI, smoking and age. There is a relationship between IHD and EFT, defined as significant independent risk factors among other risk factors. For the role of EFT as CAD risk factors there is a large control cases studies which suggest this correlation, Ahn et al(4) reveal EFT was more thick in IHD than patients without ischemia and it may give an further marker For IHD many researches shown that adipose tissue, specifically visceral fat, express many genes attributed to production of adipokine, that had significant evidence for occurrence of CAD in obese patients^{15,16,17}. Epicardial fat located in adjacent to the coronary tree that promote the paracrine effects of epicardialadipokines, as part of the pathogenesis of CAD^{18,19}. There is two important mechanisms for this association: 1- epicardial fat is a part of visceral adiposity and is related to cardiovascular risk factors and metabolic syndrome^{20}. 2- EFT had endocrine features, Ahn et al^{4}; stated that EFT active metabolite and had obvious origin of pro and anti-inflammatory cytokine creation,
this unavoidably influence cardiac role and morphology. It yield numerous bioactive particles like adiponectin, resistin, and inflammatory cytokines\(^{(21,22)}\). Transthoracic echocardiography gives a clear assessment of epicardial fat thickness. This can approved by MRI that regarded as the gold standard way to assess visceral adiposity. ECHO as a non-invasive test with little cost used for assessment of epicardial adipose tissue and diagnosis of CAD\(^{(23)}\) In our study, EFT more than 5.5 in male and 5.7 in female associated with ischemia this in agreement with lacobellis et al \(^{(9)}\) found that EFT thickness was higher in patient with ischemia. In the current study, important correlation between EF and BMI (p value 0.001). There is strong association between EPF and visceral adipose tissue BMI where demonstrated by Jin-Won et. Al.\(^{(24)}\) which show Significant association were illustrated between EFT and BMI (p=0.044). Kangwha Cohort Study demonstrated that cardiovascular diseases risk was clearly more in the BMI \(\geq 27 \text{ kg/m}^2\) group in the Korean people \(^{(25)}\). Higher epicardial fat thickness exclusively associated with the incidence of diabetes, and cardiac contractile dysfunction in diabetes \(^{(26)}\). In our study, there is higher pericardial fat thickness in diabetic patient than non-diabetic (pvalue 0.005). Increase visceral fat is linked with higher BP presumable over the renin angiotensin scheme. There is association between hypertension and EFT according research \(^{(27)}\). EAT mount increase in healthy wealthy patients with overstated BP reply to workout stress testing, all this persons with danger of coming hypertension \(^{(28)}\). EFT in ECHO showed increase in patients with hypertension not treated with non-dipper blood pressure pattern \(^{(29)}\) in our study there is higher pericardial fat thickness in hypertensive patient than non-hypertensive(p value 0.002). Cigarette smoking is an independent indicator of elevated volume of epicardial fat \(^{(30)}\). In our study, there is higher pericardial fat thickness in smoker patient than nonsmokers. (Pvalue 0.001). Obesity is important reasons of cardiovascular illness and death. Overweight, obesity reasons 2.8 million deaths worldwide annually, 3% to 9% of possible years of life misplaced, responsible for at least 35% of patients with ischemic heart disease\(^{(31)}\), it related to increase incidence of atherosclerosis and the additional rise in cardiovascular danger\(^{(32)}\). Ectopic adiposity defined to include a higher cardiovascular danger than subcutaneous adiposity\(^{(33)}\).

**Conclusion**

Patient with higher EFT had higher ischemic score i.e. EFT is a risk factor of IHD. EFT more than 5.5 in male and 5.7 in female associated with ischemia. Epicardial fat increase with higher BMI and more in HT, DM and in smoker patients.

Comparative Evaluation of Efficacy of Three Port Versus Standard Four Port Laparoscopic Cholecystectomy

Nitin Nangare¹, Aniket Survase², A.Y. Kshirsagar³

¹Associate Professor, ²Assistant Professor, ³Professor, Department of Surgery, Krishna Institute of Medical Sciences Deemed to be University, Karad, Maharashtra, India

Abstract

Background: Laparoscopic cholecystectomy has established itself firmly as the “gold standard” for the treatment of gallstone disease. The present study was conducted to compare three port versus standard four port laparoscopic cholecystectomy.

Materials and Method: The present study was conducted on 120 gall stones patients of both genders. All patients were divided into two groups viz. group I who were subjected to the three port technique and group II patients who were subjected to the conventional four port technique. Intra-operative findings, pain score etc. was compared.

Results: The mean VAS was 2.14 in group I and 4.30 in group II and mean operative time was 51.2 minutes in group I and 62.1 minutes in group II. Intra-operative complications were perforation seen 6 patients in group I and 4 in group II, stone spillage 4 in group I and 3 in group II, bleeding from liver 5 in group I and 4 in group II, cystic artery bleeding 2 in group I and 1 in group II. Post-operative complications were fever seen 4 patients in group I and 7 in group II, vomiting 5 in group I and 6 in group II, Basal pneumonitis 3 in group I and 5 in group II, seroma 1 in group I and 2 in group II.

Conclusion: Authors found that three port laparoscopic cholecystectomy found to be better than standard four port laparoscopic cholecystectomy.

Keywords: Basal pneumonitis, Laparoscopic cholecystectomy.

Introduction

The first laparoscopic cholecystectomy (LC) was performed in 1987 by Philip Mouret and later established by Dubois, Perissat, Reddick and others in 1990’s. Since then, there have been many changes and improvements in the technique.¹ Traditional LC is performed using 4-port technique. The fourth (lateral) trocar is used to grasp the fundus of the gall bladder soas to expose the Calot’s triangle. With increasing surgeon experience, LC has undergone many refinements including reduction in port size and number. It has been argued that the fourth trocar may not be necessary and laparoscopic cholecystectomy can be performed safely without using it.²

LC is now the gold standard treatment of symptomatic gallstone disease. Standard LC is performed by using four trocars.³ The fourth trocar is used to retract the liver for better exposure of Calot’s triangle or to grasp the fundus of the gall bladder, pulling upward and outward to expose Calot’s triangle (American technique). In recent years, many investigators have attempted to improve the established technique of LC.⁴ The goal has been to minimize the invasiveness of this procedure by reducing the number and size of-ports, arguing that...
the fourth trocar may not be necessary and LC can be performed safely without it. Fortunately, several studies have reported three-port LC was technically possible.\(^5\) The present study was conducted to compare three port versus standard four port laparoscopic cholecystectomy.

**Materials and Method**

The present study was conducted in the department of General surgery. It comprised of 120 gall stones patients of both genders. All patients were informed regarding the study and written consent was obtained. Ethical clearance was obtained from institutional ethical committee.

Data such as name, age etc. was reported. All patients were divided into two groups viz. group I who were subjected to the three port technique and group II patients who were subjected to the conventional four port technique. Intra-operative findings, pain score etc. was compared. Results thus obtained were subjected to statistical analysis. P value less than 0.05 was considered significant.

**Results**

Table IV, shows that post-operative complications were fever seen 4 patients in group I and 7 in group II, vomiting 5 in group I and 6 in group II, Basal pneumonitis 3 in group I and 5 in group II, seroma 1 in group I and 2 in group II. The difference was non-significant (P> 0.05).

**Discussion**

LC is now the gold standard treatment of symptomatic gallstone disease. LC has now replaced open cholecystectomy as the first-choice of treatment for cholelithiasis and inflammation of the gallbladder unless there are contraindications to the laparoscopic approach. This is because open surgery leaves the patient more prone to infection. Sometimes, a laparoscopic cholecystectomy will be converted to an open cholecystectomy for technical reasons or safety.\(^6\)

Laparoscopic cholecystectomy has established itself firmly as the “gold standard” for the treatment of gallstone disease. Existing literature has focused most exclusively on the biliary complications of this procedure, but other complications such as significant hemorrhage during laparoscopic cholecystectomy have not been documented.\(^7\) The present study was conducted to compare three port versus standard four port laparoscopic cholecystectomy.
In present study, in group I patients three port technique and in group II patients conventional four port technique. Each group had 60 patients. The mean VAS was 2.14 in group I and 4.30 in group II and mean operative time was 51.2 minutes in group I and 62.1 minutes in group II. Sharma et al\(^8\) found that the mean operative time was compared and found to be less in group A. Intraoperative and postoperative complications was similar in both groups. The postoperative pain was less in group A. The mean hospital stay was less in group A (1.27 days) than group B (1.95 days). Better cosmetic results and patient satisfaction was observed in group A. 5 patients of group A required fourth port and 3 patients of group B required conversion to open cholecystectomy.

We found that intra-operative complications were perforation seen 6 patients in group I and 4 in group II, stone spillage 4 in group I and 3 in group II, bleeding from liver 5 in group I and 4 in group II, cystic artery bleeding 2 in group I and 1 in group II. Post-operative complications were fever seen 4 patients in group I and 7 in group II, vomiting 5 in group I and 6 in group II, Basal pneumonitis 3 in group I and 5 in group II, seroma 1 in group I and 2 in group II.

Kumar et al\(^9\) found that patients in the 3-port group had shorter meanoperative time for the 4-port group and less pain at port sites. Overall pain score, analgesia requirements, hospital stay and patient satisfaction score on surgery and scars were similar between the two groups. Harsha et al\(^10\) found that the first group, three-port LC group consisted of 25 cases and the second group, the standard four-port LC group consisted of 25 cases were analyzed for the following outcome measures namely conversion rates, operating time, intra-operative complications, post-operative pain score, analgesic requirement and hospital stay. Demographic data was comparable in both groups. Conversion rate was nil in both groups. The mean operating time was comparable in both groups. Post-operative pain was significantly less in three-port group and analgesic requirement when compared with the four-port group. Hospital stay was significantly less in three port group compared with the four-port group owing to post-operative pain score. There was no statistical difference in the complications rate in both groups: gallbladder perforation, bile leakage and bleeding from liver bed.

**Conclusion**

Authors found that three port laparoscopic cholecystectomy found to be better than standard four port laparoscopic cholecystectomy.

Assessment of Psychiatric Illness in Burnt Patients

Sharad Vasant Kshirsagar¹, Ajay Deshmukh²

¹Associate Professor, ²Assistant Professor, Department of Psychiatry, Krishna Institute of Medical Sciences Deemed to be University, Karad, Maharashtra, India

Abstract

Background: Psychological distress is among the most frequent and debilitating complications post-burn injury. The present study was conducted to assess psychiatric illness in burnt patients.

Materials and Method: The present study was conducted on 102 burn patients of both genders. Incidence of pre-morbid psychopathology, marital status, education and employment status was recorded.

Results: Out of 102 patients, males were 60 and females were 42. 67 patients were married and 35 were unmarried, 38 were skilled and 64 were semi skilled, 42 had primary, 35 had secondary and 25 were uneducated. The difference was significant (P< 0.05). Major psychiatric illness were depression in 32, personality disorder in 10, schizophrenia in 5, substance disorder in 7 and Posttraumatic stress disorder in 12 cases. The difference was significant (P< 0.05).

Conclusion: Authors found high incidence of psychiatric illness such as depression, personality disorder, schizophrenia and substance disorder in burn patients.

Keywords: Burn, Depression, Schizophrenia.

Introduction

Psychological distress is among the most frequent and debilitating complications post-burn injury. Preliminary reports using the Burn Model System (BMS) dataset indicated that one-third of patients with major burns had clinically significant psychological distress at the time of discharge and the mean level of psychological distress in the BMS sample was significantly higher than that reflected in published data from a normative sample.¹ In addition, psychological distress of in-patients of the hospital predicted significantly greater physical impairment for at least 1 year post-burn.² Clinically significant psychological distress also accounted for substantial variance in concurrently assessed quality of life at 2 (58%), 6 (68%) and 12 (51%) months post-burn injury. Severe psychological distress is an important secondary complication of major burn injuries, with long-term consequences.³

The treatment of burns injuries commences with a period of specialized intensive care during wound care and surgical treatment are carried out when necessary. Management of pain and anxiety related to the accident and to burn care procedures such as surgery, are main challenges during this phase of care. For the severely injured, this first period is just the beginning of a long journey involving adaptation to post burn life.⁴ Rehabilitation of the patients starts on the day of injury and comprises measures that are also undertaken during the phase of very specialized and technologically focused intensive care. Active surgical treatment of wounds and scars, as well as physiotherapy and occupational therapy continue long after the patient has left the intensive care unit and are part of the process of regaining functional capacity.⁵ The present study was conducted to assess psychiatric illness in burnt patients.
Materials and Method

The present study was conducted at Krishna Institute of Medical Sciences Deemed to be University, Karad, Maharashtra, India. It comprised of 102 burn patients of both genders. Ethical approval was obtained from institute prior to the study. All patients were informed regarding the study and written consent was obtained.

General information such as name, age etc. was recorded. All patients were managed in the department. Incidence of pre-morbid psychopathology, marital status, education and employment status was recorded. Results thus obtained were subjected to statistical analysis. P value less than 0.05 was considered significant.

Table III, shows that major psychiatric illness were depression in 32, personality disorder in 10, schizophrenia in 5, substance disorder in 7 and Posttraumatic stress disorder in 12 cases. The difference was significant (P< 0.05).

Discussion

Distress may be manifested in other forms as well. Body image dissatisfaction appears common in patients with burn injuries. Sleep disturbances occur frequently among in-patients with burns, e.g., nightmares in 39% and significant sleep problems in 75%. Furthermore, many adult Swedish and US burn survivors continue to report nightmares (30–43%) and insomnia (37%) between 1 and 11 years post-burn. Sleep problems, PTSD symptoms and scar-related problems were highly intercorrelated in a Dutch sample. The present study was conducted to assess psychiatric illness in burn patients.

In this study, out of 102 patients, males were 60 and females were 42. We found that 67 patients were married and 35 were unmarried, 38 were skilled and 64 were semi skilled, 42 had primary, 35 had secondary and 25 were uneducated. Madianos et al in their prospective study of 45 patients with burn injuries explored the prevalence of psychological and psychiatric disorders among burn survivors. Psychological impairment was found to be 45.5 and 40% at the baseline and follow-up assessments, respectively. The extent of burns was found to be associated with psychological impairment. The prevalence of psychiatric disorders (any DSM-III nosological entity) reached 46.6% at both baseline and follow-up examinations. Posttraumatic stress disorder was diagnosed in 17.8 and 20.0% of burn survivors at the baseline and the 12-month follow-up assessments, respectively. Logistic regression analysis revealed that face disfigurement was the only burn characteristic significantly associated with the presence of psychiatric morbidity.

We found that major psychiatric illness were depression in 32, personality disorder in 10, schizophrenia in 5, substance disorder in 7 and Posttraumatic stress disorder in 12 cases. Ramchandran et al in their study, 114 patients admitted with suicidal burns above the age
of 15 years were included in the study. The patients were mostly married females in the 2nd to 3rd decade of life. Most of them had some form of pre-morbid psychopathology. 60% of patients had >50% burns and only 17% were survivors. After 1 year of psychotherapy, most patients had returned to normalcy.

Mechanisms of injury also vary widely among different countries and communities depending on factors like the way food is prepared, heating system, industrial environments and general living conditions. Males are strongly over-represented in burn statistics all over the world with India as the only exception; children are also at high risk, both in developed and in less developed countries. Psychosocial factors are clear risk factors for burns. The risk factors leading to individuals to burns are lower socioeconomic groups, financial loss, unemployment, illiterate, marital disputes, extremes of age groups (geriatric), sexual abuse, rape, substance use disorders and alcoholism, illnesses like diabetes, epilepsy, chronic disability, chronic pain, cancer and preexisting psychiatric illness like depression and PTSD.

Vlaeyen and Morley have noted that co-occurring pain and depression may activate cognitive processes that guide a person towards completing or terminating a task. For example, a person may terminate a functional activity as soon as he or she no longer enjoys the task, perhaps due to pain perceptions. Understanding associations between pain, depression and physical functioning is critical because burn survivors have considerable difficulties in returning to personal, social and community roles after their injuries have healed.

**Conclusion**

Authors found high incidence of psychiatric illness such as depression, personality disorder, schizophrenia and substance disorder in burn patients.

Evaluation of Prevalence of Depression and Anxiety among Breast Cancer Patients

Sharad Vasant Kshirsagar¹, Ajay Deshmukh²

¹Associate Professor, ²Assistant Professor, Department of Psychiatry, Krishna Institute of Medical Sciences Deemed to be University, Karad, Maharashtra, India

Abstract

Background: People who have previously used psychiatric services may be particularly vulnerable and at greater risk of mortality following a cancer diagnosis. The present study assessed depression and anxiety among breast cancer patients.

Materials and Method: The present study was conducted on 64 women with breast cancer. The Patient Health Questionnaire-2 (PHQ-2) and the Generalized Anxiety Disorder-2 (GAD-2) questionnaire were produced as ultra-brief screening instruments for depression and anxiety in all patients.

Results: Age group <40 years had 12, 40-60 years had 20 and >60 years had 32 patients. The difference was significant (P< 0.05). Maximum patients were of stage III (30) followed by stage II (18), stage IV (10) and stage I (6). Treatment given was mastectomy in 46 patients and ongectomy in 18 patients. The difference was significant (P< 0.05). PHQ- 2 with score >3 was observed in 12 and GAD- 2 with score >3 was seen in 15 patients. The difference found to be significant in breast cancer patients with or without depression and anxiety (P< 0.05).

Conclusion: Authors found that breast cancer patients had higher level of depression and anxiety level.

Keywords: Anxiety, Breast cancer, depression.

Introduction

Breast cancer is the most common cancer type among females worldwide, as 1 in 8 women will be diagnosed with the disease in their lifetime. The problems experienced by survivors include physical symptoms, psychological reactions and existential concerns, which potentially disrupt their well-being. The overall prevalence of depression in oncology patients remains unclear and according to previous studies the prevalence is reported to be between 0% and 58%.¹

People who have previously used psychiatric services may be particularly vulnerable and at greater risk of mortality following a cancer diagnosis.¹ However, the mental health needs of people with cancer, with or without a prior psychiatric history, are often given little attention during and after cancer treatment, which is primarily focused on monitoring physical health symptoms and side effects.³ Advances in the earlier detection of cancer and improved cancer treatments means that people are now living longer with cancer, presenting a significant global challenge. The total number of people who are alive within 5 years of a cancer diagnosis was estimated to be 43.8 million in 2018 for 36 cancers across 185 countries. Studies have shown that prevalence of psychological distress among breast cancer patients is high and they are at higher risk of developing severe anxiety, depression and patients mood disorders. Depression and anxiety are the two most common psychiatric co-morbidities encountered.
in breast cancer patients. The present study assessed depression and anxiety among breast cancer patients.

**Materials and Method**

The present study was conducted at Krishna Institute of Medical Sciences Deemed to be University, Karad, Maharashtra, India. It comprised of 64 women with breast cancer. Ethical approval was obtained from institute prior to the study. All patients were informed regarding the study and written consent was obtained.

General information such as name, age etc. was recorded. A thorough clinical examination was done. The Patient Health Questionnaire-2 (PHQ-2) and the Generalized Anxiety Disorder-2 (GAD-2) questionnaire were produced as ultra-brief screening instruments for depression and anxiety in all patients. In both questionnaires, each question requires respondents to rate on a four-point scale ranging from “0 = not at all” to “3 = nearly every day”. PHQ-2 and GAD-2 total scores are calculated by adding the two questions score, resulting in a range from 0 to 6 for each questionnaire, with higher score indicative of higher mental health disorder. According to receiver-operating characteristic curve analysis, the optimal cutpoint is ≥ 3 on both the PHQ-2 and GAD-2 scales. Results thus obtained were subjected to statistical analysis. P value less than 0.05 was considered significant.

</table>

Table III, shows that PHQ-2 with score >3 was observed in 12 and GAD-2 with score >3 was seen in 15 patients. The difference found to be significant in breast cancer patients with or without depression and anxiety (P< 0.05).

**Discussion**

Breast cancer is the most frequently diagnosed cancer and the leading cause of cancer death in females worldwide, accounting for 23% (1.38 million) of the total new cancer cases and 14% (458,400) of the total cancer deaths in 2008. In Asia, breast cancer incidence peaks among women at the age of 40 year whereas in the United States and Europe, it peaks among women at the age of 60 year. In India pre-menopausal patients constitute about 50% of all patients. The present study assessed depression and anxiety among breast cancer patients.

We found that out of 64 patients, age group <40 years had 12, 40-60 years had 20 and >60 years had 32 patients. Srivastava et al found prevalence of anxiety and depression among the breast cancer patients was 37.0% (n=74) and 28.0% (n=56) respectively. We found strong association of anxiety with age group (p=0.014), educational level, monthly income (p=0.001) and financial support. However, marital status, monthly
income, accompanying person and financial support were significantly associated with depression. Binary logistic regression analysis shows age younger than 50 years old, those earned less income, illiterate or low level of education, being single and receiving less financial support are more likely to have anxiety. For depression, those earned less income, being single and receiving less financial support are more likely to have depression. At the 12 month follow-up, 184 breast cancer patients were re-interviewed. We found significant improvement after 12 month follow-up in both anxiety and depression level (mean anxiety level improved from 11.14 ± 4.23 to 8.64 ± 3.63 and mean depression score improved from 6.87 ± 3.11 to 5.13 ± 4.51.

We found that maximum patients were of stage III (30) followed by stage II (18), stage IV (10) and stage I (6). Treatment given was mastectomy in 46 patients and ongectomy in 18 patients.

PHQ- 2 with score >3 was observed in 12 and GAD-2 with score >3 was seen in 15 patients. The difference found to be significant in breast cancer patients with or without depression and anxiety (P< 0.05).

Tsaraset al\textsuperscript{8} found the mean age of the patients was 53.25 years, 69.7% of the patients underwent mastectomy and 30.3% ongectomy. Chemotherapy received 46.1% of patients as adjuvant mastectomy, 15.8% radiotherapy and 38.2% received both chemotherapy and radiotherapy. A large percentage found to be classified as depressed (38.2%) and anxious (32.2%) and factors that found to be associated were age, marital status, educational level, stage of cancer from univariate analyses and place of residence, religion,symptoms burden from multivariate analysis (for depression and anxiety).

Depression and anxiety are the two most common psychiatric co-morbidities encountered in breast cancer patients. Breast cancer patient may experience depression and/or anxiety at any stage of their illness from pre-diagnosis to the terminal phase of the illness. Studies in the Western countries have shown that the prevalence of depression ranges from 1% to 56%, whereas the prevalence of depression from Asian studies is between 12.5%and 31%\textsuperscript{9}.

Maasset al\textsuperscript{10} demonstrated in a very large sample of cancer patients that the prevalence of depression among breast cancer survivors was about 32.8%. It has also been reported that 40% of the patients who experience disease recurrence would suffer from anxiety and depression.

**Conclusion**

Authors found that breast cancer patients had higher level of depression and anxiety level.

Evaluation of Incidence of Adverse Events Associated with C Section

Sanjaykumar Patil¹, Shivaji Raje², Hiren Kathiria³, Puja Priya³

¹Professor, ²Assistant Professor, ³Second Year Resident, Department of Obstetrics and Gynaecology, Krishna Institute of Medical Sciences Deemed to be University, Karad, Maharashtra, India

Abstract

Background: Cesarean section, also known as a C-section, is one of the most common operations in the world. The present study was conducted to assess adverse events associated with C sections.

Materials and Method: The present study was conducted on 438 cesarean sections. Complications and adverse events associated with C section was recorded.

Results: Age group 18-28 years had 210 patients, 28-38 years had 186 and 38-48 years had 42 patients. The difference was significant (P< 0.05). Adverse events associated with C sections was abortion in 5 cases, fetal distress in 12, malpresentations of fetus in 7, disproportion of fetus in 16, oligohydramnios in 4, preterm labor in 3 and postpartum hemorrhage in 9 cases. The difference was significant (P< 0.05).

Conclusion: Authors found that common adverse events were abortion, fetal distress, malpresentation of fetus, disproportion of fetus, oligohydramnios, preterm labor and postpartum hemorrhage.

Keywords: Cesarean section, oligohydramnios, preterm.

Introduction

Cesarean section, also known as a C-section (CS), is one of the most common operations in the world. It is a surgical procedure that may be performed to deliver one or more newborns. Taking into consideration the rate of CS is important because it reflects the index of health care coverage. Nevertheless, an “optimal” cesarean section rate remains a point of debate. The World Health Organization (WHO) stated in 1985 that the optimum rate should always remain between 10 to 15 percent.¹

The increasing caesarean section (C-section) has also been different in different countries, such that for developing countries it is much more than for developed ones. Rates of cesarean delivery continue to rise worldwide, with recent reported rates of 24.5% in Western Europe, 32% in North America and 41% in South America. Caesarean rate in Brazil, Chile and China has increased up to 40-42% while, the rate of cesarean in Iran been reported from 26- 66.5% by various studies and as 87% by some private centers. Cesarean delivery is carried out due to such various reasons as pregnancy at higher ages, lower number of a woman previous pregnancies, obesity, fetal distress, etc.²

In the presence of maternal or fetal complications, cesarean delivery can effectively reduce maternal and perinatal mortality and morbidity; however, an increasing proportion of babies are delivered by cesarean when there is no medical or obstetric indication.³ The short-term adverse associations of cesarean delivery for the mother, such as infection, hemorrhage, visceral injury and venous thromboembolism, have been minimized to the point that cesarean delivery is considered as safe as vaginal delivery in high-income countries though in

e-mail: drshivajiraje2020@gmail.com
low and middle-income countries, there is an increased risk of adverse short-term maternal outcomes even with cesarean delivery without medical indication.\textsuperscript{4} This notwithstanding, the long-term risks and benefits of cesarean delivery for mother, baby and subsequent pregnancies are less frequently discussed with women and there are few randomized controlled trials (RCTs) addressing the issue.\textsuperscript{5} The present study was conducted to assess adverse events associated with C sections.

**Materials and Method**

The present study was conducted in the department of Gynaecology at Krishna Institute of Medical Sciences Deemed to be University, Karad, Maharashtra, India. It comprised of 438 cesarean sections done in the department. All patients were informed regarding the study and written consent was obtained. Ethical clearance was obtained from institutional ethical committee.

Data such as name, age etc. was reported. Complications and adverse events associated with C section was recorded. Results thus obtained were subjected to statistical analysis. P value less than 0.05 was considered significant.

**Results**

Table II shows that adverse events associated with C sections was abortion in 5 cases, fetal distress in 12, malpresentations of fetus in 7, disproportion of fetus in 16, oligohydramnios in 4, preterm labor in 3 and postpartum hemorrhage in 9 cases. The difference was significant (P< 0.05).

**Discussion**

The increase in the number of cesarean sections worldwide is related to the improvement of the access of women to this procedure when needed, but it is also related to the indiscriminate use without medical indication. This has culminated in the recent efforts to reduce these rates, while incorporating the obstetric preferences of women. Properly performed cesarean sections that follow an accurate medical indication are life-saving procedures. However, on the one hand, the provision of safe and timely cesarean sections remains a major challenge in countries with high maternal mortality, where they are insufficient; on the other hand, their excess in certain regions results in the challenge of minimizing cesarean sections without clinical indication.\textsuperscript{6}

Cesarean delivery is carried out due to such various reasons as pregnancy at higher ages, lower number of a woman previous pregnancies, obesity, fetal distress, etc. Cesareans without indications, as compared to Normal Vaginal Delivery (NVD), would bring about many complications for both mother and the baby. Many people think there is more probability of newborns health in case of cesarean, while studies have shown that the risk of death in newborns by cesarean is 4 times as much as newborns born by NVD. The most serious complications for the babies born by cesarean are fetal respiratory problems such as Transient Tachypnea (TTN) and Respiratory Distress Syndrome (RDS), surgical blade cuts and increased rates of newborns admission in the neonatal intensive care unit. Also, experts believe that 1 min Apgar score of the newborns by cesarean is less than that of the newborns by NVD.\textsuperscript{7} The present study was conducted to assess adverse events associated with C sections.

In present study age group 18-28 years had 210 patients, 28-38 years had 186 and 38-48 years had 42 patients. Zgheib et al\textsuperscript{8} determined the risk factors associated with the high cesarean section rates. This study is based on a sample of 29,270 Lebanese women who were pregnant between 2000 and 2015. Among these, 14,327 gave birth by cesarean section and 14,943 gave
of the 29,270 pregnant women included in the study, 49% had cesarean sections while 51% gave birth vaginally. Repeat cesarean section accounted for 23% while vaginal birth after cesarean accounted for only 0.2% of deliveries. In addition, weekdays were associated with a preference of providers to carry out more cesarean sections.

We found that adverse events associated with C sections was abortion in 5 cases, fetal distress in 12, malpresentations of fetus in 7, disproportion of fetus in 16, oligohydramnios in 4, preterm labor in 3 and postpartum hemorrhage in 9 cases. Mascarello et al evaluated the presence of postpartum hemorrhage and its complications, such as hysterectomy and blood transfusion and they have found controversial results. Kamilya et al found that the women with cesarean section in the absence of complications and comorbidities, presented a 3.01 times higher death rate than women with vaginal delivery. When cesarean section was intrapartum, this chance was 4.86 (95%CI 2.47–9.56) and for cesarean section before labor, this chance was not significantly higher.

Conclusion

Authors found that common adverse events were abortion, fetal distress, malpresentation of fetus, disproportion of fetus, oligohydramnios, preterm labor and postpartum hemorrhage.

Occurrence and Dissemination of Antimicrobial-Resistant Salmonella Isolated from Diarrheic Stool Samples of Human

Abeer Mohammed Ali Al-garawy
Lecturer, Microbiology, Education for Pure Science College/Al-Muthanna University

Abstract
The current study was designed to isolate and identification of Salmonella from human stool using salmonella-shigella agar, the diagnosis of Salmonella relied on cultural properties where the Salmonella colonies on S.S. agar revealed pale with black center. Out of 72 samples were collected 59.7% were positive to Salmonella. The antibiotic susceptibility test of all positive isolates for Salmonella performed by using disk diffusion method against numerous antibiotics, The result of this test presented that the Salmonella isolates were highly resistant to Levofloxacin 43(100%), Amoxicillin/Clavulanate 40(93.0%), Streptomycin 22(51.2%), Tetracycline 19(44.2%), Imipenem 19(44.2%) and Amikacin 18(41.9%). While Salmonella isolates were moderately sensitive to Kanamycin 9(20.9%). The current study refers to Salmonella gastroenteritis treatment can be use Kanamycinas first treatment option.

Keywords: Streptomycin, Salmonella spp., S.S. agar, Plasmid.

Introduction
The microorganisms resist antimicrobial agents by many ways such as; producing hydrolyzing enzymes capable of analyzing antibiotic molecule or modulating it to inert molecules or preventing antibiotics from reaching the target it affects. Among these enzymes are beta-lactamase, which breaks down penicillins and cephalosporins groups, which are main causes of the failure of many therapeutic cases. It was found most epidemics were caused by strains producing beta-lactamase enzymes by plasmids most of them are couplings with multiple resistance characteristics, some considered it much more dangerous than resistance from chromosomal enzymes that work against β-lactam antibiotic groups[1]. The antibiotic resistance has become one of the most common problems globally on health and economic level due to seriousness of plasmids and its multiple resistance to more than one antibiotic from different groups as well as its ability to move between different isolates carrying with it resistance character[2]. Because of importance the Enterobacteriaceae therapeutically, This research focused on isolation and identification of pathogenic Salmonella from human stool, in addition to determine antibiotic susceptibility profile of the Salmonellaisolates.

Materials and Method
A total of 72 diarrheic stool samples were collected for this study. The following substances were used to isolate and diagnoses of Salmonella, furthermore test their sensitivity to antibiotics:

1. Salmonella – shigella agar (S.S. agar): Prepared according to manufacturer’s instructions and used in diagnosis of bacteria. After collection of samples, Nutrient broth (NB) used for inoculation of each sample then incubated at 370C for 24 hours, as well as, Salmonella-Shigella agar used for culture of a loop full from bacterial culture in incubated tubes, subsequently, carefully examination of plates for the existence of characteristic colonies of Salmonella[3].

2. Nutrient Agar: Prepared according to manufacturer’s instructions and used in maintaining of bacteria.

3. Antibiogram: The antibiotics used in this study comprise disks Himedia, India: Amicacine (AK), Streptomycin (S), Amoxicillin/Clavulanate (AMC), Tetracycline (TE), Imipenem (IMP), Kanamycin (KAN) and Levofloxacin (LEV). Kirby-Bauer disk diffusion method was used to evaluate the
susceptibility of *Salmonella* isolates on Mueller-Hinton agar according to CLSI[4].

4. **Preservation and maintenance of bacterial isolates**: Bacterial strains are preserved on nutrient agar slants after inoculation in 37°C for 18hr. The isolates were subculture on another new culture media for monthly maintaining. All strains are kept in the refrigerator at 4 °C. Nutrient broth added with 40 % glycerol was used For long maintenance then frozen for 6-8 months at -20 ºC [5].

**Results and Discussion**

This study showed Salmonella was found in 59.7% of the collected total samples Fig:1, the presence of turbidity in NB indicates the growth of bacteria after 24 hr. incubation at 370C. Also, the cultivation of bacteria on S.S. agar characterized by appearance of pale salmonella colonies with a black center, where the S.S. agar used to differentiate between Salmonella and Shigella from the rest of the species as this medium contains lactose sugar as a basis for differentiation between fermented and non-fermented species, the appearance of black center due to release of hydrogen sulfide and its deposition on the form Iron sulfide [6].

![Fig (1): Frequency of positive and negative infection](image1)

![Fig. (2) : Antibiotics susceptibility profile forsalamonella isolates (n=43).](image2)
All Salmonella isolates were examined for a number of the above mentioned antibiotics, it was noted that the bacteria were resistant to antibiotics as shown in Fig: 2, Amikacin 18(41.9%), Streptomycin 22(51.2%), Amoxicillin/Clavulanate 40(93.0%), Tetracycline 19(44.2%), Imipenem 19(44.2%), Kanamycin 9(20.9%) and Levofloxacin 43(100%).

The Salmonella resistance to antibiotics has been steadily increasing, numerous research related to surveillance reports revealed that Salmonella resistance phenotypes increases a two-fold from 20%-30% to about 70% during the period 1990 to 2000[7]. In this current study, we observed all Salmonella isolates were resistant to levofloxacin Fig: 2. The causes of Salmonella resistance to Levofloxacin may be due to point mutations to protect DNA gyrase or determinants of plasmid mediated resistance or efflux pumps that ejects antibiotic molecules outside the bacterial cell[8]. This type of resistance is important in public health due to latent spread among species of bacteria, in addition to fluoroquinolones resistance development among Salmonella spp. is usually slow [9]. This result poses a real risk because fluoroquinolones is one of the central drugs in the treatment of human salmonellosis. Certainly, Misuse of antibiotics, as also the use of these antibiotics frequently in food animals, pharmaceutical industries, and prophylactic. The cause of bacterial sensitivity to the mentioned antibiotics is due to several reasons, including: absence of plasmids with a definite or antibiotics-altered character, these antibiotics have not been used previously for studied bacteria, so bacteria do not have genetic genes inherited from their ancestors to resist these antibiotics and some of these antibiotics neutralize plasmid and therefore lose resistance in bacterial[10]. From the current study, we conclude that it is necessary to increase health education about the use of antibiotics properly to prevent the emergence of antibiotic resistance also to decrease the prevalence of Salmonellosis among the people to evade food borne illness. Strict health measures with proper treatment must be seriously done.

Ethical Clearance: This research underwent to the terms of ethical considerations by higher education and scientific research ministries in Iraq.

Conflict of Interest: The authors announce that they have no conflict of interest.

Impact of Serum level of L-Carnitine on Chitotriosidase in Women with Gestational Diabetes Compared to T2DM Pregnant & Non Pregnant Iraqi Women

Ali Khalaf Hasan1, Shatha H. Ali2, Wiqar Akram Hussein3

1M.Sc. Student, 2Prof. Department of Clinical Laboratory Science/College of Pharmacy-University of Baghdad, 3Lecturer In Gynecology & Obstetrics/AL-kind College Pf Medicine

Abstract

Background: Gestational diabetes (GDM) was defined as any degree of glucose intolerance that to be first recognized during pregnancy, regardless of the degree of high blood sugar. L-Carnitine appeared to act as a vitamin and thus termed as vitamin B T. Under certain conditions, the demand for carnitine may exceed an individual’s capacity to synthesize it, making it a conditionally essential nutrient. Whereas, chitotriosidase is chitinase family member enzyme, produced by activated macrophages. Enzymatic activity of chitotriosidase increases significantly during the development of acute or chronic disorders.

Aim: The study involved estimating serum level of L-carnitine & activity of chitotriosidase in women with gestational diabetes compared to type-2 diabetic pregnant & non pregnant Iraqi women. In addition to assessing the possible impact of variations of serum level of carnitine on serum chitotriosidase activity in the study groups.

Methodology: This is a case control study included seventy-five women whom attending the Al Alwaiya Maternity Teaching Hospital/Baghdad-Iraq. The participants were selected of similar age consisted of three groups: 25 pregnant women with gestational diabetes, 25 pregnant women with type 2 diabetes, and 25 healthy non pregnant women as a control. After the provision of the ethical approval from Ethics Committee of the Collage of Pharmacy–University of Baghdad. The studied biochemical markers were: total HbA1c, lipid profile, serum L-carnitine & chitotriosidase.

Results and Discussion: Data analysis for comparing the groups results (gestational diabetes, T2DM and control) indicated significant variations among them considering serum carnitine levels & chitotriosidase activity. However, HbA1C levels were positively correlated with L-carnitine among GDM pregnant women, with highest levels compared to the control & T2DM pregnant women. However, serum carnitine levels were significantly correlated with chitotriosidase activity among GDM pregnant specifically (r=-0.813, p=0.0001).

Conclusion: Serum carnitine level was significantly lowered in T2DM pregnant women, as well as in pregnant women with GDM, as being compared to healthy non pregnant women. Whereas, serum chitotriosidase level were significantly elevated in women with GDM, in comparison to T2DM and controls, it’s activity is negatively correlated with serum carnitine level.

Keywords: L-Carnitine, Chitotriosidase, Gestational Diabetes, T2DM.

Introduction

Gestational diabetes (GDM) was defined as any degree of glucose intolerance that was first recognized during pregnancy, regardless of the degree of high blood sugar. As well as diabetes mellitus which is referred to as; a metabolic disorder characterized by a high blood sugar due to defective insulin action1. Degree of hyperglycaemia and insulin resistance (specifically
Normally, in type 2 diabetes seem to be at elevated risk for carnitine deficiency. L-carnitine short-circuit the Randle cycle by sequestering inhibitory acetyl-CoA units as acetyl-Carnitine and concomitantly increasing free CoA levels. Lowering of the mitochondrial acetyl-CoA: CoA ratio would then favour glucose oxidation, L-carnitine mediated sequestering of toxic lipid metabolites may have benefited both mitochondrial performance and insulin signalling. Also L-Carnitine can play a role in the treatment of type 2diabectics by improving insulin resistance that is caused by post-receptors defect, this means that L-Carnitine may be useful for cell membrane repairing and, removal of harmful lipid from the cells may improve or decrease the resistance to insulin action by photoreceptor defect either at the membrane or intracellular level, Administration of L-Carnitine may shift the metabolic bias of the liver away from esterification and synthesis of triglycerides toward the formation of acetylcarnitines. This could decrease synthesis of triglycerides and VLDL cholesterol and likely increase mitochondrial β-oxidation of fatty acids.

Generally there are two types of carnitine deficiency. Primary carnitine deficiency; which is a genetic disorder of the cellular carnitine transport system that usually manifests itself with five years with symptoms of cardiomyopathy, skeletal muscle weakness and hypoglycaemia. A secondary deficiency of carnitine may be caused by certain disorders (such as chronic kidney failure) or under certain conditions (such as the use of some antibiotics) that reduce carnitine absorption or increase its secretion. There is scientific agreement on the value of carnitine as a prescription product for treating such deficiencies. Beyond its classical physiological role, carnitine has additional crucial functions in the body. Notably, carnitine modifies the acyl-CoA/CoA ratio, which in turn regulates the activity of several mitochondrial enzymes involved in tricarboxylic acid cycle (TCA), fatty acid oxidation, urea cycle and gluconeogenesis. It has also been shown that there are anti-inflammatory and antioxidant properties possessed by L-carnitine. It improves dyslipidemia, membrane stability, protein nutrition and insulin sensitivity.

On the other side, chitotriosidase is chitinase family member enzyme and produced by macrophage cells after activation, which show a class of evolutionarily ancient enzymes that catalyze the hydrolysis of chitin to simple sugars. Chitin is a linear homopolymer and the most abundant natural biopolymer known for being the structural component of protective structures in many eukaryotic organisms, but not be seen in vertebrates. Because of excess serum levels or increased expression in chronically inflamed tissues chitotriosidase undergoes increased scrutiny.

The enzymatic activity of chitotriosidase increases significantly during the development of acute and chronic disorders. During the active maturation of monocyes into macrophages, there is a different role for this enzyme in macrophages. Through the various stages of macrophage maturation, the levels of chitotriosidase increases significantly when modified into macrophage M1 and M2 macrophages. There is ample evidence to indicate the active role of chitotriosidase in cases of disease characterized by an inflammatory response. Patients with newly diagnosed, untreated, and uncomplicated type 2 DM have been observed to have increased chitotriosidase activity. Interestingly, it indicated that there is a new group of molecules of derivative chitinases, which may participate in inflammatory pathways in the context of type 2 diabetes and metabolic disorders, especially with regard to the development of vascular complications. It showed that the increase in chitotriosidase levels is linked to other biochemical pathways that occur in diabetes. Although...
neutrophils are involved in the inflammatory response in type 2 diabetes, macrophages are the primary cell type in the response. One of the important factors in vascular damage in diabetes is the employment of neutrophils in fatty tissues and the lining, where enzymes are released and many proinflammatory mediators, under prolonged hyperglycemia conditions, it might lead to functional impairment of neutrophils. Furthermore, some scientists hypothesized that there is a role or participation of chitotriosidase in the development of atherosclerosis, which creates a possible link to the course of type 2 diabetes. Type 2 diabetes, which results from insulin resistance or lack of it, as it is associated with many metabolic abnormalities such as obesity, dyslipidemia, and high blood sugar. These are main systemic factors, which trigger proinflammatory events, leading to endothelial dysfunction and increased prevalence of diabetic angiopathies. Moreover, it is positive association with parameters for controlling blood sugar and blood pressure, may enable the prediction of the risk of diabetic angiopathies.

Materials and Method

Subjects: A total number of seventy five women were enrolled in this study from those attending Al Alwaiya Maternity Teaching Hospital/Baghdad-Iraq, for the period from October/2019 until March/2020. Including (25) women diagnosed to have GDM (as Group-1). Besides (25) pregnant women have type 2 DM (as Group- 2).The diagnosis was made by a specialized physician according to the American Diabetes Association (ADA) criteria. A third group of apparently healthy (non-pregnant) women, whom were age matching for the patients groups to be included as a control (as Group-3) the characteristics of subjects are summarized in (Table-1). After obtaining the ethical approval from the Ethical committee of the Collage of Pharmacy/University of Baghdad.

All participants completed pre-interview questionnaire regarding family history of diabetes and medical history, other information were collected from hospital records to identify diabetes and treatment protocol.

The samples were collected by withdrawing blood specimen (5 ml) from each woman to obtain serum. Testing for HbA1C by taking (2ml) of blood to be placed into EDTA tube. The rest of blood used to obtain serum to measure glucose concentration. The reminder of serum was separated and divided into aliquots into Eppendorf tubes, which were kept frozen at 20 degrees until analysis.

Laboratory analysis: Serum components of lipids [total cholesterol (TC), triglyceride (TG) & HDL-cholesterol (HDL-C)] was measured colorimetrically. Glycated hemoglobin measurement was done according to (Bun H). Serum L-carnitine; was measured using ELISA kit purchased by (Sun Long Biotech/China). Whereas, the measurement of serum chitotriosidase was based on sandwich-ELISA principle (Elabscience/China).
Statistical Analysis: Statistical package for social sciences version 25 (SPSS v. 25) was applied for data input and analysis. Analysis of Variance (one-way): to determine the difference in means of 3 independent samples, followed by Tukey’s test (post-hoc test) to identify significantly different means among the groups. Pearson’s correlation coefficient (r): to evaluate the correlation between the parameters. All the results with (P<0.05) were considered to be significant.

Results

Serum Lipoproteins Levels Among Studied Groups: The mean value of serum total cholesterol concentrations for GDM was significantly higher than that of the control and T2DM. Meanwhile, mean value of serum LDL concentrations for GDM patients was significantly higher than control and T2DM. Although, VLDL mean value was higher in T2DM than that of the control and GDM but these values were not significantly elevated. While, the HDL mean value was higher in the control as compared to that of the T2DM and GDM but not to a significant level. The complete details of these results are presented in (figure -1).

**Hb\textsubscript{A1C} concentrations Among Studied Groups:** The mean value of blood Hb\textsubscript{A1C} concentrations for GDM patients was significantly higher than control subjects and T2DM patients as shown in (Table-1).

**Serum L-carnitine concentrations Among Studied Groups:** The mean values of serum L-carnitine concentrations for control was significantly higher than T2DM and GDM patients as illustrated in table (Figue-2).

**Mean Serum Chitotriosidase Concentrations for Studied Groups:** The mean values of serum chitotriosidase concentrations for GDM group was significantly higher than the control and T2DM, as illustrated in (Figure-3). Plasma chitotriosidase activity in patients with ongoing type 2 diabetes were described to have a relationship with anthropometric and metabolic parameters related to the diabetic state.

*Highly significant correlation (P<0.01)
Diabetes or impaired glucose tolerance develops in 2-3 percent pregnant women, previously non-diabetic, most often in the last trimester of pregnancy. Which is referred to as Gestational Diabetes Mellitus (GDM). The insulin resistance of normal pregnancy may also contribute to GDM in women in whom the capacity for insulin secretion is not sufficient to meet the increased insulin demands of pregnancy lipid abnormalities in patients with diabetes, “diabetic dyslipidemia”, are typically characterized by high total cholesterol (T-Chol), high triglycerides (Tg), low high density lipoprotein cholesterol (HDL-C) and increased levels of small dense LDL particles. Low density lipoprotein cholesterol (LDL-C) levels may be moderately increased or normal. Lipid abnormalities are common in people with T2DM and prediabetes. One of the major features of DM that is closely and causatively related to its macrovascular complications is diabetic dyslipidemia (DD). Type 2 diabetes is associated with a cluster of interrelated plasma lipid and lipoprotein abnormalities, including reduced HDL cholesterol, a predominance of small dense LDL particles, and elevated triglycerides. These abnormalities occur in many patients despite normal LDL cholesterol levels. These changes are also a feature of the insulin resistance syndrome (also known as the metabolic syndrome), which underlies many cases of type 2 diabetes. In fact, pre-diabetic individuals often exhibit an atherogenic pattern of risk factors that includes reduced HDL cholesterol, a predominance of small dense LDL particles, and elevated triglycerides. These abnormalities occur in many patients despite normal LDL cholesterol levels.

In patients with diabetes, cholesterol metabolism differs from nondiabetic patients because cholesterol synthesis is high and is reduced by insulin. According to our study the results showed that GDM was associated with increased cholesterol. This is what was previously confirmed.

Low density lipoprotein –Cholesterol (LDL-C) is one of the main factors for assessment of cardiovascular disease risk and it is more important in diabetic patients. Various method are currently used for LDL-C measurements which are compared in this study. Patients with diabetes frequently have lipid profiles that appear more benign than those of other high-risk people without diabetes. In general, LDL cholesterol levels in people with diabetes are not higher than those in people without diabetes who are matched for age, sex, and body weight (Figure-1). Nonetheless, LDL cholesterol does not play less of a role in cardiovascular risk in people with type 2 diabetes. A large number of small, dense particles characterize the LDL fraction in diabetic individuals. These particles contain less cholesterol than normal-sized LDL particles, but they are exceptionally atherogenic. Thus, levels of LDL may appear deceptively “normal” in cholesterol measurements. According to our study, the results showed that GDM was associated with increased LDL (Figure-1).

HDL is formed from lipid-free Apo-AI, which is synthesized de novo by the liver, or released from triglyceride-rich lipoproteins particles. Diabetes is associated with quantitative changes in the amount of circulating lipids – notably an increase in triglycerides, elevated LDL and a reduction in HDL. Like other lipoproteins, HDL also undergoes significant qualitative changes in diabetes, in both structure and function. However, since dyslipidemia may be present several years before the onset of diabetes, it is hard to determine which of these changes are related to the pathognomonic features of the disease, and which precede and accelerate its progression. HDL is known to be inversely correlated with cardiovascular disease due to its diverse antiatherogenic functions. These functions include cholesterol efflux and reverse cholesterol transport, antioxidative and anti-inflammatory activities. Cholesterol that reaches HDL particles is converted to cholesteryl esters by the HDL-associated enzyme lecithin-cholesterol acyltransferase (LCAT). In fact, the role of cholesterol metabolism and HDL function in the pathogenesis of Type 2 diabetes mellitus (T2DM) has recently gained a lot of attention. Native Americans carrying the R230C mutation in ABCA-1, which is associated with decreased cholesterol efflux capacities, were shown to be more prone to early age T2DM. Mice studies suggest that cholesterol accumulation in islet β-cells is the reason for their pathology. HDL also appears to protect β-cells from the toxic effects of glucose and IL-1β, and to enhance insulin secretion. In skeletal muscles, HDL was demonstrated to increase insulin activity in the form of glucose uptake. This activity was dependent on ABCA-1 activity, and included activation of AMP kinase. According to our study, the results showed that GDM was associated with increased HDL (Figure-1).

It has been shown that the VLDL production rate is correlated with insulin resistance and liver fat in patients with type 2 diabetes. Dyslipidemia is a key feature of T2DM, and may precede it by several years. Diabetic
dyslipidemia is characterized not only by a change in the levels of lipoproteins and the ratio between them, but also by changes in the structure of the lipoproteins themselves. The increase in VLDL and triglycerides presents as an increase in VLDL1 production. The normal suppressant effect of insulin on postprandial VLDL (more specifically, VLDL₄) production is blunted by hepatic insulin resistance⁴². According to our study, the results showed that GDM was associated with increased VLDL. This is what was previously proven.

Glycated hemoglobin (HbA1c) has been widely accepted as an indicator used to evaluate the blood glucose control in diabetes mellitus (DM) patients. However, evidence on the application of HbA1c in the diagnosis and follow up of gestational diabetes mellitus (GDM) and pregnancy combined DM is very poor. Herein, we summarize the available studies on this issue. In 2017, the International Diabetes Federation (IDF) estimated that there are 451 million people aged 18-99 years with diabetes mellitus (DM) worldwide, and that this will only increase to 693 million by 2045⁴³. The major advantage of HbA1c is that it is less affected by fluctuating glucose levels after meals and other short-term changes from medical conditions. However, there are still several factors that can affect HbA1c results. Haemoglobin (Hb) variants (including elevated levels of HbF) and thalassemia can affect HbA1c results, with the interference from Hb variants more pronounced in ion exchange method. This can cause falsely high/low HbA1c levels, depending on the manufacturer. In a recent study⁴⁴, HbA1c levels decrease during early pregnancy due to increased erythrocyte synthesis and decreased fasting blood glucose levels due to insulin-independent glucose uptake by the fetus and placenta. However, later in pregnancy, postprandial hyperglycemia, insulin resistance and increased carbohydrate intolerance develop due to diabeticogenic placental hormones⁴⁵. If GDM is treated intensively during the entire period of pregnancy, HbA1c may not be able to accurately diagnose diabetes at follow up shortly after giving birth⁴⁶. The screening for GDM later in pregnancy is performed between 24-28 weeks gestation, and many guidelines still recommend either one-step or two-step glucose challenge tests to screen for GDM, with diagnostic criteria based on OGTT results⁴⁷. Six Arab speaking countries namely; Saudi Arabia, Kuwait, Qatar, Lebanon, Bahrain and United Arab Emirates are among the world’s top countries with the highest prevalence of type 2 Diabetes mellitus (T2DM) affecting 32.8 million people in 2011, which is expected to increase to 60 million by 2030. Diabetes affects almost every organ of the body and causes serious complications like stroke, heart attack, kidney disease, gangrene 4 blindness and renal failure⁴⁷. Pre-existing diabetes (both type 1 and type 2) is associated with an increased risk of stillbirth. How about the relation between HbA1c and stillbirth? Tennant et al found increasing periconception HbA1c concentration above values of 49 mmol/mol (6.6%) was significantly associated with either fetal death or infant death with each 1 mmol/mol increase (above 49 mmol/mol) conferring a 2% and 3% relative increase, respectively. Table-1 presents that GDM pregnant women mean HbA1C value was significantly higher than the control & even the pregnant T2DM women.

GDM carries risks for the mother, fetus, and neonate. The Hyperglycemia and Adverse Pregnancy Outcome (HAPO) study found that there are wide-ranging and multinational scientific studies that included more than 23,000 pregnant women, which demonstrated that the risk of harmful results for the mother, the fetus and the newborn increases continuously as a function of maternal blood sugar in 24-28 weeks of pregnancy, even within the ranges that were previously considered the nature of pregnancy. There is no limit to the risk of complications and many results have led to a review of the diagnostic criteria for GDM patients⁴⁹.

Discussions and disagreements about the optimal strategies for diagnosing GDM due to the different diagnostic criteria that define different degrees of hyperglycemia in mothers. Figure-2 illustrated that serum carnitine levels were significantly lowered in pregnant diabetic (GDM & T2DM) compared to the non-pregnant control women.

Chitotriosidase is chitinase family member enzyme and produced by macrophages after activation ¹⁴, which catalyzes the hydrolysis of chitin to simple sugars. There is little evidence showing that serum CHIT1 activity is increased in patients with newly diagnosed, untreated, and uncomplicated type 2 DM (T2DM)²¹. Type 2 diabetes, the most common form of diabetes, results from insulin resistance and/or deficiency and is connected with many metabolic abnormalities, such as hyperglycemia, obesity, hypertension, and dyslipidemia. These are main systemic factors, which trigger proinflammatory events, leading to endothelial dysfunction and increased prevalence of diabetic angiopathies (DA) in T2D diabetic patients. Diabetic...
angiopathies are the major cause of decreased quality of life and increased mortality of T2D, remaining a constant target of diagnosis, monitoring and treatment\textsuperscript{25}. As data shown in Figure-3, serum chitotriosidase level was significantly elevated over that of control & T2DM groups, furthermore chitotriosidase level in GDM group was inversely correlated with carnitine level (r=-0.813, p˂0.0001) compared to T2MD group which presented with no such correlation (r=0.008, p>0.05).

**Conclusion**

serum carnitine level was significantly lowered in T2DM pregnant women, as well as in pregnant women with GDM, as being compared to healthy non pregnant women. Whereas, serum chitotriosidase level were significantly elevated in women with GDM, in comparison to T2DM and controls.

Abstract

Background: The “skin diseases” are transmissible in the developing world, especially the school students.

Aim: To shed light the prevalence of “infectious skin diseases” among school children in Heet District and the possible correlated of different socio-demographic factors.

Method: A cross-sectional descriptive study conducted from the October 2018 to December 2019 on schools children in Heet District, Alanbar Governorate, Iraq to explore the prevalence of “infectious skin diseases” and its relationship with different socio-demographic variables. A total of 2971 school children were incorporated into this study. There were 1446 females and 1525 males. The pupils living in urban areas were 1453 while those living in rural areas were 1518. The full dermatological examination was done, for the existence of any infectious skin disease.

Results: The prevalence rate of transmissible skin diseases was 30.6%. It is significantly higher among male pupils (21.9%); between 12-14 years (20.3%); rural residence(27.1%); pupils of primary schools (25.4%); low economic status in 20%; crowding index 3 in (24%); primary educational level of a father (31.1%) and mother (23%) of pupils. The viral infections (16.7%) are the more prevalent, followed by bacterial (13.4%), fungal (2.2%) and parasitic skin infections (1.9%).

Conclusions: Infection of the skin is very common in children. The viral one is more prevalent. The rural area, crowding houses, low economic status and the parent’s educational level were significantly associated with the prevalence of “infectious skin diseases”.

Keywords: Infectious, skin diseases, pupils, schools, children.

Introduction

In developing countries, the “skin diseases” are very common, predominately infections and infestations, and they are most common among the younger age group. They can affect more than 60% of the general population and usually are not well managed.¹² Special consideration to the school students, because of their vital importance to the health of the community and they are an important sector of any community. Children within the school environment are vulnerable to cross-transmission of communicable “skin diseases” among themselves and their families.³⁴ In Iraq, the prevalence of “skin diseases” were 8.8% and 33.7% for transmissible and non-transmissible skin diseases respectively. The prevalence of skin diseases in rural areas of Erbil governorate is one of the great public health problems.⁵⁶

National variations within one country like the genetic factors, environment, race, occupation, nutrition and habits can influence the pattern of “skin diseases”. This study was designed to highlight the current spectrum and prevalence of the “infectious skin diseases” among “school children” in Heet district and the possible association of different socio-demographic correlates with the prevalence of transmissible “skin diseases”.

Material and Method

A “cross-sectional study” conducted in Heet District, Alanbar Governorate, Iraq and implemented with “a multistage cluster random sampling”. The population subjected for this study was the pupils registered in the primary and intermediary schools of Heet District. The study was performed during the period between October 2018 till December 2019.

There were (129) primary schools and (48) intermediary schools distributed over the whole area of Heet District including the Heet City Center, the towns and villages that belong to the District.

The schools were divided according to the age into primary schools (6-8, and 9-11 years old) and intermediary schools (12-14 years old); then, each of them was further divided according to gender. Furthermore, all these divisions were classified into urban schools and rural schools.

The schools were chosen by simple random sampling among the schools of each location using proportionate sampling techniques. A full history and clinical dermatological examination were done in the room of the headmaster of each school and in the presence of the headmaster and the director teacher of each class about the possibility of having any signs or symptoms of an “infectious skin diseases”, including bacterial, viral, fungal, and parasites skin infections. The dermatological examination was done by 2 specialists in dermatology. Swab and direct examination were done for inquiry cases of bacterial and fungal infection.

A self-administered questionnaire was distributed to all chosen pupils to be answered and filled by the head of their families. The information requested in the questionnaire included the age, sex, number of family members, number of rooms, educational level of father and mother, and the economic status of the family (perceived). The children were asked to bring written consent from their parents for participation in the study. This study was approved by the Ethics Approval Committee, College of Medicine, University of Anbar (Ref. No 25/22-4-2020).

The data were analyzed using the programs: Excel 2010 and SPSS version 22. The Chi-squared test and Yate’s correction is used. The $P$-value of $\leq0.05$ is considered as significant.

Results

A total of 2971 pupils were included. Their age ranged between 6-14 years with a mean ±SD of 10.2 ± 2.7 years. The overall prevalence of “infectious skin diseases” was 909 (30.6%) patients, including viral (16.7%), bacterial (13.4%), fungal (2.2%) and parasitic (1.9%).

The distribution of biological causative agents of “infectious skin diseases” according to age groups showed statistically significant difference at an age between 12-14 with the rate of bacterial, viral, fungal and parasitic infections $(P<0.001)$. The viral infection was significantly encountered more than others “infectious skin diseases” in general and in each studied age groups (Table 1).

The rate of bacterial, and fungal “skin infections” was significantly higher among male pupils in (8.3% and 1.5% respectively), while in the females (5.1% and 0.6% respectively) $(P<0.001)$. While the rate of “viral skin infection” was non-significantly higher among the male pupils (8.9%) compared to that in the females (7.8%) (Table 1).

The distribution of biological agents of the bacterial, fungal and parasitic infection among pupils living in the rural area were (8.3%, 1.4%, and 1.2%) of children respectively, and showed significantly higher rates compared to those living in an urban area (5.1%, 0.6%, and 0.6%) of children respectively.

The crowding index of £3 associated with a significant difference in the prevalence of bacterial infections 8.1% and viral infections 13.3% of children $(P<0.0001)$. In the other hand, there was no statistically significant difference in the rate of fungal or parasitic infections in the school children living in a family with crowding index of $(>3)$ or $(\leq3)$ (Table 1).

This study showed the highest statistically significant prevalence of bacterial, viral, fungal and parasitic infections, among pupils having father and mother
education of primary or secondary school (P<0.05), while the lowest rate of diseases was detected among pupils whose fathers were illiterate or had a higher level of education.

Concerning the economic status of the, this study revealed that the rate of bacterial (7%), viral (8.7%), fungal (1.3%) and parasitic (1%) infection were significant in families with a low economic state (Table 1).

A higher significant prevalence rate of bacterial, viral and parasitic infection (9.8%, 10.9%, and 1.4% respectively), among pupils of primary school level than that from secondary school level (3.7%, 5.8%, and 0.5%) (P<0.0001). While the fungal infection was not statistically significant (P=0.803), concerning the school levels (Table 2).

Table 1 showed the distribution of specific bacterial, viral, fungal and parasitic skin disease.

Discussion

School children have been identified by many socio-epidemiological surveys to be at risk for exposure to various infectious skin diseases.

The present study revealed that the overall prevalence of “infectious skin diseases” among school children is 30.6%. This finding is slightly higher than that detected in previous reports in Ibadan, Nigeria (24.6%), Saudi Arabia (27.2%). Meanwhile this finding is lower than that detected in Sagamu, Nigeria 36.9%. In Iraq, a study conducted by Khalifa found that 8.8% of the school children were diagnosed as “infectious skin diseases”.

The high prevalence of “infectious skin diseases” in “school children” in the present study might be explained by the poor personal hygienic and sanitary conditions, lack of awareness and health services. Other studies stated that differences in socioeconomic standards, even within the country may be responsible for great variations in the prevalence of “skin diseases”.

This report showed that there is a significant difference in the different age groups with a significant correlation was found among the age group 12-14 years old of children. This is in disagreement with the other studies conducted in Iraq. This finding gives an idea that this age group of “schoolchildren” are exposed more to the “infectious skin diseases” since they receive the same health care facilities, they can explain their complain and have nearly the same personal hygiene.

This study found that the prevalence of the rate of bacterial, and fungal infections” was significantly higher among male pupils than females. This finding is consistent with many studies conducted in different countries. While other studies found a higher prevalence of “infectious skin diseases” among females than in males. The male preponderance in this study might be explained by the dominant active role of this gender in the study population. Also, the population in the Iraqi society take care and attention to the females.

This report revealed that there is a significant association between residency and the prevalence of the bacterial, fungal and parasitic infection among pupils living in the rural area in (8.3%, 1.4%, and 1.2%) of children respectively, than in urban “school children”. This finding is in agreement with other reports. This may be related to the bad living condition, lack of therapy and a lack of cooperation between health and teaching authorities.

According to this study, the prevalence of bacterial 8.1% and viral infections 13.3% of children with crowding index \( \leq 3 \) is significantly higher than that detected among school children with crowding index
>3 (5.4% and 5.3% respectively). In the other hand, the crowding index of (>3) or (≤3) had no significant difference in the rate of fungal or parasitic infections in the school children. This may be explained by the high contagious rate of bacteria and virus than fungus and parasite.

In contrast to this finding, in Iraq, Khalifa found a significantly higher prevalence of “infectious skin diseases” among “school children” living in families with crowding index >3 (12.1%). In Saudi Arabia, Amin found that large family size was the predictor risk factor for some transmissible “skin infections” (pediculosis and tinea). The unexpected of this study data may be due to incorrect crowding index information provided from the “schoolchildren” or their families.5, 8

A highest statistically significant prevalence of bacterial, viral, fungal and parasitic infections, among pupils having father’s education of primary or secondary school, and the mother who had primary school education. The low education donates to the low socioeconomic status of the family and less orientation about the health status of their children. This in agreement with that of Amoran OE et al.9 While Khalifa KA found that the “infectious skin diseases” was significantly associated with the educational level of the father.5

The present study showed a higher significant prevalence of bacterial (7%), viral (8.7%), fungal (1.3%) and parasitic (1%) infection among school children who were living with families having low economic status. This result is in agreement with previous reports.4,12,13

In general, this high prevalence rate might be due to that the skin diseases being neglected or even mismanaged, there were deficient in medical equipment for laboratory diagnosis, the closer contact between classmates in crowded classrooms, and poverty that have led to the evolution of the communicable “skin diseases”.

The prevalence rate of “viral skin diseases” is (16.7%) which is higher than that detected by Khalifa, (4.1%); Al-Saeed (2.4%); Ogubiyi (0.0%) and Inanir (3.8%). This variation might be caused by differences in the sample size, socioeconomic standards, and lack of early therapy and isolation.2,4,5,14

The present research found that a higher significant prevalence rate of bacterial, viral and parasitic infection among pupils of primary school level than that from secondary school level, who were older age and more aware of their skin, and could seek medical advice alone when needed.

The recognized limitations including, the diagnosis depended on eye inspection of 2 dermatologists for clinical examination, which was done mainly on the exposed parts of the body for each pupil, and sometimes all the body. Socio-demographic variables information provided from the parents (without authors interview).

**Conclusion**

“Infectious skin diseases” are very common and constitute an economic and public health problem among “school children”. “Viral skin infections” are more prevalent. Routine inspection of pupils for skin disorders by their teachers could control these diseases especially at age 11-14 years old. The rural area, crowding houses, the parent’s educational level, primary school pupils and low economic status were significantly associated with the prevalence of “infectious skin diseases”.

Comparative Study between Recurrent Tonsillitis and Tonsillar Hypertrophy Based: Histopathological Grading and Hematological Parameters in Children

Halah Amer¹, Sahar A.H. AL-Sharqi², Firas H. Bairawi³

¹Post Graduate, ²Assist Prof., Dep. of Biology, College of Science, Mustansiriyah University, Baghdad/Iraq, ³Ph.D. Specialist, Child’s Central Teaching Hospital, Ministry of Health, Baghdad/Iraq

Abstract

The current study investigates the differences between recurrent tonsillitis patients (T patients) and tonsillar hypertrophy patients (H patients) according to histopathological grading and some hematological tests in the study groups. The samples were taken (removed tonsil, and blood) from 20 children with tonsillitis and 20 children with tonsillar hypertrophy, by which tonsils kept in formalin(10%) for histopathological study. Blood samples were obtained during the period from November 2019 to January 2020. The histopathological difference in tonsils tissue was observed between the two groups. The result showed significant differences in the lymph follicles, germinal center, fibrosis, necrosis, and infiltration of inflammatory cell. No significant difference (p > 0.05) of the Erythrocyte Sedimentation Rate (ESR) level in T patient group(13.2±8.3mm/hr), compared to H patient group (13.06±7.5mm/hr). The WBC count (White blood cell) showed a non-significant difference (p > 0.05) between the groups.

Keywords: Recurrent tonsillitis, Tonsillar hypertrophy, WBC count, ESR.

Introduction

Tonsils are considered as part of the lymphatic Waldeyern ring, which is responsible for the first line of defenses against microbes since they are located at the entry of the respiratory and the digestive tract(1). There are three types of tonsils (pharyngeal tonsil, lingual tonsil, and palatine tonsils), the palatine tonsils is frequently referred to as “tonsils” in the medical terminology and sometimes known as facial tonsils. They’re located in the lateral position of the oropharynx(2). The tonsils are physiological serves as a protection against respiratory antigens and play an important role in the adaptive immune response.(3).

Tonsillitis is the most common inflammation of palatine tonsils of microbial origin. It may be either chronic or acute, that is generally caused by either viruses or bacteria(4). Recurrent tonsillitis is defined as a person suffering from multiple tonsillitis attacks annually. Recurrent and chronic tonsillitis can involve frequent episodes of inflamed tonsils that have a significant effect on patient health(5).

Tonsillar hypertrophy sometimes is idiopathic tonsillar hyperplasia that leads to unusual palatal tonsillar enlargement. Pediatric tonsillar hypertrophy is not a consequence of recurrent inflammation, acute tonsillitis or middle ear infections(6). Tonsillectomy is the most performed treatment that completely removes the tonsil, including its capsule, by dissecting the peritonsillar space between the tonsil capsule and the muscular wall surgery(7). Our study aimed to identify the histopathological, and hematological changes accompanying these complications of diseases.

Materials and Method

The study groups are 20 with tonsillitis (T patient...
group) and 20 with tonsillar hypertrophy (H patient group). The tissue specimens were obtained during operations of tonsillectomy from Central teaching hospital of pediatric in Baghdad City the haematological study was conducted at the Educational Laboratories/Medical City and from November 2019 to January 2020. The specimens of tonsil tissue were obtained from children after operations of tonsillectomy. The tissue specimens were kept in the fixation solution (formalin 10%) for histopathological study according to the method of Suvaran\(^8\). Five ml of venous blood was collected from the patient and transferred the EDTA tube. Assayed was done by using CELL-DYN Ruby haematology analyzer for WBC count. Fresh blood was used to measure ESR, disposable ESR tubes and disposable ESR pipettes.

**Statistical Analysis:** The Statistical Analysis System (SAS), the obtained data were subjected to the X2 test and one way analysis of variance (ANOVA) test to compare various groups with each other. Results were expressed as mean ± standard deviation (SD) and values of p>0.05 were considered statically non-significant while p<0.05 and <0.01,0.001 were considered significantly different, highly significantly different respectively. The statistical analysis was carried out by SPSS (V. 24).

**Results and Discussion**

**Histopathological study of Tonsils:** The histological study using H & E stain in obtained tonsil tissue after tonsillectomy. In T patients group, lymph follicle-1 was seen in 11(55%) with less than 25 follicles and in lymph follicle-2 showed and 9(45%) with more than 25 follicles, the result showed a significant difference (p<0.05) between two lymph follicle groups. The result showed a significant difference (p<0.05) when compared between two lymph follicle groups of H patients group in which the lymph follicle-1 was seen in 6(30%) with less than 25 follicles and in lymph follicle-2 showed 14(70%) with more than 25 follicles. On the other hand, there was a significant difference (p < 0.05) between the T patients and H patients group of lymph follicle-1 and -2. Also, the result showed a significant difference (p < 0.05) between germinal centers-1 which seen in 9 (45 %) and germinal centers-2 which seen in 11 (55 %) in T patients group. Also, H patients group showed a significant difference (p < 0.05) between germinal centers-1 in 8(40 %) and germinal centers-2 that seen in 12(66%). Also, when compared the T patients group with H patients group there was a significant difference (p<0.05) observed in germinal centers-1, but there was a non-significant difference (p>0.05) observed in germinal centers-2 between T and H patients group (Table-1) and (Figure-1 A,B).

T: Recurrent tonsillitis, H: Tonsillar hyperplasia.
Number of lymph follicles 1: less than 25 follicles per field of x4, 2: 25 or more follicles per x4.
Number of germinal centers 1: less than 6 germinal centers per field of x10, 2: more than 6 germinal centers per field of x10.
NS: No significant, P value: P>0.05, each group total number = 20

The histopathology examination of tonsil tissue in our study agreement with Rajeshwary et al.\(^9\) and AL-Hussaini et al.\(^{10}\) indicated the presence of multiple lymphoid follicles, germinal centers, fibrosis and infiltration of inflammatory cells. The enlargement of germinal centers of the H patients group in comparison
with those from the T patients group indicates the lymphoid follicle is very active\textsuperscript{(11)}. The lymph follicle hyperplasia and enlargement are most findings in the removed tonsils of pediatric in the lymph nodes areas of active, mixed, and chronic inflammation that may be seen\textsuperscript{(12)}. The follicular area enlargement is the main histological characterization of hypertrophied tonsil as a result to a hyperplastic disorder of lymphoid cells that can be explained due to difference in etiology and immune response in this tonsil\textsuperscript{(13)}.

The other histopathological changes in (Table-2) and Figure-1 C,D,E) fibrosis, necrosis, neutrophil in epithelium crypt, and infiltration plasmocyte between T and H patient groups as three levels (0-absent, 1-mild, 2-moderate, and 3-severe).

The result showed that percentage of necrotic tissue was very little in general, only milled necrosis was seen in 2(10\%) of the T patients group, and 1(5\%) of the H patients group that showed a significant difference (p<0.001) between the two groups of patients.

The obtained data showed fibrosis in T patients group was demonstrated in high percentage as mild fibrosis in 12(60\%), 6(30\%) as moderate fibrosis and only 2(10\%) appeared with intense fibrosis, while in H patients group fibrosis appeared with 5(25\%) mild fibrosis, 6(30\%) moderate and 9(45\%) intense fibrosis which was the highest percentage. The result showed a highly significant difference (p < 0.01) between the T and H patients group of fibrosis.

In the T patient group, the neutrophil in epithelium crypt was absent in 4(20\%) and appeared in 10(50\%) as mild and in 6(30\%) as moderate. The result showed a significant difference (p<0.01) when compared with H patients group in which the neutrophil in epithelium crypt was absent in 7(35\%) and seen in 9(45\%) as mild and in 4(20\%) as moderate.

Based on the result the plasmocyte infiltration on the T patients group was observed in 11(55\%) as mild, 7(35\%) as moderate, and 2(10\%) as intense. While in the H patient group an excessive number of plasmocyte infiltration has been observed, a mild infiltration in 8(40\%) and moderate infiltration in 12(60\%) has been recorded. The result showed a significant difference (p<0.01) when compared between the T and H patient group.

T: Recurrent tonsillitis, H: Tonsillar hyperplasia., 0-absent, 1-mild, 2-moderate, 3-intense, P value: P>0.05, each group total number n=20

The result disagrees with Reis et al.\textsuperscript{(14)} who considered the germinal center is the only difference between the two groups. The results showed neutrophils and plasmocyte cells infiltration that may be related to long time chronic infection or frequent attacks that led to the moving of more inflammatory cells to the tissue. In chronic infection, the circulation of blood is poor as a result of degenerative changes causing fibrosis like in chronic tonsillitis\textsuperscript{(12)}.

The result agree with Onal et al.\textsuperscript{(15)} and Wittlinger et al.\textsuperscript{(16)}, the small size tonsils with tonsillitis infection
had low lymphoid tissue and high fibrotic tissue large hypertrophied tonsils have high lymphoid and low fibrotic tissue. There was an increase in the neutrophil count is often seen. Blood circulating neutrophils have short life-span then die after entering the inflamed tissues\(^{17}\).

**Figure 1:** Cross section in palate tonsil detected by demonstrating, A: increased in size of lymphoid follicles, B: Germinal centers, C: Fibrosis, D: Neutrophil in epithelium crypt, E: Infiltration plasmocyte (H & E, X4).

**Erythrocyte Sedimentation Rate (ESR):** Data in (Table 3) showed the (mean±SE) of ESR in the control group was (8.9±4.3mm/hr) which showed a non-significant difference \(p>0.05\) when compared with patient groups. As well as when compared between the T patients group \((13.2±8.3\text{mm/hr})\) and H patients group \((13.06±7.5\text{mm/hr})\), the result showed a non-significant difference \(p>0.05\).

This result is agreement with the previous study Mohamed et al.\(^{18}\) and Mackway\(^{19}\) who have also found there was no elevated in ESR of patient undergo tonsillectomy and Abdelkafy et al.\(^{20}\) result where the most patient shows normal ESR. The ESR is a traditional inflammatory indicator, due to its low sensitivity and specificity and the use of newer inflammatory indicators the importance in clinical research have been reduced\(^{21}\).

**Table (3):** The ESR difference in the cases Recurrent Tonsillitis and Tonsillar Hyperplasia.

Results are expressed as mean ±Standard Error, WBCs: White Blood Cells, NS: No significant, P value: P > 0.05, each group total number = 20

The WBC count is the main blood indicators of general inflammation\(^{(22)}\). In current study, the significant increase in the count of WBC between patients and control group, even if it exists but remain within normal limits. As a result of the immune defense against microbial invasion, the total and differential levels of WBCs in blood will change\(^{(23)}\). Our result agrees with the study of Christensen et al.\(^{(17)}\), Kara et al.\(^{(24)}\) and Yorulmaz et al.\(^{(25)}\), which showed there is an increase in the total WBC count for the patient group who undergo a tonsillectomy while disagree with study of Cengiz et al.\(^{(26)}\) showed a non-significant difference in WBC count patient with the control group.

Conclusion

There is a histopathological difference between recurrent tonsillitis and tonsillar hypertrophy in germinal center, lymph follicle, fibrosis, necrosis and infiltration of inflammatory cell. In addition, significant increase in patient group when compared with control in WBC count, and no difference between T patients group and H patients group, and no significant difference in ESR level between all groups.

Abstract

COVID-19, a new, rapidly spreading coronavirus strain, has reached more than 150 countries and is gaining worldwide attention. The shortage of successful SARS-CoV-2 medicines or vaccines has exacerbated the situation even further. Therefore, research is urgently required to establish effective therapeutics and affordable diagnosis for COVID-19. It is the responsibility of the scientific research community in this time of health crisis to provide an alternative, reliable, and accessible method for vaccinating human bodies against COVID-19 viral infections, based on focused experimental approaches. Coronavirus (CoV) is an RNA virus for the forward, forming stick-shaped spikes on its surface. This is an undesirable, small RNA genome, with an infinite mode of replication. The corona virus causes numerous diseases in mammals, birds, pigs, and chickens. It causes upper respiratory tract infections, which can lead to death from respiratory diseases. Within this article the author briefly explains this abrupt occurrence Extreme lung disease, extremely pathogenic and newly discovered respiratory syndrome (MERS-CoV) in corona virus of the Middle East. It is a research paper on the detection of CoVID-19 infections and their dissemination across the world.

Keywords: Covid-19, Structure of coronavirus and Life cycle.

Introduction

Hospitals declared on 31 December 2019 in Wuhan, Hubei, China, a cluster of cases of unknown cause of pneumonia attracting great national and worldwide attention(1). Coronavirus (CoV) is a big group of positive Nidoviral RNA single-stranded viruses. There is also a list of the Arteriviridae, Coronaviridae, and Roniviridae. The Coronaviridae family is classified in the Coronavirinae and Torovirinae subfamilies. Coronavirinae even below the alpha, beta, gamma, and delta COV level(2). Such forms of viruses have been named for the phylogenetic clustering. The viral RNA genome varies in length from 26 to 32 kilobases. They can be separated from various species of animals. These involve birds, goats, and mammals including camels, bats, and masks Civets of leaves, mice, pigs, cats...

World Health Organization (WHO) named the disease on 11 February 2020 as the coronavirus disease-2019 (COVID-19), caused by this novel virus. The repeated appearance and CoV outbreaks suggest a threat to public health. This demonstrates the possibility of moving newly evolving CoVs from animal to human, and human to human. The ongoing ecological and climatic changes make these infections more likely to occur in the future.(4)

History of Coronavirus: (1960), it reported the very first corona virus outbreak with cold symptoms. According to the Canadian study of 2001, approximately 500 patients were registered as pneumonia-like conditions. In 2003, numerous studies have been published with proof of the expansion of the corona to various states such as Hong Kong, the United States, Thailand, Singapore, and China. In 2003, several cases of a severe acute respiratory syndrome caused by the corona were reported, and in March to June 2003, their death rate was around 1000 patients. In 2012 Saudi Arabian reported multiple infectious victims and deaths(5). COVID-19 was first observed and reported from the pneumonia monopoly belonging to China, Wuhan. Much of the sudden outbreak occurred..In Hong Kong, China, Singapore and other countries in North America and Southeast Asia. In December 2019, this epidemic broke out again in the city of Wuhan (China). NCoV-19 was approximately distributed worldwide to more than a hundred counties. Of all nations, 80,824 cases (54.02%) confirmed by nCoVD-19 are reported and their incidence continually increased(6).

Epidemiology of Covid-19: The coronaviruses are the single-stranded RNA viruses common to humans, other animals, and birds that cause enteric, liver, breathing, and neurologic problems. Six coronavirus species are known to cause human disease. Four viruses such as hCoV-229E, OC43, NL63, and HKU1 are prevailing and typically cause mild illnesses(7). The two new lethal diseases (coronaviruses), the 2002 severe acute respiratory coronavirus syndrome (SARS-CoV), and the 2012 Middle East Respiratory Coronavirus Syndrome (MERS-CoV), are widespread at different locations. The occurrence of new coronaviruses and the broad spread of coronavirus, genetic variation, regular genome recombination, and human and animal behavior are also correlated with the development of new coronaviruses in humans. As(8) the 2019-nCoV genome produced is therefore phylogenetically closest to other SARS-CoV identified beta-coronavirus, which according to other studies suggests are 75-80% identical to the SARS-CoV and 40% equivalent to MERS-CoV. This could be propagated by increasing SARS-CoV and MERS-CoV in the coronaviridae family. Indeed, in primary airway cells of the 2019-nCoV epithelial cell, as opposed to SARS-CoV or MERS-CoV, grow better than standard tissue-culture cells. It seems that 2019-nCoV has the same hACE2 (human angiotensin-converting enzyme 2) cellular receptor as SARS-CoV(8).

Structure genome coronavirus: The genomic structure of the coronavirus is a member of the Nidoviral, the Coronaviridae, and Coronavirinae subfamily. This subfamily is also known as coronaviruses on the basis of the phylogenetic cluster of alpha, beta, gamma, and delta. These viruses are found in RNA enveloped by 26-32 kilobases. The genome has a 5′ cap and a 3′ poly(A) tail to help serve as mRNA in the translation of polyprotein replicas(2). In addition to an untranslated region and a leading sequence, the 5′ coronavirus end comprises several loop structures that contribute to transcription and replication of the RNA. There are also transcriptional regulatory sequences at the beginning of each structural gene which supports their expression. Even the 3′UTR segment includes RNA structures that help replicate and synthesize viruses. Coronavirus accessory proteins are not needed for replication; however, it was demonstrated that some of the protein in viral pathogenesis played significant roles(9). Coronavirus virions, as confirmed by cryo-electrons microscopic and tomographical techniques, have spherical form and a diameter of about 125 nm. The form of the club is like projections on the floor. The nucleocapsid inside the virus is symmetrically symmetric, which is characterizing the negative nature of RNA virus disease(2). Virions are four main structures, namely the pike, membrane, shell, and nucleocapsid, in the 3′ end of the viral genome. The β-coronavirus group also contained a fifth structural protein, hemagglutinin esterase. It binds sialic acids to a glycoprotein’s surface and is involved in acetylesterase. These activities improve protein-mediated cell entry and distribution in S.
Coronavirus Life Cycle: The four stages of a coronavirus life cycle are: (1) entry and attachment (2) protein expression replicase (3) replication and transcription (4) assembly and release. The association of the S-proteins with their receptors marks the virion’s initial attachment to the host cell. The S-Protein and the receiver mixture is the primary determinant of a coronavirus that also affects the hosts and controls the virus’ tissue tropism. In most coronaviruses, peptidase serves as the cell receptor. The receptor reaches the cytosol in the host cell once the virus has been released.

This action is facilitated by the acid-dependent S-protein proteolytic cleavage called cathepsin or other associated proteases accompanied by cellular and viral membrane fusion. Two cleavages are formed in the S2 portion of the protein; one is necessary in order to distinguish the receptor binding and the S-protein fusion domain and another is needed for exposure to peptides. Most of the fusion however occurs in acidified endosomes, some coronaviruses fusing on the plasma membrane region. Virion entry and attachment is accompanied by the expression of replicase protein, in which the replicase gene is converted into the virion genomic RNA. The replicase gene encodes two ORFS; rep1a and rep1b, which in turn are expressed in two co-terminal polyproteins, pp1a and pp1ab. The virus uses a slippery sequence to express all the polyproteins (5’-UUUAAAC-3’) and a pseudoknot of RNA that triggers ribosomal frameshifting from the rep1a read frame to the rep1b ORF. The pp1a and pp1ab polyproteins comprise the 1–11 and 1–16 nsps, respectively. In pp1ab, after extension of pp1a into pp1b, nsp11 from pp1a becomes nsp12. The nsps are assembled in the replicate-transcriptase complex (RTC), the setting in which the synthesis of RNAs is conceived and the replication and transcription of subgenomic RNAs are primarily responsible for these. Create and translate the genome and subgenomic RNAs after virus RNA-synthesis. Subgenomic RNAs reflect the accessory and structural genes as mRNAs occurring downstream of replicas of polyproteins. Both genomic, as well as subgenomic RNAs, are produced by negative-strand intermediates. Finally, coronaviruses also have remarkable capacity to recombine with homologous and non-homologous recombinations. After replication and subgenomic synthesis of the RNA, S, E, and M viral structure proteins are encoded and incorporated into the endoplasmic reticulum (ER). Such proteins can pass through the secretory pathway into the endoplasmic reticulum-Golgi intermediate compartment (ERGIC). The N-protein bud encapsulates viral genomes into ERGIC membranes containing the viral structural proteins that form mature virions. These virions are transported to the cell surface and released via the process of exocytosis.
Conclusions

The pandemic in COVID-19 is a significant challenge to healthcare systems worldwide. The international community was alerted to future worst-case situations by the number of injuries and deaths. We have no clear information ex Strategy to treat COVID-19 patients despite our bits of knowledge of the SARS-CoV-2 infectious cycles. Different potential drugs with SARS-CoV-2 anti-viral activity are studied on the basis of recent research results and guidance. Ideally, an appropriate vaccine and best practices will be established to diagnose and treat symptomatic cases.

Ultrastructure Study of Hydatid Cyst Isolated from Sheep Exposure to Tendazol and Bendaziole

Fatimah H. Al-Ataby¹, Jalal Y. Mustafa², Suzan A. Al-Azizz¹

¹Postgraduate, ²Assist. Prof., ³Prof., Department of Veterinary Microbiology and Parasitology, College of Veterinary Medicine, University of Basrah, Iraq

Abstract

Cystic Echinococcosis is the most important zoonotic parasite with community health in addition to financial problem. This study was planned to detect a morphological structure of protoscolices of hydatid cysts that isolated from slaughtered sheep that exposure to Tinidazole and Bendaziole, and showed a different number and shape of hydatid cysts from different organs like; lungs and livers, with viability result of protoscolices. A clear be to found a hydatid sand and protoscolices distribution, and germinal layer without any treatment, all normal in shape and structure, but samples treated with drug Tinidazole and Bendaziole. It is a clear found distraction of protoscolices, and germinal layer of hydatid cyst in shape and structure. The current study explain some different between the liquid and germinal layer of cyst when sample treated with these drugs and other not treated in shape and morphological form of protoscolices.

Keywords: Echinococcus granulosus, Hydatid cyst, SEM, Tinidazole and Bendaziole.

Introduction

Hydatid cyst consider from one the most zoonotic parasite in the word with community health[1]. Pathogenicity of this parasite count on the location of the parasite in the organs and severity of infection, when occur burst of hydatid cysts some time leads to death due to bleeding and metastasis[2]. In the beginning Echinococcosis develops as a liquid bladder via cyst wall, and protoscolices from germinal layer near cyst cavity[3], Cyst development of and protoscolices taken place in fertile[4].

Scanning electron microscopy is a type of electronic microscope used in the biomedical sciences, study the morphology and distinguish the surfaces of organs and tissues[5-6]. There are little studies using SEM to diagnosis and morphological details such as hooks and protoscolices[7]. Also There are some researches that described morphological shape of worm by using SEM[8]. In addition to study using SEM of hydatid cyst include the morphology of the protoscolices isolated from sheep in Libya[9].

In Egypt a study of hydatid cyst- isolated from tissue lesions in liver and lung of camels and sheep show structures of the protoscolices by scanning electron microscope were done by SEM[10].

The aim of this study was to detect a morphological structure of protoscolices of hydatid cysts that isolated from slaughtered sheep and exposure to Tinidazole and Bendaziole.

This study was planned to detect a morphological structure of protoscolices of hydatid cysts that isolated from slaughtered sheep that exposure to Tinidazole and Bendaziole, and showed a different number and shape of hydatid cysts from different organs like; lungs and livers, with viability result of protoscolices. Tinidazole and Bendazule. It is a clear found distraction of protoscolices, and germinal layer of hydatid cyst in shape and structure. The current study explain some different between the liquid and germinal layer of cyst when sample treated with these drugs and other not treated in shape and morphological form of protoscolices.

**Materials and Method**

Hydatid cysts collection: The hydatid cyst from animal samples (sheep) were collected from slaughter house and butcher after remove the cyst from infected organ.

Scanning Electron Microscope: The isolated cyst was washed three times with normal saline (0.9%) and then separated by using centrifuge then preserve the protoscolices by ethyl alcohol (70%).

Other sample treated with Tinidazole and Bendazule according to[11], after that the samples were sent to Tehran University for scanning electron microscope which was done according to[12].

**Viability of Protoscolices:** The sediment of protoscolices were transferred to clean slid and then put one drop from eosin satin, moving circularly then examined under microscope according to the method[13].

**Result**

The current study showed a different number and shape of hydatid cysts that isolated from sheep from different organs like; lungs and livers (Fig. 1), and the viability result of protoscolices can be found in (Fig. 2).

In (Fig. 3) it clear be to found a hydatid sand and protoscolices distribution, and germinal layer without any treatment, all normal in shape and structure.

![Fig. 1: Hydatid cyst isolated from sheep (A) lung (B) liver](image1)

![Fig. 2: Viability of protoscolices isolated from sheep; live (green) and dead (red) with eosin stain (A) (40x) and (B) (10x).](image2)
Fig. 3: Ultra structure with SEM of (A) hydatid sand with protoscolices (200 X), (B) germinal layer with clear branches (500; 50 X) isolated from sheep without any treatment.

In (Fig. 4) it could be found a clear distraction of protoscolices in hydatid sand and germinal layer of hydatid cyst that treated with Tinidazole drug, while in (Fig. 5) a hydatid cyst treated with Bendaziole drug and a clear change in protoscolices and germinal layer with shape and structure.

Fig. 4: Ultrastructur with SEM of (A) hydatid sand with protoscolices (200 X), (B) germinal layer (500; 250 X) isolated from sheep treated with Tinidazol drug.

Fig. 5: Ultrastructur with SEM of (A) hydatid sand with protoscolices (200 X), (B) germinal layer (500; 250 X) isolated from sheep treated with Bendaziole drug.
Discussion

The current study including ultrastructure study of hydatid cyst by Scanning electron microscope isolated from sheep as normal without any treated and some samples treated with drug Tinidazole and Bendaziole. It is a clear found distraction of protoscolices, and germinal layer of hydatid cyst that treated with Tinidazole drug and Bendaziole in shape and structure.

This study showed a different shape and size of cyst in liquid and germinal layer of each treatment that agreement with Elmajdoub et al (2014) SEM use to examine the size, shape and hooks from different host.

In Egypt study histopathological and the structures of the Protoscolesescamel by (SEM) showed invaginated of protoscolex and the capsule of cyst. The present study also show the effect of two drug Tinidazole and Bendaziole that used these drug in vitro in sheep effect in dead of protoscolices when add to liquid of hydatid cyst after 24h when used eosin stain and also Bendaziole drug of sheep was consider the second degree after Tinidazole to dead of protoscolices of sheep and show this changes in scanning microscope in liquid and germinal layer.

Also another study may be give some similarity with current study that used Flubendazole drug in vivo in mice caused morphological changes in hydatid cyst treated with drug and also showed a similar ultra structural changes in cysts recovered from the same drug the ultra-structural different see in the membrane of cysts recovered from Flubendazole treat animals. Another study about effect the drug on hydatid cyst by scanning microscope by Morris et al (1986) showed that Praziquantel fastresult on the viability of protoscolices. SEM show breakin the tegument of cyst when treated parasite.

The great variability see in the therapeutic hit of a benzimidazole anti helminthespossibly willexplain by the host immunological condition or the facial appearance of the cysts, as well as their size and location.

A number of studies also show using SEM such as other researcher. They show fine details of immature invaginated and mature evaginated of protoscolices.

The current study explain some different between the liquid and germinal layer of cyst when sample treated with these drugs and other not treated in shape and morphological form of protoscolices.

Association between ki67 and PR Expression in Grades of Meningioma and its Prognosis

Sarah Ali Abed¹, Roaa Salih Mahdi², Ali Adnan Jabbar³, Ali Mohammed Khaleel⁴, Suha Suhiel Hussein⁵

¹Ass. Prof. Dr. College of Medicine, Al-Muthanna University/Iraq, ²Lecturer, College of Medicine, University of Babylon/Iraq, ³Ass. Prof. Dr. College of Medicine, Al-Muthanna University/Iraq, ⁴F.I.B.M.S., Specialist/Babylon Health Director/MOH/Iraq, ⁵M.Sc. Specialist/Al- Muthanna Health Director/MOH/Iraq

Abstract

Introduction: Meningioma is the very important type of tumor that occur in central nervous system (CNS) that represented 1/3 of whole tumor of CNS. In USA 97/100,000, persons recorded have meningioma. With 170,000 patients detected as meningioma. The aim of study is the aim of the present study is to evaluate the use of immunhistochemical expression of PR and ki67 for predicting the grades of meningioma, which are important in their prognosis, and line of treatment.

Method: Ninety patients with meningioma were collected from the Neurosurgical Hospital-Baghdad, during the period from January 2017 to January 2020. The data for cases were collected to study the age, gender and grade of tumor. Staining hematoxylin/Eosin (H plus E) for histological inputting and classifying of the tumors and immunohistochemically workup for PR & Ki67 done.

Results: Cross sectional study for 90 patients with age, mean (44 ± 12) years old, in current study 64% of patients was females and 36% of patients was males, strong positive PR expression represented 50% of patients, 79% of patients have low Ki 67, 15% of them have intermediate Ki67 and 6% of patients with high Ki67. Most of patients with age group 40-59 years old (51%). The mean and SD of Ki67 in (%) according to grades of meningioma I, II and III as following: (0.3 ± 0.07), (7 ± 5.9) and (38 ± 0.07) respectively. There is significant association between grades of meningioma and PR expression; 71% of grade I with PR expression strongly positive, 23% of grade II with PR expression were weakly positive and 100% of grade III with PR expression were negative. In addition, there is significant association between grades of meningioma and prognosis; 100% of grade I with good prognosis, 100% of grade II with fair prognosis and 100% of grade III with poor prognosis. In current study, also there is significant association between grades of meningioma and Ki67; 100% of grade I with low level of Ki67, 100% of grade III with high level of Ki67 and 64% of grade II with intermediate level of Ki67. There is no significant association between age and gender with grades of meningioma.

Conclusion: The mean Ki-67 was significantly more in meningioma grade III than in patients with grades II and I as WHO classification. There is strong expression of PR was found mainly in the grade I typical meningioma group. Utilization of markers for proliferation (ki-67 labeling index) and hormonal expression (Progesterone Receptor) in combination with histopathological features may help in the identification of biologically aggressive meningioma.

Keywords: ki67 & PR expression, grades of meningioma, prognosis.
detected as meningioma. Female to male ratio show females more than males 2:1 for meningioma intracranial and 10:1 for meningioma of spine all pervious tumor detected at middle age group. Two important factors that affected on the prognosis of patients with meningioma: the ratio of resection of tumor and histopathological degree of tumor. Recurrence can occur when tumor with high-score not reach complete resection. Recurrence interpreter according to WHO guide, in which recurrence of meningioma that characterize as kind, unusual and anaplastic for 20 years is 7-25%, 29-52% and 50-94%, correspondingly. Subsequently there are boundaries to repetitive histopathological checkup in expecting tumor progressivity, numerous scrutiny procedures established including cytogentic and use of immunohistochemically checkups. However, those checkups have not been accepted as usually on patients with meningioma. Approximately important immunohistochemically tests on meningioma include EMA, vimentin and cytokeratin. Ki-67 checkup, which is a proliferative interpreter, displays the outcomes as a prognostic meningioma. Therefore, the aim of study is the aim of the present study is to evaluate the use of immunohistochemical expression of PR and ki67 for predicting the grades of meningioma, which are important in their prognosis, and line of treatment.

**Method**

**Materials:** Ninety patients with meningioma were collected from the Neurosurgical Hospital-Baghdad, during the period from January 2017 to January 2020. The data for cases were collected to study the age, gender and grade of tumor. Staining hematoxylin/Eosin (H plus E) for histological inputting and classifying of the tumors and immunohistochemically workup for PR & Ki67 done.

**Specimens:** According to WHO classification the 90 cases classified into typical meningioma, atypical meningioma and malignant meningioma. From each formalin fixed paraffin embedded tissue, three sections of 5 micron thickness were obtained and stained by haematoxylin & eosin staining method and immunohistochemically by using monoclonal antibody for PR & ki-67.

**Method of staining procedures:**

**a. Deparaffinization:** This has been performed by immersion in the following:

1. Xylene for 5 minutes.
2. Xylene for 5 minutes.
3. 99% ethanol for 5 minutes.
4. 99% ethanol for 5 minutes.
5. 99% ethanol for 5 minutes.
6. 95% ethanol for 5 minutes.
7. 70% ethanol for 5 minutes.
8. Distilled water.

**b. Hematoxyline and eosin staining method:**

1. Dewax sections (deparaffinization as above).
2. Stain in hematoxyline for 3-10 minutes.
3. Wash well in running tap water.
4. Remove excess stain by differentiating the sections in 1% acid alcohol (1% in HCL 70% alcohol) for 5-10 seconds.
5. Wash well with in tap water until sections regain their blue color.
6. Stain in eosin for 2-5 minutes.
7. Dehydrate slowly through increasing grades of alcohol (i.e. 70%, 90% and 100%).
8. Clearing by xylene.
9. Mount wit DPX.

**c. Immunohistochemical staining method:** One tissue block with representative tumor was selected in each case for immunohistochemical staining. By using the Envision™ Flex, staining was performed by manual method as following:-

1. Five microns section was obtained from the formalin fixed paraffin embedded tissue block and mounted on positively charged slide. The sections were dried for 1 hour at 60°C.
2. Deparafinization was done by incubating the section in an oven at 65°C for 20 minutes followed by two changes of xylene for each.
3. Target retrieval solution, PH 9 (Dako cytomation).
4. Incubate in water bath at 95°C for 20-30 minutes.
5. After cooling, wash in Envision™ Flex wash buffer for 5 minutes.
6. Encircle tissue with Pap Pen. Wipe off buffer ½ cm above and below the tissue and draw a line with the Pap Pen.
7. Incubate with Envision™Flex Peroxide Blocking Reagent for 5 minutes.
8. Wash in Envision™Flex wash buffer.
9. Incubate with primary antibody for 20 minutes.
10. Wash in Envision™Flex wash buffer.
11. Envision™Flex/HRP secondary antibody (ready to use) for 20 minutes.
12. Wash in Envision™Flex wash buffer, incubate for 5 minutes.
13. Incubate with Envision™ Flex-DAB+ chromogen (for 10 minutes).
14. Wash in Envision™ Flex wash buffer.
15. Envision™ Flex hematoxylin (ready to use) incubates for 5 minutes.
16. Wash slides in deionized water.
17. Wash in Envision™ Flex wash buffer.
18. Wash slides in deionized water.
19. Dehydrate and mount the slides.

A. Ki-67 Scoring System: Immunohistochemistry for Ki-67 was carried out following the streptavidin–bioti n–peroxidase method (Monoclonal Mouse, Anti-Human Ki-67 Antigen/FITC, Clone MIB-1, Manufactured by Dako, Denmark). The mouse monoclonal Ki-67 antibody was used at a dilution of 1:25. Breast cancer tissue was used as positive control, and negative controls were performed by omitting the primary antibody. The Ki-67 staining index was recorded as the percentage of positive-staining tumor cell nuclei in 1000 tumor cell nuclei evaluated. The determinations were based on high magnification areas with the most immunostaining.

B. Progesteron Receptor (PR): Immunohistochemistry for PR was carried out by using polyclonal rabbit antiprogesterone was used at dilution 1:100 as the primary antibody, goat anti-rabbit IgG, and rabbit peroxidase antiperoxidase complex. Breast cancer tissue was used as positive control, and negative controls were performed by omitting the primary antibody. PR expression recorded into group I to III as follows: Group I – high staining of nucleus, group II - Weak staining if nucleus and group III - Lackingstaining of nucleus.

Statistical analysis done by SPSS 22 calculated mean and SD for age Ki67 and percentage, frequency for categorical variables. Chi square use for revealed association between categorical variables, significant association when P-value less than 0.05.

Results

Cross sectional study for 90 patients with age, mean (44 ± 12) years old, in current study 64% of patients was females and 36% of patients was males, strong positive PR expression represented 50% of patients, 79% of patients have low Ki 67, 15% of them have intermediate Ki67 and 6% of patients with high Ki67. Most of patients with age group 40-59 years old (51%). The mean and SD of Ki67 in (%) according to grades of meningioma I, II and III as following: (0.3 ± 0.07), (7 ± 5.9) and (38 ± 0.07) respectively. As show in table 1 and 2.

As in figure 1 and 2, the prognosis of meningioma is 70% of patients with good prognosis and 24.4% with fair prognosis. While the distribution of patients according to grade of meningiomas 70% of them in grade I, 24.5% in grade II and 5.5% in grade III.
Fig 1: Distribution of prognosis of meningioma.

Fig 2: Distribution of grades of meningioma.
In table 3: there is significant association between grades of meningioma and PR expression; 71% of grade I with PR expression strongly positive, 23% of grade II with PR expression were weakly positive and 100% of grade III with PR expression were negative. In addition, there is significant association between grades of meningioma and prognosis; 100% of grade I with good prognosis, 100% of grade II with fair prognosis and 100% of grade III with poor prognosis. In current study, also there is significant association between grades of meningioma and Ki67; 100% of grade I with low level of Ki67, 100% of grade III with high level of Ki67 and 64% of grade II with intermediate level of Ki67. There is no significant association between age and gender with grades of meningioma.

Discussion

Meningioma explanation more than 30% of major intracranial tumors according to WHO histologically classification of nervous system tumors. Most grade I meningioma classify as benign tumor while grade II and grade III are associated with a advanced risk of reappearance and littler survival periods. Human meningiomas unveil a heterogeneous histopathology, which may explain the repeated revisions of classification schemes. This study presents a review of 90 primary meningioma classified according to WHO classification of 2007. In current study, 64% of patients was females and 36% of patients was males this is similar to other results in other study that stated the incidence of meningioma in women was higher with a ratio of 2.1:1 compared to men. This comparison was reversed in prepubertal-age meningioma. In atypical and anaplastic meningioma cases, it was more dominant in men. The cause of the distribution is still unclear. Several studies have shown a positive relationship between the use of hormonal therapy used in women with the development of meningioma. Age has no effects on grades of meningioma, but most cases in all three grades of meningioma occur between (40-59) years at distribution 47.6%, 59.1% and 60.00% in grade I,II, and III respectively. In current study the incidence of grade I is 70% which is usually associated with good prognosis, grade II is 24.5 and grade III is 5.5% which is poor prognosis while grade II is in between regarding incidence and prognosis, this is similar to other study that stated the incidence of grade I is higher than grade II and grade II is higher than grade III. Several studies have been done to evaluate the title role of Ki-67 and PR in meningioma and to assess their character as prognostic features in assessing the performance of meningioma but many studies have given different suggestions concerning the association of Ki-67 and PR in meningioma and to assess their character as prognostic features in assessing the performance of meningioma. In current study the expression of progesterone receptor is strong in 45(71.4%) in grade I, negative PR expression in all cases of grade III, with weak expression in grade II, so PR expression strongly associated with grade of meningioma as grade of meningioma increase PR expression will be decrease. Ki-67 is a best indicator of cell proliferation eminence of the meningiomas. Ki-67 examines are progressively general because of their slight tissue necessities and appropriateness for regularly stable tissues. In the current effort, the mean Ki-67 classification index was significantly advanced in meningiomas of WHO grade III than in patients with grades I and II, like to the literature. Several studies in the past have demonstrated a proportionate increase in proliferative index and decrease progesterone receptor expression with increasing tumor grade. The assessment of proliferative activity and PR expression are a good indicator of tumor aggressiveness.

Conclusion

The mean Ki-67 was significantly more in meningioma grade III than in patients with grades II and I as WHO classification. There is strong expression of PR was found mainly in the grade I typical meningioma group. Utilization of markers for proliferation (ki-67 labeling index) and hormonal expression (Progesterone Receptor) in combination with histopathological features may help in the identification of biologically aggressive meningioma.

Distinguishing Exudative from Transudative Effusion by Using Pleural Fluid Cholesterol and Bilirubin in Comparative Study to Light’s Criteria

Hanaa Jabbar Ismail¹, Haider Abdulhameed Alqaraghuli², Hashim Mahdi Hashim³

¹Dr. Specialism, Health Department-employment in Ministry of Health/Iraq, ²Lecturer, ³Prof., Internatal Medicine Department/College of Medicine, Al-Nahrain University/Iraq

Abstract

Background: Pleural effusions are often classified into exudates and transudates based on certain biochemical parameters which include protein; lactate dehydrogenase (Light’s criteria); cholesterol and bilirubin, so the aim of the study is to evaluate the importance of pleural fluid cholesterol and bilirubin in differentiating exudative from transudate pleural effusion.

Method: Fifty patients with pleural effusion were evaluated for pleural fluid protein, lactate dehydrogenase (LDH), cholesterol and bilirubin and compared simultaneously with drawn blood sample for protein, LDH and bilirubin.

Results: In this study cholesterol in pleural fluid has a 94%, 100% sensitivity and specificity respectively and bilirubin ratio (pleural fluid bilirubin/serum bilirubin) has a sensitivity of 88% and specificity of 85% while the parameters of Light’s criteria i.e. protein ratio (fluid protein/serum protein) has 88%, 85% sensitivity and specificity respectively and LDH ratio (fluid LDH/serum LDH) has a sensitivity of 100% and specificity of 71%.

Conclusion: Pleural fluid cholesterol and bilirubin ratio have a better sensitivity and specificity in differentiating exudative from transudative pleural effusion than the parameters of Light’s measures.

Keywords: Pleural fluid cholesterol, bilirubin, exudative transudate effusion.

Introduction

The internal surfaces of the thoracic cavity are cover by pleura, includes a cover of mesothelial cells held up by a net of connective plus fibro elastic tissue. Usually, a small amount of fluid within the pleural space works like a lubricant to decrease friction amid chest wall and lung at inspiration and expiration. This fluctuation of fluid is based on the oncotic in addition to hydrostatic pressures within the parietal plus visceral pleura as well as the pressure inside the pleural space its own. Fluid is drained out mostly through lymphatics within the parietal pleura¹. Transudative pleural effusions derive from general illnesses that may not directly affect the pleura but alternatively provide an asymmetry of Starling’s forces, ending in moving of fluid within the pleural space. The analysis for transudates involve recognition of the systemic illnesses like nephrotic syndrome, congestive heart failure and cirrhosis with ascites. Treating these effusions is done by management of the underlying illness. After injury that occur in pleural surface, exudative effusions result. Intrapleural illness can be suggested by the presence of exudative effusion². In order to differentiate exudative from
transudative pleural effusion, Light et al. established\(^3\) a criteria to do so with sensitivity 99% and specificity 98% that include pleural protein/serum protein of >0.5, pleural LDH/serum LDH of >0.6 and an estimated level of LDH in the pleural fluid more than two thirds LDH serum level. Yet other studies investigating Light’s criteria showed a specificity of 70-86% and about 25% of cases identified by Light’s criteria to have exudative pleural effusion have a transudate effusion\(^4\). It has been found by Meta-analysis study on this subject that there is no single test could clearly differentiate between transudative and exudative pleural effusion\(^5,6\). Leukocytes and erythrocytes’ degeneration will increase the concentration of cholesterol inside pleural cavity. Another theory is that cholesterol of pleura originates from plasma; 70% of plasma cholesterol is low density lipoproteins (LDL), and the rest is very low density lipoproteins (VLDL) or high density lipoproteins (HDL), so plasma cholesterol enter pleural cavity after increased permeability of pleural vessels\(^7\). Pleural fluid bilirubin with pleural serum ratio of >0.6 is suggestive of an exudate with a sensitivity and specificity of 90.6% and 96.2%, respectively\(^8\). In non-diagnosed exudative effusions measuring the glucose level is of particular importance in which a decreased glucose level in the pleural fluid (<60 mg/dL) can limit the possible diagnosis to either one of these: rheumatoid and tuberculous effusion, Para-pneumonic and hemothorax or malignant effusion and the Churg-Strauss syndrome\(^9\). In Parapneumonic effusion, glucose level in pleural fluid < 40 mg/dL, so for treatment this case needstube thoracostomy. In rheumatoid effusions a glucose level in pleural fluid <30 mg/dL\(^10\). While in systemic lupus erythematosus (SLE) a glucose level in pleural fluid > 80 mg/dL\(^11\). In case of pleural effusion secondary to malignancy usually have a low glucose level and a positive cytology in the pleural fluid\(^12\). This study aims to assessing the value of pleural fluid bilirubin and cholesterol levels in differentiating the transudative from exudative pleural effusion in comparison to Light’s criteria.

**Method**

A prospective study in which 50 patients with pleural effusion age ranges from 25-70 years where admitted at the medical department at Al-Imamein Kadhimine Medical City. The study period was conducted from April 2013 to January 2014. Thirty patients (60%) were males and 20 patients (40%) were females. Inclusion Criteria: Age ≥ 16 years, patients with definite diagnosis of pleural effusion on clinical and radiological imaging.

**Exclusion Criteria:** Patients <16 years old, patients with undiagnosed pleural effusion, diagnosed patients who are on treatment, pleural effusion with renal insufficiency or pulmonary embolism because both can cause transudative and exudative effusion that can affect the result of our study. Following a thorough history, physical examination, the pleural effusion was confirmed and localized by chest X-ray. Diagnostic pleural fluid tapping was done in each case, in some cases ultrasound guided localization of effusion was done. The samples then were examined for glucose, white blood cell count, LDH, cholesterol, bilirubin, protein, acid fast stain, Gram stain, bacterial culture, and cytology. The pleural effusions were categorized as exudative and transudative according to the causative etiology, the Light’s criteria, pleural bilirubin/serum bilirubin > 0.6 mg/dL and cholesterol in pleural (considering a value of 45 mg/dL as cutoff point). Statistical analysis: The measured biochemical parameters usefulness for identifying exudates was assessed with Bayesian method in order to calculate the sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and accuracy of each parameter. The statistical significance measured by X2 analysis to test differences between means. A P value <0.05 considered significant.

**Results**

The mean age of the 50 patients included in the study was 51.6±14.9 years (range, 25-70 years); table 1 shows the age and gender distribution among patients with pleural effusion according to.

Thirty six patients (72%) had been diagnosed to have exudative pleural effusion and 10 patients (20%) had been diagnosed to have transudative pleural effusion using fluid LDH/serum LDH ratio (LDH ratio) while 34 patients (68%) had been diagnosed to have exudative pleural effusion and 14 patients (28%) had been diagnosed to have transudative pleural effusion using fluid bilirubin/serum bilirubin ratio (bilirubin ratio). There is no significant difference between LDH ratio and bilirubin ratio in distinguishing exudative from transudative effusion of pleura.

Discussion

From all 50 cases included in the study, 72% of them (36 patients) found to had exudative effusion, and 28% of them (14 patients) found to had transudative effusion based on the clinical diagnosis as shown in table 1. Tuberculosis being the most common diagnosis in exudative pleural effusion with a 48% (24 patients) followed by malignancy {8 patients (16%)} as shown in table 2, this result is consistent with C. K. Liam et al. study that showed tuberculosis as one of the most common causes of exudative effusion of pleura(13). In our study using light’s criteria the results had a sensitivity of 88% for protein ratio and 100% for LDH ratio with a specificity of 85% for protein ratio and 71% for LDH ratio as shown in table 3. According to Light et al. study the difference between exudative and transudative effusion of pleural was done with high accuracy and nearly 100% sensitivity and specificity both using LDH and protein levels in both serum and pleural fluid(3), being highly accurate and widely affordable the Light et al criteria had been the gold standard for initial categorization of pleural effusions. Yet many several followed studies failed to reproduce a similar excellent result. However many of the studies, used Light et al. criteria showed that the sensitivity for exudates effusion identification mainly remain greater than 95%, but the specificity had not exceed 78%(14). In this study 32 patients (64%) had exudative pleural effusion and 12 patients (24%) had transudative pleural effusion using fluid bilirubin/serum bilirubin ratio while 34 patients (68%) had exudative pleural effusion and 14 patients (28%) had transudative pleural effusion using pleural fluid cholesterol level. With a P-value of 0.6 means that the difference between pleural fluid cholesterol and protein ratio is statistically non-significant difference between exudative and transudative effusion of pleural, moreover, 36 patients (72%) had exudative pleural effusion and 10 patients (20%) had transudative pleural effusion using fluid LDH/serum LDH ratio while 34 patients (68%) had exudative pleural effusion and 14 patients (28%) had transudative pleural effusion using pleural fluid cholesterol level. P-value = 0.6 and 0.3 which means there is no significant difference between LDH ratio and pleural fluid cholesterol level in differentiating exudative from transudative effusion as shown in tables 4 and 6 respectively. Like studies done by Romero et al in which sensitivity plus specificity of Light’s measures for the transudates and exudates, and diagnostic exactness of Light measures and how cholesterol in pleural cavity improve this diagnosis(15). In another study done by Saad Abdul-Razzak Z. at 2001, he also found that pleural cholesterol level had a high sensitivity (100%) in differentiating exudative from transudative pleural effusion and no significant difference between protein in pleural fluid and cholesterol level in the identification of transudative from exudative effusion(16). In the current
study 32 patients (64%) had exudative pleural effusion and 12 patients (24%) had transudative pleural effusion using fluid protein/serum protein ratio while 32 patients (64%) had exudative pleural effusion and 12 patients (24%) had transudative pleural effusion using fluid bilirubin/serum bilirubin ratio. P-value = 1.0 which means there is no significant difference between protein ratio and bilirubin ratio regarding the differentiation of transudative and exudative effusion also 36 patients (72%) had exudative pleural effusion and 10 patients (20%) had transudative pleural effusion using fluid LDH/serum LDH ratio while 32 patients (64%) had exudative pleural effusion and 12 patients (24%) had transudative pleural effusion using fluid bilirubin/serum bilirubin ratio. P-value = 0.3 and 0.6 which means there is no significant difference between LDH ratio and bilirubin ratio in distinguishing exudative from transudative effusion of pleura as shown in table 5. This results also found in a study done by Meisel et al in which they found that the bilirubin qualifying measure comes to the well-accepted LDH in addition to protein criteria and may even work as another qualifying measure to differentiate an exudative from transudative pleural effusions(17).

**Conclusion**

For distinguishing exudative in addition to transudative pleural effusion. Computing pleural fluid cholesterol level carries a superior sensitivity, specificity in addition to positive predictive value comparing to Light’s criteria parameters, and it is a more cost effective, easier and more efficient way in differentiating transudates from exudates along with the ratio of Pleural/serum bilirubin has the same advantage of cost effectiveness and the easiness.

Determine the Effect of Polymorphisms of and IL23R Genes on in Psoriasis in Babylon Province

Dheyaa B. Mohammad¹, Thana M. Alsawi², Wisam AliAwadh²

¹Lecturer, ²Assiss. Prof., Faculty of Medicine, Babylon University, Iraq

Abstract

Background: IL23R Polymorphisms appear to be engaged with several different types of autoimmune diseases such as psoriasis.

Aim: We investigated the association of the Arg381Gln (R381Q) polymorphism in the IL23R gene with psoriasis risk in Babylon province.

Methodology: The IL23R-gene variation Arg381Gln (R381Q) was performed using the programmable thermal cycler gradient PCR system. We investigated the association of IL23R gene variants with different clinic pathological features of psoriasis patients.

Results: The allelic frequency of IL-23R Arg381Gln (R381Q) (rs11209026) gene showed that the frequency of AA genotype in patients with Psoriasis was more than in the control group (13 vs 8%) (OR = 2.222, CI 95% (0.476-10.357). In addition, this study suggests there is a statistical difference (P-valu>0.05) between (AG) and (AA) (P-value = 0.033), (AG) and (GG) (P-value = 0.012) genotypes in patients group compared to controls. The results also showed that the frequency of (G) Arg allele was (0.6) (0.62) in patients and control group respectively, and found no significant difference between (A) Gln and (G) Arg alleles in patients and controls (OR= 0.754), CI 95% (0.42-1.22).

Conclusion: Our results showed no significant association of the IL-23R Arg381Gln (R381Q) (rs11209026) polymorphism with psoriasis patients susceptibility in Babylon province. The IL-23R Arg381Gln heterozygote significantly increases the risk and can’t be useful as a predisposing genetic marker.

Keywords: Psoriasis, polymorphism, IL-23R Arg381Gln, Health; skin.

Introduction

Psoriasis is an immune-mediated proliferative skin disorder and chronic inflammatory disease that predominantly involves the skin, nails, and joints that have a prevalence of 3% worldwide(¹). The disease happens in the different age groups with less than 10 years occurrences is rare (incidence 0.3-0.5), and greatly between 15-40 years(²). The main reason is still unknown, historically, psoriasis is considered a primary disorder of keratinocyte(³,⁴). There is hyper-proliferation of keratinocytes and alteration in differentiation Genetic abnormality leads to keratinocytes hyper-proliferation which in turn, produces a defective skin barrier allowing the penetration of antigens which resulting in the immune response to that antigen (Ag)(⁵). Recently the genetic mapping of the MHC Class I show that region indicates that HLA-Cw6 itself is probable to be the functional variable predisposing to psoriasis, rather than sing for some other disease gene neighbor. This finding provides a molecular target for the explanation of the immunologic basis of psoriasis(⁶,⁷). TNF- α (Tumor necrosis factor-alpha), IL-17 (interleukin 17), IL-6 is a group of inflammatory cytokines produced by human

adipose tissue and plays a significant role in the begin of insulin resistance, dyslipidemia, D.M and finally cardiac disease in psoriatic patients (8). An adipose tissue macrophage is responsible for producing inflammatory cytokines α-TNF, IL-6, 7, 8, 17, 18, 23 in response to adipose tissue inflammation, which leads to increasing the level of this cytokines, and resulting in endothelial cell damage and atherosclerotic plaque additionally to initiation of psoriasis(9). This study aimed to identify the influence of IL23R gene rs11209026 SNPs variant on the susceptibility of developing psoriasis.

**Materials and Method**

**DNA Extraction:** DNA was extracted by the procedure depending on the manufacture protocol and was detected by using the agarose gel electrophoresis technique.

**IL-23RArg381Gln (R381Q) (rs11209026) genotyping:** Amplification IL23R gene was done by polymerase chain reaction (PCR). Amplification was performed in a programmable thermal cycler gradient PCR system that allows amplification of test DNA only when the target allele is contained within the sample. PCR-restriction fragment length polymorphism was used to investigate the polymorphism (rs11209026, Arg381Gln, R381Q) in the IL-23 receptor (IL23R) gene in control and psoriasis patients involved in this study. Optimization of PCR-RFLP conditions was done by using:

The different volumes of primer (1 µl, and 1.5 µl), Gradient annealing temperature and choosing the conditions that gave the best result.

A master premix of Promega® was used as mentioned with PCR conditions. Master premix components Top DNA polymerase 1 U/µl), Each: dNTP(250 mM), Tris-HCl (pH 9.0) 10 mM, KCl(30 mM), MgCl2 (1.5 mM),Stabilizer and tracking dye.

**Amplification conditions of IL-23RArg381Gln (R381Q) genotyping:** The amplification conditions used were at 94 C for 5 minutes followed by 94C for 1 min, 61 C for 1 min, 72 C for 1 min followed by the final extension at 72 C for 5minutes. The amplification products were separated by electrophoresis through 1.5 % agarose gel stained with ethidium bromide and visualized on a UV transilluminator. Primers F and R flank the exon of the IL-23R Arg381Gln (R381Q) gene, resulting in a band of 508bp to act as a control for DNA quality and quantity.

**Results**

The results of the present study showed that the frequency of AA\Arg/Arg genotype/phenotype in patients with Psoriasis was more than in the control group (13 vs 8%)(OR = 2.222, CI 95% (0.476-10.357). In addition, this study suggests there is a statistical difference (P-valu>0.05) between (AG) (Arg/Gln and (AA) Gln/Gln (P-value = 0.033), (AG) Arg/Gln and (GG) Arg/Arg (P-value = 0.012) genotypes/phenotype in patients group compared to controls. The results also showed that the frequency of (G) Arg allele was (0.6) (0.62) in patients and control group respectively, and found no significant difference between (A) Gln and (G) Arg alleles in patients and controls (OR= 0.754), CI 95% (0.42-1.22). The rs11209026 IL23R variant was a protective marker. Recent studies have shown that a functional single nucleotide polymorphism (SNP) (Arg381Gln; R381Q; rs11209026; 1142 G wild-type A reduced function) in the IL-23R gene (in exon 9) led to decreased IL-23- dependent IL-17 production (Guan et al. 2012). The disease-protective R381Q IL-23R may result in a loss of function, in primary human CD4+ and CD8+ T-cells, leading to decreases in IL-23/TH17 pathway cytokine production.

**Study Population:** All demographic characteristics of the subjects are shown as follows a total of 45 psoriasis patients and the same number of gender-matched healthy control wereanalyzed. This research was confirmed by the Research ethics committee, University of Babylon college of medicine. Blood(5ml) samples were collected from participants in EDTA and gel tubes.
Discussion

A survey by Di Meglio and Suggested that IL-23R RQ381 exerted its protective effects by attenuation of IL-23-induced TH17 functions (IL-17A production) without interfering with TH17 differentiation (10). Further, Sarin et al. 2011 showed that CD4 and CD8+ T-cells from healthy R381Q IL-23R carriers had decreased IL-23-dependent IL-17 and IL-22 production relative to WT (wild-type; G allele) cells Several mechanisms might contribute to these observations, including a reduced capacity of IL23RQ381 to activate STAT proteins due to an impaired association of JAK2 proteins with the cytoplasmic tail of the receptor(11). As a result, R381Q CD8+ and TH17 CD4+ T-cells displayed decreased IL-23- and STAT3-dependent expansion, STAT3 phosphorylation, and STAT3 activation compared with WT cells. This SNP was also associated with a lower percentage of circulating TH17 and TC17 cells. Abdollahi et al. 2015 reported that the number and activity of both circulating TH17 cells and in vitro (ex vivo)-differentiated TH17 cells did not differ between G and A allele carriers(12). This finding supported the belief for a major role for IL23 in the generation of TH17 cell effector responses during tissue inflammation (rather than in systemic inflammation) and demonstrated the importance of IL-23 in mediating TH17 effector responses in humans. Those results also provided support for a critical role for the IL-23/IL-23R signaling in generating pathogenic TH17 responses. Further, those studies explained the protective role of R381Q in autoimmune disorders and further supported the hypothesis that blocking the IL-23 pathway could lead to improvements in hosts with autoimmune disorders like psoriasis(13). Raymond et al. 2015 investigated another mechanism of function for this SNP. The results of that study showed the R381Q variant promoted the expression of a soluble IL-23R-encoding mRNA species. The R381Q polymorphism altered the IL-23R alpha-chain mRNA splicing and favored exon 9 skipping by reducing the binding of the splicing enhancer SF2. This enhanced expression of the D9 mRNA consequently diminished IL-23 signaling. Multiple splice forms of the human IL23R transcript exist and one, D9, encodes a soluble form of the receptor. Thus, a presence of an R381Q variant increases the expression of the soluble form of IL23R mRNA (which, in turn, functions as a decoy receptor) and lowers the ability of a host to develop a TH17 phenotype upon IL-23 stimulation (14). This study that we mention it agrees with our present study that patient or control that have (AA)Gln/Gln genotype/phenotype have (OR=2.222) chance possible disease occurrence and (GG)Arg/Arg genotype/phenotype have (2.074) possible chance disease when we compare with the reference group (AG) Gln/Arg that consider a protective. In conclusion, our result showed no significant correlation with IL-23R Arg381Gln (R381Q) gene in over dominant model there are no significant increases in the risk of psoriasis and it’s can’t be useful as a predisposing genetic marker for psoriasis.

Abstract

Objectives: The objective was to study the atrial electromechanical P-wave electrocardiography (ECG) gated measurement of conduction times by tissue Doppler echocardiography (TDI) and left atrial mechanical function and volumes, the non-invasive predictors of atrial fibrillation, in diabetics. Methods: The study conducted by analytic case-control study and included 100 adult patients (63 men, 37 women; mean age 50.49 ±8.1 years), diagnosed with diabetes mellitus according to the criteria of the Diabetes Association of America, and 100 adults healthy (50 men; 50 women; average age 49.25 ±9.8 years) as control. Tissue Doppler imaging (TDI) and conventional echocardiography study was done. Assessment of electromechanical delay was done with the onset of the surface ECG P-wave to the systolic ā-wave onset on TDI of the AV valve annulus of the septum, left and right ones. Using the disk method, the left atrial volumes were assessed. The mechanical function and volumes of the left atrium were computed. Results: The E/A and eˉ/aˉ mitral ratio was assessed by the left and septal annuli were the mean difference significantly less in diabetics than in controls (P=0.031) and (P=0.034 correspondingly. The electromechanical inter-atrial and intra-atrial delay were significantly greater within the diabetics, contrasted to controls (P<0.001) and (P=0.003) correspondingly. V olumes of active left atrial emptying (LAAEV) and the ratio of active left atrial ejection (LAAEF) were significantly higher in diabetics in comparison with controls (P =0.002) and (P<0.001) correspondingly. Both were significantly correlated to E/A and eˉ/aˉ. Conclusions: In diabetics, conduction times of the atrium by TDI and the dispersion of the P-wave by surface ECG were longer. Furthermore, the mechanical functions and volumes of the left atrium were affected by altering diastolic function in diabetics.

Keywords: Diastolic function, atrial fibrillation, electromechanical delay, Left atrial mechanical function, diabetic state.

Introduction

The duration time between atrial mechanical peak contraction and the electrical depolarization of the atrium is called atrial electromechanical delays (AEMDs). AEMDs prolongation might be considered as a sign to distinguish arrhythmia (PAF) in patients than in control and prediction of PAF occurrence in observational and case-control studies as Badran and his associates found(1). The clinical suggestion supports the opinion that atrial electromechanical conduction delay prolongation suggest left atrial remodeling electricity, that is fundamental for the AF maintenance(2). It is also an indicator to worse prospects in DM with valvar disease of the heart and HF(3). Oxidation stress is a principal
involving feature to endothelial vascular dysfunction in DM. It is ascribed for its multilayered character by lowering available nitric oxide (NO) and provoking pro-inflammatory reactions which aggravate oxidation stress degree. DM upsurges CVD hazard, yet in healthy persons, signifying an important demand to delineate the mechanism(4). Irregularities of atrial transmission were appraised with noninvasive methods by using TDI and ECG in previous studies(5) and also has been determined to be elongated in many diseases that influence the myocardium(6). Although the atrial conduction time indicates the electrical remodeling estimation of atrium, TDI and 2 simple P-wave maximal duration (P max) and P d markers might give information on extending the time of atrial conduction (7). Remodeling of atria, It might be electrical, operational and physical (8). A larger period of pressure (more than five weeks) can lead to damage (fibrosis and apoptosis) irreversibly. The remodeling however, manifests itself in atria as dilation lately.

Methods
A total of 100 consecutive DM patients were included between the November 2019 and May 2020, all participants were conducted by analytic case-control investigation. All sex and gender adult participants who were in sinus rhythm and diabetes mellitus, diagnosed by DM American Association criteria, taking antidiabetic therapy, in addition to adult age matched healthy volunteers, were included in this study. All contributors with a history of CAD, high BP, LVEDD hypertrophy, LVEF under 50%, primary CMP, valvar cardiac disease, arrhythmia, LBBB ECG, abnormal AV conduction, users for drugs that affect conduction system, thyroid dysfunction, electrolyte disturbance, Anemia, CKD, lung disease (COPD, sleep apnea), and inadequate quality of echo study and images of ECG were eliminated from the research. By 4-chamber outlook of heart apex, the pulsed Doppler sample volume was positioned at the LV mitral lateral annulus level, then successively, septal and tricuspid annuli. The period of time since the start on the surface ECG P-wave toward the start of the delayed diastolic a wave, named PA on TDI, was taken, starting from the lateral mitral annulus (PA lateral), septal mitral annulus (PA septal), the differentiation concerning PA lateral and PA septal (PA lateral- PA septal), was demarcated as intra-left, then septal with tricuspid was demarcated as intra-right atrial, then between mitral and tricuspid as EMD (inter-atrial). All dimensions were documented around a mean of 3 cycles of heart beats (9). Statistics study done by means of SPSS version 23. Categorical variables were given as percentages and rate of recurrence. Continuous variables were given as (mean ± S D). T-test of student has been accustomed toward contrasting averages between diabetic group and control. It was used that Chi-square test find the association between categorical variables. Correlation coefficients (r) were accustomed to assess the association between continuous variables. The significance of means was counted by p-value at ≤ 0.05*.

Results
Basic laboratory and clinical characteristics of 100 diabetics (mean age 50.49 ± 8.1 years) likewise 100 normal followers (average age 49.25 ± 9.8 years). The following parameters were significant in diabetics in comparison with the control in the following: body mass index (P=0.05*) heart rate (p=0.049*), low-density lipoprotein cholesterol (p=0.045*). White blood cell count (p=0.022*) and fasting blood glucose (p<0.001*) were considerably increasing in DM using the t-test for continuous variables. In addition, the diameter and volume index of LA were significant (p = 0.01*) respectively.

P-wave indicators and parameters of TDI have been taken in table 3. P max duration (p = 0.019*) and P d (p< 0.001*) were considerably larger in DM respectively. The duration of P min was shorter in patients with DM (p = 0.031*). The duration of conduction delay in tricuspid lateral PA (p <0.001*), septum PA (p <0.001*) and MV PA (p <0.001*) have been significantly elongated in patients with DM in comparison to control respectively.
In addition, the ratio of conduction delay duration for each annulus to LA diameter were significantly more in DM in comparison with controls. In addition, the interatrial (p < 0.001*), right intra-atrial (p = 0.003*) and left intra-atrial (p = 0.004*) EMD were significantly higher in patients with DM than in controls correspondingly. The volume of the active emptying of the left atrium (LAAEV) and the fraction (LAAEF) were significantly greater in diabetics than in controls (p = 0.004*). LAAEF and LAAEV were significantly correlated with septal and lateral, E/A, e⁻/a⁻. Maximum left atrial volume (V max) mean difference (P = 0.019*) was significantly more in diabetics. Presystolic atrial volume (V p) (p = 0.036*) were highly significant in diabetics. The minimum volume (V min), the volume of passive left atrial emptying (LAPEV) means were lower in diabetic than control means. We found that conduit left atrium volume (CV) and left atrial total emptying volume (LATEV) were statistically significant in diabetics than control.

study of the association amongst diastolic function and the considerations representing the mechanical left atrial function and volumes revealed that there had been a significantly negative correlation among LAAEF, LAAEV with mitral E/A fraction (r = -0.295, p < 0.007; r = -0.450, p = 0.000, correspondingly), lateral mitral e⁻/a⁻ (r = -0.280, p = 0.020; r = -0.263, p = 0.018, correspondingly), then tricuspid e⁻/a⁻ (r = -0.342, p = 0.003; r = -0.416, p = 0.006, correspondingly). In the same way, there has been a significant though fragile negative correlation between E/A ratio and interatrial EMCD, LAEMCD (r = -0.295, p = 0.004; r = -0.382, p = 0.000, correspondingly). We presented the investigation of multivariate regression upon intra-atrial EMCD, interatrial EMCD in addition to LAEMCD in isolation. Analysis of Regression showed the chief factors associated with LAEMCD which were mitral E/A fraction, tricuspid e⁻/a⁻, and FBG (β = -0.34, p = 0.06; β
= 0.31, \( p = 0.043 \); \( \beta = 0.36, p = 0.002 \), correspondingly). Alternatively, the principal factors correlated to inter-atrial EMCD have been BMI, FBG, then tricuspid \( \dot{e}/a^- \) \( (\beta = 0.30, p = 0.006; \beta = 0.39, p = 0.001; \beta = 0.37, p = 0.009, \) correspondingly). No connection has been presented among age, sex and atrial EMCD. Correlation relationship analysis displayed a positive relation between inter-atrial EMD and P d \( (r = 0.432, p = 0.001) \) and positive correlation between LA-size \( (r = 0.430, p = 0.001) \) figure (3).

**Discussion**

In this research, the P-wave maximum and P-wave dispersion found to be increased significantly in DM contrasted to control. P-wave minimum was significant in control. The time of EMCD in mitral, septal and tricuspid annuli relative to LA diameter were highly significant in DM. Also, we were very importantly found that the inter-atrial, left intra-atrial and right intra-atrial electro-mechanical conduction delay were significantly prolonged in DM contrasted with control. These our findings were stated by many studies said that the change relating the minimal and maximal P-wave time on surface ECG, is an ECG sign that has been linked with intermittent conduction and tissue inhomogeneity of sinus stimulus reproduction(10). The association between the increment of inter-atrial and intra-atrial delay conduction had a prognostic effect by producing arrhythmia as paroxysmal atrial fibrillation (PAF) has been thoroughly acknowledged(11). Though atrial conduction phase is intensely suggestive of atrial electrical remodeling, TDI and 2 easy ECG markers for P-max. and P-wave dispersion (P d) may give statistics going on for elongation of the atrial conduction interval(12).

In the research PA lateral, PA septum and left atrial EMD have been increased significantly in DM and is directly related to the stage of blood sugar.

Tanaka and associates, 2019 said that left electromechanical atrial conduction time delay has been appreciably greater in DM than in controls (12).

This study was also showed that the following sample mean differences \( (E/A \text{ and } \dot{e}/a^- \text{ were significant in control group, IVRT and } E/\dot{e} \text{ was significant in diabetics}) \) in agreement with Saqar who said that DM is a hazardous autonomous feature that upsetting heart structure and function(13).

In our study, we examined LA diameter and index of LA volume and parameters of LV diastolic function. This research was showed that the interatrial EMCD had an important and significant correlation with the LA volume index. Checking that a decrease in \( \dot{e}/a^- \) of LV-associated DM can provide the prolongation of inter-atrial EMCD in DM than in controls, and was discovered to support our TDI results. The regression analysis in our study showed a frail association among FBG and inter-atrial and LAEMCD. This effect can boost AF sensitivity in this patient grouping and these
results in harmony with Mahfouz who concluded that there is an important correlation between AF and diastolic dysfunction, caused by boosted filling pressure and LA stretching in the nonexistence of structural cardiac disorder. According to Mahfouz (14), we located a bigger LA diameter for the DM than in the control group. The mechanical function of LA is a significant component of LV filling. LA displays as storage during systole, as a passage at the initiation of diastole and as a vigorous contractile chamber at the diastole ending (15). The LA function automatically enables the transition between the flow in the pulmonary circulation and the paroxysmal filling of the LV (15). Through diastole, LA is directly exposed to the LV pressure, that increases when the diastolic function of the LV is compromised (16). LAAEV and LAAEF were also considerably advanced in DM matched to the control for our research. Diastolic function calculated in TDI and conventional echocardiography that have been considerably further compromised in DM than in the control. The significant rise in LAAEV and LAAEF in this study suggests that compensatory LA contraction is important in the diastolic part. The significant relation between LAAEV and LAAEF and the factors that signify diastolic disorders support our suggestion. LAPEV significant mean difference was lower in diabetics in this study. In agreement with the former analyses, Gallen realized that with DM, the LA transmission turn into slow and the LA compliance decreases, signifying the manifestation of DM associated LA wall remodeling (17), also Thomas and associates displayed that DM is a notorious reason of atrial-ventricular conduction delay along with the augmented incidence of AF (18), so this study was showed direct association between atrial EMD and DM.

Conclusions

In diabetics, conduction times of the atrium by TDI and the dispersion of the P-wave by surface ECG were longer. Furthermore, the mechanical functions and volumes of the left atrium were affected by altering diastolic function in diabetics.

Abstract

The World Health Organization (WHO) stated that accreditation is a method for ensuring quality of health services. The method was developed in Indonesia. Accreditation is a form of method to measure the quality of health center services. Malcolm Baldrige National Quality Award (MBNQA) model and The Model For Understanding Success in Quality (MUSIQ) that are developed in several countries, have not paid attention to the religious and service innovation aspects. This study was aimed to analyze the influence of religious character and service innovation toward the improvement of sustainable quality of primary health services in South Sulawesi. This research was a mixed method research. The qualitative data was obtained from 10 informants that the result was then examined by using content analysis. The samples for quantitative study were chosen through proposive stratified random sampling technique with Lame show formula to get 395 respondents.

From the result of qualitative research, it was found that religious characters have 10 indicators, namely discipline, presenting God in every activity, fair, patient, friendly, committed, tabliqh, fathanah, amanah and shiddiq. In addition, service innovation is composed of 6 indicators namely new activities/modifications, follow-up analysis, resource support, cross-sector collaboration, providing new brands and developing local wisdom.

Furthermore, from the result of quantitative research, it was found that there was a significant influence of religious character and service innovation toward the improvement of sustainable quality of primary health services by using Chi-Square test result which p value = 0.001 (p<0.05). Hence, it is recommended that community health service staff should apply religious character and service innovation to improve sustainable quality of primary health care.

Keywords: Religious character, innovation, service quality.

Introduction

Accreditation is a form of assessment or evaluation of the quality and feasibility of an institution conducted by an accreditation body. The World Health Organization (WHO) uses this system to evaluate the process of health services in improving the quality of services to serve patients. WHO expects all countries to have quality health services.¹

Moreover, accreditation is a process of evaluation and monitoring through measurement of compliance with standards, not an end result of quality. The Institute of Medicine (IOM) reported that the quality improvement approach is more results-based. Therefore, accreditation is considered as the end of quality check so that efforts to improve quality have not been sustainable.²

Malcolm Baldrige National Quality Award (MBNQA) and The Model for Understanding Success
in Quality (MUSIQ) are quality improvement concepts developed in many developed countries. One of the weaknesses is the lack of attention to aspects of religious character and service innovation. The success of the implementation is determined by multiple variables, and each of the variables is interconnected with each other. Community health center is still less than optimal in providing services to the community. This makes them prefer to get health services from clinic, hospital and other health facilities. In addition, the image and appearance of community health center far from government’s attention.

Religious characters that must be owned by community health center staff are discipline, fair, honest, clean, trustworthy, good at communicating, patient, friendly, committed and wise. Thus, the staff should be able to apply those religious characters in the workplace in order to improve the sustainable quality.

However, unsustainable quality of community health center services will result in low satisfaction of patients as well as a lack of trust. Therefore, efforts should be made to enhance the quality of community health center.

**Religious Character:** Religion, which is a particular system of belief, influences choices and behavior patterns of society. In fact, religion is a systematic culture that can create strong beliefs or values for its adherents.

Developing health care employees’ religious character will certainly have a positive impact on the ability to act in providing services to patients. This has been proven through several researches that the quality of Islamic-based service has a positive and significant impact on customer satisfaction. CARTER theory explains that there is a strong relationship between adherence to Islamic law and customer satisfaction. Cultural values, including customary norms, marriage values, loyalty values, and other values, are sacred for Indonesian people.

The application of religious character in giving services is considered to be very important for Indonesian people for they are inseparable from the aspect of religion in acting. Religious principles they hold are always applied in their daily activities.

**Service Innovation:** Innovation means creating changes or introducing new things. Innovating is transforming knowledge to be new products, processes and services, or can be said that it is the act of using something new. Innovation in public sector is more emphasized on the aspect of improvement resulted from innovation activities.

Innovation in giving service is aimed to make public services better and make it in accordance with plan. If innovation is only meant to adjust to the trend, it will not last forever. Thus, innovation must be sustainable so that it will change according to the needs and development of society.

Innovation in health services can lead to changes in better public health services. For institutions, it also will prove that they have a strong will to be better. However, creating service innovation is not easy. An organization that is able to see itself as a public servant would be able to create innovation that are difficult for themselves but are beneficial to society.

**Puskesmas (Community Health Center):** The Regulation of the Minister of Health (PMK) No. 75 Year 2014 regulated that Community Health Center is one of the places to provide first-level health service facilities that have the responsibility to provide health services to the community in the work area that has been designated for either one or several sub-districts.

In carrying out the function, puskesmas has the authority to make plans based on the analysis of existing health problems in community and services needed. Moreover, it also carries out advocacy and dissemination of health policies, communication, information, education and community empowerment in health sector, involves the community to identify and solve problems about health faced at every level of community development in collaboration with other sectors, carries out technical guidance to the network of services and community-based health efforts, enhances the competency of Human Resources (HR), monitors the implementation of development of health knowledge, and records, reports and evaluates on access, quality and coverage of health services as well as provides recommendations regarding public health issues, including support for early alert systems and responses in preventing disease.

**Quality of Health Services:** Quality, in this case, is the level of perfection of health services which on the one hand can satisfy the service users and other parties. The procedure of its implementation is in accordance with the code of ethics and the established standards. The quality
of community health center services is a series of health service activities that meet the needs of both individuals and communities carried out by professionals according to the standards and codes of ethics.4

The quality of health service has a function to provide an assessment that refers to the level of perfection in providing health services in accordance with what is needed and expected by whoever needs health services. The better the fulfillment of people health care needs, the better the quality obtained in health services.

Materials and Method

This study is a mixed method research, which is an approach to investigate an object by combining qualitative and quantitative researches in a study10 to obtain more comprehensive, valid, reliable, and objective data. The qualitative stage was carried out through focus group discussions (FGD) and in-depth interviews. The data were analyzed by means of content analysis, data reduction, and interpretation. The quantitative stage was done through cross sectional analytic of observational study observational study.

The populations of this study are members of the primary health care accreditation commission, accreditation surveyors, accreditation consultants, academics, religious leaders, community health center heads, quality control team, administration and management personnel that are responsible for the public and individual health from each community health center. Furthermore, the qualitative research was done by selecting 10 informants who have met the requirements, while the samples for the quantitative research were selected through proposive stratified random sampling technique based on Lame show formula to get 395 from 2,020 respondents.

Research Results

The qualitative research was done by conducting focus group discussions (FGD) and indepth interviews toward 10 informants. The informant defined religious character as follows.

“... discipline is a part of religious character, a strong discipline based on religious principles will develop a strong sense of awareness in improving sustainable quality ...” (SM, 62 years old)

“...religious character emphasizes more on the nature of prophethood; fatanah, amanah, siddiq, and tabligh. As well as clean, orderly, discipline, punctual, right on target, and appropriate in providing health services...” (MYY, 41 years old)

“...religious character includes prayer on time, present God in all activities, committed, and show equality in giving service to men and women ......” (GM, 48 years old). “...more discipline in doing worship, presenting God in all activities and sincerity are religious characters ...” (SR, 55 years old)

“.......... the most important part of religious character are discipline, honest, trustworthy, intelligent, present God in all activities, and friendly ...” (AB, 40 years old)

“..........religious character can be seen from sustainable service, honest, do not commit corruption, collusion and nepotism, smiles, greets others, and as what showed by the prophet, fatanah, trustworthy, siddiq and tabligh...” (AMS, 52 years old)

“.......... ... discipline, responsible, honest, committed, have strong empathy, friendly, smile, greet others, not gender biased, not differentiate male and female in giving services, not differentiate people based on race and religion, and pray before giving service ...... ..” (SP, 47 years old)

“... ... the characters had by individuals cannot be measured, such as patience, like to complain, not giving up, have high fighting spirit. As officers, they should be hard-working, discipline, istiqomah, concern on punishments and rewards, give services that are safe and do not differentiaite people based on their ethnicities, religions, capacity, being honest and responsible ...... ..” (RA, 52 years old)

Based on the result of the focus group discussion (FGD) on religious characters, the result can be seen in the following graph.
Furthermore, the informants also explained about service innovation as follows.

“... innovation is a follow-up to the results of the analysis of problems, changes in regulations, rules, or changes in technology. Innovation includes modification or new activities that are made by community health center. Innovation activities must also involve community participation …..” (RP, 52 years old)

“…… New activities or modification of activities are aimed at improving services or achievements. As well as people, money, method, materials, and machines (resources), and local wisdom ……… “(MYY, 41 years old)

“…… New activities or modification of activities, including making new terms that are attractive to the community, and also require a cross-sectoral role, and local wisdom of the community ………” (UM, 42 years old)

“…… The most important health service innovation includes brand, even though modification activities or new activities are carried out at the community health center... (AA, 42 years old)

Based on the result of the focus group discussions (FGD) and independent interview on innovation in health services, a scheme is derived and can be seen as follows.
Figure 2. Health Service Innovation Scheme

From the qualitative research using questionnaire containing 140 statements filled by 395 respondents that was then analyzed, the result is presented as follows.

1. The Effect of Religious Characters toward the Improvement of Sustainable Quality of Primary Health Services.

Source: Primary Data, 2019

According to the table above, the service innovation variable toward the improvement of sustainable quality that are categorized as bad is held by 120 people (79.5%) and that is categorized as good is held by 67 people (27.5%). In addition, the innovation service toward the improvement of sustainable quality that is categorized as good is held by 31 people (20.5%) while the one categorized as bad is held by 177 people (72.5%). The results data analysis by using Chi-square test obtained p value = 0.001 (p <0.05).

Discussion

According to the content analysis, data reduction, and interpretation of religious characters, there are 10 indicators, namely discipline, presenting God in every activity, fair, patient, friendly, committed, tabligh, fathanah, amanah and shiddiq. Moreover, there are 6 indicators for health service innovation, namely new activities/modifications, follow-up analysis, resource support, cross-sector collaboration, providing new brands and developing local wisdom.

The religious characters built in providing services can improve the sustainable quality of primary health care. Religious characters that must be owned by community health center officers are discipline, involve God in all activities, serve patients well (not gender, religious and racial biased, not distinguish patients’ status), being friendly to anyone, and being fathanah (wise), amanah (trustworthy), siddiq (honest), and tabligh (communicative).

The results of the analysis of the service innovation variable showed that there were 72.5% of the respondents, stated that service innovation has good category toward the improvement of sustainable quality, the Chi Square test result obtained a p value of 0.001 (p<0.05). This means that service innovation significantly influencesthe improvement of sustainable quality of primary health services in South Sulawesi.

The service innovation of community health service from the analysis of problems, changes in regulations, changes in service guidelines or changes in technology will certainly be able to improve services. Service innovation in the form of new activity/modification, follow-up of problem analysis result, or development of local wisdom must get the support from resources and cross-sectional role. Those kinds of service innovations are needed including making new brands to increase community motivation and interest.
Conclusion

Religious characters and service innovation have significant influence toward the improvement of sustainable quality of primary health services in South Sulawesi. Therefore, it is recommended that every officer in the community health center should apply religious characters and innovation in providing services to the community to improve the sustainable quality.

Correlation of Glycated Haemoglobin with Netrin-1 and High Sensitive C-Reactive Protein in Type 2 Diabetes Mellitus Patients

Erika Rosaria¹, Nurahmi²-³, Liong Boy Kurniawan²,⁴

¹Program Pendidikan Dokter Spesialis Patologi Klinik Fakultas Kedokteran Universitas Hasanuddin,
²Departemen Ilmu Patologi Klinik Fakultas Kedokteran Universitas Hasanuddin, ³RSUD Kota Makassar; ⁴RSPTN Universitas Hasanuddin, Makassar

Abstract

Diabetes mellitus is a group of metabolic disease with the characteristic of hyperglycemia that occurs due to abnormal insulin secretion, insulin action or both. Low level inflammation plays a role in the mechanism of type 2 DM. Netrin-1 is a laminin protein group that has anti-inflammatory properties. Netrin-1 is a new potential biomarker for diagnosing type 2 DM and its complications. High sensitive C-reactive protein is an acute phase protein produced by the liver in response to proinflammatory cytokines. Glycated haemoglobin test is a test recommended by the American Diabetes Association as a marker for diagnosis and predictor of the development of DM complications. The purpose of this study was to determine the correlation between glycated haemoglobin with netrin-1 and high sensitive C-reactive protein in patients with type 2 DM.

This cross sectional study used type 2 DM patients as a sample. Fifty two type 2 DM patients participated in this study. The sample consisted of 21 samples of controlled type 2 DM and 31 samples of uncontrolled type 2 DM. The glycated haemoglobin was measured using immunoturbidimetry method, netrin-1 was measured using the ELISA method and hsCRP by immunoturbidimetry method. Data were analyzed statistically with the Mann Whitney and Spearman test.

The results showed that netrin-1 in the uncontrolled type 2 DM group was higher than netrin-1 in the controlled type 2 DM group but there was not statistically significant (p> 0.05). High sensitive C-reactive protein in the uncontrolled type 2 DM group was higher than in the controlled type 2 DM group (p< 0.05). Glycated haemoglobin does not correlate with netrin-1 (p>0.05). Glycated haemoglobin was positively correlated with hsCRP with moderate correlation strength (p < 0.01, r = 0.418). Netrin-1 did not correlate with hsCRP (p > 0.05). It was concluded that netrin-1 and hsCRP were higher in uncontrolled DM. The higher glycated haemoglobin, the higher hsCRP too.

**Keywords:** DM type 2, glycated haemoglobin, netrin-1, hsCRP.

Introduction

Diabetes mellitus (DM) is a heterogeneous metabolic disorder characterized by the presence of hyperglycemia that occurs due to impairment of insulin secretion, insulin action or both.¹,² Chronic hyperglycemia can cause damage to many of the body’s organs, leading to disabling and life threatening health complications such as cardiovascular diseases, neuropathy, nephropathy and retinopathy.³

It was estimated that in 2019 there were 463 milion people have diabetes and this number is projected to reach 578 million by 2030 and 700 million by 2045. Diabetes also estimated to be associated with 11.3% of global deaths from all causes among adult people.³

Glycated haemoglobin or HbA1c defined as haemoglobin which is irreversibly glycated at one or both N-terminal valines of the beta chains.⁴ Glycated haemoglobin formed in a non
enzymatic glycation pathway by hemoglobin exposure to plasma glucose. Once a haemoglobin molecule is glycated, it continues to remain in the red blood cell for the rest of its life span. Glycated haemoglobin has been the mostly used and accepted test for monitoring the glycaemic control in individuals with diabetes. Glycated haemoglobin test is recommended by the American Diabetes Association as a marker for diagnosis and predictor of the development of DM complications. Several studies have shown correlation of HbA1c with microvascular and macrovascular complications.

Low grade inflammation might play a role in the development and complications of type 2 DM. Chronic hyperglycaemia induces oxidative stress and chronic inflammatory state. Chronic hyperglycaemia stimulates the release of various inflammatory cytokines such as IL-6 and TNF α and induces the secretion of acute phase reactants by the liver. C-reactive protein is an acute-phase protein, act as an inflammatory marker produced and released by the liver under the stimulation of cytokines. C-Reactive Protein measured by highly sensitive assays (hsCRP) is a very sensitive marker of inflammatory activity.

Netrin-1 is a laminin group protein encoded by the NTN1 gene which located on 17p13.1 chromosome. Netrin-1 is expressed by the central nervous system, endothelial cells of blood vessels, pancreas, liver, lymph, lungs, intestines and kidneys, which can act as an anti-inflammatory. Netrin-1 can be measured using plasma samples, serum or urine by using enzyme-linked immunosorbent assay (ELISA).

Chronic inflammation plays role in the pathogenesis of type 2 DM. Glycated haemoglobin test is recommended by the American Diabetes Association as a marker for diagnosis and predictor of the development of DM complications. C-Reactive Protein is an inflammatory protein produced by the liver and have correlation with HbA1c in many research. Netrin-1 is a protein that has an anti-inflammatory actions. Different animal model and human subjects that were induced have diabetes alone or along with various microvascular or macrovascular complications showed that the level of netrin is altered in various diseases conditions. The level of netrin in a diabetes model displayed an inconsistent expression in different clinical studies so we make a study to determine the correlation of glycated haemoglobin with netrin-1 and hsCRP in type 2 DM patients.

**Materials and Method**

This cross-sectional study was performed to analyze the correlation between glycated haemoglobin with netrin-1 and hsCRP in type 2 DM patients at Dr. Wahidin Sudirohusodo General Hospital and Rumah Sakit Unhas in Makassar. This research was conducted during June 2020. The samples of this study were all adult type 2 DM patients diagnosed by Internists based on American Diabetes Association or Perkumpulan Endokrinologi Indonesia, having data for fasting blood glucose, HbA1c, total cholesterol, HDL, LDL, triglycerides and creatinine. Patients with infection, anemia, polycythemia, thalassemia, received a whole blood transfusion or packed red cell within the last 3 months and have a history of heart disease and liver disorder were excluded. Informed consent were obtained from all participants.

All samples were examined for hsCRP level using Roche Cobas e 411 automatic chemical analysis at Parahita Laboratory and netrin-1 level by the Enzyme Linked Immunosorbant Assay (ELISA) method in the Laboratory Research Unit of Rumah Sakit Unhas, Makassar.

Data were statistically analyzed using Kolmogorov-Smirnov normalization test. Mann Whitney test was performed to compare netrin-1 and hsCRP level in controlled and uncontrolled type 2 DM patients. Spearman correlation test was performed to assess the correlation between HbA1c and netrin-1, HbA1c and hsCRP and between netrin-1 and hsCRP. The results were significant with a p value at <0.05.

The characteristics of this study samples can be seen in table 1. Total of 52 patients participated in this study. The patients age were between 35-84 years with an average of 59.2±9.4 years. The HbA1c levels were between 5.1-12.2% with an average of 7.87%. The sample consisted of 21 (40.38 %) type 2 DM controlled group and 31 (59.6%) uncontrolled type 2 DM group. The lowest and highest netrin-1 level were 183.6 pg/dL and 2241.4 pg/dL, respectively. The hsCRP level was between 0.03-2.64 mg/dL with average of 0.38 mg/dL.

Discussion

This study was conducted on 52 type 2 DM patients aged between 38-84 years old with mean of 59.2 ± 9.4 years. This result is in line with Indonesia Riskesdas 2018, which gets the proportion of DM increases with age and the highest is found in the 55-64 years age group.11 The sample consist of 35 male patients (66.7%) and 17 female patients (33.7%). International Diabetes Federation report that estimated prevalence of diabetes in women is slightly lower than in men.3

Netrin-1 level in uncontrolled type 2 DM group was higher than in controlled type 2 DM group although this results were not statistically significant. This research is in line with research conducted by Yim who found that netrin-1 in DM group was higher than IFG group and healthy group.12 Netrin has anti inflammatory action.12 Elevated serum netrin-1 is probably attributable to a compensatory response of uncontrolled DM.12

There was no significant correlation found between HbA1c and netrin-1 in this study. This result in line with research conducted by Liu in 2018 but contrass to research conducted by Ay, 2016 and Liu, 2016.9,13,14 Ay get a positive correlation between netrin-1 and HbA1c while Liu get a negative correlation.9,13,14 A reason that distinguish various results of these study might be the differences of patient characteristics. Yim and Liu recruited newly diagnosed type 2 DM patients who had never received anti-diabetic drug therapy.9,12 The sample of this research were newly diagnosed type 2 DM patients and those who are already taking anti diabetic drugs.

Moderate positive correlation strength was observed between HbA1c and hsCRP levels in this study. This result in line with the previous study before. In hyperglycemia state, concentration of advanced glycation end products is elevated and has been shown to activate macrophages, increased oxidative stress and upregulated synthesis of interleukin-1 (IL-1), IL-6 and tumour necrosis factor (TNF-α) resulting in production of CRP.15 These pro-inflammatory cytokines are engaged with different metabolic pathways applicable to insulin resistance, including insulin direction, receptive oxygen species, lipoprotein lipase activity and adipocyte function.16

Netrin-1 did not correlate with hsCRP in this study. The results of this study are in line with research conducted by Yim et al. Yim stated that netrin-1 and CRP were higher in type 2 DM group and IFG group compared to normal group but netrin-1 did not correlate with CRP.12 Netrin is a protein secreted by the endothelium which has anti-inflammatory effects while hsCRP is a protein produced by the liver in response to pro-inflammatory cytokine. Netrin will increase or decrease to suppress inflammation. Liu et al reported that higher levels of albumin trigger production of netrin-1 from proximal tubular epithelial cells via extracellular signal regulated kinase (ERK) and Akt kinase pathways.13 Patientsnephropathy diabetic with increasing albuminuria had higher systolic blood pressure, duration of diabetes, blood urea nitrogen and serum creatinin.13 We suggested that despite of pro-inflammatory cytokines, there were many factors could affect correlation between hsCRP and netrin-1 suchas albumin, duration of DM and it’s therapy.

This study has several limitations. We used heterogeneous samples, did not take healthy controls and did not analyze IL-1, IL-6 and TNF-α as pro-inflammatory cytokines.

Conclusion and Suggestion

There were no statistically significant correlation found between glycated haemoglobin and netrin-1 and between netrin-1 and hsCRP in type 2 DM patients. Glycated haemoglobin was positively correlated with hsCRP with moderate correlation strength. Further randomized prospective studies with homogeneous larger samples and classify samples into control group (healthy people), controlled and uncontrolled diabetic patients are required to support our findings.

Awareness Mental Health During Pregnancy in Practice Midwife of Bogor, Jawa Barat

Nurul Husnul Lail¹,², Rizanda Machmud¹, Yusrawati¹, Adnil Edwin¹

¹Program Doktoral, Medicine Faculty, Universitas Andalas; ²Health Science Faculty, Universitas Nasional

Abstract

Mental health problems in pregnancy still lack the attention of midwives, which is identified in the low mental health checks of pregnant women during antenatal care. A subsequent research was conducted by Idaiani in Jakarta and Bogor regions 2018 regarding the incidence of Perinatal Depression that reached 18.6% in Bogor region.

This research was a qualitative research and was conducted January 2019 in Independent Midwifery Practice in Bogor. The subjects of this research were The interview was conducted with 15 informants, they were one person from the ministry of health, coordinating midwives, chairmen of Indonesian midwives’ branch associations in Bogor with total of 5 midwives who provided services in independent midwifery practice and as a key is 3 woman pregnant and three families of pregnant women, data were analyzed by using triangulation analysis.

Based on result of the research, The Construction Model Mental Health on Mothers during pregnancy in Independent Midwifery Practice is very important and needs attention. Pregnancy is still considered as a physical change that needs to be intervened because it is easier to be handled and detected. Maternal examination during pregnancy is carried out by Midwives in the implementation of mental health checks during pregnancy for pregnant women and this role has not been carried out optimally.

This research suggests conducting socialization with midwives as well as across related sectors to get political support in carrying out activities in health facilities and independent practice midwives.

Keywords: Pregnancy, Mental Health, Nurul’s Model.

Introduction

Mental health problems in pregnancy still lack the attention of midwives, which is identified in the low mental health checks of pregnant women during antenatal care. Mental illness during pregnancy is a public health problem that should be focused on seriously. 10-20% women in the world experienced mental health problem during the first stage of labor. The common mental illness experienced by women include antenatal and postnatal depression, obsessive-compulsive, post-trauma stress, and post-partum psychosis. The prevalence of mental illness or mental health problem during pregnancy in low-income countries reached 15.6%. One of five women experienced mental health issues during pregnancy such as depression, acute anxiety and fear towards labor, and mild to moderate emotional disorders. Depression and anxiety are common during pregnancy. The prevalence rates of 6% and 17% have been reported for major and minor depression, respectively. Meanwhile, the prevalence rate of anxiety symptom is reported for 23% due to change in appearance which affects the self-efficacy, and 15% for anxiety during antenatal period due to the feeling of unworthiness caused by pregnancy.
According to World Health Organization (WHO), around 10% of pregnant women and 15% of post-partum women experienced mental illness, especially depression. The prevalence rate is even higher in developing countries that reach 15.6% during the pregnancy and 19.8% towards the labor.

Some studies focused on decreasing the effect of pregnancy to mental health – psychology, stress and depression, knowledge, empowerment, and self-efficacy by improving the quality of pregnancy examination with antenatal care. Health workers are responsible to provide education on psychosocial condition of pregnancy to pregnant women. Besides, additional care during pregnancy should also be provided by health workers (obstetric, midwife, and nurse). This attempt is needed to foster empathy among the health workers and encourage pregnant women to check their condition; which in the long term will decrease the adverse psychological condition during the pregnancy, after pregnancy, and child care.

Mental health problem and other issues during pregnancy can be dangerous for the pregnant women and their children. The children might experience premature birth, low birth weight, and others. In addition, social stigma, low self-efficacy, and negative perception will encourage pregnant women to visit the health facilities.

The prevalence rate of depression during pregnancy in Indonesia has reached 22.4% that may increase the morbidity and mortality rates of mother and children during the pregnancy and postpartum periods. Mental health problems caused adverse effects to the pregnancy and the baby.

**Material and Method**

This research was a qualitative research with explorative primary data approach. The interview was conducted with 15 informants, they were one person from the ministry of health, coordinating midwives, chairmen of Indonesian midwives’ branch associations in Bogor with total of 5 midwives who provided services in independent midwifery practice and as a key is 3 womant pregnant and three families of pregnant women, informant with under review theme and was an understanding of mental health in pregnant women and the members of Indonesian midwives’ branch associations to reveal the cause-effect finding. The research time was around January in 2019.

The data analysis was carried out by triangulation approach: source analysis and thematic analysis.

**Results**

**Perception on Mental Health during Pregnancy**

The definition of Information on Mental Health of Pregnant Women

Mental health during pregnancy regarding mental health of midwife informants is a state of mental disorders/illness in pregnant women such as depression, stress, anxiety “Mental health of pregnant women is a mental condition of pregnant women who are disturbed, mental illness usually because pregnant does not have a husband, pregnant because of rape victims so that his soul is disturbed” (Inf 1)

“Mental Health Pregnant women are the ones who know mental health. There are pregnant women who are stressed because they could be left by their husbands, or they could be due to unintended pregnancy. If there is only a general program, if there is no examination tool at the midwifery independent practice, they words are not understandable and they like to laugh, just take them to the general practitioner. For the examination of pregnant women, I used the standard, which was 10 T, as far as I know, there is no psychiatric check for pregnant women. Obstacles do not exist if there is a new expression and we have to consult a general practitioner ”(Inf 2)

“Mental health is a healthy condition not just a body but it must also be healthy inside but it is unclear whether it has become a standard in pregnancy examinations and there is no program as far as I know” (Informant 3).

“Mental health is the definition in the law of pregnant women undergoing physical, mental and social changes, to get healthy children the mother must be physically, mentally and socially healthy, then midwives need to oversee the health of these women, they are in professional standards, midwives only check the stomach, then help the childbirth. Modules do not exist yet, but there were many references, so when preparing the health of women to become mothers, it must be include the physical, mental and social health. Many factors influence among others, like, social, cultural, political, economic, policy factors. There are no obstacles, one of which is due to the limited understanding and ability of midwives in carrying out
their role of being a reliable and competent midwife, due to the lack of formation in the education process, so that graduates become midwives don’t know what to do. The lack of public awareness, about the importance of preparing to give birth to a future generation of quality, there is no pregnancy planning. Therefore midwifery care must be comprehensive and sustainable, respecting the uniqueness of women.

Based on the document review, the definition of mental health is a condition of well-being in which a person realizes his own potential, she can deal with stress normally in her life, work productively and profitably, and is able to contribute to herself or his community.14

The results of in-depth interviews and document review of the definition of Mental Health for Pregnant Women can be seen in the following table:

**Factors Affecting Mental Health**

The factors that affect mental health of pregnant women according to several informants are as follows:

“.......... Mental health will be caused by many things, especially if a pregnant woman knows about her pregnancy, preparation and support from her husband, from her family as well as her surroundings. Feeling supported by husband greatly improves the mental health of pregnant women, however, the formation of a sense of comfort and peace in pregnant women will be formed from the people and the environment closest to the pregnant mother. However, the condition of pregnant women, such as being irritable, disrespected and feeling unsure, can also affect the mental health of pregnant women, for this thing, it is necessary to support and strengthen health workers, such as midwife, whose place are often used by pregnant women to check their pregnancy ... (Informant 1)

“.......... The mental health of pregnant women, on average, is caused by their husband or spouse. Many pregnant women are stressed because of the lack of support from their husbands, but now it cannot be denied that the economic situation is rather difficult so pregnant women are needed to be strengthened so that they are not spoiled, they must be given education by midwives so that they are strong and can respect their life cycle, their nature and confidence with their abilities. (inf 12).

“........ Mental health in pregnant women sometimes becomes stressful because they already have many children, the difficult in economic problems, husbands rarely stay home, disturbances or illnesses during pregnancy, lack of information from midwives about pregnancy, unplanned pregnancy, unintended pregnancy, .... (inf 6)

Programs and Barriers to Maternal Mental Health:

Maternal Mental Health Program: Mental Health Program for pregnant women according to several informants; 1 Midwife, 1 midwifery coordinator, 1 Head of IBI, Head of Health Promotion of the Health Service and the Ministry of Health’s Directorate of Mental Health, are programs for handling cases of mental disorders or mental disorders in pregnant women. The following is an excerpt from the informant’s statement:

“...... The mental health program for pregnant women is a program that has been around since 2018 with MITO, this means that midwives already have a legal law so they must detect the extent of the mental health of pregnant women. This activity is currently being implemented in East Jakarta, and has not been socialized to the Regional Level Implementers. This program has not been evaluated even though this program has been launched since 2018 ......, (Informant (1 Directorate of Mental Health, Ministry of Health)

“...... A mental health program for pregnant women in particular does not yet exist, but in general, a general mental health program for anyone has been conducted in every Public Health Centre, mental health is important for pregnant women so that pregnant women are relax in facing their pregnancy and It should have been included in the service when a pregnancy check was carried out. Midwives as the first person and staff that pregnant women always meet must be able to carry out this mental health check, but they doubt pregnant women can go to a doctor ... (Informant (2. Head of Health Promotion, Bogor District)

“...... Mental health programs have been carried out by midwives such as Post Partum Blues. And if for pregnant women with mental disorders Schizophrenic or mental illness does not yet exist, it will only begin to be planned at the Ministry of Health and there has not been any implementation but competent midwives have to be able to identify for example the Post Partum Blues. The Ministry of Health will certainly work together with psychiatry (associations) to be able to discuss this mental health so that it does not become a danger to both mother and the fetus, also for all health workers associated with pregnant women service providers. And this will be comprehensive so that midwives and health workers must be able to communicate with pregnant women and their families including husbands ......... (Informant (3. Head of IBI) “

“...... Mental Health Program has not provided the program yet, even during the pregnancy checkup was 10 T and had not started yet for the mental health check. There are only those for Baby Blues, Post Partum Depression but there were not much that have been detected which are only checked in the Kf 1 Kf 2 Kf3 standard, usually in physical conditions such as dizziness due to low HB, breast milk production, complaints of Trobophlebitis, indeed mental health is sometimes neglected so midwives do not pay attention to this. For
mental health programs, it does not have to be specific but must be included in the examination of midwives for pregnant, childbirth and postpartum mothers ... Informants (4. BIKOR)

............ The mental health program for pregnant women does not exist, in pregnancy examinations there is also no mental health, it is usual to check for pregnancy according to the standard 10 T and must be carried out by midwives in pregnancy examinations that have become standard. If I get information about mental health, of course I will ask the head of IBI and the closest midwife, but I have never heard information about mental health ...

(Informant (7. Practical Midwife).

**Barriers to Mental Health Screening:** Obstacles in the implementation of mental health examinations and management are all attributes that do not support health examinations and promotion, such as the absence of operating procedures standard, there is no law so that the authority of midwives as examiners and mental health implementers is not implemented properly. The following data are the results of in-depth interviews with informants.

“................. there should be no obstacles because there is already a module for midwives on how to train pregnant women to become Tough and Optimistic Mothers, equipped with videos and props in pregnant women class. However, there is still no operating procedure standard for the competence of midwives in mental health examinations. However, midwives should still be able to invite and train mothers to make MITO. It is hoped that the knowledge of midwives related to mental health needs to be improved, because it must be comprehensive, so it is necessary to increase the knowledge of midwives to know about maternal mental health during pregnancy ..... “Inf 1

“...................... There are already SOP on the implementation of classes for pregnant women, but specifically regarding the mental health of pregnant women in independent midwife practices, there is no formulated about mental health so that there is an emphasis in the examination of pregnant women the importance of mental health and we will immediately formulate it with the Ministry of Health. There is no module book yet and it could be an obstacle but in fact the funds have not arrived to reproduce ... ”inf 2
“........................ Standard Operating Procedure for Mental Health Examination is not yet in the standard of examination for pregnant women, but it is only in the class of pregnant women, it sometimes mentioned about how pregnant women are still can have sexual with her husband, have jokes and look harmonious ....... inf 4

Midwives’ knowledge about mental health

Difficult in Detecting Risk factors for KSPR, PASS, EDPS on pregnant women: Pregnancy needs to be managed properly, pregnancy as a physiological process can become pathological if it is not managed properly. The difficulty of careful management of pregnant women by health workers can reduce the delay in recognizing cases as a factor of delay.

Based on the document review, the difficulty of detection of risk factors for KSPR, PASS, EDPS is an important tool but they are difficult to apply during pregnancy examinations.

Discussion

Results of this study shows that public perception on mental health is still limited to mental disturbances, meanwhile it is defined as the state of well-being and productive. KIA BOOK has contained the pictures that illustrate the symptoms of mental problems. However, it is not yet perceived the concept of mental health as the state of well-being and productive during pregnancy.

Pregnant women around the world according to the Word Health Organization say that around 10% of pregnant women and 15% of women who have just given birth experience mental problems, especially depression. In developing countries this is even higher, namely 15.6% during pregnancy and 19.8% after childbirth.

this shows the need for knowledge both from pregnant women and from midwives as a place to pit pregnant women.

Besides increasing the knowledge of pregnant women by parents there is also the need for additional care in pregnancy by health workers (obstetricians, midwives, doctors and nurses). This effort is expected to be more empathetic so that young pregnant women want to come to health workers and can reduce the adverse effects psychologically during pregnancy both the acceptance of pregnancy and parenting at the time after giving birth to a baby.

Pregnancy is accompanied by mental problems and other problems that can endanger themselves and the child they are born with. Dangers for children born such as premature birth, low birth weight, etc. Besides that, the stigma is not good in the community, feeling themselves unable, low self-efficacy, and negative perceptions will affect the mother to come to a health facility.

A program to handle maternal and child health problems already exists, but the handling is prioritized (emphasized) on physical health, compared to mental health aspects that are often ignored in low and middle income countries including Indonesia (Atif, Lovell and Rahman, 2015). This is in line with the results of research which states that the mental health of mothers during pregnancy is a public health problem that tends to be ignored. Yet when referring to the World Health Organization (WHO) the definition of health is stated to be a complete state of physical, mental and social well-being and not just the absence of disease or weakness.

The definition of health combines a spiritual dimension, which in turn, ensures a holistic approach in providing mental health care. Comprehensive care is to meet not only the physical needs of patients but also their mental, social and emotional needs. Explained further, despite adopting/using the philosophy of holistic care, perinatal mental health problems often remain unnoticed/diagnosis is ignored, mothers with mental health problems often do not communicate with health workers and no further action is taken in midwifery authority.

One of the main obstacles in improving mental health services in first-level of health facilities is the low number of trained health workers in providing mental health care (for mothers) (Saraceno et al., 2007). The assessment of mental health training needs for midwives, showed a lack of training on mental health issues related to pregnancy and childbirth (Simkhada et al., 2016). The results of this study indicated that only about 30% of midwives took adequate action.

The integrative review conducted by Bayrampour et al. (2018) stated that the low management/actions taken by midwives related to mental health are influenced by two main aspects, they are; obstacles from health workers and obstacles from the system. Internal obstacles from health workers include lack of training,
lack of clarity on the scope of practice and limited time for examinations (ANC). Whereas barriers in the aspect of system consisting of unclear pathways, services that are not connected to each other, lack of local guidelines/policies, unclear continuity of services, procedures, clinical support, supervision and accessible educational resources, lack of availability of referral resources, complex bureaucracy and challenges in expanding the scope of practice.

In order to improve mental health services for pregnant women, it is important to develop community mental health services, including appropriate training and supervision (Saraceno et al., 2007). Training, hiring and supporting midwives are essential to help the improvement of mental health service skills (Ghebrehiwet and Barrett, 2007).

This training focused on promoting mental health as a part of everyone’s life and building skills to recognize mental health problems in pregnant women and new mothers (Hodgkinson et al., 2017). The problems related to the skills of midwives which are the subject of training include the following; (1) problems related to mental health training; (2) public attitudes; and (3) support for women. Training covers the benefits and limitations of training interventions; community attitudes lead to stigma and gender differences associated with mental health problems.

Conclusion

Based on the document review, the definition of mental health is a condition of well-being in which a person realizes his own potential, can deal with stress normally in his life, work productively, and is able to contribute to himself or his community.¹

The standard for pregnancy health care should be comprehensive. Therefore, deep understanding on pregnant women mental health is needed to construct high-quality health care for pregnant women to allow optimal preparation.

Abstract

In Indonesia, South Sulawesi Province is among the top 10 highest cases nationally and is among the third highest in Eastern Indonesia after Papua and Bali. This study aims to examine the decentralization of HIV/AIDS prevention programs in the Southern Province. This research uses qualitative research method with a case study design. Data collection was carried out in South Sulawesi Province, including: Makassar City and Sidrap Regency. The location selection was based on the focus of HIV/AIDS prevention and control in South Sulawesi Province, the category of the core area. The informants in this study were the Chairperson of the Provincial AIDS Commission (KPAP) of South Sulawesi Province, the Chairperson of the Regional AIDS Commission (KPAD), the holder of the Puskesmas HIV-AIDS program and the Chair of the NGO organization concerned with HIV-AIDS in each region. The selection of informants in this study used the snowball technique. The results showed that the financing of the HIV/AIDS program in South Sulawesi Province came from the local government, the central government and assistance from abroad. Human resources for the HIV/AIDS program in South Sulawesi Province, the core focus of Makassar City and Sidrap Regency have been fulfilled and are in accordance with the qualifications consisting of doctors, nurses, laboratories, pharmacists and community health workers. HIV/AIDS logistics are provided by the central government Provincial health offices, with a one-stop system. Community empowerment in HIV/AIDS prevention has been running so that cadres are formed; cadres in the field but this empowerment has not been maximally implemented. In order for the decentralization of the HIV/AIDS prevention program to run optimally, stakeholder cooperation is needed in its implementation so that the number of HIV/AIDS cases in the province of South Sulawesi, especially in core areas such as Makassar City and Sidrap Regency, can decrease.

Keywords: Decentralization, Prevention Programs, HIV/AIDS, South Sulawesi Province.

Introduction

Asia Pacific is the second largest region with HIV/AIDS cases in the world, where 78% of new cases are in the Asia Pacific region. It is estimated that 5.9 million people are living with HIV in the Asia Pacific Region in 2018. While the three countries with the most cases in Asia Pacific are India, China and Indonesia.¹ In 2018, new cases of HIV infection in Indonesia were the highest compared to other Southeast Asian countries. There are 46,000 new HIV infections and only 51% of people living with HIV know their status².

In Indonesia, South Sulawesi Province is among the top 10 highest cases nationally and is among the third highest in Eastern Indonesia after Papua and Bali³.
Based on data from the South Sulawesi Provincial Health Office, the trend of HIV-AIDS cases has tended to increase in the last three years (South Sulawesi Provincial Health Office, 2019). Based on a report from the South Sulawesi Provincial Health Office in 2018, an estimated 16,676 people living with HIV and those found to be HIV+ were around 8,821 and 10,879 who entered care, started ART 5,965 and those who are still doing ART 3,254. As for testing in the risk group in 2018, it seems that it is still far from the expected target, especially in the MSM, FSW, Risti partner, and TB group (The number of testing in the Risti partner was 2,994 while the target was 57,839; for TB patients the number of testing was 9,108, the target was 68,054; MSM testing number 4,499 and target 16,594).

In the distribution of the number of HIV-AIDS cases in districts/cities in South Sulawesi, data were obtained from 8 districts/cities with the highest number of HIV/AIDS cases, namely Makassar City (10,819 cases), Pare - Pare (561 cases), Jeneponto Regency (369 cases), City Palopo (298 cases), Wajo District (203 cases), Sidrap Regency (198 cases) and Bulukumba Regency (178 cases). The high number of HIV/AIDS cases in South Sulawesi is a commitment of all parties in order to reduce the spread of these cases. This study aims to examine the decentralization of HIV/AIDS prevention programs in the Southern Province.

**Materials and Method**

This research uses qualitative research method with a case study design. Data collection was carried out in South Sulawesi Province, including: Makassar City and Sidrap Regency. The location selection was based on the focus of HIV/AIDS prevention and control in South Sulawesi Province, the category of the core area. The informants in this study were the Chairperson of the Provincial AIDS Commission (KPAP) of South Sulawesi Province, the Chair of the Regional AIDS Commission (KPAD), the holder of the HIV/AIDS program at Puskesmas and the Chair of the NGO organization concerned with HIV/AIDS in each region. The selection of informants in this study used the snowball technique. The data analysis technique in this study used qualitative data analysis.

**Results**

The implementation of HIV/AIDS prevention programs in South Sulawesi Province was assessed based on research variables, namely financing, human resources, logistics and community empowerment.

The source of funding for the HIV/AIDS Program in South Sulawesi Province consists of APBD funds and funds from foreign NGOs in the form of activities to support local government program activities in the HIV/AIDS prevention program. Based on the results of interviews related to funding with informants, the following information was obtained:

“The source of funding comes from the local government, from the previous year we got it from the Global fund, there is also the HIV Coorperate Intervention Program from the Australian government, the funds are for institutional strengthening support for KPA administrators in South Sulawesi Province” (KP, 50 years)

“The funds we have obtained are grants from a global fund” (N 28 years)

“... sourced from the APBD sir” (K, 30 years)

From the informant’s statement regarding funding related to HIV prevention in the South Sulawesi province, it comes from the Regional Budget (APBD) and comes from assistance from abroad such as a global fund.

Human resources in the HIV/AIDS prevention program in South Sulawesi Province include availability/adequacy, distribution and capacity building of HIV/AIDS personnel. The HIV/AIDS prevention program requires sufficient personnel both in terms of numbers and qualifications, both those who work in the health office and HIV/AIDS personnel at the Puskesmas. The health workers needed at the Puskesmas in the HIV/AIDS prevention program are doctors, laboratory staff, nurses, pharmacists and public health workers. This is as conveyed by the following informants:

“In terms of resources, Alhamdulillah it is sufficient” (KD, 45 years)

“The qualifications for the HIV/AIDS prevention program are already due to the fact that there are doctors, laboratory assistants, nurses, pharmacists and public health workers involved in the HIV/AIDS program” (KP, 50 Years)

“We here consist of doctors, laboratory assistants, nurses like me, pharmacists and community health workers” (TS, 30 years)
The distribution of HIV workers is still a concern in the utilization of human resources in the HIV/AIDS prevention program in South Sulawesi Province with a focus on Makassar City and Sdrap District. The distribution of Puskesmas personnel determines the availability of HIV/AIDS personnel at the Puskesmas. Puskesmas located in urban areas are the main choice for health workers. Meanwhile, health centers that are far from urban areas are still minimal and have not yet fulfilled service needs, due to problems in access (affordability), safety factors, availability of needs, and housing.

“The distribution of HIV/AIDS program personnel in the city of Makassar already exists in every puskesmas, but sometimes there are prevention programs that have not run optimally” (K, 45 years)

“. .. if our distribution here is good ...” (R, 40 years)

Capacity building is carried out in the form of providing training to HIV/AIDS personnel to improve skills in services and recording and reporting

“There is always capacity building, what’s more with the assistance from a global fund which then organizes training activities for us” (K, 45 years old)

“. .. So there are already training activities for fellow HIV/AIDS program holders, ... (N, 28 years old)

The logistics of the HIV/AIDS program is a supporter of the HIV/AIDS response program services in South Sulawesi Province. In general, the logistics procurement for the HIV/AIDS program in the Province of South Sulawesi comes from procurement from the Province and the APBN. Based on the results of interviews related to logistics with informants, the following information was obtained.

“Through the mechanism of the Ministry of Health then to the Provincial Health Office then the Pharmacy Warehouse then the NGO/Partner Officer” (DS, 40 years)

“For logistics at our puskesmas it is sufficient, but during this pandemic there is a lack of logistics but there is no vacancy in our puskesmas” (K, 45 years).

Community empowerment has been stipulated in various government policies, both central and local, as a form of community participation mechanism from the grassroots level in supporting access to health and social services for those infected. Community empowerment is an important strategy to eliminate discrimination against people infected with HIV/AIDS. Community participation in the context of non-governmental organizations (NGOs), at the operational level is the role of KPAD. KPAD conducts guidance and empowerment in local non-governmental organizations.

Currently, there are several NGOs engaged in HIV/AIDS prevention programs in South Sulawesi Province, namely the Gaya Celebes NGO, YMH, YPKDS, a fraternal organization for drug victims. The empowerment activities carried out by NGOs are training, assistance in taking medication, distribution of condoms, counseling about HIV, reproductive health and others. The Health Office in this case took part in providing material on training activities conducted by NGOs.

“. .. providing support for activities in the form of funds that they must be accountable for every year, each NGO is given a number of millions of assistance, for which they are accountable every year. Then there may also be empowerment activities such as training training, then there are also empowerments at the level of NGOs like them and this is the health office also providing material during activities at these local NGOs ... (AF, 42 years).

The budget for NGO activities for HIV/AIDS prevention and control programs comes from grant funding from abroad such as USAID, AUSAID and the Global Fund. However, currently the assistance from USAID and AUSAID has closed.

“. .. our funding runs with funding assistance from grants from abroad, namely the global fund. .. (N, 28 Years)

Discussion

The South Sulawesi Provincial Government funds the HIV/AIDS program from the APBD. Funding from APBD in 2010 to 2014-2020. This funding is coordinated by KPAD and the Health Office and distributed to SKPDs or agencies that work on HIV/AIDS prevention programs in districts/cities. Funds for HIV/AIDS programs in the Health Office also increase every year. However, the absorption rate of the budget only reaches 20-30%.
Apart from the budget originating from the APBD, funding for the HIV/AIDS program in South Sulawesi Province is also greatly helped by the funding that comes from foreign aid. International institutions are institutions that have high resources, financial resources and technical capabilities, whose role in the HIV/AIDS prevention program in South Sulawesi Province is not to create new programs but to provide support to local governments in implementing HIV/AIDS programs in South Sulawesi Province.

So far, the budget needs sourced from abroad for HIV/AIDS prevention have been met by the Global Fund, the Australian Department of Foreign Affairs, the United States Support Fund (USAID), agencies originating from the United Nations and International Non-Governmental Organizations (NGOI). However, the sustainability of funding from abroad cannot be ascertained, because every NGO has a certain contract period.

The decentralization of the HIV/AIDS prevention program urgently needs strengthening of human resources in terms of numbers, qualifications, distribution and capacity building of HIV/AIDS personnel at all levels, including the Health Office, health centers, hospitals, NGOs and cadres. Human resources engaged in HIV/AIDS programs include field personnel (peer educators, outreach workers, field program supervisors, field level program managers), service levels (counselors, specialists, general practitioners, laboratory staff, nurses, administrative officers, nutritionists, midwives, case managers) and coordination/KPA levels in districts/cities (program managers, monitoring and evaluation officers, and administrative managers). Human resources as input in the health system will greatly affect the operation of the health system itself. The availability of human resources greatly affects the running of the HIV/AIDS program.

Logistical management of HIV/AIDS prevention programs includes planning, procurement, storage, distribution, use and control of drugs and medical equipment for prevention, diagnostics and therapy. Logistics management in the health system is carried out by the ministry of health at the central level and health offices at the sub-national level. The logistics management system is expected to guarantee that the program implementation must arrive at the beneficiaries in a timely manner, fulfilling their needs with guaranteed quality. Procurement of drugs and medical equipment for HIV/AIDS prevention and therapy is currently still dependent, especially from foreign assistance, except for ARVs and some reagents which are fully prepared by the Ministry of Health. In general, policies related to pharmaceutical preparations are regulated in Government Regulation No. 72/1998 on Safeguarding Pharmaceutical Preparations and Medical Devices, which mandates the procurement of methadone and ARVs prepared by the central government. Apart from procurement by the central government, logistics for HIV/AIDS are also provided by the South Sulawesi Provincial Health Office.

Provincial health office decentralization policy. Distribution to districts/cities uses a one-door system. Currently, the logistics supply chain from the Provincial Health Office to service units such as puskesmas and hospitals is running well, except for areas with difficult geographic conditions. The Regency/City Office submits logistical requests every month to the Provincial Pharmacy Installation according to the number of cases in each Health Office. This is to ensure the availability of logistical supplies at the Health Office and service units.

Empowerment of MARPs and PLWHA communities is the key to independently providing sustainable HIV/AIDS services based on the community’s need to live healthily, both to protect themselves from HIV infection and to maintain the quality of life of PLWHA.

In carrying out their duties, NGOs receive budget assistance from KPADs with assistance from international donors. However, the activities of NGOs operating in districts/cities in South Sulawesi province are not well coordinated so that there are still many overlapping activities between NGOs. Even some activities overlap with activities carried out by the Puskesmas. So that the issue of coordination between NGOs and the government is still something that must be considered in the context of the success of the HIV/AIDS program in South Sulawesi Province. The current community empowerment is related to the implementation of HIV/AIDS prevention programs at the District/City Health Office. The cultural approach is one of the factors that must be considered in the HIV/AIDS prevention program.

The issue of communication between stakeholders was also found by Fritantus and Rukminingsi (2013) in their research in Surabaya, that communication between stakeholders is highly expected in the HIV/
AIDS prevention program. Communication between stakeholders will affect other needs such as financing, provision of human resources, and others. The sectoral ego is still an obstacle in HIV/AIDS prevention programs11.

Conclusions and Recommendations

This study concludes that the financing of the HIV/AIDS program in South Sulawesi Province comes from the local government, the central government and foreign assistance. Human resources for the HIV/AIDS program in South Sulawesi Province, the core focus of Makassar City and Sidrap Regency has been fulfilled and is in accordance with qualifications consisting of doctors, nurses, laboratory staff, pharmaceutical workers and public health workers. HIV/AIDS logistics are provided by the central government Provincial health offices, with a one-stop system. Community empowerment in HIV/AIDS prevention has been running so that cadres are formed in the field but this empowerment has not been maximized in its implementation.

Abstract

Tuberculosis (TB) is still prevalent in Indonesia. In 2016, TB’s incidence rate is estimated 129 per 100,000 population. In order to reduce the incidence, reducing the risk of transmission through the patient sputum drug compliance is essential.

This is quasi-experimental study design. There are 3 groups, which are the intervention group that receives bag waterproof plastic container, bottle waterproof plastic container that both contains a 4-chloroalpha-phenyl-o-cresol (klorofenol) desinfectant with concentration of 5% as a killer of TB bacilli accompanied by promotional messages and control group (without intervention). The population is all patients with pulmonary TB Acid Fast Bacilli positive (AFB+) aged > 12 years old who come for treatment to all community health centers that have Microscopic Reference Center (MRC) facility and use Directly Observed Treatment Short-course (DOTS) strategy in Medan. The sample is selected by consecutive sampling.

There is a significant difference (p<0.05) of the risk of pulmonary TB transmission according to the role of the DSS between the treatment groups using plastic bags containers and plastic bottles with control group. There is a significant difference (p<0.05) the risk of pulmonary tuberculosis transmission based on drug compliance between the treatment groups using plastic bag containers and plastic bottles with control group. The use of containers containing

the killer disinfectant of TB bacilli in sputum accompanied by promotional messages on the walls of the container is effective in reducing the risk of TB transmission from patients with Acid Fast Bacilli positive (AFB+) pulmonary TB.

Keywords: Pulmonary TB, plastic containers, DSS, Clorofenol.

Introduction

TB is a contagious infectious disease caused by the Mycobacterium Tuberculosis, which can attack various organs, especially the lungs. If not treated or the treatment is incomplete, can cause dangerous complications, even death\textsuperscript{1-3}.

Globally, in 2016 there were 10.4 million of TB cases (CI: 8.8 million - 12 million) equivalent to 120 cases per 100,000 population. Five countries with the highest number of cases are India, Indonesia, China, Philippines, and Pakistan. Most of the TB incidence in 2016 occurred in the Southeast Asia Region (45%), where Indonesia is one of them\textsuperscript{4,5}.
According to the World Health Organization (WHO), in 2016 Korea was one of the countries with the highest number of TB incidence among other high-income countries, it is estimated at 77 cases per 100,000 population.6

Based on the Integrated TB Information System report in 2016, TB incidence rate in Indonesia estimated to be at 129 per 100,000 population, it still lower than the reality and almost 2 times higher than Korea.1

According to the Indonesia Health Ministry the number of tuberculosis was 330,910 cases, this number increased compared to 2014, which amounted to 324,539 cases.

The WHO defines the high burden countries (HBC) for tuberculosis according to 3 indicators: TB, Human Immuno Virus TB (HIV-TB), and Multi Drugs Resistance TB (MDR-TB). A country can be included in one of these lists, or both, and can even be included in all three. Indonesia along with 13 other countries are included in the HBC list for all 3 indicators. It means that Indonesia has major problems in dealing with TB.

Cough is the main mechanism of Mycobacterium TB transmission by Esmail et al., and is transmitted through aerosol which spread in the air with very small range of 1–5 μm. Various respiratory activities which produce aerosols, in addition to coughing, can also be through sneezing, singing, and talking. The cough frequency is associated with infectivity but not necessarily the cause of TB transmission. Pulmonary TB patients who often cough do not necessarily transmit, in this case the ethics when coughing plays an important role in preventing transmission of pulmonary tuberculosis.11

This research is carried out for the patients with pulmonary TB AFB+ to dispose sputum and material contacted with sputum into container containing klorofenol compound with 5% concentration. The container serves as a disposal place of tissues, disposable masks, and sputum from patients with pulmonary TB- AFB+ as a killer of Mycobacterium TB after being deposited within 24 hours.

Klorofenol is a derivative disinfectant of phenol (carbolic acid), Giacomelli, et al. report that 5% of phenol was effective in decontamination of Mycobacterium TB smear slides for 10 minutes. A study by Sarumpaet and Syarifah states that the DSS role in assisting drug swallowing and sputum examination is very lacking. Drug compliance must be done to cure pulmonary TB and the role or the activeness of DSS is expected to support the patient recovery.

Based on this, research needs to be carried out on the role of DSS in reducing the risk of TB transmission and the adherence of patients with pulmonary TB-AFB+ in swallowing drugs supplemented by the intervention of containers and waterproof plastic bottles containing 5% of klorofenol solution.

The aim and benefit of the study is to analyze the differences in the transmission risk and drug compliance for patients with pulmonary TB-AFB+ based on the DSS role in the group with plastic bags and waterproof plastic bottles compared to the control group.

Materials and Method

The research type is a quantitative study with quasi-experimental design divided into 3 groups, namely groups that receives bag waterproof plastic container, bottle waterproof plastic container that both contains klorofenol disinfectant with a 5% concentration accompanied by promotional messages and control group. The container contains a klorofenol 5% which functions as a disposal place of tissues, disposable masks, and sputum as a killer of Mycobacterium TB after being deposited for 24 hours.

Promotional messages are attached to the walls of the containers in order for the patients not to forget to take medicine, the effects if they forget to take medicine, always use mask and tissues to cover mouth when coughing, and how to prepare 5% klorofenol compound into the containers.

The population and sample are all patients with pulmonary TB-AFB+ is aged > 12 years old who come for treatment with DOTS strategy to all community health centers that have MRC facility in Medan. The sample is followed for 2 months and in the last evaluation obtained 125 patient from all MRC. The duration of the intervention for 2 months is based on the evaluation of sputum examination conducted at the MRC to assess the conversion of AFB smear positive sputum to smear negative. During the observation in this study, all patients experienced sputum conversion from smear positive to smear negative.

The effectiveness of the use of bag and bottle plastic containers as a model to reduce the transmission risk of pulmonary TB-AFB+ compared to control is performed through a 2 proportions z-test.
Results

The samples are taken purposively, that all pulmonary TB-AFB+ patients who come for treatment at 10 health centers with the highest number of pulmonary TB patients visit, obtained from the health center report data in Medan. The study is amounting to 125 patients, with 34 people getting bottles waterproof plastic (Helvetia and Sentosa Baru Health Center), 40 people getting bags waterproof plastic (Amplas, Desa Binjai, Medan Johor, and Teladan Health Center), and 51 people for control (Kampung Baru, Medan Deli, Belawan, and Mandala Health Center).

In accordance with the results of the study, the proportion distribution of the patients obtained based on the intervention is in the following Table 1.

With the Kruskal-Wallis test, obtained the value of p<0.05, therefore concluded that there is a difference in the risk of pulmonary TB-AFB+ transmission based on the role of DSS between the three intervention groups.

In order to discover the differences in the transmission risk of pulmonary TB between each intervention and control group, a Post-Hoc analysis using the Mann-Whitney test can be seen in Table 3 below.

Based on table 3, concluded that there is no difference in the transmission risk of pulmonary TB-AFB+ based on the role of DSS between intervention groups that use bottles and bags. However, there is a significant difference (p <0.05) of the transmission risk of pulmonary TB-AFB+ based on the role of DSS between the intervention groups using bottles and control group as well as between the intervention groups using bags and control group.

To find out the differences between each intervention group, Post Hoc analysis is performed with the Mann-Whitney test which can be seen in table 5 below.
Based on table 5, it is assumed that there is no difference in the risk of transmission of pulmonary TB-AFB+ based on drugs compliance between intervention groups using bottles and bags (p>0.05). Although, there is a significant difference in the risk of pulmonary TB-AFB+ transmission based on drugs compliance between intervention groups using bottles and control group (p<0.05). Subsequently, there is a significant difference in the risk of transmission of pulmonary tuberculosis AFB+ based on drugs compliance between intervention groups using the bag and control group (p<0.05).

Figure 2. Bottle Image
Discussion

The result exhibits a significant difference in the risk of transmission of pulmonary TB-AFB+ based on the role of DSS between intervention groups using bag and bottle containers with control group group.

The DSS role as supervisors to remind patients to take the medication, accompanying in fetching the drugs, knowing the side effects of TB drugs, and how to dispose sputum is conveyed by the researchers when taking the samples of pulmonary TB-AFB+ patients who came to the health center at the time of the study.

With the container and the message printed on the sides of the container given to the TB patients, the promotional message can be read at any time therefore the DSS message is more easily remembered by the patients in terms of disposing sputum, as well as the regularity and compliance with the drug. Similarly, the message also will be able to increase the patients knowledge in dealing with their illnesses as the lack of the patients knowledge will make it more difficult to achieve recovery. The patients’ knowledge about symptoms, signs, causes, transmission, and treatment are also the key in preventing pulmonary TB transmission. Under these conditions, assumed that the transmission risk is smaller in patients who are given the containers than those without the containers.

The DSS role is a strategy to ensure the patients recovery with pulmonary TB (National Strategy for TB 2010-2014). A study by Firdaus KMZ in Baki Sukoharjo Health Center shows that there is an influence on the role of DSS with the success of the treatment of patients with pulmonary TB-AFB+ (p = 0.002).

Researchers Suprajitno, et al conclude that when there are mild side effects in patients with pulmonary TB, DSS can provide information to patients that it is natural and take appropriate action to overcome the side effects. Thus the patient is expected not to stop the drug and the transmission risk becomes smaller.

This research is also revealed that there is a significant difference in the transmission risk of pulmonary TB based on the drugs compliance between the intervention using bottle containers and plastic bag containers with control group. The study results of Latifatul and Umdatus also displays that there is a significant influence between family support on drugs compliance (OR = 21.99, p = 0.028). According to research conducted by Wiwit and Amila in 2018, the role of DSS for pulmonary TB patients is as a motivator, reminding sputum re-examination, supervising treatment as well as the role of educator. Furthermore, according to Rohmana, et al in 2014 that one of the factors that determine the regularity of drugs compliance of pulmonary TB patients is DSS.

Hartini T stated that the highest DSS proportion of the patients with pulmonary TB-AFB+ in Deli Serdang Regional Hospital in 2011-2012is family (81.5%). Drugs compliance is the key to the patient recovery with pulmonary TB. Since 1995 the Indonesian government has launched a program to eradicate pulmonary TB by using the DOTS strategy, which is a direct supervision of short-term treatment.

In accordance with the results of research conducted by Pameswari et al at Mayjen H.A Thalib Hospital in Kerinci Regency, it is discovered that the number of respondents who adhered to the treatment of pulmonary TBis higher than the number of patients who are semi-adherent or non-adherent patients. Out of the 27, the adherent respondents is 15 respondents (55.56%), semi-adherent is 9 respondents (33.33%), and non-adherent is 3 respondents (11.11%).

A study in India explains most of the disobedience and low motivation to seek treatment are due to lack of knowledge and awareness about the disease. The same thing is concluded from a research in Nepal, the adherence of the patients with pulmonary tuberculosis is related to the compliance, perceptions about TB, and its treatment.

Conclusion

The use of bags and bottle plastic containers containing the killer disinfectant for TB bacilli in sputum accompanied by promotional messages on the sides of the container is effective in reducing the risk of TB transmission from patients with pulmonary TB AFB+.

Abstract

A hospital is good generally considered if in providing services it pays more attention to the needs of patients and other people visiting the hospital. The purpose of this study was to analyze the service quality of inpatient room staff on patient satisfaction at the Saparua Regional General Hospital. This type of research used in this research is quantitative research with a cross sectional design. The population in this study were all inpatients at Saparua General Hospital. The samples were determined by means of incidental sampling, namely the technique of determining the sample based on chance, that is, anyone who incidentally was admitted to an inpatient at Saparua General Hospital. The results showed that there was an effect of doctor’s service on the satisfaction level of inpatients at Saparua Hospital (p value = 0.016). There was no significant effect of nursing care on the satisfaction level of inpatients at Saparua Hospital (p value = 0.134). the better the level of patient satisfaction. In order to improve the quality of human resources, especially in terms of increasing the quantity and quality of services, hospital staff need to provide training for doctors and nurses so that the services provided to patients can be better so that patients feel satisfied.

Keywords: Quality, Service officer, hospitalization, satisfaction, patient.

Introduction

Hospitals are a comprehensive form of health care organization covering aspects of health promotion, prevention, healing, and recovery for all communities that often face problems concerning patient dissatisfaction with the quality of service. Therefore, hospitals as facilitators of health services, in addition to comprehensive are also expected to provide quality health services that refer to the level of perfection of the health service1. Quality should be viewed more widely, where not only aspects are determined but also include processes, environment and humans, quality is a dynamic condition related to products, services, people, processes and environments that meet or exceed expectations.2

In the face of patient satisfaction, inevitably the provision of hospital services must maintain the quality of service continuously. Services have been patient-oriented but not in the view of healthcare providers. The size of the quality of the service provider can be seen from the service received by the patient whether it is in accordance with what has been expected.3]The quality of service has a positive and significant relationship with patient satisfaction levels, thus indicating that high levels of patient satisfaction are influenced by the high quality of service provided. The quality of service should start from the needs of the patient and end in the patient’s expectations.4]

In this study, researchers prefer patients who were hospitalized because inpatients were more likely to
experience hospital services because they received more services. Inpatient health services are one of the main concerns of hospitals around the world. This is because hospitalization is a service to patients entering the hospital who occupy a bed for observation, diagnosis, therapy, medical rehab or other medical services with daily supervision of a doctor. In addition, quality inpatient services are an important expectation because the perception of the quality of service aspect of a hospital is formed when the patient is treated.\(^5\)

A hospital is good generally considered if in providing services it pays more attention to the needs of patients and other people visiting the hospital. The quality of the service as a measure of how good the level of service provided is able to match the expectations of the customer (patient).\(^6\) Based on this definition, the quality of services can be realized through the fulfillment of the needs and desires of the patient and the accuracy of his delivery to keep up with the patient’s expectations. With Saparua hospital motto is “Patient Satisfaction is our Pride”. The purpose of this study is to analyze the quality of inpatient service to patient satisfaction at Saparua Regional General Hospital.

**Materials and Method**

The type of research used in this study is quantitative research with cross-sectional design. The population in this study was all inpatients at Saparua General Hospital. The samples in this study were some patients who were hospitalized during the study. The determination of the sample is done by way of incidental samples, namely the technique of determining samples based on coincidence, namely anyone who is incidentally admitted to an inpatient at Saparua General Hospital. Data collection techniques are primary data obtained through live interviews to respondents during the study using questionnaires, and secondary data is obtained from the medical records section of Saparua General Hospital.

**Result**

Based on table 1. The results of the study above the doctor service variable, showed that out of 42 respondents based on the doctor’s services, the most were respondents who gave a sufficient assessment of the doctor’s services as many as 24 people (57.1%) and the few who gave a poor doctor service rating of 18 people (42.9%). The nursing service showed that of the 42 respondents based on nursing services, the most were those who gave a sufficient assessment of nursing services which was 23 people (54.3%) and the fewest who rated nursing services poorly as many as 19 people (45.2%). Patient satisfaction, showed that of the 42 respondents based on patient satisfaction levels, the most were respondents who gave a satisfied rating of 23 people (54.8%) and the few who gave a disgruntled rating of 19 people (45.2%).

Based on Table 2 of the doctor service variables shows 24 respondents with sufficient assessment of the services of doctors who are satisfied with the quality of service as many as 17 respondents (70.8%) and as many as 7 respondents (29.2) who were dissatisfied. Meanwhile, of the 18 respondents with poor assessment of the service of doctors who were satisfied with the quality of service as much as 6 respondents (33.3%) and 12 respondents (66.7%) who feel less satisfied. Statistical test results obtained p value = 0.016, because the value p < α = 0.016 > 0.05 then Ho was rejected, this means that there is a statistically meaningful influence of variable doctor services on patient satisfaction in Saparua regional general hospital.

Based on the nurse service variables, 23 respondents with sufficient assessment of the care of nurses who were satisfied with the quality of service were 15 respondents (65.2%) and 8 respondents (34.8) who were dissatisfied. Statistical test results obtained p value = 0.134, because the value p > α = 0.134 > 0.05 then Ho received, this means that there is no statistically meaningful influence of nurse service variables on patient satisfaction in Saparua regional general hospital.

Discussion

The quality of medical services is consistent and sustainable with the aim of meeting the expectations of patients in Saparua regional general hospital. The effect of the quality of medical services is very influential on patient satisfaction because with the good quality of medical services make a positive contribution to the embodiment of patient satisfaction.[7] The results showed that the service of doctors with sufficient patient satisfaction, where some patients stated that satisfied with the doctor’s service. Doctors at Saparua regional general hospital strive to always prioritize patients, understand the needs and desires of patients.

The doctor’s service felt by patients visiting saparua area general hospital can be described that in providing the service the doctor explains well and details about the cause and effect of the patient’s illness, every action in the service is always followed by a good explanation and easy to understand the patient. It’s just that there are still complaints of delays in doctors conducting examinations of patients. Another study conducted by Torry et al., (2016) to determine the factors that affect health care waiting times related to patient satisfaction shows that patient satisfaction is influenced by the actual waiting time felt by the patient, and the speed of service received by the patient, whose conclusion is the main factor that prolongs the waiting time of the service and decreases patient satisfaction is the lack of optimal schedule of the doctor in charge. [8]

There are several types of services in hospitals whose quality is always assessed by patients and one of them is nursing services. Nurses as professionals have the most opportunity to provide health care, especially comprehensive nursing care by helping patients meet holistic basic needs. To perform her role properly, nurses need to have skills in clarifying grades, counseling and communication.[9] The results showed that the quality of service provided by nurses at Saparua regional general hospital was assessed by either patients or respondents. Respondents stated that officers are deft in replacing fluids, always give smiles to patients who come and officers are not picky or indiscriminate in serving and assisting patients. Respondents who were dissatisfied with the nursing services at Saparua regional general hospital were concerned with the delay in nursing services. This research is not in line with Layuk et al showing the knowledge, attitude, and skills of nurses affect the satisfaction of patients in Labuang Baji Makassar Hospital, research conducted by Nahlah et al shows that there is a human relationship to inpatient satisfaction in Pelamonia Makassar Hospital[10-15].
Conclusion

The study concluded that there is an influence of physician services on the satisfaction level of inpatients in Saparua regional general hospital (p value = 0.016). There is no significant effect of Nurse services on the satisfaction level of inpatients in Saparua regional general hospital (p value = 0.134). The better the level of patient satisfaction, in order to improve the quality of human resources, especially in terms of improving the quantity and quality of service officers the hospital needs to provide training for doctors and nurses so that the services provided to patients can be better so that patients feel satisfied.

Ultraviolet Light Application Model in Lowering Germs on Food Snacks Atelementary School in Makassar

Zaenab¹, Rafidah¹

¹Lecture of Department of Environmental Health, Health Polytechnic of Makassar

Abstract

Food is a basic need for human life. Food is very likely to be contaminated so it can cause a disease called foodborne illness. One alternative for food preservation is with irradiation. Irradiation is commonly used in food preservation with ultraviolet light.

This study aims to determine the effect of exposure for 30 minutes and 60 minutes with the application of UV light in reducing the number of germs in food snacks in the elementary school environment of Makassar. The type of research is experimental research. Sampling used in the elementary school environment of Makassar. The populations in this study are all sellers in elementary school in Makassar City. The sample in this research is 5 samples of snack food for each observation. Data obtained from examination results is tested with statistical tests which are Wilcoxon method and calculated manually. The data is presented in the form of tables, diagrams, and narration.

The results showed by UV light irradiation method on food snack samples for UV exposure for 30 minutes, according to the results of statistical tests with Wilcoxon method of 0.13 > 0.05 means that there is no effect of UV lamp used. Exposure to UV light for 60 minutes results 0.04 < 0.05 means use of UV lamps gave effect to the number of germ, the best results were obtained at UV exposure for 60 minutes, in addition to the effect of reducing the number of germs visible difference in terms of physical endurance.

The conclusion of the study is that there is no influence of UV light exposure model implementation for 30 Minutes in decreasing the number of germs in food or snack, and there is influence of exposure model of UV light application For 60 Minute in decreasing the amount of germ in snack food and snack food have durability with exposure UV rays. Suggestions for future researchers to use longer exposure time comparison. Traders can apply food preservation snacks with UV light models in lowering the number of germs.

Keywords: UV Light, Number of Germ, Preservation, Food Snack.

Introduction

In Indonesia the use of food radiation has been determined in the legislation contained in the Minister of Health Decree No. 152/Menkes/SK/II/1995 on the Amendment of Attachment of Health Minister Number 826/Menkes/PER/XII/1987 on Irradiation Food. Chintya, DR et al¹ showed the effect of UV lamp and duration of UV irradiation on physical, chemical, and microbiological properties of mulberry juice with best treatment is mulberry juice of 30 Watt UV lamp and 60 minutes irradiation time and in Suharyono’s research, et.al². The best irradiation, which took 50 seconds, in this process total microbes 1.3 x 107 CFU/ml, vitamin C content 24.64 mg/100g, and lycopene content 0.36. Irradiation with ultraviolet light does not affect the content of vitamin C and lycopene content of tomato juice. Storage for 4 days resulted in decreased vitamin C and lycopene content. 50 seconds of irradiation does not affect the color, flavor and taste of tomatoes, and is acceptable to the consumer.

One alternative food preservation is by irradiation. Irradiation commonly used in food preservation today is with ultraviolet light. This process aims to reduce deterioration due to decay and damage, and to
kill microbes. Heating is a conventional processing technology to reduce microbial contamination in foods, especially those that are pathogenic. The process of food processing with heating can cause a less favorable effect on the quality of food products in the form of decreased levels of nutrition and sensory quality. Therefore, the food processing industry continues to develop alternative preservation technologies to minimize the damage caused by excessive heat.\(^3\)\(^4\).

Long radiation is an important factor in UV irradiation. In addition to long irradiation, the rate of inactivation of microorganisms is also a factor affecting UV irradiation. Thus, the non-thermal pasteurization process needs to be developed so that the product does not experience much decrease in nutritional value but the number of microbes remain decreased so that it has a long shelf life, so I as a researcher interested to do this research titled “UV Rays Application Model In Lowering the Number of Germs In Food Snacks In Makassar City Elementary School

**Materials and Research Method**

1. **Type of Research:** The research type is experimental research that is model of application of UV rays with exposure time 30 minutes and 60 minutes in reducing the amount of germs in food snack in Makassar City and also Control to see the difference specifics.

2. **Research Sites:**
   a. **Location Inspection and sample observation:** The location of the examination and observation of samples was carried out at the Laboratory of the Health Department of the Health Polytechnic of Makassar.
   b. **Sampling Locations and Sampling:** The collection of sample is done randomly in elementary school environment in Makassar City.

3. **Time of research**
   a. The preparatory phase, including observations to prepare research proposals and data collection in January - May 2017.
   b. Implementation phase, including sampling, laboratory examination and data processing and analysis conducted in June - October 2017.

4. **Research Variables**
   a. The independent variable is the variable that influences the dependent variable ie UV light and food snack.
   b. The dependent variable is the variable that is influenced by the independent variable that is decreasing the number of germs
   c. Disturbing variables are the variables that are expected to influence the dependent variable are time, temperature and humidity.

**Objective Criteria:**

1. There is an effect of long exposure by using model of application of UV rays for 30 minutes and 60 minutes in lowering the amount of germs in food snacks.
2. No effect of long exposure by using model of UV rays There is a long effect of exposure by using model of UV light application for 30 minutes and 60 minutes in reducing the amount of germs in food snacks.
3. Physical food snacks in this study is the quality of food that includes odor, taste, and texture.
4. Time in this study is the long exposure to food that is preserved by using irradiation technique.

5. **Population and Sample**
   a. Population The population referred to in this study are all sellers in elementary school in Makassar.
   b. Sample in this research is 5 sample of snack food that is for snack food each each observation.

7. **Data Analysis:** Data obtained from the examination results in statistical tests with Wilcoxon method and done manually and presented in the form of tables, graphs, and narration.

**Results**

Based on the research that has been done and analyzed in the Laboratory of Environmental Health Department, with examination as much as 5 times repetition for the parameters of the number of germs, the results obtained examination as follows:
1. UV Exposure 30 Minutes

Table 1. Results of Checking Number of Germs Food Snack Sample with UV Light Exposure 30 Minutes.

<td>Good</td>
</tr>
<tr>
<td>2</td>
<td>Control</td>
<td>Not good</td>
</tr>
</tbody>
</table>

Based on Table 6, it can be seen that the average result of physical observation of food samples with 60 minute UV exposure that has the quality of taste and texture is still good and odorless, while the average result of control observations generally have a bad taste and texture, but no smell.

### Discussion

1. **UV Exposure 30 Minutes:** Foods consumed should not only meet the nutrients and have an attractive shape, but also safe in the sense that does not contain microorganisms and chemicals that can cause illness and safe for consumption. Safe foods are non-contaminated, containing no microorganisms or bacteria and harmful chemicals.

   Irradiation commonly used in food preservation today is with ultraviolet light. This process aims to reduce deterioration due to decay and damage, and to kill microbes. Radiation can inhibit the growth of bacteria, molds, and yeasts.

   Based on the results of examination of the number of germs on food snacks samples for UV exposure for 30 minutes obtained an average of 4.156.666 colonies/g, initial sample after 30 minutes exposure experienced a decrease in the number of germs of 1,066,666 colonies/g, sample observation to 120 minutes the number of germs increased to 4,136,666 colonies/g, sample observation to 240 minutes the number of germs decreased to 3,403,332 colonies/g, and decrease in germs still occurred in the observation sample to 360 minutes of 2,679,999 colony/g.

   Based on the result of statistical test with Wilcoxon method obtained for UV after exposure of 30 minutes result 0.13 > 0.05 meaning there is no influence of UV lamp usage. For observation after 120 minutes result 0.22 > 0.05 means there is no effect of UV lamp use. For observation after 240 minutes the result of 0.13 > 0.05 means there is no effect of UV lamp use. For observation after 360 minutes result 0.22 > 0.05 meaning there is no effect of usage of UV lamp. So when compared between laboratory results with statistical tests used it is appropriate that no effect of 30 minute UV light exposure, which is significant, but there is a decrease in the number of germs.
The physical observations on food samples with 30 minute UV exposure showed the average of good taste quality, and odorless, but the texture is not good. This is obtained from UV irradiation for samples I, II and III each having a taste and texture quality that is still good and odorless, in contrast to the IV sample where the taste with good quality on the top surface but the texture on the bottom is not good or watery as well as smelling and sample V physical qualities with an already bad taste, or watery and smelly. The difference in yield is likely due to the selection of samples or samples used on each experiment varies.

Compared with control samples the average physical observation showed flavor, and the texture was not good but odorless. This is because the control sample is not treated with UV light. So the use of UV light to see the physical quality of the food has an effect because the observed food samples are still able to survive until the second day. In this study when compared with previous studies have different objectives and different method but in essence have similarities in terms of function that with UV light irradiation can affect the quality of microorganisms that can reduce the number of germs.

In addition microorganisms can grow on food because it is influenced by several factors one of which ultraviolet light radiation with a certain wavelength and ionization radiation such as X rays and gamma rays can be easily absorbed by the cells of microorganisms. Such rays can disrupt cell metabolism and can generally be rapidly deadly. Based on the theory that ultraviolet rays have the ability to influence the function of living cells by altering the material of the intisel, or DNA, so that the creature dies. This effect is used as a basis for inhibiting the growth of microorganisms in foodstuffs. Therefore exposure to UV light for 30 minutes in general does not give a significant effect on the amount of germs so it is advisable that the duration of exposure added.

2. 60 Minute UV Exposure: Based on the research, the result of examination of the number of germs on food snack samples for UV light exposure for 60 minutes obtained the average of the initial sample of 4,156,666 colonies/g, the observation sample to 60 minutes of 1,289,999 colonies/g, 120 observation samples minutes of 2,471,999 colonies/g, a sample of 240 minutes observation of 3,413,333 colonies/g, and a 360-minute observation sample of 3,228,666 colonies/g.

Based on statistical test results with wilcoxon method obtained for UV with 60 Minutes exposure result 0,04<0,05 meaning there is influence of usage of UV lamp. For observation after 120 minutes result 0,34>0,05 meaning there is no effect of usage of UV lamp. For observation after 240 minutes the result of 0,34>0,05 means no effect of UV lamp use. For observation after 360 minutes result 0,22>0,05 meaning there is no effect of usage of UV lamp. So it can be concluded that 60 minutes of UV exposure had an effect on the first 60 minutes of observation, but observations after 120 minutes, 240 minutes, and 360 minutes had no effect, but there was a decrease in the number of germs.

Therefore, the duration of exposure has an effect on the decreasing amount of bacteria in food samples. As it is known that the decrease in the number of germs is greater when UV exposure is done longer because UV light is known to be one of the rays with radiation power that can be lethal to the organism. UV light has a wavelength of 4 nm to 400 nm with the highest efficiency for microorganism control is 365 nm. UV has a lethal effect on the cells of microorganisms, UV radiation is often used in places that require aseptic conditions such as laboratories, hospital operating rooms, and food and beverage and pharmaceutical production rooms.

On the physical observation with 60 minute UV exposure shows the average of taste and texture quality is still good and odorless. Where food samples with 60 minute UV exposure showed a better durability effect in comparison with 30-minute UV exposure because samples I, II, III and IV each had good quality flavor and texture and odorless, and the sample V was not good, the texture is not good or watery and smelly. This is because the sample used for the examination has less endurance. In addition, physically the texture of the food is easily damaged

When compared with the result of examination the number of germs on food snack samples for the control obtained average of the initial sample of 4,156,666 colonies/g, on the observation sample to 30 minutes decreased the number of bacteria amounted to 2,033,333 colonies/g, sample observation to 60 min of 3,863,333 colonies/g, observation sample to 120 mins 3,209,866 colonies/g, sample observation to 240 mins 1,970,000 colonies/g, and 360 min observational samples of 1,399,999 colonies/g, so there was a difference between 60 minutes of UV exposure and a control sample not treated with UV light.
Ultraviolet light is an energy that has the ability to penetrate into the cell wall of microorganisms and is able to change its nucleic acid composition. Ultraviolet absorption by DNA (or) RNA. The advantage of using ultraviolet light rather than chemical disinfection is very effective in killing most pathogenic bacteria such as E. coli, Giardia, Lamblia, and Cristoporidium, without chemicals, non-toxic, significant non-hazardous, non-hazardous overdose, eliminating some organic contaminants, having no volatile organic compound emissions or toxic air emissions, no odorless and odorless changes in the finished product, enough with less contact time (seconds or minutes) to chemical disinfection, and does not require storage of hazardous materials\textsuperscript{7,8}.

The results of previous research conducted by Srigede\textsuperscript{9}, is the effect of long time sterilization of ultraviolet light on the growth of Bacillus sp bacteria, the results obtained that the longer sterilization time decreases the number of bacteria Bacillus sp. Based on research data showed that there was a decrease in the number of bacteria Bacillus sp in each treatment. After sterilization of 30 minutes 60 minutes, 90 minutes, and 120 minutes using ultraviolet light seen that there is a decrease in the number of bacteria is greatest after sterilization of ultraviolet light for 120 minutes.

When compared to the two previous studies the longer the diminished irradiation of the number of different bacteria with the purpose of this study is to determine the effect of UV light irradiation method on food snacks but have similarities in terms of influence of UV rays are able to reduce the amount of germs.

So the use of UV light irradiation method in this study has an effect although the decrease is not significant is due to less exposure time and suggested to increase the exposure time\textsuperscript{10-13}.

**Conclusion**

1. There is no effect of UV model for 30 minutes in reducing the amount of germs in food snacks.
2. There is influence of UV light implementation model for 60 Minutes in decreasing the amount of germs in food snack.
3. Food snacks have long endurance with the presence of UV exposure

Abstract
Pharmacy Installation is part of the hospital responsible for implementing drug management which includes selection, procurement, distribution and use of the drug. This research aims to evaluate the planning and procurement of medicines in Dr. M. Haulussy Ambon Hospital Pharmacy Installation. Research uses descriptive design with retrospective and concurrent data retrieval. Retrospective data is data obtained by tracing the previous year’s documents (secondary data) in 2018 including financial statements, drug planning and use reports, drug procurement reports, and invoices. Retrospective data retrieval is carried out on, the percentage of conformity between drug planning and the reality of use for each drug. Concurrent data is data obtained at the time of research or is primary data with in-depth interviews with IFRS officers as well as discussions with officers/employees related to drug management. The results showed the Procurement stage of the procurement of funds for each drug item already met the standards. The suitability of planning with the wear reality for each item is not in accordance with the standard (less than 100%). It is expected to cooperate well with related parties, especially pharmaceutical installations in drug planning and management so that the use of existing funds can be more efficient and effective.

Keywords: Planning, Procurement, Medicine, Pharmaceutical Installation, Hospital.

Introduction
The hospital is a health care institution for the community with its own characteristic1-5. Hospitals are heavily influenced by the development of health sciences, technological advances, and socioeconomic lives of people who must still be able to improve quality and affordable services by the community in order to realize the highest degree of health. One of the activities in the hospital to support quality health services is pharmaceutical services. Pharmacy services in hospitals are organized by the installation of hospital pharmacies that have two main functions, namely, managerial functions and professional functions.6-7

Annual drug planning with purchases, fluctuations in drug use and government policies are changing. Inefficient management of the drug causes the level of availability of drugs to be reduced, the emptiness of the drug, the number of drugs that accumulate due to inefficiencies of drug planning, as well as the number of expired/damaged drugs due to poor distribution system so as to impact the inefficiency of budget/cost use8,9.

he development of the pharmaceutical world as well as the demands of patients and the public on the quality of pharmaceutical services require a change from product oriented to patient oriented\textsuperscript{10}. So that services to patients must be considered ranging from basic elements or supporting elements so that patient satisfaction can be fulfilled well in order to achieve the goal of improving quality of life. In addition, in order for the agency to get a good outcome as a result of maximum service\textsuperscript{11}.

The importance of drug management in pharmaceutical installations in achieving optimal health services in hospitals If the hospital is unable to plan and implement drug management properly then the hospital is not able to reach the point of success. The failure of logistics management will decrease the quality of hospital services so that patient satisfaction will also decrease\textsuperscript{12}. The non-smooth management of the drug can have a negative impact on the hospital\textsuperscript{13}.

Dr. M. Haulussy Ambon Hospital is a type B hospital with type Of Non-Educational Hospital in accordance with the Decree of the Minister of Health No. 1069/Menkes/SK/XI/1992 which in PERDA No.06 of 1994 dated December 22, is the most complete hospital in Maluku so that it becomes the only referral hospital in Maluku Province. Therefore, services at Dr. M. Haulussy Hospital should be very considered including services provided by inpatient and outpatient pharmacy installations, including services to patients of BPJS (Social Security Regulatory Agency) Health who have cooperated with the government, especially Dr. M. Haulussy Ambon Hospital. With the smelting of ASKES and JAMKESMAS into BPJS on January 1, 2014, coupled with the expansion of BPJS program services to the general public who want to have health insurance, more and more BPJS participants must be served in pharmaceutical installations\textsuperscript{14}.

One of the important components of supporting the achievement of the hospital’s goal in providing quality health services\textsuperscript{15-17}. The quality of drug management, where the management of medicine in the hospital is the task and responsibility of the installation of hospital pharmacy with the aim of organizing professional drug management activities based on pharmaceutical procedures and professional ethics. Drug management based on applicable rules and standards, evaluating and providing quality services, conducting supervision based on applicable rules, conducting research and development in the field of pharmacy and method improvement, and facilitating and encouraging the formulation of hospital treatment and formulary\textsuperscript{18}.

According to Quicket al (2012) the drug management cycle covers four stages, namely: selection, procurement, distribution and use. Drug management at each stage in this cycle of drug management is interconnected which must be managed properly and organized in order for activities to run properly and support each other so that the availability of medicines can be guaranteed to support health services and become a potential source of hospital revenue\textsuperscript{19}.

Related to the above, in general there are some problems related to drug management in The Pharmacy installation of Dr. Regional General Hospital. M. Haulussy Ambon year 2016, among others the percentage of drug availability has not reached the indicator of availability of drugs set for hospital accreditation standards namely 80%, found expired/damaged drugs, high demand for fickle types of drugs from prescription authors, delay sending drugs from suppliers, high copy of prescriptions, not to the maximum function of pharmaceutical committee and therapy in developing policy and evaluation of drug management thus affecting the process of planning and procurement of drugs in Hospital Dr. M. Haulussy Ambon. The purpose of this research is to evaluate the process of planning and procurement of drugs at Dr. M. Haulussy Ambon Hospital.

**Materials and Method**

The study used a descriptive design with retrospective and concurrent data retrieval. Retrospective data is data obtained by tracing the previous year’s documents (secondary data) namely 2018 including financial statements, planning and drug use reports, drug procurement reports, and invoices. Retrospective data retrieval is carried out on, the percentage of conformity between drug planning and the reality of use for each drug. Concurrent data is data obtained at the time of research or is primary data with in-depth interviews with IFRS officers as well as discussions with officers/employees related to drug management.

**Result**

In-depth interviews conducted by researchers to informants at Dr. M. Haulussy Ambon Hospital as the main data retrieval technique supported by interview guidelines. What is curious in this study is
how the management of the drug in the Pharmaceutical Installation of Dr. M. Haulussy Ambon Hospital has been implemented which includes the stages of planning and procurement.

At the planning stage of pharmacy installation the hospital uses consumption method for the drug planning process, while for the procurement of drugs is carried out by procurement directly according to the needs ordered directly to the supplier. In this case the supplier already has cooperation with the hospital and that provides a lower price than other suppliers. The efficiency of drug management at this stage is measured using several indicators, among others: Percentage of capital/funds available with the overall funds needed for drug procurement.

In this indicator can be seen whether the allocation of available funds is sufficient or not to meet the needs of the purchase needs of hospital patients’ drug needs, by limiting the total allocation of funds provided with the real need for funds needed for the purchase of medicines. Data is obtained retrospectively. The percentage of funds available with the required is presented in table 1.

### Table 1. Percentage of available capital/funds with total funds required for drug procurement

| Description                  | Total Value (IDR) | Fund (%) | Score  
|------------------------------|-------------------|----------|--------
| The amount of funds required | 22,506,097,800.00 | 85       | 100    
| Available funds              | 19,149,270,000.00 | 15       |        
| Amount of Funds Required     | 3,356,827,800.00  | 100      |        

Source: Secondary data RSUD Dr. HM Haulussy Ambon

Table 1 shows the percentage of hospital funding provided to IFRSUD Dr. H. M. Haulussy is 85%. Based on the results of interviews with informants about the planning and procurement stage about the percentage of capital/funds available with all the funds needed for drug procurement. Here’s an excerpt from the interview:

“The procurement of medicines and BHP handled directly by the Hospital” (RT, 58 Years)

“The first fund. If a special method does not exist, it is ordered as needed and the hospital procurement is adjusted to the hospital planning made by the hospital planning department”. (RT, 58 Years)

“Obviously not enough because the funds are lacking, so it’s right that the drug order is tailored to my needs and has to go through i can just order medicine” (RT, 58 Years)

“The drug procurement budget has so far been adjusted to the proposal of the planning department. Of course not enough to meet the drug purchase budget” (DR, 47 Years)

“Yes, because it is often cut during budget discussions” (SA 49 Years)

Percentage of planning suitability with the wear reality for each drug item. The purpose of the indicator of planning conformity with the reality of use is to know the suitability between the procurement of drugs done in the hospital and the reality of the existing drug can be known with certainty. Observations are made by taking data on the number of drug items in The Pharmaceutical Installation of Dr. H. M. Haulussy Ambon Hospital in 2018 compared to the number of drug items that are in accordance with the planning. The percentage of suitability of drug items with planning can be seen in table 2.
Table 2: Percentage of planning suitability with actual use for each drug item

Source: Processed secondary data, 2020

Table 2 shows that the number of drug items in IFRS RsUD Dr. H. M. Haulussy Ambon listed is 358 items, while the number of drug items contained in the reality of use is 340 items, and the number of drug items not included in the procurement of 18 items. From the observations made the percentage of conformity between the procurement of drugs carried out by IFRS Hospital Dr. H. M. Haulussy Ambon with the reality of use is 94.7%. The percentage result obtained is good enough, but it is still said not to be in accordance with the standard stipulated in Pudjaningsih (1996) which is 100%, so it is necessary to strengthen the use of hospital formulary and implementation priorities by the hospital management. Because the accuracy of drug planning based on formulary greatly affects the function of the budget.

Based on the results of interviews with informants about the planning and procurement stages about the percentage of planning suitability with the reality of use for each drug item. Here’s an excerpt from the interview:

“The data on the needs of the first drug from the pharmacy first that I checked, if it was appropriate i just submitted to the planning to be processed and matched with financial condition. so can’t order drugs haphazardly without my consent” (RT, 58 years old)

“First of all, the proposed planning of medicines and consumables from pharmaceuticals is put into our section and then processed.” (SA, 49 Th)

“The one who devised the drug needs plan was my staff in the warehouse because he knew in and out of medicine. Which drugs are widely used and underused. Selection is conducted by the Therapeutic Pharmacy Committee but is not involved in planning and procurement” (PB, 38 Years)

Discussion

Researchers found that the funds allocated for the purchase of drugs were not all used for the purchase of drug needs but also for non-medicinal, e.g. the purchase of laboratory reagents, radiological materials, as well as consumables that turned out to spend nearly 70% of the total funds on existing drug purchases. This causes the allocation of drug purchase funds to decrease. This problem may not occur if the allocation of existing funds is all only for the purchase of the drug and is not divided by purchases other than the drug. Thus, it is hoped that the need for a planned drug purchase fund can be sufficient for patient services. Other research results in accordance with similar research conducted by Costa (2016) at Ungaran Hospital obtained a percentage of the provision of funds by the hospital to Ungaran hospital pharmacy installation for drug procurement is 100%.

The installation of pharmacy is a revenue center in the hospital, therefore the function of the budget is one of the important basic data to be known in the planning of the supply of drugs both of type and quantity so that the drug manager must be involved to the maximum in the discussion of the budget and allocation of drug procurement funds. When viewed from the results of this study, the funds provided are standardized at 36.69% but still insufficient because the value of the needs is higher than the value of the allocated funds and this fund is also included for the purchase of reagents from laboratories, rontgen materials, and consumables. So it’s not purely just for the purchase of drugs.

Percentage of capital/funds available with the overall funds needed for drug procurement. The results obtained in this study are 85%. This is not in accordance with the Standard in Pudjaningsih which is 100%. In accordance with information from the Director of Dr. M. Haulussy Hospital that the amount of funds obtained so far is not sufficient to meet all the needs of medicines in the hospital, so many medicines that have been planned cannot be purchased or medicines forced to be reduced in number from those already planned to meet all needs other than medicines.
The increase in the efficiency of the percentage of capital/drug procurement funds in Dr. H. M. Haulussy Ambon hospital can be done by selectively planning the needs of the drug with correction referring to ven method i.e. classifying drugs based on (vital, essential and non-essential), ABC analysis method, adjustment of consumption method with epidemiological method based on disease pattern, data on number of visits as well as frequency of disease.

Other research results are in accordance with similar research conducted by Costa (2016) in the hospital. Ungaran obtained the percentage of the provision of funds by the hospital to the pharmaceutical installation of Ungaran hospital for the procurement of drugs is 100 %\(^2\), while Mompewa (2019) in Poso Pharmacy Installation of Central Sulawesi Province is 89.31%\(^2\), Mahdiyani et al (2018) that the percentage of the allocation of drug procurement funds in Muntilan Hospital Pharmacy Installation, in 2015 amounted to 26.13% and in 2016 amounted to 27.57%\(^2\).

From observations made by researchers at Dr. M Haulussy Ambon Hospital, researchers found that the funds allocated for the purchase of medicines were not all used for the purchase of drug needs but also for non-medicinal, e.g. the purchase of laboratory reagents, radiology materials, as well as consumables that apparently spent almost 70% of the total funds purchasing existing drugs. This causes the allocation of drug purchase funds to decrease. This problem may not occur if the allocation of existing funds is all only for the purchase of the drug and is not divided by purchases other than the drug. Thus, it is hoped that the need for a planned drug purchase fund can be sufficient for patient services.

Percentage of planning suitability with the wear reality for each drug item. In this study, the results were obtained by 94.7%. This indicates that the percentage of planning conformity with the reality of use for each drug item in the Pharmaceutical Installation of Dr. M. Haulussy Ambon Hospital has not been in accordance with the standard of 100%. The results of this study do not correspond to some similar studies namely by Endarti that the comparison between the number of drug items in the planning and the number of drug items in the reality of use obtained results for 2015 by 104.08% and in 2016 there was a decrease with a result of 80.80%. Research conducted by Mompewa amounted to 96.28% at Poso Central Sulawesi Hospital Pharmaceutical Installation\(^2\).

This is influenced by the allocation of funds provided by hospitals that do not meet the needs or are still lacking. Due to the lack of funds, it has an impact on cutting the number and items of the drug held. Another factor that affects the ineffectiveness of planning with the reality of using the drug is the addition of certain drug items outside of the drug items that have been planned in the middle of the budget year to answer the needs of medical services not to the maximum application of the drug needs plan system is also affected by the absence of planning system based on information management system technology, the system used is still a manual method. prescribing patterns by doctors have not been consistent because of the lack of clinical pathways.

Another thing that quite affects the design of drug planning with the reality of use is if there are new cases of disease that have not been prepared for drugs and are not included in the hospital formulary. Cases like this cause prescribing to change and additional funds are needed to meet treatment needs. In addition, clinical pathway is also not fully run so the prescribing of the drug has not been as expected. This should be of concern to the hospital management to implement clinical pathways in order for the prescribing of the drug to be controlled\(^2\).

**Conclusion**

Based on the results of research conducted at Dr. H. M. Haulussy Ambon Hospital Pharmacy Installation on drug planning and management can be concluded that the procurement stage of procurement fund allocation of each drug item already meets the standards. The suitability of planning with the wear reality for each item is not in accordance with the standard (less than 100%). It is expected to cooperate well with related parties, especially pharmaceutical installations in drug planning and management so that the use of existing funds can be more efficient and effective.

Abstract

Hospitals are as one of the health facilities to provide health services to the public and have a very important role in accelerating the improvement of the degree of public health. The purpose in this study is to analyze the Influence of Access Dimensions and waiting times on the satisfaction of inpatients at Level III Hospitals Prof. Dr. J.A. Latumen Ambon. The type of research used is quantitative research with cross sectional study design. The population in this study was 37,167 patients in the Inpatient installation in January-October 2019. The data analysis technique used is univariate and bivariate analysis, performed to look for the influence of each free variable with variables bound by using chi-square test. The results showed No accessibility affects the satisfaction of patients in Prof. Dr. J.A. Latumen Ambon Hospital. There is an effect of waiting time on patient satisfaction at Prof. Dr. J.A. Latumen Ambon Level III Hospital. It is very important for Prof. Dr. J.A. Latumen Ambon Level III Hospital to evaluate and improve the patient’s complaints that trigger patients to feel dissatisfied with the hospital service.

Keywords: Access, Waiting Time, Satisfaction, Hospitalization, Hospital.

Introduction

In Indonesia, the health world is experiencing very significant development and has a pretty good prospect. These conditions make the competition more competitive. Therefore, every company engaged in the healthcare industry must be able to use various ways to attract customers through the quality of service¹-². The higher the level of public education causes the public to become more aware of the importance of quality³. People tend to demand better and faster health care. This has led to increasingly intense competition not only between fellow hospitals but also with health centers and health clinics in cities and in increasingly numerous areas⁴. Many healthcare providers are aware of this, so inevitably they have to realize the satisfaction of those customers in various strategies in order to be able to maintain customers⁵.

The quality of service and customer satisfaction were chosen as variables in this study because research on customer satisfaction is very important to research because customer satisfaction is the most often discussed issue in all Hospital patients⁶. Services provided by medical personnel or doctors are an integral part of the
health service in the hospital, which has a very strategic position in an effort to improve the quality of service and satisfaction of consumers or patients coming to the hospital, which results in the satisfaction of the patient, organization or hospital. Hospital Service Satisfaction depends heavily on the customer. If the customer no longer believes in the Hospital because of the poor results, then the Hospital will lose customer trust due to the poor response that was formed.

Hospitals are as one of the health facilities to provide health services to the public and have a very important role in accelerating the improvement of the degree of public health. This requires health care providers, namely hospitals to improve the quality of better services, not only services that are disease-healing but also include preventive services. Therefore, hospitals are required to provide services that are in accordance with established standards and can reach all walks of life.

The quality of hospital services has two components, namely the fulfillment of the quality standards that have been set and the fulfillment of customer satisfaction. Hospitals should provide services that focus on customer satisfaction. Improvement in the quality of health care services can be started by evaluating every element that plays a role in shaping patient satisfaction. The health care system can be improved through clinical pathways, services, including patient perspectives such as how well health care services they need.

Prof.dr. Level III Hospital J.A. Latumen is one of the Basic Health Governing Bodies of the XVI/Pattimura military which has the main task of providing Health services to Indonesian National Army Personnel and Civil Servants of the Indonesian National Army and their families in the ranks of Regional Military Command XVI/Pattimura. Prof. dr. J.A. Latumen Level III Hospital is the highest referral hospital in the Regional Military Command XVI/Pattimura range of lower-level army Health Units. The number of visits of Prof. Dr. J.A. Latumen Ambon Level III Hospital in 2016 was 43,706, in 2017 43,305, in 2018 59,032 and the number of visits in October 2019 was 47,372 visits. from the data, inpatient visits experienced ups and downs. Patient perception of the quality of service with the level of patient satisfaction, especially for patients hospitalized level III Prof. Dr. J.A. Latumen Ambon is very important to improve better service.

The hospital needs to provide services in accordance with the patient’s expectations. Patient satisfaction depends on the quality of service with the appropriate service then the patient’s expectations for the service of a service can be met or even exceeded its expectations, thus causing satisfaction in the patient, the patient’s disappointment will arise if the performance of the health service obtained is not in accordance with the expectations. In achieving patient satisfaction-oriented service objectives, it is important to note that it is important to determine the perception of patient quality, including facilities, the role of doctors, medical personnel and nurses. The purpose in this study is to analyze the influence of access and waiting times dimensions on the satisfaction of inpatients in hospitals level III Prof. Dr. J.A. Latumen Ambon.

**Materials and Method**

The type of research used is quantitative research with cross sectional study design. The population in this study was 37,167 patients in the Inpatient installation in January-October 2019. The samples in his study were calculated using a large sample calculation according to Lameshow so that a large sample of 100 respondents was obtained. Technique of taking a sample using purposive sampling method. Data collection is obtained through interviews using computerized data processing questionnaires using the SPSS program. The data analysis technique used is univariate and bivariate analysis, performed to look for the influence of each free variable with variables bound by using chi-square test.

**Result**

Based on table 1 it is known that the characteristics of respondents based on the most age are the age group of 45 – 54 years and 55 years and above which is 39 people (39.0%). The characteristics of respondents based on the most gender are those with a male gender of 56 people (56.0%). The characteristics of respondents based on the most recent education were those with higher education of 50 people (50.0%)

Source: Primary Data, 2020

Based on Table 2 shows that of the 100 respondents in Prof. Dr. J.A. Latumen Ambon Hospital, 56 respondents (56.0) with affordable access and as many as 44 respondents (44.0%) with unreachable access. Based on the waiting time variable shows that out of 100 respondents in Prof. Dr. J.A. Latumen Ambon Level III Hospital, 84 respondents (84.0%) provide a good waiting time assessment and as many as 16 respondents (16.0%) the waiting time assessment is not good. Based on satisfaction variables showed that out of 100 respondents at Prof. Dr. J.A. Latumen Ambon Level III Hospital, 57 respondents (57.0%) assessment and 43 respondents (43.0%) who give dissatisfied judgment

Table 3 shows that of the 56 respondents with affordable access, 36 respondents (64.3%) satisfied and as many as 20 respondents (35.7%) expressed dissatisfaction. Meanwhile, of the 44 respondents with unaffordable access, 21 respondents (47.7%) satisfied and as many as 23 respondents (52.3%) expressed dissatisfaction. Statistical test results obtained a value of p = 0.097, since the value p > α = 0.097 > 0.05 then Ho is accepted, this means that there is no statistically meaningful influence of accessibility variables on patient satisfaction in Prof. Dr. J.A. Latumen Ambon Level III Hospital.

Based on waiting time variables shows that of the 84 respondents with a good assessment of waiting time as many as 56 respondents (64.3%) satisfied and as many as 30 respondents (35.7%) expressed dissatisfaction. Meanwhile, of the 16 respondents with poor rating on waiting times, 3 respondents (18.8%) satisfied and as many as 13 respondents (81.2%) expressed dissatisfaction. Statistical test results obtained a value of p = 0.001, because the value p < α = 0.001 < 0.05 then H0 is rejected, this means that there is a statistically meaningful influence of waiting time variables on patient satisfaction in Prof. Dr. J.A. Latumen Ambon Level III Hospital.

Discussion

Good access is that health care should be achievable to the community, not hindered by geographical, social, economic, organizational and language circumstances. Geographic access is measured by distance, length of travel, cost of travel, type of transportation, and other physical barriers that can deter a person from getting health care. The access dimension can measure the quality of service about how patients reach the desired health service, whether the access is good or not so from here that will later cause satisfaction in patients.

The location of the hospital where they are undergoing treatment is difficult to access because it feels the distance traveled by far and most respondents already do not have a private vehicle and the language used by health workers is not easy to understand. Meanwhile, respondents who felt good access or service were easily accessible because their location of residence was close to the hospital and already owned a private vehicle.

This research is in line with herman et al research which shows that there is no relationship of quality of service access (affordability) with patient satisfaction ($\rho = 0.057$). Another in line study was conducted balqis et al where the results of the chi square test analysis obtained a value of $p = 0.525$, because the value of $p \geq 0.05$ means it can be concluded that there is no relationship between affordability or access to the quality of service. This research is not in line with this research in line with rivai et al research which highlights the Dimensions of affordability/access to services ($p = 0.177$).

The waiting times in this study include the time that patients use to get health care from enrollment to admission to a doctor or nurse. As the theory of waiting time is the time that patients use to get health care starting from the place of registration to get doctor’s care. The results showed that patients were satisfied with waiting times related to fast file or file preparation skills, user satisfaction that used SIMRS in managing data and providing health care, both in terms of efficiency, effectiveness, satisfaction, but still patients who were dissatisfied with the discipline of doctors who came in was not on time.

Satisfaction of users who use SIMRS in managing data and providing health care, both in terms of efficiency, effectiveness, satisfaction.

His research is in line with research conducted by Laeliyah et al which showed a link between the waiting times for patients in the outpatients and the satisfaction of patients in the hospital’s hospital services, with a score of 0.042. His proves that with long waiting times for outpatient services there will be increasing dissatisfaction with patients’ dissatisfaction with outpatient services, and vice versa.

Conclusion

This study concluded that There is no accessibility effect on patient satisfaction in Prof. Dr. J.A. Latumen Ambon Hospital. There is an influence of waiting time on patient satisfaction at Prof. Dr. J.A. Latumen Ambon Level III Hospital. It is very important for Prof. Dr. J.A. Latumen Ambon Level III Hospital to evaluate and improve the patient’s complaints that trigger patients to feel dissatisfied with hospital services.

Evaluation of the Ability Family Planning Center Officers in the Youth Counseling Information Center Program in South Buru Regency

Samna Detek¹, Sukri Palutturi², Muhammad Alwy Arifin³, Amran Razak², Arsunan Arsin³, Nurhayani², Anwar Mallongi⁴

¹Magister Student, Program Departement of Health Administration and Policy, Public Health Hasanuddin University, ²Professor of Departement of Health Administration and Policy, Public Health Hasanuddin University, ³Professor of Departement of Epidemiology, Public Health Hasanuddin University, ⁴Professor of Departement of Environmental health, Faculty of Public Health, Hasanuddin University

Abstract

Adolescent problems are very complex problems ranging from large numbers to health risk problems. The purpose of this study to evaluate the ability of Family Planning Center officers in the Youth Counseling Information Center Program in South Buru Regency. This type of research is qualitative analysis. The data collection techniques in this study are indepth interviews and document studies. The informants in this study were divided into 2 sources, namely the key informants in this study as many as 2 people, namely 1 Head of Population control and Family Planning, 1 head of the Program Section of the Youth Counseling Center of South Buru Regency and the usual informant in this study as many as 7 people namely 6 Heads of Family Planning Hall in each sub-district in South Buru Regency, 1 person chairman of youth counseling information center at SMAN 1 Namrole as ambassador representative of Youth Counseling Information Center. The results showed that the ability of youth counseling information center officers in carrying out the Youth Counseling Information Center program in South Buru District is sufficient. To improve the skills and skills of youth counseling information center officers, there is regular training every year at both the district and provincial level. Not every sub-district can participate in training because there is never another invitation to attend training in the district or in the province, thus requiring to seek literature and study self-taught. The government is expected to realize the consistency of training (refreshing) for each district hall officer, centered in the district or in BKKBN Province with professional coaches by inviting all district hall officers so that each officer has the same ability and knowledge.

Keywords: Officer capability, Program, Counseling Information, adolescents, Buru South.

Introduction

Adolescence is one of the fastest phases of human development, according to the World Health Organization, adolescents are those aged 10-19. Adolescent problems are very complex problems ranging from large numbers to problems around adolescent reproductive health. The number of teenagers in the world as of January 2018 is about 1.2 billion people¹. Globally the leading causes of death among adolescents are road injuries, HIV, suicide, lower respiratory tract infections, and interpersonal violence²-³. The problem of adolescents is also a fairly complex problem especially in urban areas. Adolescents face specific health risks, especially those related to reproduction and sexuality. 11% of all births and 14% of maternal deaths worldwide occur in women aged 15 to 19, of which 95% of teen births occur in developing...
Poor, marginalized, and life-losing youth suffer the highest burden of disease, for example, homeless teenagers face a higher risk of HIV infection. Adolescents with disabilities are particularly vulnerable to sexual harassment and the result is unplanned pregnancies and HIV and other sexually transmitted.9-10

Based on Data on Indonesia Population Projection 2000-2025, the proportion of the population of adolescents aged 10-19 years in 2010 was about 18.3% of the total population or about 43 million people.11 The condition of teenagers in Indonesia is currently very concerning. In 2017, the percentage of women and men who smoked before the age of 13 was higher in the 15-19 age group compared to 20-24 years of age, where 27% of women aged 15-19 had started smoking before the age of 13 and 22% in women aged 20-24. 70% of men and 58% of women started drinking alcohol in the 15-19 age group.

However, it found 2% of men and 6% of women started drinking alcohol under the age of 10. Most women (80%) and men (84%) 45% of women and 44% of men start dating between the ages of 15-17. Teenage courtship behavior showed that as many as 8% of men and 2% of women reported having sexual intercourse, arguing that 47% loved each other, 30% were curious/curious, 16% just happened and 3% were forced and influenced by friends. Among women and men who had had sexual intercourse before pre-marriage, 59% of women and 74% of men reported starting to have sexual intercourse first at the age of 15-19 where the highest percentage occurred at the age of 17 both male and female.12

The way to know the performance of the officer in dealing with the problem of the implementation of a program can be done by evaluating the performance of the officer, in the application process or at the end of the application. Performance evaluation is an activity that management does to assess the performance of employees in an organization or company by comparing job descriptions that have been set before.13-14 The purpose of this research is to evaluate the ability of family planning center officers in the youth counseling information center program in South Buru Regency

Materials and Method

The type of research used is a qualitative research method. The data collection techniques in this study are indepth interviews and document studies. The informants in this study were divided into 2 sources, namely the key informants in this study as many as 2 people, namely 1 Head of Population control and Family Planning, 1 head of the Program Section of the Youth Counseling Center of South Buru Regency and the usual informant in this study as many as 7 people namely 6 Heads of Family Planning Hall in each district in Kab. Buru Selatan, 1 person chairman of youth counseling information center at SMAN 1 Namrole as ambassador representative of Youth Counseling Information Center.

Results

The evaluation of the capabilities of the officers referred to in this study is an explanation of the Youth Counseling Information Center program, activities that are already underway in the Family Planning Center related to the Youth Counseling Information Center program, views on the ability of youth counseling information center officers in the Family Planning Center, things that have been taken in improving the ability and skills of youth counseling information center officers in the Family Planning Center.

Based on the results of interviews with informants, it is known that some informants said that the ability of youth counseling center officers is in line with expectations because officers have work experience in the Central Embassy beforehand so have a good understanding of the Youth Counseling Information Center program as well as the access to training. While some informants said it was not as expected because it had never previously socialized to the community so in the beginning it was constrained in communication. Here’s an excerpt from the interview:

“... Family Planning Hall, I must know there is only one family planning doctor Outag Planning Center who is in charge in Leksula Sub-District (IbuLamatokang), the other personnel comes from contractual midwives, civil servants are only a few who come in, so speaking residency (Youth Counseling information center), it’s all empty, only Lamatokang’s mother understands the concept of BKKBN. In terms of a lot of energy, but hr skills are dilemma, I claim to be weak as a pioneer, so from the bottom all look weak.” (KW, 55, Head of Population Control and South Buru)

“... Not fully formed Ambassadors have the ability because there must be maximum training before they counsel personally to their friends or classmates. Honestly gendre action district has never katong
ambassador involved, since I have two years working because it has no transportation cost to the expensive district. Giving certificates to ambassadors, beta submit with their teachers, for the purposes of documentation per monthly report, although the ambassadors I form have not been quite active but they are slowly not as expected.” (AW, 31, Head of Family Planning Center of Kepala Madan Sub-District)

“... Of all family planning field counseling personnel in Namrole sub-district two workers consist of Midwives and Nurses, Wesama Sub-District one midwife, Leksula sub-district one midwife, FenaFafan sub-midwife, One nurse in Madan Head Sub-district, and Ambalau sub-midwife. And only one pure BKKBN power one person from Leksula. Namrole’s best evaluation results, only Namrole has Gendre Ambassadors, for the future plan to be planned to select Gendre Ambassadors in each sub-district.” (NP, 36, Head of Program Section of South Buru District Youth Counseling Information Center)

Other informants said that some youth counseling information center officers were in line with expectations because the ambassador chosen was an accomplished student and often participated in activities in the field. Here’s an interview excerpt:

“... officer’s ability has been slightly in line with expected because all the Youth Counseling Information Center groups that we have shaped all of our achievement categories are not inecuated, so every activity that will be carried out is all involved in the management of their respective work areas until cooperation with cross-sector even they are involved.” (RM, 25, Head of Namrole District Family Planning Hall)

“... Midwives are used to going down in the community if called to get involved, as last month involved the inauguration of Family Village planning on the beach of the village wali.” (AN, 15, Chairman of SMAN 1 Namrole Youth Counseling Information Center)

Based on the results of an in-depth interview between the head of population control and Family Planning, The head of the Youth Counseling Information Center program and head of the Family Planning Center, Chief Madan, said that the ability of youth counseling information center officers in general is still not as expected because some districts are still constrained by access and funding to improve the capabilities of officers, thus requiring 5 Heads of Family Counseling center planning to slowly spur their ability to achieve the expected output, despite equipping themselves with limited literature, but they can form a group of Youth Counseling Information Centers, consisting of high-achieving teenagers, despite only running in 3 subdistricts.

Based on the results of interviews with informants, it is known that in improving the ability and skills of youth counseling information center officers, there is training of Youth Counseling information center or action genre district and provincial level. Training is usually filled by speakers from BKKBN District/Provincial Training Hall through lecture method, q&A and games. The targets in this study were youth counseling information center officers to increase knowledge and awareness through the Adolescent Counseling information center on adolescent reproductive health. Here’s an excerpt from the interview:

“... Training for all staff of the Family Planning Center or Clinic is very rare, so learn more self-taught.” (KW, 55, Head of Population control and family planning of South Buru Regency)

“... Human Resources Counseling field family planning should understand the program so it should love a lot of training from the previous year because this (Youth Counseling information center), must understand this program tiered, advocacy, counseling, and know the truth of the Youth Counseling information center.” (NP, 36, Head of Program Section of South Buru District Youth Counseling Information Center)

“... During 2019 there has never been beta training, except 2018 followed 3 trainings in the province, whereas many additional programs require self-study for additional programs related to youth counseling and kb information centers.” (AW, 31, Head of Family Planning Center of KepalaMadan Sub-District)

“... Skill improvement training so far only in 2018, but sometimes I go to BKKBN Province to participate in training because for the district level has not been penah done, as the only staff in the family planning hall
lekula sub-district completed the program well because it was assisted by the midwife coordinator of lekula health center.” (VL, 55, Head of Family Planning Center Leksula Sub-District)

“... The challenge of the beginning is just, because it is still learning from the field and many helped to see updates from youtube or google. The usual material is prepared about reproductive health, namely knowing the characteristics of puberty, knowing the risk of pregnancy with one sex, and knowledge of Sexually Transmitted Diseases (STDs).” (AN, 15, Chairman of SMAN 1 Namrole Youth Counseling Information Center)

Overall, the ability of youth counseling information center officers in South Buru Regency is sufficient. All eight informants already have a common understanding of the Youth Counseling Information Center program. Youth Counseling Information Center activities have been conducted in each school and village and each already has a group of Youth Counseling information centers although some informants say that they are unable to reach each village to conduct youth counseling information centers because access to locations is quite difficult (sea). To improve the skills and skills of youth counseling information center officers, it should be organized in the planning of district activities but not done. Similarly, the province does not invite participants from all halls in South Buru Regency because there is no proposal from the district. The lack of planning and supervision from province to district and district to each of its halls led to various training programs not running as they should.

Discussion

There are three groups of variables that affect performance and behavior, one of which is individual variables, which include abilities and skills where ability and skill are the main factors that affect individual performance15-21. The ability of officers is seen to assess the extent to which carrying out various tasks in a job is possible and one can get the job well done20. In order to improve their skills and skills, Youth Counseling Information Center officers are given training/action genre districts and provinces every year.although only lekula sub-district family planning center officers have been training in the province since 2019. While other hall officers never participated in youth counseling information center training, because there was never any more invitation to attend training in the district or in the province, thus requiring to seek literature and study self-taught.

This is certainly an evaluation for the officers of the Provincial or District Family Planning Center so that in the future each officer of the District Family Planning Hall gets an invitation to participate in training in the District and Province so that all officers of the District Family Planning Hall get the same opportunity to improve the skills and skills regarding the Youth Counseling Information Center program.

Research conducted by Salla et al shows the ability of officers not to be able and skilled in running the program and some officers do not yet have a registration certificate as a guarantee of the quality of health workers22-23. Human resource quality improvement activities have also been carried out by BPPKB Banyuwangi Regency by holding training for educators or peer counselors, but the training is still not optimal karen not implemented regularly 24-25.

Inadequate resources will create a barrier to policy implementation26-30.outh life is a very decisive life for their next future life. The activities that have been carried out by youth counseling information center officers in South Buru District are (1) establish a counseling information center in the school environment to provide information services and counseling about 8 Family Functions, Marriage Age Maturity, TRIAD KRR, Life Skills, Gender, Advocacy and Communication information and education. (2) Promote and socialize the Youth Counseling Information Center in the community to introduce the existence of youth counseling information center to all relevant parties in order to expand access and development of support and network of youth counseling information centers. (3) Prepare and empower human resources managers of youth counseling information centers to prepare and empower human resources both for the newly grown youth counseling information center and to replace the no longer active human resources with various causes (regeneration) for the continuity of youth counseling information centers. (4) Conduct administration, recording and reporting to improve administrative order and document activities in the management and service provided by the youth counseling information center, including human resources, facilities, infrastructure and method.
Conclusion

This study concluded that the ability of youth counseling information center officers in carrying out the Program of Youth Counseling Information Center in South Buru District is sufficient. To improve the skills and skills of youth counseling information center officers, there is regular training every year at both the district and provincial level. Not every sub-district can participate in training because there is never another invitation to attend training in the district or in the province, thus requiring to seek literature and study self-taught. The government is expected to realize the consistency of training (refreshing) for each district hall officer, centered in the district or in BKKBN Province with professional trainers by inviting all district hall officers so that each officer has the same skills and knowledge.

Analysis Risk Factors of Stunting Incidence on Toddlers in the Working Area of Porto Haria Public Health Center

Zacarias Latupeirissa¹, Indar², Amran Razak², Muhammad Alwy Arifin², Andi Zulkifli³, Muh. Yusri Abadi², Anwar Mallongi⁴

¹Magister Program Departement of Health Administration and Policy, Public Health Hasanuddin University, ²Professor and Lecturer of Departement of Health Administration and Policy, Public Health Hasanuddin University, ³Professor of Departement of Epidemiology, Public Health Hasanuddin University, ⁴Professor of Departement of Environmental Health, Public Health Hasanuddin University

Abstract

The prevalence of stunting events in Central Maluku Regency is still high, with 26 toddlers experiencing stunting in 2018 and 27 in 2019 at Porto Haria Public Health Center. This study aims to analyze the risk factors of stunting events in toddlers in the working area of Porto Haria Public Health Center. This research is a type of analytical observational research with the design of case control study. The case population in this study was a toddler who was diagnosed stunting in the working area of Porto Haria Public Health Center as many as 37 toddlers and the control population in this study was an not diagnosed toddler stunting in the working area of Porto Hariapublic Health Center as many as 814 toddlers. The sampling used purposive sampling and found 72 toddlers were divided into 36 cases and 36 controls. Data analysis using univariate and bivariate statistical analysis using Odds Ratio. The results showed that the immunization of toddlers scored OR=0.680, health care rating OR=0.727, parental education (family head, OR=1.400, Mother’s value OR=0.769). Parental education is a risk factor, while toddler immunization and utilization of health services are protective factors. Parents (Mothers) are advised to pay attention to nutritional intake both during pregnancy and afterwards, in order to monitor the growth and development of children in terms of food and drink. For health care institutions, especially in nutrition health workers are expected to provide more intensive information and education about the dangers and causes of stunting.

Keywords: Stunting, breast milk history, immunization of toddlers, birth weight, Public health center.

Introduction

Stunting is defined as a height index by age less than minus two standard deviations (-2 SD) or below the existing standard average. Stunting in children is a long-term result of chronic consumption of low-quality diets combined with morbidity, infectious diseases, and environmental problems¹-². The high prevalence of stunting in children aged 24-59 months indicates that stunting is unlikely to be reversible³-⁴ so it is necessary to commit from state and local leaders to pay attention to stunting handling in order to lower the prevalence of stunting⁵. Health and stunting are related to politics and culture ⁴-⁹. Health care and stunting actually refer to a setting or regional approach to cover various health problems ¹⁰-¹³.

In Maluku Province, the prevalence of stunting is still volatile from 2016-2018. There was an increase in the prevalence of stunting in 2016 by 29.0% to 30.0% in 2017, however, there was a decrease in the prevalence of stunting toddlers from 30.0% (2017) to 22.9% (2018), although there was still a decrease but there were still 7 districts/cities that experienced an increase in the prevalence of toddler stunting from 2016 to 2017 namely...
West Southeast Maluku regency 25.1% (2016) increased by 31.7% (2017), Southeast Maluku regency 27.8% (2016) increased by 30.0% (2017), Central Maluku Regency 23.2% (2016) 31.4% (2017), Seram West district 23.6% (2016) increased 28.9% (2017), East Seram district 27.4% (2016) mangalami increase 40.6% % (2017), Buru South regency 23.7% (2016) increased by 31.0% (2017), and Tual City 27.4% (2016) increased to 40.6% (2017). There was an increase in the prevalence of toddler stunting in 2 districts/cities from 2017 to 2018, namely Southeast Maluku regency 30.0% increased to 31.4% (2018), and Ambon City 21.9% (2017) increased to 22.0% (2018)14.

The Government of Indonesia is committed to reducing the number of stunting by up to 5% in 2015. Internationally, Indonesia joined the Nutrition Improvement Movement, a global movement with the aim of giving everyone the right to healthy and nutritious food. In September 2012, Indonesia launched a program called “The First 1000 Days of Life Movement” or the First 1000 Days of Life. This movement aims to encourage improved nutrition for a better future for Indonesian children15,16. Public knowledge of the golden age of life or the First 1000 Days of Life needs to be established early, especially for early childhood to improve their understanding in order to become a more qualified generation15.

In order to realize the optimal level of health for everyone, there must be constant attention to the implementation of health-minded national development, the guarantee of health care, improved professionalism and decentralization of the field of health5,17. The main targets of public health services are the community and certain groups. Meanwhile, for public health services, the workers who serve are public health experts. The focus is to prevent disease and the main goal is certainly society as a whole18.

But what happens in the field is still high number of stunting incidents, especially in Central Maluku Regency, Maluku Province. Central Maluku Regency is one of the districts of 3 districts designated by the Ministry of Health as locus stunting. Saparua sub-district is one of 17 sub-districts in Central Maluku district with the number of public health centers as many as 3 public health centers namely Porto Haria public health center, Saparua public health center and BooiPaperu public health center. Porto Haria public health center has 2 working areas namely Porto State and HariaState.

Based on the report of stunting coverage according to the Central Maluku District Health Office in 2018 shows that as many as 26 toddlers experienced stunting in Porto Haria public health center. While the number of stunting incidents in Haria State in 2018 was 23 people out of a total of 157 toddlers, and in 2019 a total of 27 people out of a total of 685 toddlers with details namely babies 0-11 months with a male gender of 58 men and women as many as 47 people, while 1-5 years with male sex as many as 295 men and women as many as 285 people14.

The problem of nutritional status in toddlers in Indonesia has a disparity between regions/provinces. Based on the size of the stunting problem, a region is considered to have mild stunting problems when the prevalence of stunting is between 20-29%, moderate when 30-39% and weight when ≥ 40%19,20. The problem of stunting is one of the problems faced by the world, especially in poor and developing countries. Stunting becomes a health problem because it is related to the risk of pain and death, suboptimal brain development, so that motor development becomes late and inhibits mental growth. This poses a serious threat to the existence of children as the next generation of a nation. Stunting is a poor predictor of the widely accepted quality of human resources, which then degrades a nation’s productive capabilities in the future21.

There are various factors that are the cause of stunting in toddlers. According to Rachmi et al research (2016), some of the risk factors for stunting events stem from child factors such as gender, anthropometry at birth, lactation history and age of complementary food recognition, from parental factors such as parental age, marital status, parental anthropometry such as weight and height, antenatal care history, parental education, and family wealth, as well as from soy factors such as residence, type of residence, caste class, ecological environment, and geographical location22.

The utilization of health services has an influence on stunting events due to the incidence of disease infection (morbidity) closely related to access and utilization of health services. In addition, the health and sanitation services of the environment are also closely related to morbidity and ultimately affect nutritional status23.

Based on the data of toddlers in the working area of Haria public health center there are 62 toddlers from 2 countries in the working area of Porto Haria public health center is a stunting person. This kind of
thing the community needs to get mentoring because the community has not been able to be empowered independently. Problems like this need special treatment and prevention should be carried out early on. Because stunting cannot be cured directly. However, early prevention can lower the risk of stunting in future generations.

Basically there are already programs held by the Public Health Center such as the administration of blood-added tablets in the working area of portoharia public health center. The administration of blood-added tablets is carried out every week precisely on fridays. However, these programs have not had a significant effect in solving stunting problems in the working area of portoharia public health center. This is because the programs are caricature and temporary. The purpose in this study was to analyze the risk factors of stunting events in toddlers in the working area of portoharia public health center

**Materials and Method**

The type of research used in this study is analytical observational research with the design of the Case Control Study. The case population in the study was a toddler diagnosed stunting in the working area of portoharia public health center as many as 37 toddlers and the control population in this study was an undiagnosed toddler stunting in the working area of Porto Haria public health center as many as 814 toddlers. The sampling used purposive sampling and found 72 toddlers were divided into 36 cases and 36 controls. Data analysis using univariate and bivariate statistical analysis using Odds Ratio.

Table 1 shows the distribution of respondents based on research variables. Based on the variable immunizations of toddlers in the case and control groups each showed a lower risk of 26 people (72.2%) and 23 (63.9%). Based on the variable utilization of posyandu in the case and control groups each showed more low risk of 33 people (91.7%) and 32 (88.9%). Based on the educational variables parents show for the education of the head of the family in the case group more high risk as much as 21 people (58.3%) and the control group at both low and high risk showed as many as 18 people (50.0%). While the education of parents (Mothers) in the case group and control group each showed a high risk of 24 people (66.7%) and 26 (72.2%).

Source: Primary Data, 2020

Based on Table 2 of health service utilization variables the results of statistical test analysis show that the value of OR=0.727 (CI 95%: 0.151-3,510) means that this variable can only act as a protective factor rather than as a risk factor for stunting events. Similarly, the parental education variables of statistical test analysis show that in the education of parents (head of family) the value of OR=1,400 (CI 95%: 0.552-3550) means that parental education is a risk factor for stunting events. While in parent education (Mother) value OR=0.769 (CI 95%: 0.281-2.104)which means that this variable is a protective factor against stunting events.

**Discussion**

Immunization is the process of inducing artificial immunity both by vaccination (active immunization) and by administering antibodies (passive immunization) (Peter, 2003). Immunization in children has an important goal which is to reduce the risk of morbidity (pain) and mortality (death) of children due to diseases that can be prevented by immunization. The OR scores obtained show that this is in line with research conducted by Swathma, Lestari & Ardiansyah (2016) showing that most toddlers have received complete basic immunizations in both the case group and the control group.

Toddler immunization can play a protective role in stunting. It also means that toddlers with good or complete immunizations can reduce the risk of stunting. The OR scores obtained show that this is in line with research conducted by Swathma et al (2016) showing that most toddlers have received complete basic immunizations in both the case group and the control group. Similarly, research conducted by Azrizul et al (2018) shows that...
toddlers who do not get fully immunized are more at risk of stunting because immunization is one way of preventing infectious diseases, especially PD3I given to both infants and adults. However, complete immunization does not guarantee a person not to experience the disease as it can be affected by the benefits and effectiveness of immunizations such as the quality of the given vaccine. Therefore, either a fully immunized or incomplete child has the same opportunity to experience stunting.

The cause of the onset of nutritional problems is multifactor consisting of direct and indirect factors. Therefore, basic health service efforts are directed towards improving the health and nutritional status of children so as to avoid early death and low physical quality in the utilization of health services is not separated from the efforts of health officials to encourage the public in order to socialize the activities that exist in the health service both health promotion efforts, disease prevention, treatment and recovery of health.

Conclusion
The study concluded that the immunization of toddlers is a protective factor against stunting events in the working area of Portoharia public health center. Toddlers with the utilization of health services are protective factors of stunting events in the working area of Porto Haria community health center. Variable parental education (parental education-head family is a risk factor, while parent-mother education is a protective factor in the occurrence of stunting events in the working area of Porto HariaPublic health center. Parents (Mothers) are advised to pay attention to nutritional intake both during pregnancy and afterwards, in order to monitor the growth and development of children in terms of food and drink. For health care institutions, especially in nutrition health workers are expected to provide more intensive information and education about the dangers and causes of stunting.

Abstract

Covid-19 is an infectious disease that has the potential to cause a public health emergency. Therefore, preventive measures against these types of infectious diseases must be carried out as soon as possible. Indonesia as a rule of law, therefore the prevention of these types of infectious diseases must be established in a rule or regulation. The purpose of this literature review is to describe an intervention regarding the use of masks and hand sanitizers against the incidence of Covid 19. The database searches used include ProQuest, SciVerse Science Direct, Scopus, Pubmed, Cochrane library, Springer and Sci-hub. Keywords used in the search for articles were mask, hand sanitizer, preventive, COVID-19. There are 18 journal articles obtained through objective analysis, topic suitability, research method used, sample size, research ethics, the results of each article, and the limitations that occur. There have been effective results in implementing the distribution of covid 19 events related to the use of masks and hand sanitizers. There have been effective results in using masks and hand sanitizers against the incidence of covid-19

Keywords: Covid 19, masks, hand sanitizer.

Introduction

The Indonesian government has declared a disaster emergency status related to this virus pandemic. The government made a policy to implement physical distancing to decide the spread of covid 19. People are advised not to make direct contact with other people, avoid mass gatherings. Work, study and worship activities are carried out at home¹. Current information indicates that the two main modes of transmission of the COVID-19 virus are respiratory droplets and contact. Respiratory sprays are generated when a person coughs or sneezes. Anyone who is in close contact (within a radius of 1 m) with a person who shows symptoms of respiratory distress (coughing, sneezing) is at risk of exposure to respiratory tract splashes that could possibly cause infection (infectious). Splashes can also fall onto surfaces on which the virus remains active; therefore, the immediate environment of an infected person can be a source of transmission (contact transmission).²,³

The mechanism that occurs is by capturing particles or aerosols from the air with a filtering or absorption method, so that the air that passes through the mask is clean from particulates⁴. Prevention of transmission of Covid19 to the community is carried out with various efforts. Based on the health protocol issued by the WHO, the government instructs the public to always wash their hands with soap in running water, and always wear a mask when outside the home. Why wear a mask? A recent study by the Standing Commission for Infectious Diseases and 21st Century Threats in the United States
said that COVID-19 can be transmitted through normal conversation and breathing with an exposed person. Based on the research, the Ministry of Health (2020: 2) explained that this disease can be spread through small droplets from the nose or mouth when coughing or sneezing. The droplet then falls on the surrounding object.

Masks are necessary for everyone so that they do not spread the virus to each other because this virus is transmitted between humans and humans and spreads very quickly. A high chance of transmission can occur when exposed people interact with healthy people and healthy people interact with other people and so on. Seeing the current tense situation, namely the Covid-19 pandemic that has occurred throughout the world, it is necessary to make efforts to prevent the spread of the corona virus. Thus the Community Service team felt the need to carry out activities to break the distribution chain of Covid-19 by distributing free masks and hand sanitizers to the Manggarai community in the Puni Ruteng market, Manggarai Regency.

Hand-saitizer is a product in the form of a gel that contains an antiseptic as a hand sanitizer which, if used, does not need to be rinsed with water. Using it is very effective at killing transient and resident flora compared to using water, using ordinary soap or antiseptic soap. FDA) that hand-sanitizers can kill germs in less than 30 seconds\(^5\). The purpose of this activity is to make the public aware of the importance of health in this pandemic situation, always wash their hands with soap, use a hand sanitizer and wear a mask to stop transmission of the virus to others.

Materials and Method

The method used in this review literature uses a comprehensive strategy, such as searching for articles in research journal databases, searching through the internet, reviewing articles. The database searches used included ProQuest, SciVerse ScienceDirect, Scopus, Pubmed, Cochrane library, Springer and Sci-hub. The keywords used in the search for the article were the study of covid 19, health promotion, use of masks, use of handsanitizers and Covid 19. There were 18 journal articles and were analyzed through objective analysis, topic suitability, research method used, sample size, research ethics, results. of each article, as well as the limitations that occur.

**Results**

Discussions

Some efforts are made by the government through the covid-19 control team and health team to reduce the risk of contracting the corona virus, among others; remind the public to maintain health by washing hands after making contact with anyone in flowing water, consuming vitamins that can increase endurance, quarantining people suspected of being infected with the corona virus, wearing masks when they are outside the home and in places -public places, maintain distance, and do not make direct contact with other people.

This is consistent with research conducted by WHO on influenza, influenza-like illness (influenza-like illness), and coronavirus in humans providing evidence that the use of medical masks can prevent the spread of splashes that can cause infection from an infected person to another. and possible environmental contamination from these splashes. Evidence that the use of medical masks by healthy people inside the home or by people who have contact with patients, or by people in large gatherings serves as a preventive function is limited. Research by (Moudy & Adlia, 2020) states that the correct use of masks is known by almost all respondents, namely masks are worn with a position to completely cover the nose, mouth and chin (96.6%), and throw away the masks that have been used (79.7 %). More than half of the respondents know that if the mask is wet or dirty, it must be replaced immediately (75.1%) and wash their hands after removing the mask (59.4%). Only a small proportion of respondents chose the wrong option, namely touching the front surface of the mask while wearing it and taking it off (14.1%), and using one disposable mask repeatedly (13.5%).

Research by Rivai, Ayini S, Yesintha states that Hand sanitizer is a product that can clean hands that contain an antiseptic in the form of a gel which when used to wash hands no longer need to rinse with water. Alcohol-based products, which include almost all “disinfectant” products, contains a high percentage alcohol solution (usually 60-80% ethanol) and kills viruses in a similar way. But soap is better because it requires only a small amount of soapy water, which, by rubbing, covers the entire hand easily.22-28
Conclusion

The relationship between the use of masks and hand sanitizers to the incidence of Covid 19. Covid-19 is an infectious disease that has the potential to cause a public health emergency. Therefore, preventive measures against these types of infectious diseases must be carried out as soon as possible. Indonesia as a rule of law, therefore the prevention of these types of infectious diseases must be established in a rule or regulation. Prevention of transmission of Covid-19 in the community is carried out with various efforts. Based on the health protocol issued by the WHO, the government instructs the public to always wash their hands with soap in running water, and always wear a mask when outside the home. In addition, the use of hand sanitisers that contain antiseptics as hand sanitizers, which if you do not need to be rinsed with water, are very effective in killing transient and resident flora compared to using water, using ordinary soap or antiseptic soap.

Analysis Influence of Characteristics and Knowledge of Health Workers on the Management Public Health Centers in Ambon City of Maluku Province

Vonny Bathseba Leatemia¹, Darmawansyah², Amran Razak², Sukri Palutturi², Anwar Mallongi³, Masni⁴, Dian Saputra Marzuki²

Abstract

The knowledge of each individual in the organization is definitely different so the cause of knowledge does not develop evenly with in the organizational environment. The purpose of this study is to analyze the influence of health workers capacity based on the characteristics and knowledge of health workers on the management of public health centers. The type of research used is quantitative research with cross-sectional study design. The population in this study is the entire Head of public health center, Head of Administrative and Program Manager of public health center in Ambon City year 2020 which numbered 143 people. The samples in this study used non-random sampling/non probability sampling techniques, namely purposive sampling, the sample set out in this study amounted to 44 health workers namely the Head of public health center and Head of Governance in Ambon city public health center in 2020. The data analysis techniques used are univariate analysis and bivariate analysis conducted to look for the influence of each free variable with variables bound using chi-square test. The results of this study show that Knowledge Based Health Capacity affects the health management of all public health centers in Ambon City. It is recommended that trainees be able to add insight into planning knowledge (P1), implementation (P2), and assessment (P3) of community health center management and develop the implementation of community health center management obtained at the training site

Keywords: Knowledge, Management of public health centers, Ambon.

Introduction

In an effort to improve the degree of public health as mandated by the above law, health workers who have the capacity of competence and professionalism in their field so as to be able to apply the knowledge and knowledge that it has in health services to the public. Law No. 36 of 2014 on Health Workers states that Health Workers are everyone who devotes themselves in the field of health and has knowledge and/or skills through education in the field of health which for some kind requires the authority to conduct health efforts¹.

The health workers intended above are medical personnel, clinical psychologists, nursing personnel, obstetricians, pharmaceutical workers, public health workers, environmental health workers, nutritionists, physical therapists, medical engineering personnel, biomedical engineering personnel, traditional health workers, and other health workers. According to the Indonesian Dictionary (KBBI) the capacity is the
The Center for Public Health as one of the first types of health care facilities that have an important role in the national health system, especially the sub system of health efforts. In the approach of solving health problems public health centers are as a micro setting that requires collaboration with other sectors. A public health center is a health care facility that organizes public health efforts and first-rate individual health efforts, with promotive and preventive efforts in priority, to achieve the highest level of public health in its working area. Various health problems can actually be addressed at the highest level of public health in its working area. The knowledge of each individual in the organization is definitely different so the cause of knowledge doesn't develop evenly with in the organizational environment. Knowledge Management is one of the solutions to help with knowledge processing, so that individuals in training or learning classes can be just as knowledgeable. Understanding the importance of public health center management in the regulation of the minister of health no. 44 of 2016 has previously been introduced since 1980–2015, with the drafting of the Guidelines management of public health centers.

Public health centers have the task of carrying out health-minded development in their working areas in order to support the realization of healthy sub-districts. The success of the implementation of the task of the public health center depends heavily on the management of existing resources including human resources (Health Workers) as health care providers to the public. Public health center is a First Level Health Facility responsible for organizing public health efforts and individual health efforts in its working area (Regulation of the minister of health 7 on public health centers). In order for public health centers to carry out health efforts properly and sustainably in achieving their goals, the first must be done public health centers are: 1) Develop planning (P1) programs and activities of public health centers based on pdca cycles (plan,do,check,action) according to Decree 44 of 2016 on the management of public health centers) as well as the cycle of budgeting planning that exists in the area, 2) Carry out the mobilization and implementation of activities (P2) through The Monthly Mini Workshop and Tri Monthly public health center in accordance with the plan of activities/programs prepared later, 3) conduct supervision, control and assessment of the performance of public health centers (P3) followed by efforts to improve and improve the quality of public health centers.

Materials and Method

The type of research used is quantitative research with cross sectional study design. The population in this
study is the entire Head of public health center, Head of Administrative and Program Manager of public health center in Ambon City in 2020 which numbered 143 people. The samples in this study used non random sampling/non probability sampling techniques, namely purposive sampling, the sample set out in this study amounted to 44 health workers namely the Head of public health center and Head of Governance of public health center in Ambon City in 2020. The data analysis techniques used are univariate analysis and bivariate analysis conducted to look for the influence of each free variable with variables bound using chi-square test.

Results

Table 1 shows that of the 44 respondents based on the most age in the age group - 34 (77.3%) and the least number of respondents in the age group ≥ 50 years is 10 people (22.7%), based on gender indicating that of the 44 respondents based on the most gender are respondents with a female gender of 35 people (79.5%) while the least male sex is 9 (20.5%). Based on the position shows that of the 44 respondents based on the position consisting of two types of positions, namely the Head of public health center and head of administrative with the same result as 22 people (50%) each

Effect of Health Personnel Capacity based on Knowledge on Public Health Center Management All public health centers in Ambon City

The influence of knowledge variables on the management of public health centers can be seen in the table as follows.

Table 3 shows that of the 21 respondents who were classified with less knowledge as much as 11 respondents (52.4%) management capabilities of public health centers and as many as 10 respondents (47.6%) management capabilities of public health centers. While of the 23 respondents who are classified with enough knowledge as much as 2 respondents (8.7%) management capabilities of public health centers and as many as 21 respondents (91.3%) with sufficient public health center management capabilities. Statistical test results using Chi-Square test with Fisher Exact test obtained p-value value = 0.002, because the value p<α = 0.002 > 0.05 then Ho was rejected, this means that there is a statistically meaningful influence between the capacity of health workers based on knowledge of the management of public health centers throughout the community health center in Ambon City.

**Discussion**

Knowledge is the result of knowing and this happens after people do sensing a particular object. The process of seeing, witnessing, experiencing, or being taught determines the event of knowledge in a person. Knowledge is a very important factor for the formation of an over behavior. Because if someone doesn’t know about an object, it won’t appeal to someone. The same is the case with the capacity level of health workers.

The knowledge of a person can be obtained both from experience and from the educational bench which is the basis of one’s insight as well as a means to facilitate a person who receives new knowledge and behaviors of the level of formal education that one has ever obtained will increase the knowledge of his or her reasoning.

Knowledge is also influenced by the level of education. Yava et al (2013) states that health workers with higher levels of master’s degree education and health workers with a bachelor’s degree have significantly higher statistical knowledge scores than high school graduate health workers; health workers who have taken postgraduate pain management programs have significantly higher statistical knowledge scores than those who do not; similarly, health workers who read books or journals about their disciplines have significantly higher knowledge scores than others.

Knowledge of Regulation of the Minister of Health of the Republic of Indonesia No. 44 of 2016 on The Management Guidelines of public health centers can affect the behavior of health workers in increasing the capacity of public health center services to improve health management.

Knowledge is very important in providing insight into the form of attitudes, which will then be followed by actions in choosing health services that are believed to be capable. The level of knowledge has an influence on the management of public health centers. If health workers do not know about the majemen of public health centers that are good and correct, then in the implementation of public health center services will be irregular. Knowledge is everything that happens in one’s daily life. Attitude is one’s readiness or willingness to act and is not an execution of a particular motive. In other words the function of attitude is not yet an action or activity, but is a predisposition of behavior or action. This indicates that the domain of behavior is a unit of knowledge, attitude and action (activity).

Research conducted by Yusraa shows that the year has an effect on the utilization of elderly posyandu (p = 0.000 < 0.05), other research conducted by asyara et al (2020) shows Knowledge Management and Service Leadership have a positive and significant effect on the Quality of Service.

The level of individual knowledge will have a profound effect on awareness to increase capacity in health and have an impact on behavior. But when further analyzed the process of forming an awareness is not only influenced by his knowledge.

Knowledge alone is not enough to make someone change their behavior. Behavior change or adoption is a complex process and takes a relatively long time. In theory, a person’s behavior changes to accept or adopt new behaviors in his or her life through three stages, namely the knowledge that before a person adopts a behavior (new behavior), he must know in advance what the meaning or benefit of the behavior is to himself or his family, the attitude that is after a person knows the
stimulus or object, the next process will assess or behave against the stimulus or health object, the practice or action that is after a person knows the stimulus or health object, then conducts an assessment or opinion on what is known or behaved$^{10,29-32}$.

**Conclusion**

This research concluded that Knowledge Based Health Capacity affects the health management of all public health centers in Ambon City. Recommended to trainees can add insight into planning knowledge (P1), implementation (P2), and assessment (P3) of public health center management and develop the implementation of community health center management obtained at the training site.

Abstract

Background: Hypertension (HTN) is a chronic medical condition in which the systemic arterial blood pressure is elevated. AIM OF STUDY: The present study compared the effects of atenolol, enalapril and amlodipine on diastolic and systolic pressure & heart rate in hypertension and effects on serum lipid were also assessed.

Patients and Method: A total of 200 patients with hypertension and 100 normotensive controls. The hypertensive patients were randomly allocated into three groups each of 100 patients and were treated with either atenolol (50-100 mg) or enalapril (10-20mg) or amlodipine (5-10 mg) for three months.

Results: Patients taking atenolol showed a significant reduction of SBP, heart rate, while the group taking enalapril showed a significant reduction of SBP, DBP, and no significant change in heart rate while with amlodipine showed a significant decreases of SBP, DBP whereas the change in heart rate was not significant on ther hand Amlodipine was significantly better than atenolol and enalapril at reducing total cholesterol level. Amlodipine was significantly better than atenolol and enalapril at reducing LDL cholesterol level .Enalapril was significantly better than amlodipine and atenolol at increasing serum HDL level . Discussion In this study There was no significant change in heart rate in patients taking, enalapril, or amlodipine while the heart rate was significantly reduced by atenolol. On other hand the enalapril treated group a significant increase of HDL cholesterol. The favorable lipid changes observed with a mlodipine, a significant decreases of total cholesterol and LDL cholesterol levels.

Conclusions: The systolic and diastolic BP values were significantly reduced after, atenolol, enalapril, or amlodipine therapy. There was no significant change in heart rate in patients taking, enalapril, or amlodipine which is consistent with that reported else On the other hand heart rate was significantly reduced by atenolol. on other hand amlodipine are to be preferred in hypertensive patients with elevated LDL-cholesterol levels and enalapril is valuable in hypertensive patients with low HDL-cholesterol levels.

Keywords: Anti-hypertention medication, lipid profile, Heart rate.

Introduction

Hypertension (HTN) or high blood pressure is a chronic medical condition in which the systemic arterial blood pressure is elevated. It is the opposite of hypotension. It is classified as either primary (essential) or secondary. About 90–95% of cases are termed “primary hypertension”, which refers to high blood pressure for which no medical cause can be found ¹. The remaining 5–10% of cases (Secondary hypertension) are caused by other conditions that affect the kidneys, arteries, heart, or endocrine system², hypertension is defined as a systolic blood pressure of 140 mm Hg or higher and/or diastolic
blood pressure of 90mm Hg or greater. When the systolic blood pressure ranges between 140-159 and the diastolic blood pressure ranges between 90 – 99, hypertension is considered mild.

Moderate hypertension is labeled when the systolic blood pressure ranges from 160 – 179 and diastolic blood pressure ranges from 100-109. When the systolic blood pressure is ≥ 180 and diastolic blood pressure is ≥ 110 it is considered as severe.

Antihypertensive drug treatment with special reference to the drugs used in this study: Calcium Channel Blockers (Amlodipine) is a dihydropyridine calcium antagonist (calcium ion antagonist or slow-channel blocker) that inhibits the transmembrane influx of calcium ions into vascular smooth muscle and cardiac muscle. Amlodipine inhibits calcium ion influx across cell membranes selectively, with a greater effect on vascular smooth muscle cells than on cardiac muscle cells. Angiotensin Converting Enzyme Inhibitors (ACEI): provide multiple benefits to the heart without the potential of any adverse effect on the heart. The benefits of ACE inhibitors include the greatest degree of LVH regression, improvement in coronary flow reserve improvement in coronary vasomotor responses relief of angina in some patients. In addition reduction of mortality following myocardial infarction and inhibition of atherosclerosis in animal models. Enalapril is effective in promoting regression of LVH in hypertensive patients and improving LV diastolic function. Beta blockers: are reducing the overall morbidity and mortality in patients with hypertension. Moreover they are effective in promoting LVH regression in hypertensive patients. Atenolol is a beta selective adrenoceptor blocker that is appropriate for initiation as well as subsequent therapy for all degrees of hypertension, documented that atenolol to be effective in causing regression of LVH in hypertensive patients and improve LV diastolic function. Aims of the study: The present study was undertaken to assess and compare the effects of the beta1-adrenoceptor blocker (atenolol), the angiotensin converting enzyme inhibitor (enalapril) and the calcium channel blocker (amlodipine) monotherapy in patients with mild-moderate hypertension, Changes in serum lipid profile.

Patients and Method

Two hundred consecutive hypertensive patients (average age 50±15 years) and one hundred normotensive controls (55± 15 years) attending the teaching hospital IBN ALNAFEES CARDIOVASCULAR TEACHING HOSPIT in BAGHDAD city/Iraq in the period between 2018 and 2020 were included in this study. In all patients, supine BP was measured by a mercury sphygmomanometer using the first and fifth Korotkoff sounds to identify systolic and diastolic values, respectively. The average of three measurements was used as the clinic blood pressure. Patients included in the study were allocated randomly into 3 equal groups each of 300 patients as: Group I received atenolol tablet 4 (50-100 mg once daily). Group II received enalapril tablet Enopril, (10-20 mg once daily). Group III received amlodipine tablet amlong, (5-10 mg once daily). The drug doses were titrated to keep blood pressure consistently below 140/90. These patients together with the normotensive controls were studied and followed for 3 months. Hypertensive patients and the normotensive controls. Biochemical studies: The following biochemical tests were performed for each patient at the initial visit and repeated after the study period: serum lipid profile including total cholesterol, LDL cholesterol, HDL cholesterol, and serum triglycerides.

Results

Two hundred hypertensive patients and one hundred normotensive controls were enrolled into the study. A number of the above mentioned hypertensives and controls discontinued the study with out an obvious, sixty five patients treated with atenolol (44 M and 21 F), sixynet patients treated with enalapril (44 M and 21 F), eighty patients treated with amlodipine (60 M and 20 F) and eighty five control (77 M and 8 F) The mean age of hypertensive patients was 50 ± 15 years versus 50±15 years in the control group. Baseline serum lipid levels showed a significantly higher total cholesterol levels, and a significantly less HDL cholesterol levels in hypertensive patients as compared to normotensive controls.

Effects of treatment on blood pressure, heart rate: Patients taking atenolol showed a significant reduction of SBP, heart rate & see Table (1) figure (1,2,3).
Table (1): Effects of atenolol, enalapril, amlodipine on blood pressure, heart rate.

Table 3 depict the effects of enalapril on serum lipid. After 3 months of treatment the total cholesterol level was reduced by enalapril but not significantly while HDL cholesterol level was significantly elevated.

In the amlodipine treated group a significant reduction was found in serum total cholesterol level and a significant decreases were found in serum LDL levels while the changes in serum HDL cholesterol and serum triglyceride levels were not statistically significant, Amlodipine was significantly better than atenolol and enalapril at reducing total cholesterol level. Amlodipine was significantly better than atenolol and enalapril at reducing LDL cholesterol level .Enalapril was significantly better than amlodipine and atenolol at increasing serum HDL level.

**Discussion**

In this study compare between antihypertensive drugs & we take three kinds which are atenolol, enalapril, or amlodipine and effect on patient significant increases in heart rate, SBP,DBP and subsequently mean arterial BP were observed in both hypertensives and normtensive control group . Concerning serum lipid levels,it was shown that hypertensive patients had a significantly higher total cholesterol levels and significantly less HDL cholesterol levels as compared to normotensive controls . These finding are consistent with that reported by Claudio Marone, 2001)9. It reflects the common association of hypertension withdyslipidaemia (Hunninghake, 1991)10. Effects of therapy on blood pressure and heart rate: The systolic and diastolic BP values were significantly reduced after, atenolol, enalapril, or amlodipine therapy . The anti-hypertensive efficacy of these drugs in patients with mild to moderate hypertension was comparable as was shown in earlier studies (Karlberg et al., 1999, Thurmann 1998)11,12. There was no significant change in heart rate in patients taking, enalapril, or amlodipine which is consistent with that reported else where (Karlberg et al., 1999)11. On the other hand heart rate was significantly reduced by atenolol which was expected from its beta blocking effect. Effects of therapy on serum lipids Hypertension commonly occurs in association with dyslipidemia and atherosclerosis. In the enalapril treated group a significant increase of HDL cholesterol was found and this support the view that ACE inhibitors have a beneficial effects on lipid metabolism (Hunninghake, 1991) 13. The favorable lipid changes observed with amlodipine, namely a significant decreases of total cholesterol and LDL cholesterol levels are in agreement with that reported by(Stein et al., 1991; Richard et al., 1996)14,15 have suggested that calcium channel blockers especially amlodipine cause up regulation of LDL receptors in the liver with enhanced LDL clearance .Beta1, selective blockers like atenolol may induce a shift toward a more atherogenic lipid profile namely a decrease of HDL cholesterol and an increase of LDL cholesterol .These effects are attributed to the inhibition of lecithin cholesterol acyl transferase (LCAT) enzyme and decrease in hepatic LDL receptors (pesant et al., 1999)16 by these drugs .Our study did not document statistically significant adverse effects of atenolol on serum lipid levels. In fact, there was a decrease of HDL cholesterol but the reduction was not statistically significant.

**Conclusion**

Patients taking atenolol showed a significant reduction of SBP, heart rate & The group taking enalapril showed a significant reduction of SBP, DBP, while there was no significant change in heart rate . The amlodipine –treated patients showed a significant decreases of SBP, DBP whereas the change in heart rate was not significant. Concerning the effects on serum lipid profile the following favorable changes were observed : HDL-cholesterol was significantly increased by enalapril while LDL-cholesterol and Total cholesterol was significantly reduced by amlodipine . The amlodipine are to be preferred in hypertensive patients with elevated LDL-cholesterol levels .On the other hand, enalapril is valuable in hypertensive patients with low HDL-cholesterol levels.

3. ESC-ESH Guidelines for the Management of Arterial Hypertension2018

Effect of Lifestyle, Dietary Pattern, School Based Weight Control Program on Overnutrition among Schoolchildren in the Northeast of Thailand

Pannee Banchonhattakit¹, Surachai Phimha², Petcherut Sirisuwan³

¹Associate Professor, Department of Public Health Administration, Health Promotion, and Nutrition, Faculty of Public Health, KhonKaen University, Thailand, ²Lecturer, Department of Public Health Administration, Health Promotion, and Nutrition, Faculty of Public Health, KhonKaen University, Thailand, ³Assistant Professor, Department of Science and Technology, Faculty of Liberal Arts and Science, Roi Et Rajabhat University, Thailand.

Abstract

**Background:** Overnutrition are dramatically raising among school age group in lowand middle-income countries.

**Method:** A cross-sectional study was conducted among 494 grades five and six pupils from ten primary schools in four provinces of the Northeast of Thailand. The multiple logistic regression was used to determine the association between dietary pattern, school-based program, lifestyle, socio-demographic and overnutrition among school children in the Northeast of Thailand.

**Results:** 14.2% of the pupils were overnutrition. The multivariable analysis indicated factors that significantly associated with overnutrition among school children were; consumed high calories food (adj. OR= 4.67; 95%CI: 2.46-8.85), did not participate in school weight control program (adj. OR=4.08; 95%CI: 2.08-8.02), did not join weight control school lunch program (adj. OR= 4.49; 95%CI: 1.89-10.85), did not consume weight control food (adj. OR=3.46; 95%CI: 1.64-7.30), no physical activity (adj. OR = 3.02; 95%CI: 1.56-5.76), when controlling the effect of other covariates.

**Conclusion:** Almost one-sixth of the pupils were overnutrition. Dietary pattern, school-based program, lifestyle, socio-demographic had influence on overnutrition. Appropriate management on food consumption and school-based program, improving lifestyle would help control overweight and obesity.

**Keywords:** Dietary Food Consumption, Lifestyle Socio-Demographic, School Based Program, Overnutrition, Overweight and Obesity.

Introduction

The increasing rates of overnutrition which comprises overweight and obesity (OW/OB) were almost doubled since 1980¹. Overnutrition is a key factor of noncommunicable diseases which are the leading cause of death worldwide². In Thailand, the overall picture is unclear³ due to differences in year of survey, sampling, the age range of children studied and the criteria used for defining OW/OB. For example, a national survey of 10 provinces in 2003 found 5.4% of children aged 6-14 years were OW/OB⁴. In the same year an OW/OB of 10.8% was reported in a survey among children aged 7-9 years in a province in the Northeast⁵. The OW/OB rate at 13.7%, was report for older age group (12-18 years) in the same area⁶. The Thailand Multiple Indicator Cluster Survey in children aged 6-14 years over the period 1995-
2009, and the latest data indicated a national prevalence for primary school children of 9.7%.

Continuous surveillance is necessary due to the associated short- and long-term problems. Perhaps the most serious consequence is the likelihood that childhood obesity will prevail in adulthood. In the USA overweight kindergarten children are four times more likely to become obese as young teenagers than normal weighted kindergarteners, a study showed that infant weight and preschool body mass index (BMI) were strongly associated with overweight in later childhood and adolescence, and a systematic review concluded that obese children and adolescents are more likely to be obese as adults.

In Southeast Asia region (SEAR), Malaysia had the highest obesity prevalence at 14%, while Thailand (8.8%) had the second ranking. According to WHO, the prevalence of overweight and obesity in Thai females was higher than males. In Thailand, these are likely to be different from those found in other countries, especially western developed countries.

Many factors have been indicated as associated with childhood OW/OB. These include gender, high birth weight, dietary behavior, high media consumption, dietary concerns, body satisfaction and psychosocial factors, skipping breakfast, excess energy and fat intakes, television viewing. Family-based factors have included low literacy of mothers, parental OW/OB, family dysfunction, neighborhood socioeconomic status are the factor influence on the OW/OB. Fried food sales around the school are the factor considered as the school based program influence on the OW/OB.

There was limited study on OW/OB and its determinants among school children especially in the Northeast of Thailand. Therefore, it is important to determine the prevalence of overnutrition and its associate factors including dietary intake, school-based weight control program, lifestyle, socio-demographic among school children in the Northeast of Thailand.

**Method**

**Study Design and Population:** This cross-sectional study was conducted among schoolchildren in the Northeast of Thailand. The total of 494 participants were recruited by using a multistage random sampling from ten primary school in four provinces. The inclusion criteria were 1) pupil in the age 10-11 years, 2) studying in the grade 5th and 6th of primary school, 3) agreed to participated in this study with a written informed consent from their parents. The pupil who suffering with severe illness or had mental health problems were excluded. An anthropometric measurement was performed by trained health teachers. A self-administered structured questionnaire was used to assess socio-demographic, lifestyle, dietary intake, school-based weight control program. The outcome variable was and overweight status (overweight and obesity), using the weight-for-height growth chart developed by the Ministry of Public Health (MoPH), Thailand that standardized to WHO and the IOTF. Subjects were categorized by the number of SDs which their weight-for-height at their age was above or below the reference value: obesity (>+3 SD), overweight (>+2.0 to +3.0 SD), slightly overweight (>+1.5 to +3.0 SD), normal (-1.5 to +1.5 SD), slightly underweight/thin/underweight (<-1.5 SD). The slightly underweight, thin and underweight categories were combined because children in these groups were outside the focus of the present study. All the anthropometric measurements were assessed by teachers trained in school health using a Xiangshan EB9003L electronic weighing scale and an Invicta B8A7415 to measure height.

**Statistical Analysis:** Descriptive statistics including frequency and percentage were used to describe categorical data, whereas mean, standard deviation were for continuous data. A simple logistic regression was used to identify the association between each independent variable and OW/OB. The independent factors that had p-value <0.25 were processed to the multi variable analysis using the multiple logistic regression to identify their association with OW/OB when controlling the effect of other covariates.

**Results**

Among the total of 494 respondents, 55.9% were males with an average age of 10.9 ± 0.5 years old. Majority of the respondents stayed with parents (76.1%) and at least one family member had history of obese in their family (29.6%). Their family financial status was had enough income with saving. Most of them had physical activities and aware of their own body image (84%). Majority of them did not consumed weight control food. Almost all of them had low to average levels of overnutrition prevention and low to average level of overnutrition prevention behaviors. A quarter
usually consumed high calories food. Concerning school factor, nearly half joining exercise provided by school all the times, 92.9% participated in weight control school lunch program, 40.1% participated in school weight control program and majority of these pupils had information on high calories diet and drinks.

Most of the pupils had normal weight (65.2%), 13.3% were underweight. Concerning overnutrition; Slightly overweight was 7.3%, overweight and obese were 5.7% and 8.5%, respectively which means 14.2% of the pupils were overnutrition.

The multiple logistic regression indicated four factors that were significantly associated with over nutrition among school children in the Northeast of Thailand included; consumed high calories diet(adj. OR= 4.67; 95% CI: 2.46-8.85), did not join school weight control program (adj. OR=4.08;95%CI: 2.08-8.02), did not participate in weight control school lunch program (adj. OR= 4.49; 95%CI: 1.89-10.85), did not consume weight control food (adj. OR=3.46; 95%CI: 1.64-7.30), no physical activity (adj. OR =3.02; 95%CI: 1.56-5.76), had family history of obesity (adj. OR=2.52; 95%CI: 1.19-5.34), were males (adj. OR=2.08; 95%CI: 1.17-3.72), when controlling the effect of other covariates (Table 1).

### Discussion

The present study indicated the prevalence of overnutrition (OW and OB) among school children in Northeast of Thailand was 14.2% which was higher than the age-adjusted rate of 10.7% reported in 2012 for children aged 7-9 years in major urban areas of the same region using a similar definition of OW/OB. This prevalence exceeds 10% of minimized a risk problem
of the Thai Ministry of Public Health (MoPH) in the National Health Development Plan XII (2017-2021)\textsuperscript{32}. This finding is consistent with those of previous studies in Thailand over the period 2006 to 2013\textsuperscript{31,34,35}. This suggested the problem of increasing prevalence over the past decade. The rise in OW/OB in Southeast Asia is likely to have been largely due to the increasing consumption of fast foods which tend to be very fattening. A study of Chinese Singaporeans by Odegaard et al.\textsuperscript{36} found the relationship between fast food consumption with Type 2 diabetes (T2DM) and coronary heart disease (CHD). Therefore, fast food consumption was critical issue to weight gain and obesity risk\textsuperscript{37}.

Factors that were significantly associated with (OW/OB) of participants included; consumed high calories diet, did not participated in school weight control program, did not participate in weight control school lunch program, did not consume weight control food, no physical activity, had family history of obesity, and were males.

The finding also indicated that did not participate in weight control school lunch program is also associated with OW/OB that consistent with previous study indicated that school lunch program were significantly associated with OW/OB. Lunch provided by school was important\textsuperscript{18,28}, and regarding to dietary changes effected to dietary behaviors for childhood obesity\textsuperscript{20,21}. Physical activities at school were unrelated to the prevention of OW/OB. According to the children, their schools played was less satisfactory role in reducing the prevalence of OW/OB. Most of schoolchildren denied attending any school’s prevention and control of OW/OB programs. Therefore, schools need to review their contribution on reducing the problem of OW/OB. This major suggestion to school healthy policy, a global challenge for healthy meals in schools by multi-sectors was essential\textsuperscript{38}.

Being males were more likely to be OW/OB than females. This is inconsistent with previous research studies in Thailand, but consistent with elsewhere\textsuperscript{19,34}. The presence and direction of gender differences in OW/OB do appear to vary with ethnic and cultural factors\textsuperscript{34}. Perceived obesity in family members (first-degree relatives and grandparents) was associated with OW/OB. This finding is consistent with many previous studies in other parts of the world\textsuperscript{19,25,29}. Families can also have considerable influence over the diet of younger family members, and they also act as role models for patterns of food consumption and behavior which lead to overnutrition. Families should always be involved in attempts to reduce the prevalence of overnutrition in children.

### Conclusions

Almost one-sixth of the pupils was overnutrition. Dietary pattern, school-based weight control program, lifestyle, socio-demographic had influence on the school children overnutrition. Appropriate management on dietary food consumption and school-based program, improving lifestyle would help control the overnutrition problems among school children in the Northeast of Thailand.

Neonatal and Birth Complications in Adolescent Pregnancy of Tikrit City

Marwa Thair Abass¹, Massriyah Rashad Hussein²

¹Gynecologist, M.B.Ch.B., Salah-Aldin General Hospital,
²Assist. Prof, Department of Obstetrics and Gynecology, Medical College, University of Tikrit, Iraq

Abstract

Background: Adolescence is a transitional period from childhood to adulthood characterized by significant physiological, psychological and social changes. World Health Organization defines Teenage Pregnancy as “any pregnancy from a girl who is 10-19 years of age”, the age being defined as her age at the time the baby is born.

Aim of the Study: To study the correlation study between of fetal risk and adolescent pregnancy.

Patients and Method: A cross sectional study conducted in Department of Obstetrics and Gynecology in Salah El-Din teaching hospital at the period from the 1st of Feb. 2018 to the end of August 2018. Convenient sample of (100) teenage pregnant women, who are willing to participate in this study and available at the time of data collection include.

Results: The frequent outcome of pregnant women was birth (32%), followed by; birth & oligohydrominous (14%), the neonatal complications were present in 68% of pregnant woman’s neonates. The delivery complications were absent in 32% of pregnant women while present as episiotomy (50%), in general, delivery complications were present in 68% of pregnant women.

Conclusion: The neonatal complications were present in 68% of pregnant women.

Keywords: Neonatal; birth complications; adolescent pregnancy; Tikrit city.

Introduction

As to problems with the newborn, gestation during adolescence is associated with higher rates of low birth weight (LBW), preterm delivery, respiratory diseases, and birth trauma, besides a higher frequency of neonatal complications and infant mortality(1).

Many risk factors lie with parents themselves. In addition to the behaviors, one also has to look at one’s medical history. Parental obesity, combined with an excessive mother’s weight gain during pregnancy, increases the risk of the baby becoming overweight(2).

In many developing countries, the number of teenage pregnancies has decreased compared to the late 1990s, and some sub-Saharan countries are increasing. The latest UNFPA report on teenage pregnancy summarizes data worldwide and indicates the need for action to reduce risk factors.

According to the report, childbirth complications are the main cause of death for girls and women in developing countries, in addition to fetal death(3). The number of stillbirths and infant mortality is much higher among teenage mothers than among older women. The study explains that the consequences of unprofessional abortion also pose a major birth threat(24) therefore, the aim of current study to study the correlation study between of fetal risk and adolescent pregnancy in Tikrit city.

Study Design and Setting: A cross sectional study conducted in Department of Obstetrics and Gynecology in Salah El-Din teaching hospital at the period from the 1st of Feb. 2018 to the end of August 2018.
Study Subjects: Convenient sample of (100) women, who are willing to participate in this study and available at the time of data collection include.

Data were collected via modifiable questionnaire form put it and modified by supervisor senior. Questionnaire forms consist of (socio-demographic, obstetrical and maternal history, complications, infant history and complications questionnaires)

Results

Gravidity history of pregnant women showed primigravida (59%), 1-2 gravida (26%) and >2 gravida (15%). Parity history revealed nulliparity (63%), 1-2 children (30%) and >2 children (7%). History of abortion was detected in 6% of pregnant women. The gestational age of pregnant women was distributed as followings; 2% <28 weeks, 20% 28-36 weeks, 74% 37-40 weeks and 4% >40 weeks. Half of pregnant women had menarche at age of 12 years and younger.

More than half (53%) of pregnant women had married at age 14-16 years, 22% of them had married at age of 17-18 years and 25% of them had married at age of older than 18 years. (table 1).

Discussion

The present study showed that neonatal complications occurred in 68% of pregnant women’s newborns and the delivery complications were absent in 32% of pregnant women while present as episiotomy (50%), hemorrhage (16%) and perineal tear (2%). In general, delivery complications were present in 68% of pregnant women.

Results of Yazlle et al., 2009 showed complications in 38.3% of the adolescents and among the most frequent diagnoses were problems with the fetus or the placenta, and problems with the membranes and amniotic cavity and, also Santos et al., 2009 showed that 18.4% (119/648) of the newborns of adolescent mothers were transferred to the neonatal intensive care unit (NICU).

Conclusions:

The neonatal complications were present in 68% of pregnant women.

Conflict of Interest: none

Source of findings: self-findings.

Ethical consideration: the study was approved by the ethical committee of the Najaf scientific council for medical specialization of the obstetrics and Gynecology, and not to be used for other research object

Dental Faculty’s Knowledge and Attitude Regarding Covid 19 Disease in Qassim University, Saudi Arabia

Asma Munir Khan1, Shazia Nawabi2, Muhammad Qasim Javed3

1Assistant Professor, Department of Conservative Dental Sciences, College of Dentistry, Qassim University, Al-Qassim, Saudi Arabia, 2Associate Professor, Department of Prosthetic Dental Sciences, College of Dentistry, Qassim University, Al- Qassim, Saudi Arabia, 3Assistant Professor, Department of Conservative Dental Sciences, College of Dentistry, Qassim University, Al-Qassim, Saudi Arabia.

Abstract

Background: Present study aimed to explore the knowledge and attitude of dental faculty at Qassim University, regarding novel COVID 19 disease.

Method: The cross-sectional survey was conducted on the faculty at undergraduate dental school. The self-designed e-survey was administered to 78 faculty members to assess their knowledge and attitudes towards the COVID-19 disease. Data analysis was conducted by using SPSS version 23. Descriptive statistics were reported as frequency and percentages. Chi-square test was utilized to identify the correlation between the independent and dependent variables. The inferential statistics (Kruskal-Wallis tests and Mann-Whitney U test) were utilized for assessing the significance between study variables. The association between knowledge and attitude was evaluated by using Spearman’s rank correlation coefficient.

Results: A total of 55 faculty members (70.5%) responded. Mean knowledge score was 10± 2.71. 37 (67.3%) respondents showed positive attitude towards COVID-19 while 18(32.7%) displayed negative attitude. The mean attitude score was 4.08±0.50. Significant difference was found in knowledge (p-value=0.04) and attitude (p-value=0.015) of dental faculty based on designation.

Conclusions: Qassim University dentists were mindful of the COVID-19 symptoms, means of transmission, Cross-infection control and operative protocols practiced within dental clinics. However, dentists exhibited inadequate knowledge about the specific dental procedures that safeguard the dental staff and patients from COVID-19 in context of current outbreak.

Keywords: Knowledge, Attitude, COVID-19, cross-infection control, practice management.

Introduction

Human Coronaviruses have recently gained global attention after the emergence of a novel coronavirus that resulted in COVID 19 disease.1 COVID19 is a highly contagious viral infection that is caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2).2 It is composed of a single strand of RNA, 65-125nm in diameter. SARS-CoV-2 has crown like spikes on its outer surface that binds to receptors of target cells and facilities its entry into the host cells.3 Additionally, its high binding affinity to the human angiotensin converting enzyme receptors (ACE2) enables it to enter and target the human host cells.4

The subgroups of coronaviruses family are alpha(α), beta (β), gamma (γ) and delta (δ) coronavirus [5]. Alpha and beta coronaviruses mainly cause disease

Corresponding Author:

e-mail: asma.munir.k@gmail.com
in humans and mammals infecting their respiratory, gastrointestinal and central nervous system.\textsuperscript{5} SARS-CoV-2 is phylogenetically related to the two highly pathogenic respiratory coronaviruses i.e Severe acute respiratory syndrome coronavirus (SARS-CoV) and Middle East respiratory syndrome coronavirus (MERS-CoV). All of these belong to $\beta$-CoV based on viral genotyping\textsuperscript{6} and are profusely present in nasopharyngeal and salivary secretions of affected individuals.\textsuperscript{7} Initially, these viruses were believed to cause disease only in animals until the SARS-CoV triggered an outbreak in Guangdong, china in year 2002 resulting in severe acute respiratory syndrome (SARS) in humans.\textsuperscript{8} In 2012, another pathogenic coronavirus, known as Middle East respiratory syndrome coronaviruses (MERSCoV) caused an endemic in Middle Eastern countries.\textsuperscript{9}

SARS-CoV-2 is a zoonotic pathogen that is believed to have been originated in bats and pangolins and later transmitted to humans. It can be transmitted from animal to human and then from human to human contact.\textsuperscript{8} This particular strain of coronavirus has recently originated from a seafood market in Wuhan city, China in late December 2019. The affected patients reported with a novel viral pneumonia with classical symptoms of fever, cough, myalgia, fatigue, with abnormal chest CT. The other symptoms reported were sputum production, headache, hemoptysis, diarrhea and respiratory distress. Later, it disseminated to other parts of world leading to global emergency.\textsuperscript{10}

Novel coronavirus was officially announced as a causative agent of COVID -19 by the Chinese Centre for Disease Control and Prevention.\textsuperscript{10} Owing to rapid dissemination World Health Organization (WHO) affirmed COVID-19 as a public health emergency of international concern (PHEIC).\textsuperscript{12} Subsequently, due to continue spread at an alarming rate WHO has formally declared outbreak a pandemic disease on 11th March 2020. Up till now (April 17th, 2020) it has swept more than 205 countries globally with 2,206,535 confirmed cases and 148,651 deaths.\textsuperscript{13}

The current epidemiological data show COVID-19 has higher transmissibility than SARS-CoV and MERS-CoV. The possible routes of transmission in humans include direct contact through respiratory droplets inhalation and indirect through fomite transmission.\textsuperscript{7} Incubation period for COVID-19 is between 2 to 14 days and it can also be transmitted through asymptomatic patients.\textsuperscript{14} Thus, social distancing, proper hand hygiene, and surface disinfection are highly recommended to stop its rapid spread. Moreover, it was also found in saliva of infected patients. This can be attributed to its high binding capacity to ACE2 receptors which are highly concentrated in salivary glands.\textsuperscript{4} Thus, its high mutation rate, pathogenicity and numerous routes of transmission may contribute to nosocomial spread in healthcare settings especially dental offices. Up till now, no treatment or vaccine is available to treat COVID-19 disease and the main stay of the treatment is supportive care. The only critical intervention, available is preventive measures as advised by WHO is early viral testing for disease confirmation and ensuring symptomatic relief for infected patients.\textsuperscript{13}

Dental professionals and patients are at an increased risk of contracting COVID -19 due to specific nature of dental procedures which involves frequent face to face contact with the patients, their saliva and contaminated materials. Owing to rapid spread and poor understanding of the disease, the American Dental Association has suggested that all elective dental procedures should be deferred and only patients with true dental emergencies should be catered.\textsuperscript{15} Also, universal precautions, careful prescreening of patients and additional preventive measures are deemed necessary before treating the patients in dental settings.\textsuperscript{13}

It is mandatory for health professionals to provide good and safe patient care. Therefore, it is imperative that proper information and training sessions should be imparted to dental professionals to ensure awareness and readiness regarding this global emergency. Absence of proper training will not only delay the necessary treatment required for such patients but can contribute to rapid spread of disease. Hence, the present study aimed to explore the knowledge, and attitude of dental faculty at Qassim University, regarding novel COVID-19 disease. This survey intended to provide an insight regarding level of awareness among dentists about the Covid-19 disease and may help in shaping future guidelines, strategies, and fool proof infection control policies that will be implemented in dental settings.

**Method**

**Study Design, Participants and Site:** The current cross-sectional study was conducted on the Faculty at Qassim University College of Dentistry from 15\textsuperscript{th} to 31\textsuperscript{st} March, 2020. All the faculty members were briefed about the context and purpose of the research. An
online e-survey questionnaire was administered through an electronic mail to 78 faculty members to assess their knowledge and attitudes towards the COVID-19 disease. The study instrument was devised by a panel of experts according to the guidelines proposed by WHO and CDC. The instrument was then sent to the researchers from dental background to provide expert opinion on the ease of understanding, relevancy and time needed to fill. A second review was done and the modification in the questionnaire was carried out according to local requirements. Subsequently, a pilot study was carried out on limited sample of dental professionals (N=6). The professionals provided suggestions on making the study instrument shorter and simpler. After a comprehensive discussion, the study instrument was finalized. The instrument was found to be reliable with the Cronbach’s alpha of 0.77. The study instrument was divided into 3 parts. The first section of the e-survey constituted demographic questions inquiring about gender, designation and specialty. The second section included 13 research questions pertaining to participants’ knowledge regarding COVID-19 disease where yes and no options were provided for each question. The third part of the survey used 9 questions to ascertain the attitude of the faculty members towards COVID-19 disease on a 5-point Likert scale that was developed with balanced responses and neutral midpoint. The study tool assessed the awareness of faculty by probing about the mode of transmission, prevention, treatment and management of patients in the dental settings. The score for knowledge assessment ranged from 0 to13. The cutoff point of less than 9 (<9) was set for insufficient knowledge and greater than or equal to 9 (≥9) for sufficient knowledge. Attitude assessment was conducted, and the responses were documented on 5 point Likert scale. A score of 5 was assigned to strongly agree, 4 to agree, 3 to undecided, 2 to disagree and 1 to strongly disagree. A mean score of >4 was taken as positive attitude whereas score of <4 was considered as negative attitude.

Ethics, consent and permissions: The study was approved by the ethical committee of the Qassim University College of dentistry (Ref no ST/6074/2020). Furthermore, written consent was not obtained as the returning of filled questionnaires from respondents was taken as implied consent. Moreover, participants were informed about intent and content of study and were ensured about confidentiality of data.

Statistical Analysis: Data analysis was done by using SPSS version 23 (IBM Corp, 32 Armonk, N.Y., USA). Descriptive statistics were described in terms of frequency and percentages. In order to show association between dependent and independent variables Chi-square test was employed. Statistical significance was set at less than 0.05 (p-value<0.05). Also, the inferential statistics (Kruskal Wallis tests and Mann–Whitney U test, p < 0.05) were utilized for assessing the significance between study variables. The aforementioned non-parametric tests (Kruskal Wallis tests and Mann–Whitney U test) were applied because of smaller sample size. Spearman’s rank correlational coefficient was used to appraise any link between knowledge and attitude. (p < 0.05).

Results

A total of 55 faculty members, 31 females and 24 males, responded out of 78. About 74% of the participants belonged to clinical specialties and majority of the respondents were Lecturers (38.2%). The distribution of respondents’ characteristics is shown in Table 1.

Overall the mean knowledge score of the participants was 10± 2.71. Sufficient knowledge was exhibited by 72.7% of respondents whereas 27.3% displayed insufficient knowledge. The study participants showed excellent knowledge (between 98% to 80%) for the stems that enquired about mode of transmission, urgent dental care procedures, significance of PPE while patient examination, use of high volume suction and WHO guidelines regarding hand hygiene. On the other hand, knowledge was good to fair (between 80% to 70%) for questions regarding rubber dam isolation, use of N95 masks, four handed dentistry, extraction protocol, antibiotic use and tele screening. Lastly, inadequate knowledge was evident in reaction to two questions, one regarding safety of use of ultrasonic in Covid-19 suspected patients and the other was related to efficacy of 1% of hydrogen peroxide mouthwash as a pre-rinse. Response was 61.2% and 38.2% respectively. Table 2 describes knowledge of participants regarding COVID-19 disease in detail.

Attitude of the respondents is summarized in Table 3. Of 55 respondents, 37 (67.3%) showed positive attitude (>4) towards COVID-19 while 18 respondents (32.7%) displayed negative attitude (<4) regarding disease. The mean attitude score was in range of 4.08±0.50. Overall faculty showed positive attitude.
when asked about fear of getting infected with COVID 19, treating only emergency cases, seeking patient’s relevant medical history, asking about recent travel, checking body temperature and avoiding procedures that cause aerosol production. Conversely, the most negative attitude (3.42±1.08) was noted when the faculty was asked if they would like to volunteer their services in support of medical teams in case of future emergencies. Moreover, mean scores were found to be <4 in questions related to anxiety, caries removal and training sessions. Significant correlation was noted between designation and attitude for items number 6 (p-value=0.001) and 7 (p-value= 0.03).

In table 4, the relationship of demographic characteristics with mean attitude and knowledge amongst dental faculty is displayed. Results of the present study showed no significant correlation of gender and specialty with both knowledge and attitude. However, a meaningful disagreement was found in knowledge and attitude of dental faculty on the basis of designation. The results showed that Professors/associate professors were equipped with better knowledge and attitude regarding COVID-19 disease than lecturers. Spearman correlation showed significant positive correlation between the knowledge level and attitude of faculty members about COVID-19 (r=0.557, p value=0.01).

Discussion

Pandemic of COVID-19 has led to global crisis. The rapid surge of COVID-19 disease has not only raised widespread public health concerns but has collapsed world’s economy. It has put immense strain on social stability and the global health systems, particularly challenging the health care workers including the Dental care professionals (DCP). It is, therefore, crucial that prudent information should be relayed to health care professionals in the time of this global emergency. Considering this, the current study investigated the knowledge and attitude of dental faculty towards the COVID-19 disease. To date, only limited studies are reported that explored dentists’ awareness and attitude towards COVID-19 contagion. Due to scare data available, the comparison of our outcomes has been done mainly with other associated conditions.

The current study revealed generally adequate knowledge and positive attitude of Qassim University dental faculty towards the COVID-19 disease. Most of the participants exhibited sufficient knowledge about questions related to mode of disease transmission, urgent dental care procedures, significance of PPE while examination, use of high volume suction and WHO guidelines regarding hand hygiene. These outcomes are in accordance with the results reported by Khader et al. in their study on the Jordanian dentists. These results are comparable to some of the studies done mainly with other associated conditions. Moreover, the findings are consistent with other studies which showed mean positive value in attitude domain. These results might be due to the inadequate briefing of the relevant authorities on the management issues during the educational campaign. Moreover, moderate knowledge about the aforementioned questions in our study might be due to the fact that in Saudi Arabia after the outbreak of COVID-19 more seminars are held for medical healthcare workers as compared to dentist community. Inadequate knowledge was ostensible in reply to two questions, one regarding safety of use of ultrasonic in Covid-19 suspected patients and the other was related to efficacy of 1% of hydrogen peroxide mouthwash as a pre-rinse.

Moreover, further insight into the study showed a positive mean value in attitude domain. These results are consistent with other studies which showed mean positive attitude of physicians. Dental faculty showed most affirmative response and positive attitude in reply to questions about anxiousness regarding cross infectivity, to accommodate only emergency cases, seeking patient’s relevant medical and travel history and minimization of aerosol generating procedures. The anxiety of our faculty regarding cross infectivity are contradictory to results of recent study, where most of the dentists (71.7%) perceived COVID-19 as moderately dangerous disease and almost one third believed that COVID-19 is not a serious public health issue. Although same study concluded that dentists should evaluate patients through measurement of the body temperature as a routine procedure and should be asked about any history of recent contact or travel [18],

On the other hand, with regard to the questions related to rubber dam isolation, four handed dentistry. Use of N95 mask, role of antibiotics, tele-screening and recommended extraction protocol and faculty exhibited moderate knowledge. Possible explanation for these findings could be the knowledge gap and poor understanding of disease transmission via high aerosol production during dental procedures. These results are comparable to some of the studies which concluded that dentists’ knowledge of respiratory disease contagion and its management was less as compared to other healthcare providers. Despite their proximity to the patient during treatment. Likewise, in a study conducted in Qassim in perspective of MERS, majority of health workers (57.6%) replied incorrectly when asked whether antibiotics are first choice drugs. This outcome is comparable with the result of another study where 40% of participants gave negative response when asked about specialized management protocols. This might be due to the inadequate briefing of the relevant authorities on the management issues during the educational campaign. Moreover, moderate knowledge about the aforementioned questions in our study might be due to the fact that in Saudi Arabia after the outbreak of COVID-19 more seminars are held for medical healthcare workers as compared to dentist community. Inadequate knowledge was ostensible in reply to two questions, one regarding safety of use of ultrasonic in Covid-19 suspected patients and the other was related to efficacy of 1% of hydrogen peroxide mouthwash as a pre-rinse.
and these results are in accordance with our study. These findings are also in harmony with another study in which health care workers displayed positive attitude in using personal protective gear and were adamant that goggles and gloves should be worn when dealing with healthcare related nosocomial infections.\textsuperscript{32}

The most negative attitude was seen in question no 9 (3.42±1.08) in which faculty was asked if they would like to volunteer their services in support of medical teams in case of future emergency. So far, there is no comparable data to assess the attitude of dentists about their involvement in COVID-19 emergency support teams but there is one recent study, which has presented model of dental outreach program in case of any untoward emergency situation in current diseases outbreak.\textsuperscript{33}

In present study mean scores were also found to be negative (less than 4) in question no 7 and 8, regarding willingness of dental faculty to attend any training sessions to handle any untoward Covid 19 situation. The reason for this negative response may be wrong perception of faculty, to link these training sessions as part of building volunteer teams. It was noticed that experience was appreciably linked with attitude, as senior faculty responded more positively as compared to younger ones, and this finding is comparable to study done during MERS outbreak in Middle East.\textsuperscript{21}

The relationship of demographic data with mean awareness and attitude was analyzed and results showed no significant correlation among the demographic variables, gender and specialty. These results are supported by literature which does not support the connection of gender with the awareness and attitude of healthcare workers.\textsuperscript{34} Although, the correlation of experience with awareness and attitude, has been stated meaningful by studies.\textsuperscript{35} Our study also exhibited a significant disparity in knowledge (p-value=0.04) and attitude (p-value=0.015) of dental faculty with respect to their designation. Professors/Associate professors were equipped with better knowledge and attitude regarding COVID19 disease than lecturers. This can be attributed to vision and experience of senior faculty members earned through years than the lecturers who are relatively young and new to the field.

The aforementioned findings, endorses meaningful association of awareness and attitude of dental faculty with regard to COVID -19. In light of this, it could be inferred that dentists depicting positive attitude are highly determined to gain information and to enhance their knowledge and skills to fight against disease. This can be rationalized by the philosophy of Reasoned Action, which states that an individual’s intent to a particular action depends on their attitude towards that conduct.\textsuperscript{36} Nevertheless, more extensive studies in future should be undertaken to explain possible correlation between knowledge and attitude displayed by dental faculty at Qassim. The merits of this study lie in its concept of addressing current pandemic dilemma and highlighting the area where little research has been done until now.

The key results of present study may be used to create awareness in designing efficient infection control measures of COVID-19. However, our study has certain limitations, the lower than expected response rate of faculty and short period of data collection has led to comparatively smaller sample size. Moreover, this pandemic has affected every aspect of life and caused many to be busy in making personal, official, and financial arrangements. This could have been resulted in selection bias and sampling error, which may limit the ability to generalize our results. Future studies are required in this context.

Conclusions

In summary, Qassim University dentists were mindful of the COVID-19 symptoms, means of transmission, Cross-infection control and operative protocols practiced within dental clinics. However, dentists exhibited inadequate knowledge about the specific dental procedures that safeguard the dental staff and patients from COVID-19 in context of current outbreak. Study recommends establishment of focused dental education drives to span the gap between the current and the requisite knowledge, to influence their attitude positively towards COVID-19.

Abstract

The objective of this study was to verify the effects of engineering design of IVS 2 progesterone with 2 cm thick sponge and 2 cm length and 5 cm silicon plate in the middle with 13 cm nylon cord ties to pull the sponge position. Try to determine the effective dose of progesterone (MAP) with a dose of 60 mg progesterone, eCG, GnRH and PGf2α on pregnancy of ewes subjected to a short-term synchronization of estrus. Tail fat sheep ewes strain sapudi Islands received 60 mg MAP sponges model IVS 2 during 12 days plus 500 IU eCG folligon and 2.5 mg d-cloprostenol capriglandin (0.5 ml) submucosa vulva 24 h prior to IVS 2. Control groups (T0) 10 Ewes were assigned to receive 0.9% NaCl solution 2 ml im only when estrus sign showed waited for natural estrus. Group treatment 10 Ewes were (T1) IVS2 + 500 IU eCG folligon and group treatment 10 Ewes were (T2) IVS2 +500 IU eCG folligon 21.5 µg (0.5 ml) GnRH fertagyl gonadorelin, 24 hours after withdrawal. Each group was assigned to intracervical insemination by Vaginoscopy (n = 30). Artificial insemination was performed with a single dose of fresh semen on egg yolk skim milk dilluters. For controlled mating, females were exposed to males 48 hours after sponges removed. Ten females per treatment were subjected to transrectal ultrasound examination at 35 days late after AI. Estrous response (100.0%), pregnancy rates (T0 80% T1 70% and T2 70%), did not differ between T1 and T2 respectively (p >0.05). Administration of GnRH 24 hours after IVS 2 removed does not improve pregnancy rate in estrous synchronization in Tail fat ewes strain sapudi Islands (p >0.05) on day 35.

Keywords: Artificial insemination, intravaginal MAP progesterone model IVS 2, pregnancy rate, tail fat ewes strain Sapudi Islands.

Introduction

The IVS 2 intra vaginal sponge design technique contains progesterone/MPA (medroxy progesterone acetate) with a sponge diameter of 2 cm and a length of 2 cm thick and its center contains a T rod made of plastic silicon. This tool was created with the aim of efficient use of the hormone progesterone. Fat tailed sheep Sapudi Madura is a pure plasma of Sapudi Madura Island, East Java Indonesia. The hallmark of this sheep is having a sigmoid fat tail with an average width of 15 cm with a length of 25 cm. This tail is the accumulation of fat tissue as a source of energy and is typical. The average adult weight of males reaches 35 kg and females 25 kg¹. MPA belongs to a group of steroid hormones whose chemical composition is 6 methyl 17α acetoxy progesterone giving a 60 mg MPA sponge combination with a 500 IU intra-muscular Pregnant Mare Serum Gonadotropin (PMSG) or eCG, GnRH and PGf2α on pregnancy of ewes subjected to a short-term synchronization of estrus. combination will give very satisfying results. Research on the effect of giving intra vaginal sponge assemblies

Corresponding Author:

e-mail: herrypro59@yahoo.com
of medroxy progesterone acetate (MPA) to the speed
of onset of sheep estrus, the results showed that the
extraction on the 12th day was almost the same as the
speed of estrus by using PGF2α 7 mg intra-muscular
which is about 48 hours after the extraction had been
tested try MPA sponge2,3,4,5.

The use of MPA progesterone dose and its
combination with eCG folligon is given an injection of
300 IU intra muscular on the 12th day when the extraction
of progesterone. Intra vaginal vaginal progesterone
hormone given to 60 boar goats with a difference of
progesterone 30 mg and 60 mg given intravenously for 12
days did not show estrus differences both 100% showed
symptoms of lust but differed significantly in oestrous
period duration (p <0.01) was shorter in the control group
(29.3 hours versus 28.0 hours for Indigenous and Boer
goats, respectively), compared to the period induced to
60 mg. (31 and 32 h) or 30mg (40 h compared to 34 h) for each Boer goat6, 60 mg in case in ewe7. The use
of eCG (PMSG folligon) injection applied with the use
of intravaginal sponges MPA. 300 IU intra-muscularly
coinciding with the removal of sponge day 12 and the
dose of 500 IU eCG in ewe on the same day followed
by estrus on the day to day 14. The combined use of
progesterone and PGf2α on ewes subjected to a short-
term synchronization is usually used when injecting
2.5 mg d-cloprostenol capriglandin (0.5 ml) submucosa
vulva for efficient use or general dosage intra-muscularly
7.5 mg or (1.5 ml) is done simultaneously when sponge
release progesterone aims to lyse the corpus luteum8.
The combination of the GnRH hormone in this study
aims to grow follicles when injected on day 0 can serve
to stimulate anterior hypophysis to release FSH to
stimulate follicular growth in the follicular phase and if
injected the 13th day after being removed vaginal sponge
progesterone on the 12th day will serve as a trigger
anterior hypophysis to release LH which functions to
ovulate the gravian follicle. Fertagyl which contains the
GnRH hormone Gonadorelin is usually given at a dose
of 25 ug intra-muscularly9.

Materials and Method

A total of 30 Tail fat ewes strain sapudi Islands
that were confirmed to be 2 years old that had a body
score of at least 2 were previously treated with milk
concentrate A protein 15-17% (Phok Phand) 0.05 kg/
day/head for increased of body score condition(16,
19), for 1 month randomly divided into 2 groups with
each treatment received 10 replications of T0 (control
Groups) 10 ewe: Injected 0.9% NaCl solution 2 ml intra
muscular injections of control group, and T1 (treatment
groups 1) 10 ewe: IVS2 MAP progesterone, eCG and
PGf2 combined and T2 (treatment groups 2) 10 ewe: IVS2 MAP progesterone, eCG, PGf2 and GnRH.

Insemination using fresh semen is performed when
signs of estrus Artificial insemination was performed
with a single dose of fresh semen on egg yolk skim milk
dilluters. For controlled mating, females were exposed
to males 48 hours after sponges removed. IVS 2 design
type specifications required material sponge imprints
diameter 2 cm long Thick 2 cm in the middle there is a
silicone T shape with a length of 5 cm and is equipped
with a 15 cm long rope. Sponge contains Medroxy
Progesterone Acetate (MPA) 60 mg Cyprofloxacine 500
grams in vasceline alba.

Treatment and control groups are: T0 (control
Groups) 10 ewe: Injected 0.9% NaCl solution 2 ml intra
muscular, T1 (treatment groups 1) 10 ewe: IVS2 MAP
progesterone, eCG and PGf2 combined, T2 (treatment
groups 2) 10 ewe: IVS2 MAP progesterone, eCG, PGf2
and GnRH.

Statistical design and analysis: The research
design used was a complete random design and data
analysis was carried out using proportional quantitative
and qualitative analysis on estrus and pregnancy in
Tail fat ewes strain sapudi Islands. Some types of data
analysis that will be used are: Analysis of Variance
Analysis (ANOVA) and Honest Difference Test (SPSS
22)10.

Results and Discussion

The results showed no significant differences p
>0.05 in estrus sign, where average estrus of the 14th
all of p0 and groups of treatment showed real estrus.
This event allows the ovaries to give the opportunity
to develop sub-ordinate follicles into de Graaf follicles
in the injected Pg2α lysis stimulus of corpus luteum
periodic on day 12 and after that on the 14th day all
of them group showed symptoms of 100% estrus sign.
Contain FSH and LH on eCG folligon can be suport
follicle grow on folliculary phase on 12 days until 14th11.
The LH receptor is also expressed on granulosa cells.
have reported that the signaling pathways of LH do not
completely overlap, and this fact may have implications
for LH use in assisted reproductive techniques (ART)
a gonadotropin-releasing hormone (GnRH) agonist,
initially presented as a substitute for hCG, has led to a new
era of administering a GnRH agonist followed by hCG triggering for ovulation to give 24 hours after removed of the sponge. The response to superovulation, yield and quality of the embryo, is evaluated after increasing the time of exposure to exogenous progesterone during superstimulation, with or without the addition of GnRH agonists. Thirty-four females of the Santa Inês type were synchronized with an intravaginal progesterone device with the addition of GnRH 25 mg of gonadorelin when removed device in day 12. These results indicate the relationship of progesterone exposure longer plus the administration of GnRH during the release of progesterone device is an alternative to increase the rate of oocyte fertilization when insemination time is still used AI twice at 36 hours and 42 hours after the release of the progesterone device.

The results showed no significant differences where the injection of PGF2α and eCG of the 12nd all of The Tail fat ewes strain Sapudi Islands showed real estrus. This event allows the ovaries to give the opportunity to develop PGF2α stimulus on day 12 after removed sponge and eCG grow follicles in the follicular phase. After AI on the 14th day all of them in group T0, T1 and T2 showed positive pregnancies of 80% (8 tail) in control groups, T1 70% (7 tails) and T2 70% (7 tails) in treatments groups. The uterus, and the fetus, have been described (Amrozi and Setiawan, 2011). Pregnancy diagnosis using USG on day 24 after AI or day 48 shows embryo images with hyper ecocgetic type Transrectal ultrasonography real-time B-mode shows embryonic vesicles early on the 12th day after marriage, but sensitivity is very low (12%) and higher on the 25th day after the marriage. Transcutaneous ultrasonography achieves the greatest accuracy for pregnancy diagnosis (94-100%) and determination of the number of fetuses (92-99%).

Administration of GnRH 24 hours injected after IVS 2 removed does not improve pregnancy rate in estrous synchronization in Tail fat ewes strain Sapudi Islands (p <0.05). Perhaps as a reason why GnRH does not show potentiation of increased number of pregnancies, it appears in the T1 group that the ability of endogenous LH or the ability of eCG can grow follicles based on the ability of the FSH they contain to be able to develop intra-cellular LH growth in the pituitary. In another study, all sheep were planted with progesterone with a combination of 400 IU eCG and 25 ug GnRH 36 hours after removed progesterone, apparently GnRH injection did not affect the efficiency of estrus synchronization progestin with GnRH, 85.1% compared to progestin without GnRH, 90.3% and pregnancy rates after laparoscopic artificial insemination progestins with GnRH, 53.7% compared to progestins without GnRH, 61.3%. Here we dare ourselves that GnRH is less efficient if it turns out that T1 compared to T2 seems to be no significant difference. Another reason that hormones stimulate the release of gonadotropins (GnRH) is a key neuro-peptide that controls the reproductive function of vertebrates, especially in ewe expected to experience spontaneous ovulation, ovarian steroids released by mature ovarian follicles controlling pulsatile patterns of GnRH release from the hypothalamus, in turn, stimulates the preovulatory secretions of the luteinizing hormone (LH) by the anterior pituitary gland.
Intravaginal progestagen sponge in sheep treated with two doses of 100 microgram cloprostenol while releasing progestagen sponge for 14 days. The percentage of sheep that responded to the synchronization treatment with signs of estrous behavior was similar at 72.4%. The use of progestagens resulted in the highest follicular diameter being higher to 5.9 mm, and showed the same fertilization rate of 70.6%. The new technology 50 µg of GnRH (Acegon, Lab. Syva, Leon, Spain), was prepared by mixing 1 mL of Acegon (equivalent to 50 µg of GnRH) with 4 mL of propylene-glycol, protocols based on a short-term intravaginal progesteron treatment and a single subcutaneous dose of GnRH in propylene-glycol at 36 h after progestagen removal induced. 80% of the animals developed estrus in a narrow timing 75%. administration of GnRH in propylene-glycol recommended in the intravaginal progesterone technique. The conception rate of the G14 days of P4 bunch was measurably higher than that of the other bunches (83.3%). 14 days of progesteron norgestomet treatment delivered higher conception rates and a more prominent number of pregnancies at the starting of the breeding season. Protocol for estrus synchronization the norgestomet implants were cut in half using scissors. One half (containing 1.5 mg norgestomet) was implanted subcutaneously in the ear of each ewe. At the time of implant removal, 400 IU of eCG (Folligon; Intervet) and 22.5 µg D-cloprostenol (Preloban; Intervet) were injected intramuscularly into every ewe and AI 0.5 ml semen.

Conclusion

In summary, the effects of model IVS 2 MAP progesterone, eCG, GnRH, and PGf2 on pregnancy of subjected to a short-term synchronization of estrus followed by estrus and pregnancy of the tail fat ewes strain sapudi Islands sign of estrus will be shown on day 14 and served of AI. 35 days late after AI treatment between control a research groups used diagnosis of pregnancies using USG for pregnancies diagnose. The result showed that no different \( p > 0.05 \) between control and treatment groups in estrus and preganatn. Injected of GnRH 24 hours after removed of sponge does not improve estrus or pregnancy rate in ewes.

Sociodemographic Profile of Thyroid Masses: A Cross-Sectional Study

Basumatari Bharati1, Borah Pollov2, Mahanta Putul3, Hazarika Devid4

1Assistant Professor, Department of Radiology, Fakhruddin Ali Ahmed Medical College and Hospital, Barpeta-Jania Rd, Joti Gaon, Assam 781301, 2Associate Professor of Anaesthesia, Jorhat Medical College, Jorhat, Assam, India, 3Professor of Forensic Medicine, 4Assistant Professor of Surgery, Assam Medical College, Dibrugarh, Assam, India

Abstract

Introduction: Thyroid gland is the most superficial endocrine gland of the human body in the region of the neck and is easily accessible to both clinical and radiological examinations. The thyroid masses must be diagnosed and managed as early as possible to avoid any malignancy.

Objectives: To evaluate the socio-demographic profile of patient including age and gender distribution in thyroid lesions.

Materials and Method: This prospective study was a cross-sectional descriptive one, which was conducted over the 50 subjects with thyroid masses. The collected data were subjected to a statistical analysis which was performed using a Statistical Package for the Social Sciences (SPSS) software version 20.0. Descriptive statistical method were computed, and the statistical significance was tested by chi-square test and student’s t-test. A p-value of less than 0.05 was considered statistically significant. Ethical clearance was taken from ethics committee (H).

Results: There was a female preponderance of 70% associated with this disease entity, against its male counterpart as 30%. The male to female ratio is 1:2:33. A maximum number of patients in our study is in the age group of 31-40 years of age, i.e. 40%. Most of the patients (76%) are from a rural area.

Conclusion: Female preponderance of thyroid masses in the age group of 31-40 years was observed and was more in rural areas. The sociodemographic profile is useful for better future planning of the management of thyroid masses.

Keywords: Female preponderance; young age group; rural involvement.
It has been very fascinating and challenging for a clinical radiologist to evaluate the thyroid gland and diagnose the thyroid pathologies.

In a study, out of the 70 patients who had thyroid diseases, the author reported 78.5% females and 21.4% as males. Maximum numbers of patients in the age group of 41-50 years were also reported in the same study, accounting for 35.7% of the cases.

Thyroid nodules are 4 times more common in women than men and their frequency increases with age and low iodine intake. The gender disparity is perhaps explained by the hormonal influences of both estrogen and progesterone, as increasing nodule size and new nodule development have been demonstrated to be related to pregnancy and multiparity. Exposure to ionizing radiation, either during childhood or as occupational exposure, will cause a rate of development of thyroid nodules of 2% per year, reaching a peak incidence in 15 to 25 years.

Clinically thyroid diseases present as painless gradual swelling of the neck. Sonography is only one of several diagnostic methods for use in the evaluation of thyroid diseases. Sonography images determine the morphology, the level extent of the masses and lymphadenopathy at different levels.

There are several sociodemographic factors which may cause the thyroid to become enlarged. A diet deficient in iodine can cause goitre but this is rarely the cause because of the readily available iodine in our diets.

A combination of clinical assessment and radiological examination provides an accurate diagnosis in the wide majority of cases. However, the sociodemographic profile of the cases is also important in managing these cases. This paper aims to evaluate the sociodemographic profile of the thyroid masses.

**Materials and Method**

This study was a cross-sectional descriptive one, which was conducted in the Department of Radiology with the help of the department of pathology at Gauhati Medical College Hospital. A total of 50 subjects were subjected to this research. All the patients were selected from outpatient departments and indoor wards of various departments (mostly from ENT & Surgery department). A thorough clinical examination was done in all the cases and the data were recorded accordingly in predesigned pre-tested proforma.

Finally, the sociodemographic data were subjected to a statistical analysis which was performed using a Statistical Package for the Social Sciences (SPSS) software version 20.0. Descriptive statistical methods were computed, and the statistical significance was tested by chi-square test and student’s t-test. A p-value of less than 0.05 was considered statistically significant. Ethical clearance was taken from ethics committee (H).

**Results**

The present study is an analysis of the sociodemographic profile of subjects having thyroid swelling. Initially, 62 patients of thyroid swelling were taken for study. Out of that, 50 cases were taken for study because other 12 cases the adequate amount of aspirate cannot be obtained.

**Sex distribution pattern:** It is evident from Table 1 and Figure 1 that there was a female preponderance of 70% associated with this disease entity, against its male counterpart 30%. The male to female ratio is 1:2:33.

**Table 1: Sex wise distribution of the cases**

**Discussion**

Evaluation of thyroid pathology is one of the most common problems encountered in day today medical practice and the brunt of its diagnosis is falls on ENT and Head & Neck surgeon. Almost affecting the thyroid like degenerative diseases, hyperthyroidism, thyroiditis, a benign or malignant tumour can present as a circumscribed or diffuse swelling. Moreover, most of the patient are female so we have to take care of proper cosmetic. We should also try to preserve the normal function of thyroid for all cases in the rest of the life postoperatively.

In the present study, there was a preponderance of this disease entity towards female 70% as compared to male counterpart 30%. This can be explained by the increasing demand for iodine in females. Male to female ratio is found 1: 2.5, whereas, in most of the western series, the ratio being reported as 1.1.53. These findings are in agreement with the finding of Mazzaferri EL.8,9,10

In our study, the average age is 38years. In males, the mean age was 39.4years and females 30years. MC Gershengorn et al.13 also reported a mean age of 39in male and 35yrs in females respectively which agree with the current results.

Most of the patient in our study hailed from the rural area and since females outnumbered male and as the majority of female did not have any specific occupation and they are busy with their household work, maybe a factor of higher age incidence.

Ultrasonographic Evaluation of Thyroid Masses with Pathologic Correlation

Basumatari Bharati¹, Hazarika Devid², Mahanta Putul³, Borah Pollov⁴

¹Assistant Professor, Department of Radiology, Fakhruddin Ali Ahmed Medical College and Hospital, Barpeta-Jania Rd, Joti Gaon, Assam 781301, ²Assistant Professor of Surgery, Assam Medical College, Dibrugarh, Assam, India, ³Professor of Forensic Medicine, Assam, India, ⁴Associate Professor of Anaesthesia, Jorhat Medical College, Jorhat, Assam, India

Abstract

Introduction: Thyroid gland is easily accessible to both clinical and radiological examinations. The thyroid masses must be diagnosed and managed as early as possible to rule out malignancy. Thyroid masses are typically found on physical examination or incidentally when other imaging studies are performed.

Objectives: Evaluation of the clinical profile of thyroid masses with ultrasonography (UGC) of the patient having thyroid lesions with pathologic correlation.

Materials and Method: This prospective study was a cross-sectional descriptive one, which was conducted over the 50 subjects with thyroid masses detected on USG, were further evaluated with Fine-needle Aspiration Cytology (FNAC) and Histopathological Examination (HPE). The USG features such as internal composition, echotexture, shape, margins, presence or absence of peripheral halo, calcification and internal vascularity were correlated with the final diagnosis. The collected data were subjected to a statistical analysis which was performed using a Statistical Package for the Social Sciences (SPSS) software version 20.0. Descriptive statistical method were computed, and the statistical significance was tested by chi-square test and student’s t-test. A p-value of less than 0.05 was considered statistically significant. Ethical clearance was taken from ethics committee (H).

Results: In USG diagnosis, goitre is the most common benign lesion in 63% followed by benign cyst 16%. Follicular carcinoma, medullary carcinoma and undifferentiated carcinoma 1 case of each variety was also detected at USG. Cytological examination of 50 cases, 44 (88%) cases revealed benign nature of thyroid swelling and 6 (12%) cases as malignant. The malignant thyroid cases diagnosed clinically and cytologically.

Conclusion: USG and FNAC with HPE are the primary diagnostic modalities a surgeon utilizes to determine the extent of thyroid surgery.

Keywords: Thyroid nodule; FNAC; Thyroid cancer; Molecular markers.

Introduction

The thyroid mass is a common thing. While autopsy data indicate a 50% prevalence of thyroid nodules larger than one centimetre in patients without clinical evidence of thyroid disease, the prevalence of palpable nodules is only 4 to 7%.¹,²

USG is far more sensitive than palpation, as it detects nodules of any size in up to 67% of the general population.³ Thyroid nodules warrant removal when they are large enough to be symptomatic, or if there is a concern for malignancy. The majority of nodules are asymptomatic, and with only 5 to 10% of nodules being malignant, the decision to operate is made on therapeutic or diagnostic grounds.⁴,⁵

Ultrasound imaging studies and cytology from FNAC are the main tools used by the clinician to decide whether surgical excision of a thyroid nodule is warranted. Molecular genetic biomarker analyses are now being used to increase the accuracy of FNAC, and appear to substantially alter the clinical decision-making process as they become more widely available and more thoroughly evaluated.  

Alongside USG, FNAC found to be rapid, simple, safe, and cost-effective diagnostic modality in the investigation of thyroid disease with high sensitivity, specificity, and accuracy. It can be used as an excellent first-line method for investigating the nature of lesion. 

Therefore, in this paper, the USG evaluation of the thyroid masses with pathologic correlation was done.

**Materials and Method**

This study was a cross-sectional descriptive one, which was conducted in the Department of Radiology with the help of the department of pathology at Gauhati Medical College Hospital. A total of 50 subjects were subjected to this research. All the patients were selected from outpatient departments and indoor wards of various departments (mostly from ENT & Surgery department). A thorough clinical examination was done in all the cases and the data were recorded accordingly in predesigned pre-tested proforma.

Initially, a thorough clinical examination was done in all the cases and followed by necessary routine and special investigations were done as when it is necessary. In 62 cases FNAC was done and postoperative histopathology was done. In 12 cases FNAC report was inclusive and so they are excluded from the study. In 50 cases both cytological and histopathological examination was done and the results were correlated and analyzed independently.

For USG, patients were examined in the supine position on the USG table with the neck mildly hyperextended so that the examined can be done thoroughly. When the possible patient is examined with quiet breathing and swallowing suspended. The examination is completed with Colour Doppler study.

After taking the proper history, clinical examination and laboratory investigations, the patient is prepared for USG with a fully extended neck. Hitachi and Seimens Colour Doppler, Linear probe 13MHz is used for USG. Apart from routine blood investigation, X-Ray- A.P. & lateral view of the neck, P.A. View of the chest was done. The clinical diagnosis was done with Cytological examination (FNAC).

Finally, the data were subjected to a statistical analysis which was performed using a Statistical Package for the Social Sciences (SPSS) software version 20.0. Descriptive statistical method were computed, and the statistical significance was tested by chi-square test and student’s t-test. A p-value of less than 0.05 was considered statistically significant. Ethical clearance was taken from ethics committee (H).

**Result**

The present study is an analysis of USG of the thyroid swelling with pathologic correlation. Initially, 62 patients of thyroid swelling were taken for this study. Out of that only 50 cases were selected because the other 12 cases don’t give the adequate amount of aspirate.

**Benign lesion diagnosed by USG:** In USG diagnosis, goitre is the most common benign lesion in 63% followed by benign cyst 16% as shown in Figure 1.

**Malignant tumour diagnosed by USG:** Follicular carcinoma, medullary carcinoma and undifferentiated carcinoma 1 case of each variety were detected at USG.

**Distribution of thyroid lesion in order of frequency of ultrasonography report:** The distribution of thyroid lesion in order of frequency of ultrasonography report is shown in Figure 2.
Benign lesion diagnosed cytologically: Cytological examination of a total of 50 cases revealed benign nature of thyroid swelling in 44 cases (88%) and malignancy in 6 cases (12%). Among the malignant thyroid cases diagnosed clinically and cytologically, 3 cases were referred to B. Barooah Cancer Institute for further management.

Table 1 Various benign lesion diagnosed cytologically

<table>

</tr>
</tbody>
</table>

The cytologically diagnosed benign group contains 54% of colloid goitre, 16% of the benign cyst (hemorrhagic and colloid cyst) and follicular adenoma of 14% of cases. Subacute-thyroiditis and hyperplastic thyroid nodule are 2% each as shown in Table 1.

Criteria for cytological diagnosis of the benign lesion was set as follows:

For Colloid goitre:
1. Abundant colloid.
2. Follicular cell is scanty, microfollicular structure occasionally preserved.
3. Degenerated RBC.
4. Free phagocytes with foamy cytoplasm.

Follicular adenoma:
1. Colloid material is usually scanty.
2. A number of the follicular cell are high and arranged in monolayer. They usually preserved follicular structure.

Subacute-thyroiditis: They usually shows polymorphonuclear leukocyte, necrotic tissue and few follicular cells.
Type of thyroid lesion diagnosed cytologically:
Out of 50 cases, 6 cases are found to be malignant on cytology. Out of the 33% is papillary carcinoma and follicular carcinoma each. And medullary carcinoma and anaplastic carcinoma are 17% each. Criteria for diagnosis malignant lesion cytologically:

Follicular carcinoma:
1. Increase nuclear size.
2. Increase cellularity.
3. Decrease the amount of colloid.
4. Microfollicular structure preserved.

Papillary carcinoma:
1. Increase cellularity.
2. Scanty colloid.
3. A papillary cluster of the cell.
4. Variation of cell size.
5. PSAMMOMA bodies (laminated calcification).
6. Intranuclear cytoplasmic inclusion.

Anaplastic Carcinoma:
1. Cell with either single or multiple nuclei present.
2. Necrotic material, cell debris, inflammatory cells mainly granulocytes present.

Correlation between ultrasonography and cytodiagnosis of different thyroid swelling: Our study shows the fallacy in diagnosing malignant lesion. In benign lesion, its accuracy is quite high as shown in Table 2.

Cytological pitfalls: Among the study of 50 cases false positive was found in one case of follicular adenoma as follicular carcinoma and two cases two papillary carcinomas as follicular adenoma. Our study shows the fallacy in diagnosing malignant lesion.

Discussion

Evaluation of thyroid pathology is one of the most common problems encountered in day today medical practice and the brunt of its diagnosis is falls on ENT and Head & Neck surgeon. Almost affecting the thyroid like degenerative diseases, hyperthyroidism, thyroiditis, a benign or malignant tumour can present as a circumscribed or diffuse swelling. Moreover, most of the patient are female so we have to take care of proper cosmetic. We should also try to preserve the normal function of thyroid for all cases in the rest of the life postoperatively.

Radioactive thyroid imaging focuses attenuation on non-functioning areas, but at least 80% of these are benign. Ultrasound has proved useful in delineating cystic lesion, through up to 10% of which may harbour malignant.

The rate accuracy of the benign lesion was 97% and malignant was 69%. The overall accuracy rate was 92% excluding false-positive and false-negative result. The rate of accuracy documented in the present study is consistent with Marqusee E et al.

Although the number of cases in our study was small the accuracy rate was quite high in comparison to the above studies. Out of 50 cases in 3 (6%) cases, USG was inaccurate, out of these three cases, one case was diagnosed as follicular adenoma as follicular carcinoma and two cases of papillary carcinoma diagnosed as follicular adenoma. Thus the false positive report was 2%and the false-positive was 4%. As reported by in a study false-positive report was 3.3% in our study, we take the small number of cases so false-negative result shows high value. Moreover, in most of the patients, we have taken the aspiration from one site which may not be the proper site of aspiration in cases of a malignant lesion. So if we had taken the aspiration from multiple sites than false-negative rate may be decreased. In our series of study, we have taken the aspiration just after clinical examination and palpation of swelling. With the help of the USG technique, we select the proper site for aspiration in our study one case of follicular adenoma is missed diagnosed as follicular carcinoma. Another two cases of papillary carcinoma were diagnosed as follicular adenoma. It may be because in follicular adenoma also cellularity of the smear increases colloid become scanty and monomorphic mono layered follicular cell are present, which are also the characteristic of papillary carcinoma. Moreover in papillary carcinoma intranuclear cytoplasmic invagination and psammoma bodies is the characteristic finding. In these studies, our aspirated material may not be sufficient enough or maybe not from the proper site to demonstrate the specific cytology.

In the present series clinically we have found 58% of the solid nodule, 16% of cystic and rest of mixed consistency. J Martin Miller et al. he reported 82% solid 11% cystic 7% mixed consistency.

When the result of the USG was compared with cytology it was observed than out of 7 malignant cases were misdiagnosed as a benign lesion. Two cases of papillary carcinoma as follicular adenoma and one case of follicular adenoma as follicular carcinoma. In our study shows 100% accuracy in the diagnosis of the benign cystic lesion which includes benign colloid cyst and benign hemorrhagic cyst.

In our present study, the diagnosis of the benign lesion in colloid goitre was made from the simple pattern of colloid and follicular cells.

Conclusion

The majority of thyroid nodules are benign, but they warrant surgical excision when they are large enough to be symptomatic or if there is a concern for malignancy. Ultrasound is the primary study by which the thyroid gland is imaged. However, some masses with sonographically suspicious warrant cytologic analysis through fine-needle aspiration biopsy to determine the risk of malignancy. USG and FNAC are the primary diagnostic modalities a surgeon utilizes to determine the extent of thyroid surgery.

Effect of Alcohol Consumption Severity on Oral Health Status in Relation to Salivary Parameters, Smoking and Tooth Wear in Baghdad, Iraq

Ali Hadi Fahad¹, Rafeef Ahmed Mohamed², Noor Mohammed Hadi Layedh²

¹Assistant Prof. of Preventive Dentistry, ²Assistant Lecture of Preventive Dentistry, College of Dentistry, University of Kufa

Abstract

Background: Alcohol consumption not only affects the general health yet in addition the dental and gingival health of a person. Heavy drinkers are at high danger of creating dental caries, gingival health alteration and tooth disintegration. This condition brings about change in the salivary gland function. Alcohol abuse with smoking have diverse effects on oral health. This study presented to evaluate the effect of alcohol consumption severity on oral health in relation to salivary parameters, smoking and tooth wear in Baghdad, Iraq.

Materials and Method: One hundred and twenty 35-40 years old men with alcohol consumption selected randomly. Alcohol consumption individuals classified into three groups according to frequency of alcohol consumption: regular drinker (GA), frequent drinker (GB) and occasion drinker (GC). Each group consists of 40 individuals. Gingival (GI), calculus (CI) and dental caries (DMFT) indices were utilized to assess dental and gingival health for all individuals. Parameters of saliva including flow rate and pH assessed immediately. Tooth wear (TW) was estimated according to the presence or absence of dentine. Smoking was recorded directly from individual. The results of present study was dissected utilizing SPSS version 23.

Results: The median is higher in GA than GB and GC with highly significant difference between groups. For PII, median is higher in GC than other groups, but the mean rank is higher in GA than other groups (no significant difference). For both GI and CI, median and mean rank are higher in GA than others with significant difference between them. Salivary flow rate and pH means are higher in GC than other groups with highly significant differences regarding pH. The high percentage of drinker with tooth wear was recorded in GA compared to other groups with significant difference. The median and mean rank are higher in smoking drinker than non-smoking drinkers with highly significant difference.

Conclusion: Dental caries, periodontal diseases, tooth wear and lower salivary pH were more presented in individuals with more frequent alcohol consumption. Alcohol drinking with smoking increase the occurrence of dental caries.

Keywords: Alcohol consumption; Regular drinker; DMFT; Tooth wear.

Introduction

Alcohol drinking may be an expansive haul utilized to any drinking about it that bring about mental or physical wellbeing issues. Problems of alcohol occur as a result of excessive consumption of it that affect not just with individuals, at will their families, groups and culture in general. Utilizing of liquor can influence all
component of body, yet uncommonly influences defense mechanism, liver, heart and nervous responses[1]. Alcohol drinking not only can affect the integrity of the whole body but also can affect the proper oral environment of a person[2,3]. It has been found that drunkards are at high danger of creating dental lesions, gingival impairment and may expose to the risk of oral cancer. Alcohol drinking whether in little or enormous sum can have huge influence on oral environment of a person in light of carelessness and may prompt various oral problems[4].

In long term alcohol drinkers, generally the parotid glands may get enlargement. This issue is called sialadenosis and ordinarily connected with ethanol incitation[5,6]. Unsettling influences in the salivary glands function happened because of sialadenosis. Decrease in the salivary discharge along with decline in buffering limit along with less oral cleanliness may prompt more chance of dental caries and gingival impairment[7]. Other hindering components comprise of utilizing of sugared beverages and cariogenic food and liquor. The acidic idea of mixed drinks along with utilization of sugar rich food bring about creation of acids and cause diminish in salivary pH underneath basic level. Obsoletely, it might cause advancement of dental lesions. Also, liquor misuse may cause expanding in Blood Lead Levels (BLLs) in people and BLLs which is associated with dental lesions[8].

An investigation got more caries activity among drunkards, likewise the heavy drinkers had more number of endodontically filled teeth in correlation non-heavy drinkers. Alcoholic drinkers had an extracted tooth three times more than the non-drinker for comparing ages [9]. Other research also found a positive relation between alcohol abuse and caries activity [10].

Alcohol consumption can prompt periodontal impairment for various reasons involving: gingival tissue aggravation; less oral cleanliness propensities among incessant liquor consumers; improper dietary patterns causing nourishing inadequacies among interminable heavy drinkers causing alteration of defense mechanism to exposing destructive compounds; less salivary discharge from liquor misuse make the microbes and plaque develop on the grounds that they are not eliminated away by salivation; progression of diseases to more serious condition as a result of ignorance of early symptoms of gingival diseases may lead periodontal impairment[11, 12].

An increased risk of developing dental erosion occurs as a result of people addiction to alcohol consumption. This happened because of alcohol use that considered the potential for expanding the debasement rate components and by the immediate and roundabout ethanol impacts [13]. The palatal surfaces of maxillary teeth are the most generally influenced tooth surfaces because of erosion followed by the occlusal surfaces of posterior teeth while the lower teeth and buccal surfaces of the maxillary teeth are least influenced by erosion [14]. It also found that alcohol use in conjunction with smoking cause increasing in the occurrence of dental lesion for individuals. Tobacco and alcohol consumptions cause changes in oral microorganisms that may assume a basic part in the development and exaggeration of dental lesion [15].

To the extent, no Iraqi investigation was led among individuals with alcohol consumption in Baghdad concerning the link between severity of alcohol consumption and dental caries, gingival diseases in relation to salivary parameters, smoking, and tooth wear. For all these clarification, this research was planned.

Materials and Method

One hundred and twenty 35-40 years old males with alcohol consumption from Baghdad City were included in this study. Individuals were selected randomly by making a special free offer at 4 alcohol stores (2 on the side of Karkh and 2 on the side of Al-Rusafa). This free offer includes doing a prophylaxis for an examination and a saliva sample collection which done in the private dental clinic last four months. Alcohol consumption individuals classified into three groups according to frequency of alcohol consumption [16]:

1. Regular drinker (GA) (More than four a week), 2. Frequent drinker (GB) (One to four days a week) and 3. Occasion drinker (GC) (Less than three days a week) Each group consists of 40 males. Gingival aggravation evaluated by utilizing gingival list (GI) of Löe and Silness[17]. Oral cleanliness status assessed by using Ramfjord calculus index (CI)[18], and plaque index (PlI) from claiming Silness and Löe[19]. Caries experience for each drinkers recorded according to WHO criterion utilizing DMFT index[20]. To assess salivary parameters, every person was approached to plunk down and loosen up much as could be expected under the circumstances and solicited to chew a piece from
Arabic gum for one minute before expectoration; for ten minutes, chewing was proceeded with a similar bit of gum and the assortment of salivation by spitting was finished within this time [21]. By dividing the absolute volume of saliva gathered in milliliter on the time of assortment in minute, flow rate of saliva was estimated. pH of saliva recorded by utilizing electronic pH meter.

According to the absence and present of dentine, tooth wear (TW) recorded was essentially dichotomized depending on the criterion of Bardsley et al[22].

Selected parameters were analyzed by utilizing SPSS 23 version (Statistical Package for Social Sciences).

**Results**

Table 1 illustrates the median and mean rank values of DMFT index among drinkers groups with statistical significance. The median and mean rank are higher in GA than GB and GC with highly significant difference between groups (Kruskal Wallis value = 10.000, p-value = 0.007). Mann-Whitney test for DMFT index shows highly significant difference between GA and GC (Mann-Whitney value = 487.000, Z = -3.050, p-value = 0.002), and significant difference between GB and GC (Mann-Whitney value = 579.500, Z = -2.150, p-value = 0.032), while no significant difference between GA and GB.

Median and mean rank of PII, GI and CI among drinker groups are demonstrated in Table 2. For PII, median is higher in GC (1.73) than other groups, but the mean rank is higher in GA (69.03) than other groups (no significant difference). For both GI and CI, median (1.71, 1.67 respectively) and mean rank (74.74, 72.39) are higher in GA than others with significant difference between them (Kruskal Wallis value = 11.214, 8.087, p-value = 0.004, 0.018 respectively). Mann-Whitney test for GI and CI record significant difference between (GA and GB), also between (GA and GC), while no significant difference between GB and GC.

Table 3 records mean values of stimulated salivary flow rate and pH among drinker groups with statistical differences. A higher value of SFR was found among GC (1.55 ml/min) compared to other groups with no significant differences between them, but t-test shows significant difference between GA and GC (p-value = 0.017, t-value = -2.438, df = 78). For salivary pH, also mean is higher in GC (6.66) than other groups with highly significant differences (p-value = 0.002, F-value = 2.903, df = 2). Using t-test highly significant difference was concluded between GA and GC (p-value = 0.001, t-value = -3.455, df = 78), also significant difference was recorded between GB and GC (p-value = 0.020, t-value = -2.369, df = 78).

The distribution of drinkers with tooth wear among drinker groups with statistical difference is presented in Table 4. The high percentage of drinker with tooth wear was recorded in GA (42.5%) compared to other groups with significant difference (p-value = 0.039, $\chi^2 = 6.48$, df = 2).

Table 5 shows the distribution of smoking drinkers among drinker groups with statistical difference. The high percentage of smoking drinker was shown in GA (42.5%) with no significant difference between drinker groups.

Table 6 concludes median and mean rank of DMFT index among smoking and non-smoking drinkers with statistical significant. The median (13) and mean rank (65.88) are higher in smoking drinker than non-smoking drinkers with highly significant difference (Mann-Whitney value = 550.500, Z = -3.626, p-value < 0.001).

Discussions

The problems of severe alcoholism have been linked with alteration in oral tissues and neglecting of oral health. Many researches recorded the association between alcohol drinking and oral health \[23, 24, 25].

This study showed that dental caries experience was higher in regular drinker than other groups. The amount of alcohol taken and prevalence of dental caries are associated positively. This finding is agreed with many studies\[11, 26, 27, 28, 29\]. Alcohol drinkers are known to have bad oral hygiene. It was found that alcohol user had incorrect personal and professional health care and also had dry mouth at night. Also, the consumption of high amount of refined carbohydrates may be the cause for high caries experience noted among them \[27\].

Periodontal disease represent many problems that can be ranged from simple inflammation of the gingiva to more serious one. Usually, it started in the mouth with bacterial growth along with building of plaque on the gingiva. This can be lead to inflammation or even a severe infection. Some kinds of gingival disease may be also become worse by alcohol consumption. It has been found in this study that mean rank of PII, GI, CI are higher in GA group than others and this is may be due to irritation to the gingival tissue. This result is in line with many studies\[11, 12, 13, 30, 31\]. Also, the individuals who are involved in alcohol user tend to have a bad dental hygiene habits. This result in making them more susceptible to such problems. The alcoholics persons tend to eat poorly, and this may cause nutritional deficiencies leading to all kinds of a disease to happen. Deficiencies in the diet can also make lowering in effectiveness of the immune response and so increasing the developing of gingiva disease. The persons who drink alcohol will often display the early symptoms of gingival disease which mean that easily treatable case of gingivitis will be progressed to a more serious one that involved permanent damage to the gums and teeth. In general, a poor oral health and bad dental care were associated with the periodontal problems in alcohol abusers \[32\].

It has been found in this study that the salivary flow rate is higher in GC group than other groups and this result agree with other studies \[33, 34\]. The reason for these results that the parotid gland become more swollen with excessive drinking (sialadenitis) that lead to alteration in the excretion and metabolism of the salivary glands \[35\].

The current study concludes, the high percentage of drinker with tooth wear was recorded in GA compared to other groups and this result similar to some studies \[13, 28, 29\]. The prolonged and regular abuse of acidic drinks as alcohol making the oral cavity more acidic in nature. This acidification result in dissolving the enamel surface and will make teeth surfaces more susceptible to a mechanical damage as tooth-brushing. Frequent vomiting occurs as a lowering in esophageal sphincter relaxes under the effect of alcohol. Enamel erosion occurred as a result of entering the acidic content of the stomach to the mouth (vomiting). This acidification along with reduction in salivary secretion and reduction in buffering capacity lead to raising the risk of enamel erosion \[13, 36\].

It has been recorded that smoking and alcohol consumption make adverse effects on individual as a general and oral health. In this study, the higher percentage of smoking was found among the GA group. The mean rank and median of DMFT are higher in smoking drinker than non-smoking drinkers with highly significant difference. There is a positive association smoking and alcohol abuse \[37, 38\]. Several mechanisms may lead to the relation between smoking and alcohol drinking, involving the genes which include in a regulating neurotransmitters, cross-sensitization and cross-tolerance, and common psychological and social factors \[39, 40\]. The high DMFT founded among smokers with alcohol abuse reflects the physical improper of oral hygiene measures and variation in oral micro-flora \[15\].

Effects of Stress, Depression, Self-efficacy, and Social Support on Quality of Life of Community Dwelling Elderly with Chronic Diseases

Hee Kyung Kim

Professor, Department of Nursing, Kongju National University, Gongju, Republic of Korea

Abstract

Background/Objectives: The purpose of this study was to analyze factors having effects on the quality of life of elderly with chronic diseases.

Method/Statistical Analysis: This study targeted 113 subjects in their 60 or up, residing in M city, D metropolitan city, C city, and G city. The data were analyzed using the descriptive statistics, t-test, ANOVA, Pearson’s correlation coefficient and stepwise multiple regression using the SPSS Window 23.0 program.

Findings: The stress (r=-.54, p<.001), and the depression and quality of life (r=-.62, p<.001) of subjects showed negative correlations while the self-efficacy (r=.68, p<.001), and the social support and quality of life (r=.69, p<.001) showed positive correlations. The self-efficacy (β=.39), social support (β=.39), the number of diseases (β=.14), depression (β=-.18) and age (β=.13) had effects on the quality of life of subjects, which showed 68.0% explanatory power.

Improvements/Applications: It would be necessary to increase self-efficacy that is confidence in their abilities, and to encourage and support elderly. In order not to get exposed to more diseases in the current state, it would be needed to seek for the measures for supporting, daily life management, and use of medication, decreasing depression, and giving a boost to live younger even when getting aged.

Keywords: Chronic disease, Elderly, Social support, Depression, Self-efficacy, Quality of life.

Introduction

Due to the rapid aging in Korea, the aged in their 65 or up which was 14.9% in 2019 is estimated to be increasing to 46.5% in 2067. The change rate of medical expenses under health insurance for the aged in their 65 or up in 2018 was 14.7%, which was 2.8% higher than the whole change rate (11.9%). The elderly evaluate their own health status as average or pretty bad, and more and more of them regard their health status as bad as they get older[1], so that there should be efforts in health care of the elderly.

Meanwhile, as a subjective well-being that evaluates the multi-dimensional elements of physical, functional, emotional, and social well-being, and also implies the concept of happy, satisfactory, and positive emotion and spirit, the quality of life expresses the well-being and satisfaction of life[2]. Especially, in the results reviewing the preceding researches related to the quality of life of the elderly, the elderly with chronic diseases had the lower quality of life than the elderly without chronic diseases[3], so that there should be more researches targeting them. They have to live with their chronic diseases for the rest of their lives. And as they get older, the quality of life gets lowered by various physical diseases.
As the factors having effects on the quality of life, the daily stress\cite{4}, the number of chronic diseases, depression, social support as social networks\cite{5}, and self-efficacy were presented. Once the social support was provided with the mediation of self-efficacy, the quality of life of the elderly got improved\cite{3}. Thus, when the degree of daily stress and depression was higher, the quality of life tended to be lowered, which showed the inverse correlations between stress and quality of life, and between depression and quality of life\cite{4,6}. When the self-efficacy is higher, the quality of life gets increased, so that it would be necessary to increase the self-efficacy. And it has been reported that the quality of life is high when the elderly perceive the receipt of social support\cite{3}. However, there are not many researches comprehensively reviewing such factors.

The purpose of this study is to establish the basic data for the development of nursing intervention necessary for improving the quality of life through the maintenance/enhancement of health of the elderly with chronic diseases, by analyzing the relations of those variables, and revealing the influence factors on the quality of life.

METHOD

1. **Subjects:** The subjects of this study are the elderly in their 60 or up with chronic diseases, actively working in religious institution and senior citizens center while residing in D metropolitan city, M, C, and G city. To verify the fitness of the sample size, the G*Power 3.1.9.4 program was used and a significance level of .05, effect size of .15, verification power of .80 and 11 predictive factors were applied to the regression analysis to acquire the final number of 111 subjects. Total 113 copies were used for the final analysis.

2. **Instruments:**

2.1. **Stress:** This study used the BEPSI-K which was modified/complemented by Lim, et al\cite{7}. Total 12 items are based on the 4-point Likert scale. The higher score means the higher degree of stress. When the tool was developed, the reliability was Cronbach’s $\alpha=.85$, which was .83 in this study.

2.2. **Depression:** This study used the Short Form Geriatric Depression Scale with 15 items, which was standardized into Korean-version short form geriatric depression scale by Kee\cite{8}. This tool has total 15 items based on the two-point scale like 0 or 1 point. The higher score means the higher degree of depression. When the tool was developed, the reliability was Cronbach’s $\alpha=.84$, which was .83 in this study.

2.3. **Self-efficacy:** This study used the general self-efficacy scale developed by Chen, Gully, & Eden\cite{9}, which was adapted by Noh\cite{10}. This tool has total eight items based on the 5-point Likert scale. The higher score means the higher degree of self-efficacy. In the research by Noh, the reliability was Cronbach’s $\alpha=.83$, which was .96 in this study.

2.4. **Social support:** This study used the scale used by Kim\cite{11} by modifying/complementing the MSPSS (Multi-dimensional Scale of Perceived Social Support). This tool has total 12 items based on the 5-point Likert scale. The higher score means the higher degree of social support. When the tool was developed, the reliability was Cronbach’s $\alpha=.90$, which was .94 in this study.

2.5. **Quality of life:** This study used the Korean-version WHO Quality of Life Short Form Scale developed by Min et al\cite{12}, which was modified/complemented by Shin\cite{13}. This tool has total 26 items based on the 5-point Likert. The higher score means the higher degree of the quality of life. In the research by Min et al, the reliability of this tool was .90, which was .94 in this study.

3. **Data collection & Ethical consideration:** Approval was acquired by the ethics committee of K University (KNU_IRB_2020_24). After explaining the research purpose and contents to the presidents of religious institutions and senior citizens centers in D metropolitan city, M, C, and G city, and then receiving their permission, the researcher and the trained research assistant explained the research purpose and how to fill out the questionnaire to elderly people, and then received the written consents. We collected data by reading the questions in the questionnaire to help them to complete the questionnaire. It took about 20-25 minutes to fill out the questionnaire.

Data Analysis: Using the SPSS 23.0 program, this study used the descriptive statistics like percentage for the general characteristics and the degree of variables, the t-test and ANOVA for comparing the quality of life of subjects according to the general characteristics, and the Scheffe test for post-test. This study also used Pearson correlational coefficients for the relations of variables,
and the stepwise multiple regression for analyzing the factors having effects on the quality of life.

**Results**

1. **General characteristics of subjects:** There were total 113 elderly people with chronic diseases, and they were suffering from various types of diseases such as hypertension, diabetes, heart diseases, joint diseases, respiratory diseases, nervous diseases, thyroid gland diseases, cerebral diseases, and hearing disorder. Subjects’ age was from 60 to 91, and the mean age was 72.01±7.65. The female elderly were more than the majority (n=80, 70.8%). The case of cohabiting with spouse was more than the majority (n=68, 60.7%). The graduation from middle school or higher was more than the majority (n=74, 66.1%). The number of mean diseases of subjects was 2.77±1.21. The case of having two diseases was 39.4% while the case of having three diseases was shown in 27 subjects (24.8%). Most of the cases responded to their health status as pretty good or average (n=91, 81.3%). The case of exercising regularly or sometimes was more than the majority (n=75, 66.4%). In case of doing exercise, total 18 subjects (25.4%) mostly walked everyday, and 21 subjects (30.4%) exercised for about 60 minutes each time. The exercise hours were evenly distributed from ten minutes to 120 minutes. The case of responding to their economic status as average was more than the majority (n=63, 55.8%).

2. **Degree of stress, depression, self-efficacy, social support, and quality of life of subjects:** The subjects’ stress scored 2.19 point out of 4 points, depression scored 0.37 point of 1 point, self-efficacy scored 3.03 point out of 5 points, social supports scored 3.54 point of 5 points, and quality of life scored 3.22 point out of 5 points [Table 1].

3. **Differences in the quality of life according to the general characteristics:** There were differences in the quality of life in the statistically-significant level according to the age (F=3.92, p=.023), relationship with spouse (t=4.17, p<.001), the number of diseases (F=8.82, p<.001), occupation (t=2.61, p=.010), health status (t=4.08, p<.001), exercise (t=4.14, p<.001), and economic level (F=11.34, p<.001).

4. **Correlations of stress, depression, self-efficacy, social support, and quality of life in subjects:** The stress (r=-.54, p<.001), the depression and quality of life (r=-.62, p<.001) of subjects showed such negative correlations while the self-efficacy (r=.68, p<.001), the social support and quality of life (r=.69, p<.001) showed such positive correlations [Table 2].

5. **Factors having effects on the quality of life in subjects:** To understand the factors having effects on the quality of life of subjects, this study conducted the multiple regression analysis by performing the dummy treatment on the age, spouse, number of diseases, occupation, health status, exercise, and economic status that showed the significant results in the general characteristics, and also the independent variables. Regarding the issue of multicollinearity expected in case when conducting...
In the multiple regression analysis, the tolerance limit was \(0.550-0.933\), which was higher than 0.1. The Variance Inflation Factors (VIF) were \(1.071-1.819\), which was not higher than the standard as 10, so that there was no problem with the multicollinearity. Also, the Durbin-Watson value was 2.068, so that there was no problem of autocorrelation.

In the results of analysis, the self-efficacy \((\beta=0.39)\), social support \((\beta=0.39)\), the number of diseases \((\beta=0.14)\), depression \((\beta=-0.18)\) and age \((\beta=0.13)\) had great effects on the quality of life of subjects, which showed \(68.0\%\) explanatory power [Table 3].

## Discussion

In the results of this study, the subjects showed the inverse correlations between stress, depression and quality of life while showing the positive correlations between self-efficacy, and social support and quality of life. Such results accord with the results\(^5\) showing that the quality of life related to health of subjects had positive correlations with self-efficacy and social support. The daily stress and quality of life of the elderly in long-term care facilities had a negative correlation\(^4\), and the depression of female elderly at home showed the inverse correlation with the quality of life\(^6\). When the stress and depression of the elderly get higher, the quality of life could get lowered. And the social support of the elderly with disaster damage showed the positive correlation with the quality of life while the depression showed the inverse correlation with the quality of life\(^14\). With the mediation of resilience of the elderly, stress showed the indirect effects and partially-mediating effects on the quality of life. Therefore, it would be necessary to develop and vitalize the community health enhancement program. This study recommends to conduct a further research by adding a variable of self-efficacy with a meaning similar to resilience.

Also, the self-efficacy, social support, the number of diseases, depression, and age of subjects were the variables having effects on the quality of life, which showed 68.0% explanatory power. This was similar to the results\(^5\) of a study reporting that the age and self-efficacy had effects on the quality of life, and the social support had effects on the quality of life related to health with the mediation of self-efficacy. By considering Korean culture regarding family as important, this is similar to the results\(^13\) reporting that the family support had effects on the quality of life of the elderly. Thus, the social support from others might have very important effects on the quality of life. The effects of depression on the quality of life would be different depending on the level of social support\(^14\). It would be necessary to apply the nursing intervention for improving the quality of life to the self-efficacy programs, and it would be also helpful to provide the programs related to social support. The subjects are the elderly with one or more chronic diseases. Considering that the health status gets poorer when the age is higher, it would be needed to establish the support programs providing helps from family and experts, by increasing the self-care ability related to chronic diseases. The results were similar to the results\(^6\) of a study reporting that the depression of the female elderly at home had negative effects on the quality of life with the mediation of daily activities. It would be
necessary to seek for the measures for lowering the depression by researching the progress of diseases when the age gets higher.

The local governments and healthcare specialists should vitalize the volunteer activity programs targeting the elderly with chronic diseases in community, and also operate the physical/psychological healthcare programs for the elderly in which the residents could actively participate.

Conclusions

To improve the quality of life of the elderly with chronic diseases in daily life, it would be necessary to increase the self-efficacy which is confidence in abilities and also to encourage and support them all the time. Also, in order not to get exposed to more diseases in the current state, it would be needed to seek for the measures for educating and supporting in relation to disease control like medical check-up, daily life management, and use of medication, decreasing the feeling of depression, and giving a boost to live younger even when getting aged. This requires not only the efforts from the elderly, but also the active development and operation of programs by their families and experts. This study suggests a further research for revealing much more factors.

Abstract

In this study, Class 1 Integron co-associated with some antibiotics resistant bacteria was investigated from different spots on Izmir bay of Aegean sea as a first report about analysis and track of influences human and animal wastes on water environment in a period between July 2019 – January 2020.

Our results showed variations in Neomycin and Ciprofloxacin resistance bacteria, Neomycin resistance bacteria was detected in 100% of all sampling points ranged from 4.2×10^2 in (BOS) samples to 1.98×10^3 revealing wide distribution of Neomycin resistance bacteria in different spots on Izmir bay receiving sewage water.

Ciprofloxacin resistance bacteria founded in 25% of collected samples it was only founded in (BS) sampling point, Class 1 integron investigation, showed wide range distribution during sampling campaign among different sampling points, the main results showed that 75% of samples was positive to class 1 integron presence, it was founded in Balçova Ilica (BS), Melez (MS), Bornova (BOS) points with no appear in the fourth point Bostanli streams (BTS).

During the investigations we noticed that Class 1 integron elements was associated 100% with Neomycin resistance bacteria in four sampling points (BS, MS, BOS & BTS) while showed weak association with Ciprofloxacin resistant bacteria.

Keywords: Neomycin resistance bacteria, Class 1 integron, Izmir bay.

Introduction

Integrons, especially class 1 integron is a platform that allow capturing, storage, cleavage and re-arrangement of many genes in the same frame calling gene cassettes,Class 1 integron {intI1} possess genes encodes for producing of integrase factor. This element considers one of the most critical transportable genetic elements due to its role in the spreading of antibiotic resistance genes (ARGs) through horizontal gene transfer (HGT) between bacterial communities, facilitating their transfer into a wide range of pathogenic bacteria and carry antibiotic resistance genes from one bacteria to another bacterial cells imposing risks to public health(1-3).

Although Integrons similar to plasmids and transposons as a HGT element but different from theme by capability of capturing gene forming resistance gene cassettes incorporated into integron frame then enables
integrons to mobilizing across different microbial species making it to be predominantly associated with multi drug resistance-MDR gram-negative bacteria, also sometimes embedded in promiscuous transposons and plasmids(4-6).

Generally, class 1 integron composed of three main parts: an (intI1) gene encodes for integrase enzyme which enabling this platform to capture and expression of exogenous genes into second part (attI) called recombination site forming gene cassettes, third part is a promoter (P_C) catalyze inserted genes expression. (7-8)

There are many researchers reported that Class 1 integron exists in different environments with considerable sequence diversity Gillings et al. 2008b also previously reported to be the most abundant intI in Wastewater treatment plants without completely elimination by different treatment processes. In addition, investigated in Chicken Meat (9), ready-to-eat foods in China (10), Clinical isolates (11-12), prevalence in pigs and pork (13), founded in about of 81% of Escherichia coli isolates from waterfowls in China (14), recovered among fruits and vegetables (15) also detected in guts of Salmo salar fish farms (16) all these reports reveal the size of this element distribution.

The most interested point of class 1 integron is linking of this element not only with antibiotics resistance, also associated with heavy metals resistance genes making it responsible for disseminating of resistance from pathogenic microbes to environmental non-resistance microbes and spreading from its common origin gram-negative bacteria into gram-positive bacteria species(1-2; 7).

intI1 gene has a specificity to be a generic marker of anthropogenic produced pollution including high abundance in domestic animals and human’s bacteria, a consequently high representation in streams, based on these, many researchers have used of intI1 analysis to track animal & human influence on water environment(7).

Understanding the presence, origin and fate of these elements is important for the practical control of antibiotic resistance and for exploring how lateral gene transfer can seriously impact by human activities, also the association of this mobile gene element MGE with ARB can accelerate the dissemination of ARGs through HGT in the water environment making the problem of antibiotics resistance more sever(17).

However, due to limited data are available on the class 1 integron distribution and its association Ciprofloxacin-Neomycin Resistant bacteria in entire Turkey and no previous investigations about prevalence of class 1 integrons in Izmir bay therefore, we started screening this element presence to determine the range of distribution from sewage water to Izmir bay and recording a first documentation to serve in future works regarding to antibiotic-resistant bacteria (ARB) and ARGs associated with class 1 integron.

Material and Method

Study area and Samples processing: Izmir Bay (also Smyrna golf) is located on Aegean Sea in Izmir city between 38° 18’ 00’ - 38° 43’ 00” latitudes and 26° 23’ 00’ – 27° 11’ 00” longitudes. Its length 64 km by 32 km in breath. About 20 streams flowing into the inner part of the Izmir Bay. Samples collected from Balçova Ilica (BS), Melez (MS), Bornova (BOS) and Bostanli streams (BTS) as marked in figure(2-A, B, C, D).

Grab sampling method applied for collecting of samples in a period between July 2019 – March 2020 water samples were brought to the laboratory in a freezer in glass container and stored in the refrigerator at + 4°C for further investigations.

Antibiotics resistant bacteria (ARB) counting: Bacterial counting was performed to test phenotypic resistance of both Neomycin and Ciprofloxacin resistance. R2A agar + interested antibiotic solution and plate pouring method was applied to perform this step following standard protocol of Clinical and Laboratory Standard Institute - CLSI instructions(18-19).

Antibiotic solutions were Neomycin:10 μg and ciprofloxacin:5 μg. Both of them were sterilized by 0.22 μM Millipore filters and added to R2A agar before pouring.

DNA extraction and manipulation: Total DNA was extracted directly from water samples using commercial Kit (NorGenbiotek™ Canada) following the manufacturer’s instructions. All DNA extracts were checked for its quality on 1 % of gel electrophorese and Nanodrop™.

Primers & PCR reaction: The occurrences of class 1 integron in the water samples were first determined using convenient PCR, the PCR running conditions is presented in Table 1. Specific primers were ordered
from Genaid™, all primers were analyzed by BLAST program, these quences and other details of the primers showed in Table 2.

PCR program was done as following steps: initial (ID) at 94°C for 3 min, followed by 30 cycles of denaturing (D) at 94°C for 30 s, annealing (ANN) was 64°C for 1 min, and elongating (EL) at 72°C for 90 s, final elongation was at 72°C for 5 min. All PCR products were run on the agarose gel electrophoresis again to see int1 bands. detection and characterization of class 1 integron was performed as described previously by (20-21).
A: Balçova Ilica stream, B: Melez stream, C: Bornova stream, D: Bostanlı streams.

Results and Discussion

The presence of Neomycin and ciprofloxacin resistance bacteria with class 1 integron consider strong relationship for anthropogenic effects of antibiotic resistance bacteria on water environment especially natural water resource like our sampling spot in Izmir bay that receive sewage water contain different antibiotic resistance bacteria and transposable elements like class 1 integron.

As well as using of Neomycin in clinical it’s also used in veterinary field for the treatment of diseases in sheep, cattle, goats and swine, so, the presence of this antibiotic associated with class 1 integron consider marker for pollution of sewage water with animal related waste which increase the impact on normal flora of sea water. The same issue with Ciprofloxacin, a fluoroquinolone antibiotic used in clinical and animal like dogs and cats for control diseases, even its isolated from poultry products(24) may play a role as marker of...
pollution by animal products wastes that may discarded into some sewage that finally flowed into sea water by streams.

Our results showed variations in Neomycin and Ciprofloxacin resistance bacteria, Neomycin resistance bacteria was detected in 100% of all sampling points ranged from $4.2 \times 10^2$ in (BOS) samples to $1.98 \times 10^8$ revealing wide distribution of Neomycin resistance bacteria in different spots on Izmir bay receiving sewage water.

Ciprofloxacin resistance bacteria founded in 25% of collected samples it was only founded in (BS) sampling point; this result is much lower than neomycin resistance bacteria in our work area may be due to using of Neomycin more than ciprofloxacin especially in veterinary uses.

In other work by(25) reported that all strains, except SI40 strain were resistant to Neomycin and other tested antibiotics for samples isolated from chicken broils.

As we explained until now there is no previous works on the same antibiotics resistance to make a compression but there are some works related to the same antibiotics in other project(24) founded that among all isolates tested 91.4% were phenotypically resistant to ciprofloxacin(26) Kuang et al. 2018 reported that about 2.23% of water samples was resistant to ciprofloxacin while no resistance record for isolates investigated by Abbasoglu and akcelik in the same work discussed above.

The resistance to Ciprofloxacin (fluoroquinolones) is mainly related to amino acids substitutions in the quinolone resistance determining region - QRDR in ciprofloxacin resistance gene (27) this case confirmed by(28) when they observed amino acid change that lead to ciprofloxacin resistance.

Regarding to genotypic resistance characterization our results not matched with Neomycin and Ciprofloxacin appeared phenotypic resistance this may due to inhibitors founded in sewage water samples.

Class 1 integron investigation, showed wide range distribution during sampling campaign among different sampling points, the main results showed that 75% of samples was positive to class 1 integron presence, it was founded in Balçova Illica (BS), Melez (MS), Bornova (BOS) points with no appear in the fourth point Bostanli streams (BST) figure(3), these points may adjacency with some animal farms and mini livestock breeding houses that may discharge their waste to these streams, especially results not appeared at fourth sampling point (BST) for all sampling campaign.

During the investigations we noticed that Class 1 integron elements was associated 100% with Neomycin resistance bacteria in four sampling points (BS, MS, BOS & BTS) while showed weak association with Ciprofloxacin resistant bacteria.

![Fig. (3): PCR amplification products image on 1.5 % agarose gel electrophoresis for class 1 integron using specific primer for different sampling spots, M; DNA ladder (100 bp), BS: Balçova Illica stream, MS: Melez stream, BOS Bornova stream (900-923 bp) prospectively.](image_url)
The relationship of class 1 integron with Neomycin–Ciprofloxacin resistant bacteria and other antibiotics resistance discussed in many previous reports. (29) Li et al 2013 observed strong relationship of Class 1 integron and resistance to a variety of drugs like ciprofloxacin (both phenotypes and genotypic). among 176 isolates of Klepsiella pneumoniae class 1 integron positive isolates exhibited resistance to number of drugs as much as higher than those negative isolates that miss to integron also the extensively drug resistant isolates and including those located outside and within of frame was significantly higher among class 1 integron positive isolates.

The worst point of association between integron and antibiotic resistance is persistence in the polluted water even after treatment, (30) Wang et al 2019 demonstrated that the wastewater treatment systems could not completely able to remove the antibiotic resistance genes that associated with mobile genetic material like integrons, as a results probably be transferred into human forming great threats on public health.

Conclusion

The increasing amount of antibiotics using in clinical and veterinary field consider the basic reason for dissemination of antibiotics resistance, the worst point of this problem when disseminate by mobile genetic elements harbor many resistance genes cassette like class 1 integron.

The expanding of articles submissions concerned with class 1 integrons genes indicates that this situation is evolving and poses a potential clinical problem that could get more complex to be solved in advance.

In conclusion this study represents the first report showing screening of integron associated with some antibiotics resistance in Izmir bay, the investigations showed that the variations of Neomycin and Ciprofloxacin resistance bacteria, revealing wide distribution of Neomycin resistance bacteria in different spots on Izmir bay receiving sewage water.

Ciprofloxacin resistance bacteria was only founded in (BS) sampling point; this result is much lower thane neomycin resistance bacteria in our work area may be due to using of Neomycin more thane ciprofloxacin especially in veterinary uses.

wide range distribution of Class 1 integron in Balçova Ilica (BS), Melez (MS), Bornova (BOS) pointsmay adjacency with some animal farms and mini livestock breeding houses that may discharge their waste to these streams, especially results not appeared at fourth sampling point (BST) for all sampling campaign.

Finally, tested parameters may be changed with different seasons or in case establishment of waste water treatment systems before discharged into this bay.

The Effectiveness Meaning of Life and Antiretroviral Therapy (Metart) Modul to Improve Antire to Viral Therapy Adherence among Newly Diagnosed HIV/AIDS: Pre Intervention Survey

Yafi Sabila Rosyad1, Firmina Theresia Kora2, Rika Monika3, Salis Miftahul Khoeriyah4, I. PutuJuni Andika5

1Asist. Prof., Dept. of Mental Health in Nursing, STIKes Yogyakarta, Indonesia, Rosyad, 2Asist. Prof. Dept of Basic Science and Fundamental of Nursing, STIKes Yogyakata, Indonesia, 3Dept. of Community in Nursing, STIKes Yogyakarta, Indonesia, 4Dept. of Pediatric in Nursing, STIKes Yogyakarta, Indonesia, 5Dept. of Basic Science and Fundamental of Nursing, STIKes Yogyakata, Indonesia

Abstract

Adherence to ART is the primary determinant of viral suppression. Adherence of at least 95% is needed for optimal suppression. One of relationship with HAART is meaning in life. This study aimed at assessment meaning in life and adherence antiretroviral therapy before intervention about METART book.

This method use descriptive statistic analysis to explain social demographic, meaning in life, and adherence antiretroviral therapy.

The Result: Characteristics gender people new living with HIV/AIDS this study is 75.6% is Male with 38.5% homosexual. The age range of respondents is in the adult (65.4%). Single merital status is 74.4%. The total respondent with ARV medication is 30.8% under one year. 74.4% has meaningful life but 65.4% respondent has lack adherence ARV.

Conclusion: This research get data pre intervention METART modul about demographic, meaning in life, and adherence ARV.

Keywords: Adherence ART, meaning of life, HIV/AIDS.

Introduction

Adherence to ART is the primary determinant of viral suppression and the risk of transmission it decreases the viral replication and viral load which in turn preserves the CD4 level, decreases the progress of AIDS, and reduces deaths(1). Adherence of at least 95% is needed for optimal suppression(2,3). Antiretroviral therapy has an impressive clinical effect in that WHO has a target that 90% of People Living with HIV/AIDS (PLWHA) already underwent ART by 2016, but the target realization is only 53%. From year to year, PLWHA who undergo antiretroviral therapy is increasing. In 2016, there are 19.5 million or about 53% of the total number of PLWHA, and in mid-June 2017 the number has progressed to 20.9 million or about 56.9% of the total number of PLWHA(3,4). Although adherence is important to the outcomes of therapy(5).

Out of 231 respondents in Nepal, 87.4% (95% CI: 83.2–91.6%) of them had an optimal adherence level and 12.6% of the respondents had an adherence level less than the opti-mal within the last month. i.e. 87.4% of the respondents’ attained 95% adherence to...
prescribed ART regimen\(^3\). Results of the evaluation of adherence to ART in Brazil using CEAT-VIH indicated that 50% (109/220) of the patients presented good adherence, 36% (79/220) presented strict adherence, and 14% (32/220) presented low adherence\(^6\). Based on the results research in Iran, 30.4% (65) of patients were non-adherent and 69.6% (149) showed good adherence to their medication protocols. The most important reason for discontinuation of medication was the patients’ unknown personal reasons (n=60, 61.2%), from the non-adherence group\(^7\). Many determinant factors to present non-adherence; quality of life, distress psychology, meaning in life, self-efficacy, peer group, economy, health worker, stigma, motivation, gender\(^3,7–11\).

Effect of non-adherence ARV increases mortality and morbidities. HIV/AIDS has effect to biological, psychological, social, and spiritual. Thus, prevention of co-morbidities, improving knowledge through health education. Psychoeducation should be conducted at the initial evaluation to reduce negative beliefs regarding antiretroviral therapy. Assessment of anxiety and depression symptoms should be done throughout therapy as both psychological conditions are associated with patient adherence, success of treatment, and ultimately with patients’ quality of life. This study researcher will be increasing of meaning in life to increasing adherence ARV people living with HIV/AIDS.

**Material and Method**

The study protocol and consent procedures were reviewed and approved by the Institutional Review Boards of Sekolah Tinggi Ilmu Kesehatan Ngudia Husada Madura with number of ethical clearance 709/KEPK/STIKES-NHM-/EC/IX/2020. In accordance with the approved protocol, written informed consent was obtained from all study participants prior to data collection. This study is assessment pre intervention of meaning in life and antiretroviral therapy (METART) to promoting adherence antiretroviral therapy. Researcher use meaning in life questionnaire Indonesian version\(^12\) and Morisky 8-scale\(^13\) to assessment meaning in life and adherence antiretroviral therapy. Data analysis, descriptive statistic\(^14–16\) were used to determine statistical differences in demographic variables (i.e., gender, education, marital status, CD4 status, Viral load status, Sexual orientation), meaning in life and adherence ART.

**Result and Discussion**

**Demographic Characteristics**: A total of 78 PLWHAs were invited to participate in the study. Demographic Characteristics Are gender, sexual orientation, age, education level, marital status, ARV medication, CD4 status, and viral load status (Table 1).

Characteristics gender people new living with HIV/AIDS this study is 75.6% is Male with 38.5% homosexual. Homosexual is romantic sexual attraction, behavior with same sex\(^{(17)(18)(19)}\). The age range of respondents is in the adult (65.4%) age range which is above 25-45 where this age is a productive to developmental task of choosing a job and marriage. This time is also a time to build the peak structure of life \(^{(20)}\). Siglemerital status is 74.4%. the total respondent with ARV medication is 30.8% under one year. Almost respondent have CD4 under 500, a normal CD4 cell count is about 500 until 1,500 cells/\(\text{mm}^3\). Clinicians use this test to monitor the destruction of CD4 cells, and it also monitors the effectiveness of the antiretroviral treatment (ART). For a physician, the CD4 cell count has become the best indicator of disease progression and is used to stage disease and guide medical therapy. Per the Center for Disease Control and Prevention (CDC), one of the indications for the diagnosis of AIDS is when CD4 cell count drops below 200 cells/\(\text{mm}^3\). The decline of CD4 T cells can lead to opportunistic infections, and it increases mortality. The results of a viral load test are described as the number of copies HIV RNA in a milliliter of blood, when somebody has undetected of viral load is described if the copies of HIV RNA of blood in very low and its good for healthy\(^{(10,11)}\).

**Meaning of Life:** The result showed 74.4% people with newly diagnosed HIV/AIDS had meaningful life (Tabel 2).

Meaning of life is comprehended from every event that occurred and experienced both pleasant and distressing events. It will bring a person into a meaningful life so that the feeling of happiness will emerge, on contrary it can lead one to a meaningless empty life if they unsuccessful\(^{(23–25)}\). Meaning of life had a different function for each individual, but according to Mackenzie & Baumeister (2014), the function of meaning in life could be divided into three function themes\(^{(26)}\). The first function was to help someone in recognizing and discussing signs and patterns in the environment. The second function was for communication. The third function was for self-control. The meaning of life according to Starck (2014), was said to be the phase where a person reached his life goal\(^{(27)}\). The meaning of life have correlations with adherence ARV\(^{(11)}\).

From the research results obtained that 59 respondents or 57.8% were adherence to antiretroviral therapy and the rest did not comply as much as 43 respondents or 42.2%. This level of adherence was seen from the accuracy of the dosage and the frequency of time-consuming ARV. The non-adherence of respondents based on the questionnaires due to forgetting to take the drugs by 26.5% and difficult to remember to consume the drugs by 28.4%.

ART treatment has the potential to reduce mortality and morbidity that associated with HIV infection, and improve the quality of life \(^{(28,29)}\). A person is said to be adherent in undergoing an optimal antiretroviral therapy if (>95%) never forgets to take the drug, but it is recommended that the adherence is (100%). According toBangsberg, Kroetz, & Deeks, (2007), ART adherence should be observed to discern the compliance level of the
treatment, as some studies indicate that with treatment adherence of (95%) or more indicates the effectiveness of antiretroviral therapy\(^{(30)}\), but on adherence (75%) shows a rise of viruses with retention against drugs\(^{(31)}\). Some patients fail to maintain ART adherence\(^{(32)}\). Optimal ART adherence was significantly associated with being virally suppressed\(^{(1,7,9,10)}\).

Many factors to associate ART is motivation on the relationship between HIV stigma and ART adherence\(^{(10)}\).

**Conclusion**

Characteristics of participants ages from 18 to 54 years, 75,6% identified as Male, 64,1% had completed high school, 74,4% sige, 38,5% identified as homosexual and 30,8% pastisipants had ART medication under one year. The participant reported 74,4% was having meaningful life and 65,4% reposted had lacked ART Adherence.

**Abstract**

H. pylori is a gram-negative micro organism residing in the stomach of human. It is a important cause of acid peptic disorders. Bismuth based triple therapy, triple therapy regimens (Triple PPI) and Quadruple therapy are the available treatment options to eradicate H. pylori. Controversy still presents regarding the superiority of treatment modality and results of available studies are variable. Hence this study was undertaken to evaluate and compare the efficacy of triple PPI, Quadruple therapy, and bismuth-based triple therapy in treating acid peptic disorders and Helicobacter pylori eradication. Methode: This study was a prospective interventional. After the establishment of a clinical diagnosis of the acid peptic disorder, the patient was posted for endoscopy. H. pylori status was determined by the rapid urease test and culture examination. All patients divided into three groups and offered three different medical treatments the first group received bismuth bases triple therapy, the second group got Tripple PPI therapy and the third one received quadruple therapy. efficacy and comparison of all these treatment modalities were evaluated and assessed by symptoms, endoscopic findings, and results of the rapid urease test after 6 weeks. Results: In the present study, 150 patients with upper gastrointestinal symptoms were studied It was found that the maximum number of subjects belonged to the age group 31-40 yrs. Male outnumbers than females. Maximum patients had pain in epigastric region and were having gastritis as a commonest diagnosis., Symptomatic relief by Triple therapy with PPI was maximum than other therapies. Rapid urease test (RUT) was also suggest that treatment with it gives superior eradication rates. Discussion: In our study, we have found that the treatment regime with PPI Triple therapy has given maximum symptomatic relief, there is an association of H. Pylori infection in an acid peptic disorder like duodenal ulcer (86.66%), gastric ulcer (75%), and gastritis (82.85%). the efficacy of the Rapid urease test is 66% and that of culture is 38.66% in the diagnosis of H. pylori infection in acid peptic disorder. Conclusion: PPI Triple therapy is most effective in symptomatic relief and healing of the duodenal and peptic ulcer.

**Keywords:** Gastritis, rapid urease test, dyspepsia, tetracycline.

**Introduction**

The acid peptic disorder is a disorder in which due to hyperacidity, there is the damage of inner lining (mucosa) of the stomach and duodenum causing various manifestations like inflammation, ulcer, etc. A major symptom of the acid peptic disorder is a pain in the abdomen typically non radiating, burning, and located at in epigastrium, Other include nausea, vomiting, dyspepsia, haemtemesis, and melena, etc. Upper gastrointestinal tract disorders are common in surgical practice. A disease of the stomach and duodenum range from a benign disease like gastritis, peptic ulcer diseases which are usually having a self-limiting although a prolonged course with a potentially dangerous complication like perforation with its attendant’s peritonitis both chemical and bacterial, to malignant diseases like carcinoma of the stomach. The upper gastrointestinal disease forms
a major part of the total number of patients attending the outpatient clinic for gastrointestinal disorders. The treatment of peptic ulcers has been based on Schwartz dictum “No acid, no ulcer”. Marshall and Warran in 1984 described microorganisms in the stomach of patients with gastritis and peptic ulceration first time in history. These investigators identified a spiral-shaped flagellated organism associated with peptic ulcer originally referred to as campylobacter pyloride. The organism is now known as Helicobacter Pylori.

H. Pylori is a gram-negative organism resides in the stomach of human and other animals, affecting half of the population of world.

H. Pylori is a common cause of peptic ulcer of stomach and duodenum leading to clinically present as recurrent abdominal pain. It is correlated with around 90% of duodenal ulcers and 80% of gastric ulcers, major cause of morbidity. Mortality associated however is low but can result in chronic illness leading to significant manpower loss. It can also cause lymphoma and gastric carcinoma.

Present understanding about the aetiology of peptic ulcer disease, gastric cancer, and dyspepsia is under evolution. The invention of Helicobacter pylori as an infective agent change our method to treat and diagnose it. Human beings are the only reservoir for Helicobacter Pylori. Direct transmission from person to person occurs via saliva and feces and infection also through contact with contaminated water.

The Nobel prize in physiology or medicine for the year 2005 was awarded to both J. Robin Warren and Barry Marshall. These Nobel winners made an astonishing and unbelievable invention that chronic inflammation in stomach and duodenum (Gastritis, gastric and duodenal ulcer), is due to an infection by bacterium H.Pylori. Many tried to disprove it. As recent trend of decrease evidence of peptic ulcers was observed from last 40 years. The discovery of Helicobacter Pylori had a further major impact on the incidence of ulcer.

Bismuth based triple therapy comprising of colloidal bismuth subcitrate (120 mg, q.i.d), tetracycline (500 mg, q.i.d) and metronidazole (400 mg, t.i.d) for 14 days is low cost, safe and have high success rates in metronidazole sensitive strains. Few investigators reveals upto 90 percent success rate. If tetracycline was replaced by amoxicillin then success rate decreased to 70 percent to eradicate H.pylori. Triple therapy (Tripple therapy with PPI) is a combination of a proton pump inhibitor and two antibiotics have now almost replaced the use of the classical bismuth-based triple therapy in all over world. This is due to less side effect and better eradication rate. Quadruple therapy is a try to get 100% removal of H. pylori by the addition of anti-secretory agents to the classic bismuth-based triple therapy. It has been noted that this quadruple treatment is more effective when a PPI is used as an anti-secretary agent rather than an H2 receptor antagonist. Huang et al reported a promising eradication rates of 95% when omeprazole was added to the classical triple therapy.

Controversy still presents regarding the superiority of treatment modality and results of available studies are variable. Hence this study was undertaken to evaluate and compare the efficacy of triple PPI, Quadruple therapy, and bismuth-based triple therapy in treating acid peptic disorders and Helicobacter pylori eradication.

Method

The present study was undertaken in the department of surgery, Jawaharlal Nehru Medical College, Wardha in collaboration with Datta Meghe Medical College Hingana, Nagpur, Datta Meghe Institute of medical science (DMIMS), Sawangi, Meghe, Wardha, Maharashtra India. This study was a prospective interventional. The duration of this study was from September 2018 to September 2019. The numbers of patients were 150.

Sample size- 150

The sample size was calculated as per formula was around 134. Hence 150 sample size was sufficient.

\[
N = \frac{(Z_{\alpha} + Z_{1-\beta})^2 \sigma^2}{\Delta^2}
\]

The present study was carried out on the patients attending surgical OPD as well as the surgical ward from September 2018 to September 2019 in a tertiary center. We selected 150 patients having gastrointestinal complaints. The complaints were a pain in the abdomen, usually, in the epigastric region, dyspepsia, nausea, vomiting, haematemesis, melena, etc. Detail history of patients was taken with regards to the symptom, their duration, and severity, other complaints, drug history. A thorough clinical examination and routine haematological examination of patients was done. After the establishment of a clinical diagnosis of the acid peptic disorder, the patient was posted for endoscopy. H. pylori status was determined by the rapid urease test and histopathological examination.
Inclusion Criteria: Patients between 15-60 years were having symptoms of the acid peptic disorder.

Exclusion Criteria:
1. Patients taking antibiotics and bismuth compounds or omeprazole 4 wks before endoscopy
2. Pregnancy.

Detail of procedure followed: Patients with clinical symptoms of APD were advised to attend the Gastroscopy clinic. The patients were kept nil orally at night and were advised to attend endoscopy clinic early in the morning. Endoscopy was performed with Fujinon Gastroduodenoscope after obtaining informed consent. Esophagogastroduodenoscopy of each patient was done under surface local anesthesia with 4% Xylocaine viscous. Findings were noted and biopsies from the antrum and suspicious lesions were taken. Out of biopsies, one was subjected for a rapid urease test and the second biopsy specimen was used for histopathological examination. Endoscopic findings were recorded as gastritis, duodenal ulcer, gastric ulcer, gastric carcinoma, and endoscopically normal mucosa as per standard criteria.

All patients divided into three groups and offered three different medical treatments the first group received bismuth bases triple therapy, the second group got Tripple PPI therapy and the third one received quadruple therapy. Efficacy and comparison of all these treatment modalities were evaluated and assessed symptoms, endoscopic findings, and results of the rapid urease test after 6 weeks.

Data Collection: The data collected included the presenting complaints, clinical signs, endoscopic findings, results of rapid urease test, and histopathological examination.

Statistical Analysis: The presence of H pylori infection was correlated with symptoms, and endoscopy findings. This calculation was derived using SPSS 17.0 statistical software.

Ethical approval for the study was obtained from the ethics committee of DMIMS University.

Results

In the present study, 150 patients with upper gastrointestinal symptoms were studied. It was found that the maximum number of subjects belonged to the age group 31-40 yrs. i.e. 26.66% followed by age group 21-30 yrs. i.e. 22.66%. It was found that of subjects male 112 and female 38. M: F 2.94:1. It was found that maximum no. subjects had pain in epigastric region 120 cases i.e. 80% followed by symptoms nausea 75 cases i.e. 50%.

Discussion

In this study, 150 patients (112 men and 38 women), within the range of 15 to 72 years, with symptoms suggestive of acid peptic disorder, were included.

In our study, we found that acid peptic disorder was more common in the age group 31-40 years (26.66% cases). Followed by 21-30 years (22.66% cases) and 41-50 years (17.33% cases). In our study in patients with acid peptic disorder rapid urease test was positive in 99 patients (66%).

In present study, the result with 3 different modalities of treatment was used as follows Bismuth triple therapy symptomatic relief in 34 patients (89.43%), PPI Triple therapy in 76 patients (92.68%) and Quadruple therapy in 28 patients (93.33%).

As per another study by Vikram Kate (2005) Bismuth therapy was used symptomatic relief in 30 – 90% patients, PPI triple therapy in 85-95% patients, and Quadruple therapy in 86-98% patients.

In present study, we found gastroscopic findings were improved 134 patients (88.93%) and not improved 16 patients (10.66%) after six weeks of treatment.

the cure rate of 80-85 % was achieved using combination therapy. Richard Guan et al, showed eradication of H. Pylori in 90% cases after a week with a triple regimen.

The present study was carried out on the patients attending surgical OPD as well as admitted patients in the ward who had clinical symptoms suggestive of acid peptic disease from September 2018 to September 2019 in the tertiary care center. A total of 150 patients were studied and advised to attend the Gastroscopy clinic.

1. The symptoms of acid peptic disorder were more in 31-40 years followed by 21-30 years.
2. In our study, we have found there was male predominance with male to female ratio of 2.94:1.
3) In our study, we found that there was an association of symptoms of acid peptic disease with H. Pylori infection. Pain in the epigastric region (80%) and nausea (50%) were the most frequent symptoms associated with H. pylori infection followed by dyspepsia (30.66%).
4. In our study, we have found that there is a strong association between H. Pylori in duodenal ulcer (86.66%), gastric ulcer (75%), and gastritis (82.85%).
5. In our study, we have found that the rapid urease test for H. Pylori was positive in 66% of patients and culture was positive in 38.66%.
6. In our study, we have found that the treatment regime with PPI Triple therapy has given maximum
symptomatic relief (95.12%). The other treatment regimens and the symptomatic relief provided by them are as follows:

a. Quadruple therapy 73.33%

b. Bismuth triple therapy 60.52%

**Conclusion**

From the study we could draw the following conclusion:

1. In our study, we have found that the incidence of Helicobacter infection in acid peptic disorder is 66%.
2. In our study, we have found that there is an association of H. Pylori infection in an acid peptic disorder like duodenal ulcer (86.66%), gastric ulcer (75%), and gastritis (82.85%).
3. In our study, we have found that the efficacy of the Rapid urease test is 66% and that of culture is 38.66% in the diagnosis of H. pylori infection in acid peptic disorder.
4. PPI Triple therapy is most effective in symptomatic relief and healing of the duodenal and peptic ulcer.

The highest positivity of RUT was seen in patients of duodenal ulcers (86.66%), followed by gastritis (82.85%) and gastric ulcer (75%).

Discussion

In this study, 150 patients (112 men and 38 women), within the range of 15 to 72 years, with symptoms suggestive of acid peptic disorder, were included. In
our study, we found that acid peptic disorder was more common in the age group 31-40 years (26.66% cases). Followed by 21-30 years (22.66% cases) and 41-50 years (17.33% cases).

In similar studies following results were seen:

In our study, we found a maximum number of duodenal ulcer cases (86.66%) followed by gastric ulcer cases (75%) and gastritis (82.85%).

Symptom Analysis: In our study, we found epigastric pain, nausea, dyspepsia, and vomiting as the most common symptoms associated with the acid peptic disorder as detected on endoscopy (see table 3).

Vandana Berry in their study found that most common symptoms are epigastric pain, nausea, vomiting, and dyspepsia

Tom Richard Okello (2006) in their study found that the most common symptoms are a pain in the epigastric region, dyspepsia, haematemesis recurrent abdominal pain, vomiting, and miscellaneous. The findings in the present study are comparable to these studies

In our study in patients with acid peptic disorder rapid urease test was positive in 99 patients (66%).

Conclusion

The present study was carried out on the patients attending surgical OPD as well as admitted patients inward who had clinical symptoms suggestive of acid peptic disease from September 20017 to September 2019 in the tertiary care center. A total of 150 patients were studied and advised to attend the Gastroscopy clinic.

1. The symptoms of acid peptic disorder were more in 31-40 years followed by 21-30 years.
2. In our study, we have found there was male predominance with male to female ratio of 2.94:1.
3. In our study, we found that there was an association of symptoms of acid peptic disease with H. Pylori infection. Pain in the epigastric region (80%) and nausea (50%) were the most frequent symptoms associated with H. pylori infection followed by dyspepsia (30.66%).
4. In our study, we have found that there is a strong association between H. Pylori in duodenal ulcer (86.66%), gastric ulcer (75%), and gastritis (82.85%).
5. In our study, we have found that the rapid urease test for H. Pylori was positive in 66% of patients.

From the study we could draw the following conclusion:

1. In our study, we have found that the incidence of Helicobacter infection in acid peptic disorder is 66%.
2. In our study, we have found that there is an association of H. Pylori infection in an acid peptic disorder like duodenal ulcer (86.66%), gastric ulcer (75%), and gastritis (82.85%).

Professor, Dept of Strirog and Prasuti Tantra, Govt Auto, Ayurved College, Jabalpur; ³Professor, Dept. of Kriya Sharir, DMAMCHRC, Nagpur; ⁴Associate Professor Dept. of Paediatrics Jawaharlal Nehru Medical College, DattaMeghe Institute of Medical Sciences, SawangiMeghe, Wardha-442001

Abstract

COVID-19 has put the globe in an unforeseen and unexpected situation. COVID-19 has affected everyday life all over the world. Human population came face to face to this virus so gravely for the first time. During the initial days nearly all countries imposed lockdown to break the chain of viral spread. This created significant knock-on effects on the daily life of citizens. With the updates on COVID-19, the guidelines issued by medical authorities, categorized geriatric and paediatric age groups to be at high risk. In order to flatten the rising curve of exponential spread of the virus ban on gatherings resulted in enforced shut down of schools. Therefore children were bound to stay home. They were automatically exposed to the over use of electronic gadgets for recreation as well as education purpose. Hence, their screen time increased many fold. This paper describes the impact of COVID-19 and use of electronic screen on children.

Keywords: COVID-19, Lockdown, screen time, children.

Introduction

COVID-19 has taken a toll on every aspect of human life. Its rapid spread around the world, has posed enormous health, economic, environmental and social challenges to the global population. As a result, for the protection of their population mostly all the countries opted for lockdown. Nearly all nations are trying to slow down disease transmission by monitoring and treating patients, quarantining suspected individuals by touch surveillance, banning large gatherings, enforcing complete or partial lock-downs etc. The pandemic of corona virus is a serious disruption to the global economy. With the passage of time, to boost the sinking economy, gradually lockdowns are being lifted up. As, no records of any clinically approved antiviral drugs or vaccines that are effective against COVID-19 have been published so far. Therefore clinically vulnerable geriatric and paediatric age groups are forced to stay indoors, only. Due to schools shut all over still, over 1.2 billion children are out of the classroom globally.¹² As, the pandemic continues to exist globally, the education sector had to shift to the online method of teaching and learning.

During lockdown, children were already made to sit home. Due to lack of physical activity and social interaction, children engaged themselves with cell phones, computers, laptops, tablets and televisions. This added to many fold increase in the screen time of children. Parents also are struggling to maintain balance between work and childcare.³ This is also one of the factors contributing to acceptance of kids engaging with gadgets.

Though, earlier there was high growth in education
technology, it has been observed that there is a significant rise in usage of language apps, virtual tutoring, video conferencing tools, or online learning softwares, since COVID-19.[4]

The World Bank is working actively with education ministries in dozens of countries to support their efforts to use all kinds of educational technologies to provide distant learning opportunities to students while schools are closed, as a result of the COVID-19 pandemic.[5]

The Diksha, E-pathshala, Swayam, The National Repository of Open Educational Resources, are various free digital e-Learning platforms shared by the Ministry of HRD, India.

The decision of online schooling, is however, contributing to the increased screen time. During pandemic, the start of online education, urged parents to buy smart phones for schooling of kids. Not just schooling, many other online hobby classes also emerged on the web platform. Kids are being engaged in these activities, too. Thus, children are definitely spending much time on screen.

**Aims:** To assess the impact of pandemic on children education and health

**Objectives:**
1. To understand the effect of Covid-19 on education sector
2. To know the effect of online and offline screen activities on child health
3. To explore the possible solution to the problem

**Materials and Method**

Various Research articles, news bulletins, international reports, websites online available books, book chapters were reviewed thoroughly to understand and produce the contents.

**Discussion**

Many a number of researchers have done a comprehensive study on the evil effects of smart phones or cell phones on human health. Smartphones, Cordless phones emit radio frequency radiation (RF). During the use of cell phones, brain is the easy target for radiations. Considering this fact, IARC (International Society for research on Cancer) evaluated the knowledge in case-control human studies by the Hardell group from Sweden and the IARC Inter-phone study. These studies provided supportive evidence of increased risk for brain tumors, like glioma and acoustic neuroma. (IARC Monograph, 2013). The scientific panel concluded that RF radiation in the frequency range 30 kHz–300 GHz is a Group 2B possible human carcinogen.[6]

There are various possible health risks associated with overuse of mobile phones to mental and physical well-being, especially low IQ & inadequate behavioral growth in children, sleep deprivation, brain tumors and psychiatric disorders are major problems.[7]

During growing age, healthy spine is a prerequisite. When kids are slouching over a cell phone for many hours every day, their neck and back muscles are affected. So, they experience nagging pain in these parts. Pain, strain and aching neck muscles can cause a severe headache. Berolo, Wells, & Amick III in 2011 and Ning, Huang, Hu, & Nimbarte, in 2015, mentioned that hand held devices like smart phones and tablets have been associated with musculoskeletal pain and discomfort, particularly in children.[8][9]

Riadh et al., 2011 stated that as kids develop more quickly, their cell division is faster. Also their heads are more slender, hence they have bigger effect on their brain. Now, the prevalence of mobile phones use is increasing in children and possibility of children to be more sensitive than adults to potential adverse effects from exposure to RF-EMF, continuous monitoring of children’s health in relation to mobile phones and tablets is needed.

Children spend 7-8 hours of time on smart phones/computers alone, which is longer than they spend on any other activity. [10]

As children get used to personal space, it may further decrease children’s social interaction. Face-to-face social interaction during childhood, is a major factor affecting the development of children’s social competence [11] There is also the possibility of bidirectional associations between child social-emotional development and media use.[12]

Use of cell phones prior to sleep may affect the initial part of sleep by making changes in brain activity.[13]

Excessive screen time may lead to accelerated myopia excessive screen time.[14] Mobile phones are smaller devices that are generally held at a distance of
20–30 cm from the eyes, leading to digital eyestrain. It has been reported by Long et al that if the viewing distances are closer, the resulting eyestrain symptoms are greater after reading for 60 min from a smartphone.\[14\]

Mostly digital screens are backlit and emit blue light or high-energy visible (HEV) light wavelengths. It has been found that eyes are sensitive to blue light exposure. Gradually, after a passage of time the overall damage may increase the chances and severity of eye disorders. (e.g. age-related macular degeneration and cataracts)\[13\]

Pediatric age group is growing up with touchscreen technology at their fingertips. The speculations that the rising prevalence of asthenopia in the young may be due to over use of smart phones seems to be reasonable.\[11\]

An eye examination, reducing the amount of time that a child can continuously use the computer, the position of the computer, the lighting for glare on the computer screen, reduction of the amount of lighting in the room are the requirements for appropriate viewing habits in children.\[14\]

Similarly, the use of smart phones or tablets should also be under proper guidance by following sop of their usage.

Kesari et al. reported that mobile phone radiation may increase the reactive oxygen species, which plays an important role in the development of metabolic and neurodegenerative diseases. In an animal study, chronic exposure to Wi-Fi radiation appeared to cause behavioural alterations, liver enzyme impairment, pyknotic nucleus, and apoptosis in brain cortex.

With the advent of digital technology, entire population is exposed to some or the other effects of technology. Earlier generations have never been exposed during childhood and adolescence to this kind of radiation. Hence, it is going to take a long time to evaluate and conclude about the effects of radiation on younger population. Neuro-degenerative and carcinogenic changes take decades to manifest. But when earlier studies have already proved, use of smart phones as one of the possible causes of rise in cancer, education policy makers must keep in mind these established facts while designing education policy for younger population of the country.

In India, Swayam Prabha, a group of 32 Direct To Home (DTH) channels is devoted to telecasting of educational programs round the clock. The programmes are available across the country. The channels air courses for school education (class 9-12), higher education (undergraduate, postgraduate) as well as for out-of-school children, vocational education and teacher training.

A start up Think Zone” in Odisha, India has taken an initiative to reach out to children with no access to internet facility. It is broadcasting activity based learning modules with the help of a local radio channel for students aged 3 to 10.

Similarly, there is a need to explore other options of teaching and learning which are less harmful to paediatric age group. Many intellectuals assert that education system was already losing its relevance but the varying effectiveness of online learning cannot compete with the absence of classrooms.

**Conclusion**

To think of any long-term effects of the current online education scenario, will be a hasty step. But definitely a serious thought must be given to the future consequences of screen use by pediatric age group. Perhaps it is too necessary to educate children, but it still isn’t that big problem at all. So, it is the need of the hour to think about affordability of imparting education at the cost of health. Thus, the other ways out for educating children must be explored. More the hours of use, more will be the absorption of raditions, so children must be taught to refrain from mobile phones. Landlines, Skype, and computer phone services, when connected to the internet with a cable, don’t give off radiations, therefore the parents should take care that kids use those. The Wi-Fi routers in the home should be placed away from where people, particularly children, spend most of their time. To keep children healthy, overuse of cell phones and other wireless devices by kids must be restricted. We must not undermine children’s mental and physical state day-by-day, caused by the excessive usage of cell phones for education as well as recreation.

Abstract

In a fairly short time, the worldwide spread of COVID-19 has brought a dramatic reduction in industrial
activities, road traffic and tourism. During this time of crisis restrained human interaction with nature
has appeared as a blessing for nature and the environment. Reports from around the world indicate that
environmental conditions, including air quality and water quality in rivers, are improving after the COVID-19
outbreak, and wildlife is blooming. India has always been a pollution hub with enormous populations. But
since COVID-19 announced the lockdown, air quality has begun to improve and all other environmental
parameters such as water quality in rivers have begun to offer a positive sign of restoration.

Keywords: COVID-19, Lockdown, Impact, society, Environment, Trade, Unemployment.

Introduction

As of 21 August 2020, Covid-19, who emerged in
Wuhan somewhere back eight months in December 19,
has now taken shelter in host bodies in 213 countries
across the globe infecting 22,589,017 people and 792,475
deaths. India has also reported more than 2,905,823
positive cases with 54,849 death tolls on the same day1.
The disease remains uncontrolled, and the virus has no
proven cure. Locking in homes and social distances is
the only preventive step the country as a whole is taking.
But as the human activities in most areas are limited,
the country’s natural environment has begun to heal
itself. Factories, trade, aircraft and aviation are all at a
standstill. Social media has immerged out as platform
for people to stay connected with each other. Lockdown
due to COVID-19 has also affected employment status
of whole world. Worldwide import and export has been
reduced substantially.

Aims and Objectives:
1. Discussion about the various effects of lockdown
due to COVID-19 on environment, mental health,
trade, unemployment etc.
2. Try to find solutions on adverse effects.
3. Try to find out solutions to maintain positive effects
of lockdown.

Materials and Method

Material and data for this article is collected from
authentic official websites and news channel reports
from national and international platform.

Result

Due to lockdown, environment and society is
influenced as follows:

Air Quality: Thanks to the effect on travel and
industry of the coronavirus outbreak many regions
and the world as a whole witnessed a decrease in air
pollution.2 The Energy and Clean Air Research Centre
estimated that strategies for suppressing coronavirus
spread, such as quarantines and travel bans, resulted in a 25% reduction in carbon emissions. NASA uses an instrument for ozone monitoring (OMI) to measure and monitor the ozone layer and contaminants such as NO2, aerosols and others. According to scientists at NASA, the decline in NO2 emissions originated in Wuhan, China and spread gradually to the rest of the planet.

**Water Quality:** Water in the canals in Venice cleared and saw greater flow of water. The increase in water clarity was attributed to the settling of sediment which is disturbed by boat traffic and the decrease in air pollution along the waterways listed.

**Wildlife:** Some animals have been seen in towns as people remain at home due to lockdown and travel restrictions. Sea turtles were seen laying eggs on the beaches they once avoided (such as the Bay of Bengal coast), due to lower human intrusion and light pollution rates.

German scientist Rainer Froese has said that fish biomass will increase due to the sharp decline in fishing, and has projected that some fish such as herring could double their biomass in European waters.

**Carbon emission:** A study published in May 2020 found that the daily global carbon emissions declined by 17 percent during the lockdown steps in early April and could lead to an annual decrease in carbon emissions of up to 7 percent, which according to researchers would be the largest drop since World War II. They attribute these declines largely to reducing the usage of transport and manufacturing activities.

**Public mobility:** Public mobility has deteriorated dramatically due to constraints, including the imposition of a lockout in several countries, a Google Study reveals. Across India, shopping and leisure places saw the steepest decline across people’s presence between February 16 and March 29 relative to traffic between January 3 and February 6. There was a significant rise in phone traffic from homes, meaning more people were staying at home. Visits to restaurants, shopping malls and movie theatres plummeted by 77 per cent between Feb. 16 and Mar. 29 compared to the period from Jan. 3 to Feb. 6. Visits to stores, markets and pharmacies have dropped by 65%. Visits to national parks, beaches and public gardens have been reduced by 57%. Compared to the period between Jan. 3 and Feb. 6, the use of public transport facilities such as buses and trains fell 71 per cent between Feb. 16 and Mar. 29. Workplace visits declined 47 per cent as many people were told to work from home. People stayed 22 per cent more at home than they did between January 3 and February 6.

**Impact on trade:** Trade in United States has been declined which shows impact on the trade in other countries of world.

</tbody>
</table>

**Impact on Unemployment:** The International Labour Organization (ILO) projected that the spread of corona virus would threaten more than 25 million jobs globally. Four out of five people (81 per cent) in the 3.3 billion global work forces are currently impacted by the complete or partial closure of the workplace. The United States, the United Kingdom, Canada and most European and Asian countries have already registered huge jobs losses leading to significant increase in unemployment. The ILO in its report ‘‘*‘ describes COVID-19 as ‘worst global crisis since World War II’*.

Low-paid and low-skilled informal workers are particularly concerned in low- and middle-income countries, where the industries and services have a high proportion of these informal employees, who account for...
61 per cent of the global workforce or 2 billion men, and lack any social security. The sudden loss of livelihood will make them horrifying.

The CMIE (Centre for Monitoring Indian Economy) report showed a major job loss and corresponding substantial unemployment rate rise in March 2020. The unemployment rate in March 2020 stands at 8.7 per cent, which is far higher than the government’s estimate of unemployment in 2017-18 at a 45-year high of 6.1 per cent. This is the highest jobless rate since September 2016. Over the same time, the unemployed have also risen from 32 million to 38 million. The situation got worse when we went into the lockdown time last May week and the unemployment rate rose to 23.48%.

Role of Social media during lockdown: During the lockout the social media plays a significant role. During the lock down social media always update people’s current affairs. The role of social media is very important in managing the anger, tension, and fear of the people and in helping they update the current scenario. Also Study indicates that active use of social media is better for you than passive use, so consider writing a blog or sharing status updates as a way to connect. And it will help you organize virtual encounters with family and friends. These should not limit themselves to chatting; they will engage in community activities such as watching films, playing drama and online conversation through video calls and share their views on academic aspects and other aspects of cooking together. Teachers are conducting online lectures for their students so they do not skip their academics by use of social media applications during the lockdown.

Only a couple of days of isolation may cause anxiety and depression to develop. Add to it the imminent possibility of constantly hammering a terrible disease through the media, and you have a prescription for several shades of mental and physical distress.

Impact on Mental health and behavior: Human beings have evolved into social beings, and are designed to live in collaborative communities. Feeling removed from families, friends and employers can be unbalanced and stressful for most people and can lead to psychological and physical health issues in the short or even long term. Psychological consequences of isolation may include a rise in levels of anxiety, aggression, depression, forgetfulness and hallucinations. In those with inherent pre-existing susceptibilities psychiatric disorders that are precipitated and even manifest without precondition in several others. Personal relationships help us cope with tension, and if we lack this outlet for steam, a massive emotional voice will result which, for an average person, is difficult to deal with.

Solitary inmates and patients in segregated medical facilities have also had negative psychological effects including elevated anxiety, panic attacks and elevated paranoia rates. This has been found that social isolation has a correlation with greater alcoholism. Researchers who had to live in remote areas such as deserts, the Antarctica, forests and outer space have confirmed that overcoming loneliness is a tough challenge. Yossi Ghinsberg, an Israeli explorer who spent several weeks alone in the Amazon, admitted making imaginary companions to fend off the loneliness. The shutdown of Covid has put forced isolation on many.

Young people live away from their families, trapped in small apartments with abysmal cooking skills. Many senior citizens living on their own seek companionship by meeting up in community parks with age mates. We find themselves marooned, robbed of social contact and even from their children’s sporadic visits. Lack of playtime with peers causes children to become irritable and edgy.

Staying in a confined space with family is not a pink picture for everyone. It may be extremely oppressive and claustrophobic for large low-income families huddled together in small single-room houses. Children are not lucky enough to have a lot of board/electronic games or books to keep them busy. Add to this the profound uncertainty of running out of food funds and basic necessities. On the other hand, there are people with dysfunctional family dynamics, such as dominant, abusive or alcoholic partners, siblings or parents, who make a period of trial stay at home. There has been a worldwide increase in the incidence of suicide and physical abuse against women. Higher anxiety and depression often impair an individual’s immune system and make them more vulnerable to disease.

Discussion

The issue today is not whether the Covid-19 passage will bring similar socio-political changes; experts predict it will be a long and damaging fight. This needs to be preparing for the long term. We need to control our population’s physical and psychological harm by urgently diverting full resources to improve our health-care system. We have to maintain a fair distribution of
food and essential needs among the less favoured groups. Before the lockout we tripped badly by misunderstanding their worries. Even more bungling will lead to messy rioting scenarios and food theft. The Government needs to move into action quickly to prevent losing legitimacy. A higher death toll also means that many families deprive members of their earnings and put greater burden on the welfare system. Throughout India, losses are the highest in the males of the 22-40 year age group, which is also the most active.

Import and export trade has decreased all over the world due to lack of transport; but environment is seen to be recovering up to great extent.

Today, social media like Twitter, Face book and Instagram have become the main information sources. They are also platforms for misinformation and false news.

Conclusion

Stigma and blame targeted at outbreak-affected communities may hinder international trade, finance, and relationships, prompting further unrest. Care needs to be taken to erase the stigma associated with disease, racism, religious propaganda and psychosocial impact and to be implemented through regular discussions with trained and specialist healthcare staff by setting up task forces and execution teams that are directly involved in healthcare delivery systems without creating any communication gaps between policy makers and ground level.

It is desperately necessary to set up mental health organizations specific to future pandemics with branches in many nations and individual healthcare institutions for research, delivery of mental healthcare and organization of awareness programs at both personal and community levels. To relieve psychological anxiety in the general population over this continuing pandemic, standardized websites and toll-free helpline numbers can be introduced. Social media should be used in good sense to educate people about dynamics of transmission, disease symptoms, and time when precise medical consultations are required. Strict government laws and legislation regarding fake news, social media rumours, disinformation and misinformation should be implemented to protect social media from devaluations.

The COVID-19 pandemic has clearly shown us how, even in the 21st century, a “virus” can adversely impact our lives and at the same time make us aware that the greatest assets of humanity are health, goodwill, compassion, unity, creativity and awareness.

Participation in Community-Based Road Safety Program Associated with Motorcycle Helmet Use in Udon Thani Province, Thailand

Surachai Phimha¹, Attapong Rittitit², Nakarin Prasit³, Nathakon Nilnate⁴, Prachak Boupahan⁵

¹Lecturer, Department of Public Health Administration, Health Promotion, and Nutrition, Faculty of Public Health, Khon Kaen University, Thailand, ²Research Scholar, ASEAN Cancer Epidemiology and Prevention Research Group, Faculty of Public Health, Khon Kaen University, Thailand, ³Doctoral Student, Faculty of Public Health, Khon Kaen University, Thailand, ⁴Lecturer, Department of Public Health, Faculty of Nursing Science, Phetchaburi Rajabhat University, Thailand, ⁵Associate Professor, Department of Public Health Administration, Health Promotion, and Nutrition, Faculty of Public Health, Khon Kaen University, Thailand.

Abstract

Background: Road traffic fatalities remain a significant cause of premature death in Thailand, with motorcycle riders comprising the largest proportion of deaths. Helmet use improves road safety outcomes; therefore, it is important to understand how to improve helmet use. The purpose of this study was to determine whether community participation in road safety meetings was associated with helmet use and to identify other factors associated with self-reported helmet use.

Objective: To determine the participation in community-based road safety program associated with motorcycle helmet use in Udon Thani Province, Thailand

Method: Multivariable logistic regression was used to analyze the association between self-reported participation in community meetings about road safety and other factors with self-reported helmet use behaviors among 2,474 motorcycle riders (55.4% female, aged 53.4 ± 12.3 years) in Prachaksinlapakhom District, Udon Thani province, Thailand.

Results: Regular participation in community road safety meetings (ORadj.=1.61; 95% CI=1.24 to 2.08, p-value <0.001) was associated with increased self-reported helmet usage. Risk factors for non-compliance included being female (ORadj.=0.64; 95%CI=0.53 to 0.77, p-value <0.001), elderly (i.e., ≥60 years old) (ORadj.=0.65; 95%CI=0.54 to 0.79, p-value <0.001), and smoking (ORadj.=0.79; 95%CI=0.62 to 0.97, p-value = 0.029).

Conclusions: Regular community participation was associated with increased self-reported helmet usage after adjusting for other factors. Further research should assess whether helmet use outcomes improved following participation in community road safety activities.

Keywords: Community participation, motorcycle helmet use, road safety program.

Introduction

Globally, over 1.3 million people die from road traffic injuries, or 18.2 per 100,000 population, per year. Rates vary substantially across regions. South-East Asia has one of the highest road traffic death rates, at 20.7 deaths per 100,000 population, with 43% occurring among users of two- and three-wheeled motorized
vehicles—the highest such proportion among World health Organization regions.1

Traffic injuries are a major public health problem in Thailand.2 Thailand is frequently ranked as having one of the top five highest per capita death rates from road traffic accidents, with a mortality rate of 32.7 per 100,000.1 Accidents have increased 1.65 percent every year, while related deaths have increased by 4.01 percent every year.3 Nearly three out of every four road traffic deaths occur among riders of motorized two- and three-wheeled vehicles in Thailand.1

Helmets are one of the most effective methods to reduce the severity of injuries in motorcycle accidents and reduce the loss of life.4 Nationwide helmet use in Thailand, however, is estimated around 44%. Moreover, pillion riders were 2.5 times less likely to wear a helmet than drivers (19.3%).5 Higher compliance with helmet laws would substantially improve Thailand’s outcomes in road safety. It is estimated that increasing the nationwide helmet compliance to 90% would reduce total road traffic deaths by 23%.6

Several factors influence helmet usage among motorcyclists. For example, accident experience can predict helmets use.7 Additionally, personal factors such as gender and family income correlate with helmets use.8 Helmet laws and law enforcement also have been shown to affect vehicle driving behavior9 and decrease the morbidity of head injuries.10 To improve helmet usage, several programs, including community participation projects, have been proposed. In one such program an increase of 13.2% in the rates of helmet usage was found.4 This study aimed to measure the relationship between participation in community-based road safety programs and helmet, as well as identify other factors associated with helmet use.

Materials and Method

Study Population: Prachaksinlapakom District is located in Udon Thani province, Thailand. The district has a population of 25,621.11 The area is suburban with an agriculture (71.49%) as the most common occupation. Udon Thani is one of the largest provinces in the northeastern region. Annually, between 6,596 and 6,980 people were injured in the province between 2017 and 2019.12

Data Collection: Data was collected by the District Health Coordinating Committee between 2017-2018 using a “Health Information Status” questionnaire. Questionnaires were collected by village health volunteers. The instrument requested participants to report helmet use behaviors, participation in community activities, demographics, smoking status, alcohol consumption, and chronic disease. The primary outcome was helmet use. The main factor of interest was community participation.

A total of 3134 records, representing most of the families in the district, existed within the governmental database. To be eligible, records were included in the study if the respondent was aged between 15 and 80 years and reported using a motorcycle in daily life (n=3035). After removing records without the primary outcome (helmet use) and primary factor (community participation), the final sample size was 2474.

Statistical Analysis: Prior to univariate analysis, any continuous variable (i.e., age) was recoded into categorical format. Univariate logistic regression was then used to analyze the association between each factor and helmet use and identify factors to be included in the initial model. Factors were included in the initial model if significant in the univariate analysis (p<0.25) and confounding factors.

Multivariable logistic regression analysis was utilized to fit models and assess the relationship between helmet use and community participation, while adjusting for potential confounding factors. Backwards stepwise elimination method was used to remove factors (p > 0.05). Model fit was assessed using AIC. Statistical analysis was performed with STATA software version 15.0.

Results

Sample Characteristics: A total of 2,474 participants were included (Table 1). Most of the subjects (55.4%) were female, and the average age was 53.4 ± 12.3 years old. Agriculture was a major occupation of participants (71.5%), and most of the education level was a primary school (68.7%). Almost all participants were married (73.0%). Most participants did not smoke, drink alcohol, or have chronic disease (74.2%, 64.5%, and 78.2%, respectively). Most participants reported participating in community activities of subjects was seldomly (46.1%) or usually (40.3%) (Table 1).

**Univariate Analysis:** Crude analysis identified three factors for inclusion in the initial model (Table 2). They were community participation (usually: OR = 1.60; 95% CI = 1.24 to 2.06, p-value < 0.001), gender (female: OR = 0.72; 95% CI = 0.61-0.85, p-value < 0.001), and age (≥60 years old: OR = 0.68; 95% CI = 0.57 to 0.81, p-value < 0.001).

**Multivariable Analysis:** The final multiple logistic regression retained all confounding factors and showed that three factors strongly associated with outcome were community participation (usually: OR adj. = 1.61; 95% CI = 1.24 to 2.08, p-value < 0.001), gender (female: OR adj. = 0.64; 95% CI = 0.53 to 0.77, p-value < 0.001), and age (≥60 years old: OR adj. = 0.65; 95% CI = 0.54 to 0.79, p-value < 0.001). In addition, smoking status who have smoking were associated with helmet using behavior (OR adj. = 0.79; 95% CI = 0.62 to 0.97, p-value = 0.029).

**Discussion and Conclusion**

**Discussion:** Our main finding indicates that community participation is associated with self-reported helmet use. Participation in community activities provides an opportunity to receive information and share ideas among many stakeholders. Previous studies have found that the community participation projects can increase the rates of helmet usage. Increased knowledge and awareness are likely explanations for this relationship. Studies have found that knowledge and greater awareness of safe driving was related with safe driving, and motorcyclists with low exposure to road safety awareness campaigns were more likely not to use helmets when compared to higher exposure groups. Moreover, widespread awareness programs have been shown to increase motorcyclist’s helmet use and improve road safety of motorized users.

Females, elderly, and smokers were also associated with lower self-reported helmet use. Gender is a personal factor that is different from lifestyle and behavior factors. Females have certain physical characteristics that may hinder the use of helmets. Previous studies have shown lower helmet usage among adult female motorcyclists in Thailand. However, the relationship between helmet use and gender may differ depending on the population. Male adolescent motorcycle drivers and male bicycle riders were shown to have lower self-reported helmet compliance than females. Among university students in Thailand, men engaged in motorcycle accident risk behavior more often than women. When the younger and older demographics were mixed, the relationship was not significant, suggesting age and gender may be compounding.

Another factor, age, is one of the factors involved in wearing a helmet, because it is representative of experience and daily living. This study found that the
elderly were less likely to report wearing a helmet. The injury and prevention program should focus on the older aged group because their injuries are more severe than younger adults. Along with being female and not wearing a helmet, increasing age was associated with an increased risk of death among two-wheeled vehicle traffic accidents in Spain. However, this study’s sample primarily consisted of adults and did not include many young or adolescent people. Therefore, the elderly were less likely to report helmet use as compared to primarily middle-aged adults. If younger adults are studied, previous studies show low helmet use among teenagers and young adults. On the other hand, older adults and elderly were shown to have lower rates of motorcycle injuries in a Thai cohort study. Therefore, while helmet compliance may be lower, usage may differ to include only short-distance or low-risk driving situations relative to younger groups that are more dependent on motorcycles as the primary mode of transportation.

Smoking was also shown to be associated with lower helmet use. Smoking may hinder helmet use, because smoking makes it difficult to use a helmet. Smoking may also indicate high risk-taking behaviour or lower safety compliance, such as seatbelt use.

**Conclusions**

This study found that regular community participation was associated with increased self-reported helmet usage after adjusting for other factors. Being female, older than 60, and smoking were also shown to be associated with lower reported helmet use. Further research should assess whether helmet use outcomes improved following participation in community road safety activities. Efforts should be made to expand community participation in road safety campaigns.

**Ethical Considerations:** This study was approved by the Khon Kaen University Ethics Committee for Human Research based on the Declaration of Helsinki and the ICH Good Clinical Practice Guidelines (reference number HE 622120).

Abstract

Background: CKD is associated with various mucocutaneous manifestations that impair the quality of life. The objective was to study the incidence of various cutaneous manifestations in CKD patients.

Materials and Method: 130 (M:F = 4.2:1) patients aged 15–78 (Mean age- 50.32 years) having CKD for 3 month to 5 years were studied for mucocutaneous manifestations. Forty (30.7%) patients were on hemodialysis for 1-3 months. Detailed medical history, clinical and mucocutaneous examination and lab investigations were performed. KOH mounts, skin biopsy, Gram’s and Giemsa staining, bacterial or fungal cultures were performed as required.

Results: Xerosis in 104 patients (80%), skin pallor in 76(58.4%), pruritus in 52 (50.9%) patients, pigmentation in 45(34.6%) and purpura in 12 (9.2%) patients were the major dermatoses. Perforating folliculitis occurred in 1 (0.76%) patient. Mucosal findings included coated tongue in 14(11.66%), xerostomia in 11(9.16%) and macroglossia with teeth markings and fissured tongue in 9 (7.5%) patients each, angular cheilits in 3 (2.5%), and aphthous stomatitis and black pigmented tongue in 1 (0.83%) patients each. Hair abnormalities included sparse scalp and body hairs in 43 (33%), 11 (8.4%), respectively and lusterless hair in 22 (16.9%) patients. Major nail abnormalities were half and half nails or Lindsay’s nails in 33(25.3%), longitudinal ridging in 29(22.3%), leuconyicha in 13(10%), onycholysis in 9(6.9%), Beau’s lines in 6(4.6%), koilonychia in 4(3.07%), Mee’s lines in 1(0.76%) and Meuhrrcke’s lines in 1(0.76%).

Conclusions: Xerosis, pruritus, skin pallor/pigmentary changes, half and half nails, longitudinal ridging, discoloration, sparse hairs, coated tongue, xerostomia, macroglossia, and infections were the most common mucocutaneous manifestations in the studied patients irrespective of hemodialysis status.

Keywords: Cutaneous manifestations, end-stage renal disease, skin diseases.

Introduction

Chronic kidney disease (CKD) is a term that encompasses all degrees of decreased renal function, from damaged–at risk through mild, moderate and severe chronic kidney failure. The guidelines define CKD as either kidney damage or a decreased glomerular filtration rate (GFR) of less than 60 mL/min/1.73 m\textsuperscript{2} for at least 3 months.\textsuperscript{(1)} It is a worldwide public health problem. Studies report the prevalence of Chronic kidney disease (CKD) to be 17.3% in India.\textsuperscript{(2)} CKD is more prevalent in the elderly population. However, while younger patients with CKD typically experience progressive loss of kidney function, 30% of patients over 65 years of age with CKD have stable disease.\textsuperscript{(3)} Most patients with severe CKD progress to end-stage renal disease (ESRD). Cutaneous manifestations are common in all stages of CKD
particularly towards ESRD with a prevalence of 50–100%.(4,5) An earlier study by Uday Kumar et al. reported all patients with ESRD on hemodialysis to have at least one skin manifestation.(6) The skin manifestations maybe due to the fact that at present dialysis is not as efficient as a normal kidney and cannot replace its endocrine function resulting in electrolyte imbalance and build-up of uremic substances. Some of the manifestations may be as a result of dialysis and immunosuppressive drugs used.(7) Skin manifestations specific to dialysis patients include acquired perforating dermatosis, calcific Uremic arteriolopathy (calciphylaxis), bullous lesions and nephrogenic fibrosing dermopathy. On the other hand, pruritus, xerosis, nail disorders, hair disorders, pigmentary changes, purpura, mucosal changes and pallor though not specific to hemodialysis, are more frequent in patients with CKD. However, it may be difficult to implicate either CKD or hemodialysis alone for any particular cutaneous manifestation as many of them are associated with both.(8) The aim of the study was to analyse the various cutaneous and mucosal manifestations in patients with CKD. We have limited studies on the pattern of mucocutaneous manifestations in CKD patients in India, so this study was carried out.

**Materials and Method**

A hospital based cross sectional study was conducted on 130 patients admitted in Rama Hospital for duration of 1 month after taking informed consent. The study was approved by ethical committee of the hospital. Patients with history of Human immunodeficiency (HIV), renal transplant recipients and patients with acute renal failure, hepatobiliary, pancreatic, or thyroid disorders, cutaneous, or systemic malignancies were excluded from the study. Details of medical history, clinical and mucocutaneous findings and investigations were recorded. KOH mounts, skin biopsy, Gram’s and Giemsa staining and bacterial or fungal cultures were performed when needed. The diagnosis and clinical staging of CKD was as per the National Kidney Foundation severity assessment criteria.

**Statistical Analysis:** Statistical analysis was done using Chi-square test to find associations between various cutaneous manifestations. Biochemical values were expressed as mean. To explore relationship of cutaneous findings and biochemical parameters, the unpaired t test was used. A p value of less than 0.05 was considered significant.

**Results and Discussion**

Of the 130 patients, 105 were males and 25 were females (M:F=4.2:1). The age of patients ranged from 15-78 years with the mean age being 50.32 years having CKD for 3 months to 5 years.

Out of 130, 40(30.7%) patients were on hemodialysis for 1-3 months. At least one cutaneous manifestation was present in 98% of the patients recruited in the study. Diabetes mellitus (DM) was the most common cause (45%) of renal dysfunction followed by hypertension (HTN) in 35% cases and glomerulonephritis in 4% cases.

Xerosis was the most common cutaneous finding as reported in 104 patients (80%) with severe and ichthyotic in 10 (8.33%) patients irrespective of the dialysis status. This is consistent with the previous studies also.(9,10,11,12) It can be correlated with decreased sweating and lowered levels of lipids in the skin surface. The decreased sweating may be due to a decrease in the size of the eccrine duct.(5,6) The second most common finding after xerosis was pruritus as seen in 82 (63%) patients. The pruritus intensity was mild to moderate in 52 (50.9%) patients with xerosis. It may be generalized or localized, episodic or continuous. It may or may not improve from hemodialysis and occurs in 15–49% during predialysis and in 19-90% hemodialysis patients.(5,6,10,13) However, there was no significant difference among patients with or without hemodialysis. The pathogenesis of uremic pruritus is poorly understood but its intensity is directly proportional to the severity of xerosis(14). In addition to pruritus, associated with xerosis is elastosis and premature skin wrinkling in 33-40% patients.(14,15,16) Only 4 (3.3%) patients showed early skin wrinkling in this study.

Skin hyperpigmentation is another common finding in patients especially with ESRD. In our study, 45(34.6%) CKD and 48% of the hemodialysis patients had hyperpigmentation which is consistent with previous studies also.(10,12) This may be attributed to the accumulation of Melanocyte Stimulating Hormone (MSH) due to failure of kidneys to excrete it. Extremities and photoexposed areas were more severely affected.

Pallor of the skin due to anemia was observed in 76(58.4%) patients and was significantly more common among patients on hemodialysis. The anemia may be due to anoxia and decreased erythropoiesis due to reduced erythropoietin secretion by the kidney.(17) Ecchymosis/purpura was seen in 12 (9.2%) patients...
but said to improve after hemodialysis.\(^6,12,16\) These are attributed to the increased vascular fragility and platelet dysfunction resulting from high blood urea levels or heparin use during dialysis. Perforating folliculitis of unclear pathophysiology is significantly common among diabetic CKD patients.\(^6\) which was observed in only 1(0.76%) in our study.

Mucosal abnormalities occurred in 55 (42.3%) patients including coated tongue in 14 (11.66%), xerostomia in 11 (9.16%), macroglossia with teeth markings and fissured tongue in 9 (7.5%) patients each, angular cheilitis in 3 (2.5%), and aphthous stomatitis and black pigmented tongue in 1 (0.83%) patients each.

The consistent nail change characteristic of CKD with or without dialysis is Lindsay’s “half-and-half nails,” a band of discoloration over the distal nail plate from increased density of nail bed capillaries, with a reported prevalence of 17–76%.\(^6,18\) In our study, half and half nails or Lindsay’s nails was seen in 33(25.3%) cases and longitudinal ridging in 29(22.3%) cases. Other findings were leuconychia in 13(10%), onycholysis in 9(6.9%), Beau’s lines in 6(4.6%), koilonychias in 4(3.07%), Mee’s lines in 1(0.76%) and Meuhrcke’s lines in 1(0.76%)

Hair abnormalities were seen in 65 (54.1%) patients. The findings were sparse scalp and body hair and lusterless hair in 43 (33%), 11 (8.4%), and 22 (16.9%) patients, respectively consistent with previous studies.\(^11,12,18\) The factors responsible for these changes are anemia, reduced sebum production and parathormone levels, stress of ESRD/dialysis or neglected hair.\(^6,15,16,18\)

There is increased susceptibility for bacterial, fungal, and viral cutaneous infections in 28–70% of CKD patients due to reduced immunity.\(^5,15,19\) In this study, fungal infections 22(16.9%) were more common than bacterial infections 15(11.5%) and viral infections 7(5.38%).

Gynaecomastia was seen in one patient of end stage renal disease in our study. Udaykumar et al reported gynecomastia in 1% of cases.\(^6\)

There was no significant association between biochemical parameters and various cutaneous findings (p>.05). There was no significant association between duration of dialysis and cutaneous manifestations (p>.05).

**Conclusion**

Xerosis, pruritus, skin pallor/pigmentary changes, nail pallor, nail discoloration, sparse hairs, coated tongue, xerostomia and macroglossia and infections were the most common mucocutaneous manifestations in majority of studied patients irrespective of their hemodialysis status.

The Predictive Power of Moral Intelligence on Professional Commitment of Nurses

Madineh Jasemi¹, Hossein Habibzadeh², Rasool Gharaaghaji³, Parivash Karimi⁴

¹Associate Professor of Nursing Education, ²Associate Professor of Nursing, School of Nursing and Midwifery, ³Associate Professor of Biostatistics, Department of Biostatistics and Epidemiology, ⁴M.Sc. Student in Nursing, Student Research Committee, School of Nursing and Midwifery, Urmia University of Medical Sciences, Urmia, Iran

Abstract

Background: Nurses’ adherence to ethical values in the field of patient care is affected by various factors, especially moral intelligence. The role of moral intelligence on professional commitment is an issue leading to improving the quality of services and health promotion. The aim of this study was to investigate the predictive power of moral intelligence on professional commitment of nurses.

Method and Materials: This descriptive-analytical study was carried out on 100 nurses and 300 patients selected by stratified random sampling. Data were collected using the Lenik & Kiel moral Intelligence Questionnaire and Nurse Professional Commitment Questionnaire. Data were analyzed using descriptive analysis and regression.

Results: The results showed that there was a significant statistical relationship between moral intelligence and professional commitment (P=0.001). There was a significant relationship between demographic variables, age and work experience with moral intelligence and two variables of gender and professional commitment (P <0.05). In addition, regression showed that dimensions of nurses’ moral intelligence account for 41% of the variance of nurses’ professional commitment. of the four dimensions of nurses’ moral intelligence, compassion had the most significant effect (P=0.03, β=0.32).

Conclusion: The results of this study showed that moral intelligence is associated with professional commitment and is able to predict it. Therefore, it is recommended that nursing managers and authorities to put the Strengthening nurses’ moral intelligence in the list of their priorities.

Keywords: Moral Intelligence, Professional Commitment, Nursing.

Introduction

Nowadays, health care environments are rapidly changing, and nurses meet various ethical issues in their daily practice¹. Among the factors that influence the performance of nurses in enforcing standards, providing professional and ideal care and making the right decisions, attention is paid to ethical values². Nurses’ adherence to ethical values in the field of patient care is influenced by various factors, especially moral intelligence³. Moral intelligence is one of the four dimensions of intelligence (intellectual, emotional, spiritual, and moral) that encompasses the mental capacity of individuals to apply human principles rather than personal goals and values⁴. In fact, moral intelligence provides a framework for proper human performance and is a behavior predictor⁵. Kiel considers moral intelligence to include the
principles of righteousness, responsibility, compassion, and forgiveness. People with high moral intelligence link their work to ethical principles, which in turn increases their commitment and responsibility and thereby improves individual and group performance.

Professional commitment is a practical and social dimension of ethics that has created a positive emotional tendency to respect the rights of others in the context of ethics; adherence to it promotes the nursing profession and increases the satisfaction of nurses and patients. Given the role of professional commitment in increasing the efforts of individuals to devote themselves to their profession, this issue has received special attention by managers of different professions around the world. Professional commitment is one of the main subjects of the nursing profession. So that professions commitment, belief in and acceptance of professional values and goals, strives for its realization and better service delivery.

A review of existing studies of professional commitment indicates the relationship between professional commitment and various performance indicators including job satisfaction, loyalty to the profession, individual stability, and staying in the profession and job performance. Studies show that commitment is one of the factors influencing the intention of nurses to leave work, in such a way that the higher the commitment of nurses, the lower their rate of leaving work. According to the findings of various researches, professional commitment not only leads to better care delivery by nurses, but also job satisfaction and striving for career advancement. While only 1.2% of nurses reported high job satisfaction in our country, most of them did not have much commitment and desire to leave the nursing profession. As the nursing profession has increased, the quality of nursing care has also declined.

Nurses with high moral intelligence appear to be more capable and willing to provide comprehensive care. Given the proven impact of professional commitment on various indicators, the present study investigated the predictive power of moral intelligence on professional commitment of nurses working in educational centers of Urmia. It should promote and, at the same time, improve the quality of nursing care.

**Method and Materials**

This descriptive-analytical study was carried out on 100 nurses working in educational centers of Urmia city (Imam Khomeini, Taleghani, Motahari, Seyyed al-Shohada hospitals) and 300 patients selected by stratified random sampling.

Inclusion criteria for nurses were having at least one year of clinical experience, having at least a bachelor’s degree, nurses working in all wards with the exception of intensive care units, emergency departments, clinics, children, infants, psychiatrists, operating rooms, angiography, burning, and willingness to participate in the study.

Inclusion criteria for patients were being hospitalized for at least three days, having no serious communication problems such as blindness and hearing loss, having no serious physical or psychological problems, hospitalized patients in all departments except the wards that was mentioned for nurses.

Exclusion criteria for both groups of patients and nurses were unwillingness to continue cooperation. Data were collected using demographic questionnaire, Lenik & Kiel Moral Intelligence Questionnaire and Nurse Professional Commitment Questionnaire (NPCS). We used Moral Competency Index of Lenik & Kiel to investigate moral intelligence with 40 questions including 10 items of moral competence. Distribution of scores of nurses’ moral intelligence were excellent (90-100), very good (80-89), good (70-79), and poor (>69).

The validity and reliability of the moral intelligence questionnaire were confirmed by Martin and Benjamin. The NPCS was first designed by Lachman and Aranya in 1968 with a reliability of 0.86. This questionnaire was first used in Iran by Shali and Joolaei with acceptable reliability, so that Cronbach’s alpha coefficient was 0.72.
Statistical Analysis: Data were coded and analyzed through SPSS version 16 (SPSS Inc., Chicago IL, USA). Descriptive statistics (frequency, mean, and standard deviation) and analytical statistical tests were used to access the research objectives. Kolmogorov-Smirnov test was used to determine if the data were obtained from a normal distribution. According to the normal distribution of the data, Pearson’s correlation coefficient was used. Stepwise regression was used to investigate the predictive power.

Results

The mean and standard deviation of nurses’ age, nurses’ work experience and patients’ age were (29.56±5.48), (5.53±4.87) and (43.74±16.88) respectively. The education of 90 nurses was bachelor’s science and 10 was master’s science, and 27 nurses participated in seminars or workshops (Table 1). Most nurses had a good level of moral intelligence (Table 2). The mean score of moral intelligence and professional commitment among nurses was 71.79±8.87 and (84.50±11.42) respectively (Table 3). There was a significant direct relationship between the overall score of moral intelligence and professional commitment (r = 0.47 and p = 0.001) (Table 4). Multiple correlation coefficient results indicated that based on the first model, the dimensions of nurses’ moral intelligence explained 41% of the variance of nurses’ professional commitment, and of the four dimensions of nurses’ moral intelligence, only the compassionate dimension had the most significant effect (P = 0.03, β= 0.32) (Table 5).

Discussion

In this study, the level of nurses’ moral intelligence was assessed at a good level. The results of the present
study are consistent with the results of Mohammadi et al. and Khosravani et al. who rated the level of moral intelligence at a good level. The findings of the present study were not in line with the findings of the study by Bahrami et al., who assessed the level of moral intelligence of faculty members and staff of Yazd Shahid Sadoughi University of Medical Sciences at very good level. The differences in findings regarding the level of moral intelligence can be related to the different community and study sample. Nursing is a profession in which ethics is an important principle in providing care to patients. The result can therefore be a confirmation of the morality of the profession. According to the search, no external study that examined nurses’ moral intelligence was found. Therefore, the researchers were satisfied to compare the level of moral intelligence in this study with the studies in Iran.

The professional commitment of the nurses under study was good and more than average value. In the study by Shali et al, the mean total score for professional commitment of nurses was 86 indicating high level of professional commitment of nurses under study. A study by Lu et al, conducted in Taiwan to assess the professional commitment of nurses revealed that nurses had a high level of professional commitment. In the study by Moradi et al., the professional commitment of nurses working in Qazvin educational centers was evaluated at a moderate level. Al-Hamadan also reported a moderate level of professional commitment of nurses working in private centers and educational hospitals in Jordan. In this study, there was a significant and direct relationship between the total score of moral intelligence and professional commitment and the dimensions of nurses’ moral intelligence explained 41% of the variance of nurses’ professional commitment, and of the four dimensions of nurses’ moral intelligence, only the compassionate dimension had the most significant effect. In the study of Lakeh et al., the results of multivariate linear regression model showed the effects of honesty and compassion subscales of moral intelligence on job satisfaction of university faculty members. Compassion means paying attention to others and creating an atmosphere in which people care about those around them, such as colleagues or patients. Compassionate people give priority to others. As a result, they show greater devotion to the profession, patients and colleagues and seems to have more job satisfaction.

**Conclusion**

In general, the results of this study showed the predictive power of moral intelligence on the important concept of professional commitment of nurses. Appropriate training programs that enhance nurses’ moral intelligence level simultaneously affect the important concepts of professional commitment.

**Competing Interests:** Authors have declared that no competing interests exist.

Abstract

Stunting is a nutritional problem in Indonesia which prevalence has experienced an increased every year. One way to overcoming nutritional problems, especially stunting, is the availability of technology, including early detection [tool] for prediction of stunting. The general objective of this research was to develop an early detection tool for predicting stunting. This research was a cross-sectional study. This research was conducted in Kendari and Semarang, from April to December 2019. The research population was children under two years-old in Kendari and Semarang. The samples of this research were children under two years-old in Kendari and Semarang. The data analysis was done using the SPSS program. The research results are: The prediction of stunting is formed when the maternal height variable is a predictive factor for stunting \(p_{v} = 0.004 \ C I\) (1.573–11.438); shorter maternal height with a tendency of 4.242 times. Feeding is a predictive factor for stunting \(p_{v} = 0.047 \ C I\) (1.015–14.229); feeding to baby is only breast milk with a tendency of 3.800 times. The maternal education is a predictive factor for stunting \(p_{v} = 0.012 \ C I\) (1.153–3.225); lower maternal education with a tendency of 1.929 times. The use of drinking water is a predictive factor for stunting \(p_{v} = 0.027 \ C I\) (1.072–3.213); the use of unfiltered drinking water with a tendency of 1.858 times. The prediction of stunting is formed when the variable of maternal height is short, feeding to baby is only breast milk and milk, Antenatal Care is lacking, maternal education is low, the drinking water used is unfiltered, the type of toilet used is other than gooseneck toilet and the birth weight is LBW, then the prediction of stunting would be 85%. Suggestions given in this research are that –from the models(variables) taken, namely inappropriate feeding, inadequate ANC and low maternal education can predict stunting status thus it is necessary to make improvements to these variables.

Keywords: Stunting, baduta, early detection.

Introduction

Stunting is one of the nutritional problems faced by all countries\(^1\)-\(^3\), particularly in poor and developing countries. Stunting is a problem with an increased risk of illness and death, slow brain development resulting in delayed motor development and stunted mental growth. Stunting is a predictor of poor quality of human resources which in turn will affect the development of a reliable nation’s potential\(^4\). It is estimated that 40% of children under five years-old suffer a loss of developmental potential; and stunting is a major risk factor\(^5\),\(^6\).

The nutritional status of children with short parent(s), one or both, are more at risk of growing short (having stunted growth) than children with parents of normal height\(^7\). If the parents are short because of the genes on the chromosomes that carry the short trait, it is likely that the short trait will be passed on to their children. But if the short trait of the parents is caused by food consumption or pathological problems, then the short trait will not be passed on to their offspring or children\(^8\).

A study conducted in Ethiopia identify factors associated with high stunting in breast-fed babies. The results show that babies of mothers who have low zinc levels in their breast milk are more likely to be stunted\(^9\). One of the problems in infant feeding is the cessation of
breastfeeding and insufficient complementary feeding. WHO recommends exclusive breastfeeding for the first 6 months of life and continued with the introduction of complementary foods in addition to breast milk until the age of 2 years.

Basic Health Research data in 2013 shows that the prevalence of stunting by province and national was 37.2%, meaning there was an increase compared to 2010 with 35.6% and 2007 with 36.8%. The prevalence of stunting was 37.2%, consisting of 18.0% being very short and 19.2% being short. In 2013, the prevalence of very short (stunted) decreased, from 18.8% in 2007 to 18.5% in 2010. The prevalence of short (stunted) increased from 18.0% in 2007 to 19.2% in 2013\(^{10}\). The results of monitoring the nutritional status in 2015, the description of the national nutritional status for the very short category reached 10.1% and 18.9% for the short category. Meanwhile, the nutritional status of children aged 0 — 59 months by province in 2015 reveals that the prevalence of very short children under five y.o in Southeast Sulawesi was 9.2% and the prevalence of short children in 2010 explains that the prevalence of stunting in Indonesia was 35.6%. The prevalence of stunting in Central Java is considered high, namely 33.6%, with 17% of short children and 16.9% of very short children. One of the areas in Central Java with a high prevalence of stunting is Semarang. Meanwhile, the sub-district with the highest prevalence of stunting is East Semarang sub-district which is 40.16%.

Harahap’s research results on the Disorders of Growth and Development in Children Aged 0.5– 1.9 Years Associated with Poor Food Intake and Parenting explain that protein intake, socio-economic status and child care are risk factors for growth and developmental barriers in children\(^{11}\). Other researches explain that The factor most influencing the occurrence of stunting in children under five years-old in rural and urban areas is the level of zinc adequacy\(^{12}\).

Indicators of the program success can be seen between the suitability of the process and the planned program, the conformity with objectives, the use and utilization of resources effectively and efficiently, and the ability to guarantee the conformity of processes and achievement of goals – through a harmonious control mechanism in one measuring instrument. One system to monitor early detection of stunting assessment activities is in the form of a screening module\(^{13,14}\).

Stunting early detection information system is a tool to track stunting prediction, procedures and policies used to manage early detection of stunting to support the implementation of monitoring of nutritional status (stunting) in an integrated and comprehensive manner within the framework of early detection of stunting. This program will describe the early detection of stunting and intervene when there are indications of stunting\(^{15,16}\).

**Materials and Method**

This research was a cross-sectional study. This research was conducted in Kendari and Semarang from April to November 2019. The population of this research was children under two years-old with a large sample size; 245 people (Kendari with 125 people and Semarang with 125 people). The sampling technique in this research was purposive sampling. The data analysis was done using the SPSS program. The data that has been analyzed are presented in tables and narratives to discuss the results of the research.

**Results**

This research was conducted at two locations, namely Kendari and Semarang. The sample characteristics are shown in Table 1.

</tbody>
</table>
The determination of nutritional status according to the H/A index reveals that those who experience stunting are 42.9% while those who are normal are 57.1%. The gender of the sample is almost equal between male and female, wherein for the male is 53.5% while the female is 46.5%. The percentage of sample age group of 6-12 months is 51.0% and 12-24 months is 49%. Meanwhile, for the categorization of maternal age of <20 y.o is only 2%, 20-35 y.o is 84.9% and >35 y.o is only 13.1%. Most of the maternal education is in the moderate category at 65.7%, while those in the low category are 12.2% and those in the high category are 22.0%. Most of the paternal education is in the moderate category at 66.2%, while those in the low category are 11.4% and those in the high category are 22.4%.

After the multiple logistic regression test was carried out in 5 steps with variables consisting of the maternal height, feeding, pregnancy desire, Antenatal Care (ANC), maternal education, death of siblings, use of drinking water, type of toilet and birth weight, the models for the formation of stunting in this research are presented in Table 2.

</tbody>
</table>
The emerging models inform that maternal height is a predictive factor for stunting $p_v = 0.004, \text{CI} (1.573 - 11.438)$. Children of mothers whose height is less (short) are likely to experience stunting as much as 4.242 times greater compared to children of mothers with normal height.

Feeding is a predictive factor for stunting $p_v = 0.047, \text{CI} (1.015 - 14.229)$. Babies who are fed with only breast milk or milk have a tendency to experience stunting as much as 3.800 times greater compared to those who are fed with solid food in addition to breast milk/milk.

Maternal education is a predictive factor for stunting $p_v = 0.012 \text{CI} (1.153 - 3.225)$. Children of mothers with low education have a tendency to experience stunting as much as 1.929 times compared to children of mothers with high education.

The use of drinking water is a predictive factor for stunting $p_v = 0.027, \text{CI} (1.072 - 3.213)$. Babies who use unfiltered (unsafe) drinking water have a tendency to experience stunting as much as 1.858 times greater compared to those who use filtered water.

After the calculation of the models, so as to see the prediction of stunting from all variables then the following equation (Eq) is used:

$$y = \text{constanta} + B (BH) + B (\text{Feeding}) + B (\text{maternal education}) + B (\text{the use of water}) + B (\text{birth weight})$$

$$y = -3.047 +1.443 +1.375 + 0.657 + 0.618 +1.003$$

$$y = 0.133855$$

$$p = 1/1 + e^{-y}$$

$$p = 1/1 + (0.133855)$$

$$p = 85\%$$

From this calculation, it shows that if the variable of maternal height is short, feeding to baby is only breast milk and milk, Antenatal Care is lacking, maternal education is low, the drinking water used is unfiltered, the type of toilet used is other than gooseneck toilet and the birth weight is LBW, then the prediction of stunting would be 85%.

**Discussion**

The determinants of health, including stunting, are very complex, ranging from health, sanitation, parenting patterns to political issues\textsuperscript{17-26}. The emerging models inform that maternal height is a predictive factor for stunting $p_v = 0.004, \text{CI} (1.573 - 11.438)$. Children of mothers whose height is less (short) are likely to experience stunting as much as 4.242 times greater compared to children of mothers with normal height.

The height of the parents is closely related to the physical growth of the child. A short mother is one of the factors associated with and predicts the occurrence of stunting\textsuperscript{27}. The results of this study are in line with Rahayu (2011), which states that children born to short mothers or fathers are at risk of becoming stunted. One or both parents who are short due to a pathological condition (such as growth hormone deficiency) have a gene on the chromosome that carries a short trait, increasing the chances of the child inheriting the gene and growing stunted. However, if the parent is short due to nutritional deficiencies or disease, the child may grow to a normal height as long as the child is not exposed to other risk factors. As many as 40% of children have stunted growth (loss of developmental potential) due to stunting\textsuperscript{6}.

Another research also concludes that a short mother, short father, low education level and low income are risk factors associated with the occurrence of stunting in children\textsuperscript{28}. Other studies also state that genetic factors in mothers, namely height, have a strong correlation and can predict the occurrence of stunting in children under five\textsuperscript{5,29}.

Feeding is a predictive factor for stunting $p_v = 0.047, \text{CI} (1.015 - 14.229)$. Babies who are fed with only breast

### Table 1: Coefficients and confidence intervals for predictive factors of stunting.
milk or milk have a tendency to experience stunting as much as 3,800 times greater compared to those who are fed with solid food in addition to breast milk/milk.

This the test results are in accordance with other studies that reveal the level of food consumption, for example lack of vitamin C, is a risk factor for the occurrence of stunting with an OR value of 2.97, meaning that the respondents with lack of vitamin C consumption have a risk of stunting 2.97 times greater compared to those with sufficient level of vitamin C consumption30,31.

Food consumption that must be well cared for in children is the consumption of calcium nutrients (the most abundant mineral in the body – about 99%). The total calcium in the body is found in hard tissues, namely bones and teeth. Lack of calcium during growth period can cause growth disorders. Calcium plays a role in phosphate metabolism by forming solubility in the form of bone mineralization30,32.

The research conducted in Guatemalan explain that children with insufficient consumption will experience stunting (F = 7.069, p = 0.013), for example children who do not consume a sufficient amount of protein source, will likely to experience stunting. Likewise, for not consuming sufficient amount of milk.33. Whereas, a research in Uganda on millet porridge as the main food for children reveals that they could only meet <60% of the recommended daily nutritional intake34.

The research on the Predictors of stunting for children aged 6 – 59 months in the Sodo Zuria District, Southern Ethiopia illustrates that children who receive pre-lacteal feeding are predictors of stunting (AOR = 3.8; 95% CI: 1.2 – 12.2). This happens because children are introduced to complementary foods that are not suitable for the age of feeding35. Meanwhile, the nutritional status of children living in institutionalized care is revealed to have half of the study results on dietary information with inappropriate intake or dietary diversity. Likewise, younger children will experience higher stunting than older children36.

Maternal education is a predictive factor for stunting pv = 0.012, CI (1.153 – 3.225). Children of mothers with low education have a tendency to experience stunting as much as 1.929 times compared to children of mothers with high education. Maternal education level is determined by formal education that has been completed. The level of maternal education is the basis for achieving good nutrition for children because theoretically, the low level of maternal education is a risk factor and can predict the children’s growth. The provision (feeding) of appropriate ingredients and food menus for children in an effort to improve their nutritional status will be realized if the mothers have a good level of education and knowledge. Maternal education and knowledge level influence attitudes and behaviors in choosing quality food ingredients which will affect the nutrition of their family.37

The research on Children Malnutrition in the Metropolitan City of Southeast Nigeria explains that the risk factor for malnutrition is maternal education. Where it is explained that mothers with sufficient level of education will easily seek daily information (about appropriate nutrition for their family) compared to those with low level of education38.

The level of education is related to how mothers can easily get and receive access to information about nutrition and health from outside. Mothers with higher level of education are more likely to receive information from others, compared to mothers with low level of education. The level of education in families of children under five years-old who experience stunting is mostly in the low category, this is due to the economic limitations, including eating which sometimes is just what it is.39

The use of drinking water is a predictive factor for stunting pv = 0.027, CI (1.072 – 3.213). Babies who use unfiltered (unsafe) drinking water have a tendency to experience stunting as much as 1.858 times greater compared to those who use filtered water. Clean drinking water sources are important factor for body health in order to reduce the risk of various diseases such as diarrhea, cholera, and typhus. Children are susceptible to infectious diseases because naturally their immune system is classified as low. The deaths and morbidity of children are generally associated with contaminated drinking water sources and inadequate sanitation.40.

Filtered drinking water sources are healthy environmental sanitation that indirectly affecting the health of children under five years-old, which in turn can affect their nutritional status, in this case – the occurrence of stunting. Nutritional problems, apart from being caused by a lack of nutrient intake, can also occur due to poor environmental sanitation. In this case, unfiltered sources of drinking water and bad personal hygiene make it easier for infectious diseases to occur. This is in line
with other studies which state that there is a relationship between environmental hygiene and sanitation with the occurrence of stunting as these condition can predict the occurrence of stunting in children.

Based on the results of the calculation that if the variable of maternal height is short, feeding to baby is only breast milk and milk, Antenatal Care is lacking, maternal education is low, the drinking water used is unfiltered, the type of toilet used is other than gooseneck toilet and the birth weight is LBW, then the prediction of stunting would be 85%.

**Conclusion**

Based on the results and discussion, the conclusion of this study is that the prediction of stunting is formed when the variable of maternal height is short, feeding to baby is only breast milk and milk, Antenatal Care is lacking, maternal education is low, the drinking water used is unfiltered, the type of toilet used is other than gooseneck toilet and the birth weight is LBW, then the prediction of stunting would be 85%. The suggestions given in this study are that from the models (variables) taken, namely inappropriate feeding, inadequate ANC and low maternal education are proven to be able to predict stunting status, thus it is necessary to make improvements to these variables.

Factors Affecting Subjective Well-Being of the Middle-Aged Class

Hae Kyung Chang

Professor, Department of Nursing, Seosan-si, Republic of Korea

Abstract

Background/Objectives: The purpose of this study is to identify the factors influencing the subjective well-being of the middle-aged class and to identify the relative influence of the variables.

Method/Statistical Analysis: The subjects of this study consisted of a middle-aged class group, aged 40 to 64, among the panels of an online research company, and data was collected from a total of 196 subjects. The collected data were analyzed using descriptive statistics, t-test, ANOVA, post-test Scheffé test, Pearson’s correlation coefficient and stepwise multiple regression using SPSS 22.0.

Findings: The average score of the subjective well-being of the middle-aged class was 3.34. The difference in subjective well-being according to general characteristics was found to be significant according to education (F=4.89, p=.009) and economic status (F = 9.76, p<.001). Subject’s subjective well-being was positively correlated with health status (r=.56, p<.001), meaning in life (r=.66, p<.001), generativity (r=.76, p<.001), self-efficacy (r=.62, p<.001), and social support (r=.57, p<.001). As a result of stepwise regression analysis, generativity (β=.424, p<.001), health status (β=-.209, p<.001), social support (β=.190, p=.001), and self-efficacy (β=.150, p=.014) were factors affecting subjective well-being, and the explanatory power of these 4 variables was 62.6%. The most influential variable was generativity.

Improvements/Applications: This study considered variables in various fields to provide nursing intervention to promote subjective well-being of the middle-aged class, and as a result, it will contribute to promoting a qualitative life by improving the health potential of the middle-aged class.

Keywords: Subjective well-being, health status, generativity, meaning in life, self-efficacy, social support.

Introduction

The middle-aged class has served as a key generation of growth in countries and businesses, and an economic backbone in the home. However, the middle-aged class generation is also a generation that suffers from various difficulties as physical health is weakened, the loss of roles and anxiety about economic sources of income are heightened while preparing for retirement in the labor market.

Especially in middle age, people feel that they have somewhat reached personal achievement, feel emotional stability through social stability, aim to find their identity, and feel true happiness when they find meaning in life\(^1\). Efforts to find meaning in life become the power to lead life well as an opportunity to grow by discovering its meaning in adversity or pain experienced in life\(^2\). The meaning in life is an indicator of psychological health related to happiness and is a variable that has an important influence on quality of life and well-being\(^3\).

In general, the social-psychological development task of middle-aged people is generativity versus...
stagnation, and generativity is the degree of personal internal development that is important for having an identity as a middle-aged adult and indicates the maturity of psychosocial adaptation. However, if the generativity is not obtained at this time, the person may fall into a sense of stagnation and self-righteousness, and the relationship with spouses and others becomes difficult and can suffer psychological difficulties such as atrophy, anxiety, depression, and decreased self-esteem. Generativity is a concept that exists within an individual, but in a social relationship, an individual can increase psychological well-being and increase generativity by perceiving the support of social support systems or resources.

Well-being is divided into two categories, subjective well-being focusing on “hedonic” results and psychological well-being emphasizing “eudaimonic” results. In particular, subjective well-being is a concept that encompasses emotional experiences and cognitive judgments related to life, and cognitive judgment means evaluation of life satisfaction, and emotional experience means static and negative emotional reactions in life conditions. Personal factors affecting subjective well-being include physical change and health status, and health status is becoming a source of effective coping skills by increasing social activity and giving positive meaning in life and value through interpersonal relationships and interactions with others. In addition, subjective well-being is affected by self-efficacy, expectations, environmental support and resources, and social support is an important influencing factor.

So far, many studies on quality of life have been conducted in nursing, but studies on well-being considering the developmental tasks and comprehensive concepts of middle-aged classes are rare. For helping middle-aged classes achieve their development tasks and give them new meaning in life, and in order for them to experience well-being and prepare for successful aging, nursing intervention is needed considering various aspects. Therefore, this study aims to find an intervention that can improve the well-being of the middle-aged class by identifying factors affecting subjective well-being of the middle-aged class.

Method

Subjects: The subject of this study is a panel of a specialized online research company, and is a middle-aged class aged 40 to 64 years old. The minimum number of samples is 178 when calculated by setting the statistical power for regression analysis to 90%, medium effect size 0.15, significance level 0.05, and 11 predictors using the G*Power 3.12 program, and a total of 196 questionnaires were included in the final analysis subject considering the dropout rate of 10%.

Tools:

Subjective well-being: It is a 5-point scale of 30 questions developed by Bakand Hong. The higher the score, the higher the subjective well-being score. The reliability in this study was found to be Cronbach’s α = .75.

Health status: It is a 5-point scale of 4 questions that Chang and Oh developed. The higher the score, the better the subjective health status. The reliability in this study was found to be Cronbach’s α = .90.

Meaning in life: The Korean version meaning of life scale of Won et al. was used. It is a 7-point scale of 10 questions, and the higher the score, subjectively the more meaning in life. The reliability in this study was found to be Cronbach’s α = .87.

Generativity: It is a 5-point scale of 27 questions developed by Lee and Lee, and the higher the score, the higher the level of generativity. The reliability in this study was found to be Cronbach’s α = .95.

Self-efficacy: It is a 4-point scale of 10 questions developed by Schwarzer and Jerusalem, and the higher the score, the higher the level of self-efficacy. The reliability in this study was found to be Cronbach’s α = .90.

Social support: It is a 5-point scale of 12 questions developed by Zimet et al., and the higher the score, the higher the level of social support. The reliability in this study was found to be Cronbach’s α = .90.

Data collection: Data collection was conducted from June 12, 2020 to June 30, 2020, and it was deemed to have been agreed upon if the person who received the participation e-mail from the company among the panel the of online research company went online and proceeded to answer the questionnaire.

Ethical considerations: This study was approved by deliberation and written consent exemption from the Public Institutional Review Board of the Ministry of Health and Welfare (PO1-202006-22-009).
Data analysis method: The collected data were processed by computer statistics using SPSS/WIN 22.0 program. Descriptive statistics for the general characteristics and variables of the subjects were obtained. The difference in subjective well-being level was determined according to general characteristics t-test, ANOVA, and post-test Scheffé test. The correlation between the subjective well-being and the variables was analyzed by Pearson’s correlation coefficient. In addition, in order to identify factors affecting subjective well-being, it was analyzed by stepwise multiple regression after multicollinearity diagnosis.

Result

General characteristics of subjects: The distributions of the gender were 94 male (47.5%), 104 female (52.5%). Mean age of the subjects was 52.7(±7.93) years old and 60 to 64 years old group was the most among these with 196 persons (33.8%). University graduates were the most with 128 (64.6%); 152 (76.8%) had their spouses; 115 (58.1%) had no religion; and 156 (78.8%) had occupations. With respect to the economic status, 132 (66.7%) answered as

**Influencing factors on subjective well-being:** To identify factors affecting subjective well-being, education and economic status, which showed significant differences in general characteristics, were converted into dummy variables, and a total of 7 variables, such as health status, meaning in life, generativity, self-efficacy, and social support, were input to perform regression analysis in a stepwise manner (Table 4). As a result, generativity ($β=.424$, $p<.001$), health status ($β=.209$, $p<.001$), social support ($β=.190$, $p=.001$), and self-efficacy ($β=.150$, $p=.014$) were identified as significant variables explaining subjective well-being. The explanatory power of these 4 variables was 62.6%, and the most influential variable was generativity ($β=.424$, $p<.001$). The concept of self-efficacy is applied in various fields in nursing or health-related fields, and since it acts as a determinant in creating behavioral change and characteristics was found to be significantly different according to education and economic status. In the study of Chang and Sohn$^{10}$ using the same tool for middle-aged men and women, subjective well-being was found to have a significant difference according to economic status, which was consistent with the results of this study. However, early studies of well-being reported that the influence of demographic variables on subjective well-being is low, so further studies are required$^{16}$.

The average of subjective well-being of the subjects was 3.34 points. In the study of Chang and Sohn$^{10}$, the score was 3.36, which was similar to the results of this study.

Subjective well-being was shown to correlate with health status, meaning in life, generativity, self-efficacy and social support. These results are consistent with the results that meaning in life is closely related to quality of life and well-being and health status$^{13}$. In addition, generativity correlates with social support$^{17}$, and subjective well-being correlates with meaning in life, self-efficacy, and social support$^{18}$, supporting the results of the study.

As a result of stepwise regression analysis to identify factors affecting subjective well-being, generativity, health status, social support, and self-efficacy were found to be significant variables for explaining subjective well-being. The most influential variable was generativity. Generativity is related to psychological well-being, self-esteem and life satisfaction, and subjective well-being can be felt in the process of obtaining generativity$^{6}$. The second influential variable was health status, which was shown in the study by Chang$^{18}$ as a variable influencing middle-aged well-being, which was consistent with the results of this study. Health status means physiological adaptation, and as the health status worsens, the quality of life is reported to decrease$^{11}$, supporting the results of this study. Social support appears to be an important factor influencing well-being and supports the results of this study$^{7}$. However, the result of the study by Chang$^{18}$ showed that social support did not affect middle-aged well-being, which was contrary to the results of this study. These results are estimated to be the result of different variables input as subjects, measurement tools used, and predictors, and further study is needed.

**Discussion**

Subjective well-being according to general...
synchronization for problem solving in the middle-aged class\textsuperscript{20,21}, it can be confirmed that it is a factor influencing subjective well-being.

On the other hand, although meaning in life was highly correlated with subjective well-being, it did not appear as a variable affecting subjective well-being in the middle-aged class. However, meaning in life is a decisive component\textsuperscript{13} of well-being, and repeated studies using the same measurement tool are needed for these contradictory results.

Through the above results, it is necessary to provide information and build a system to utilize the community infrastructure to establish the middle-aged identity and strengthen the support system. Furthermore, it is necessary to promote the physical and mental health of individuals to prepare for retirement and to actively reorganize and understand the meaning in life from middle to old.

**Conclusions**

Generativity, health status, social support, and self-efficacy were identified as significant factors predicting the subjective well-being of the middle-aged class.

This study is meaningful in that it considers physical, mental, and social variables to promote subjective well-being and prepare for successful aging by increasing generativity, a development task of middle-aged class. In particular, by identifying factors affecting subjective well-being of the middle-aged class, it provides a framework for exploring individualized nursing intervention method, and it will contribute to improving the quality of life by improving the health potential of the middle-aged class, their family and, furthermore, the elderly.

E-Learning Innovation in Indonesia: Journal Sharing of Critical Care (JSCC) for Nursing Students in the Pandemic Covid-19

Heru Suwardianto1,2,3, Vitaria W.A.3

1Associate Lecturer, Certified Expertise Critical Care (CECC), 2Indonesian Critical Care Nurses Association (ICCNA), 3Baptist Hospital Health Collage in Kediri Indonesia

Abstract

The challenge during the COVID-19 pandemic was Nursing Students studying at home. The innovation of e-learning encourages Clinical Reasoning, patient safety, self-actualization, clinical decision, professionalism, and competences. The purpose of this study was to determine the effectiveness of the E-Learning Innovation: Journal of Sharing Critical Care (JSCC) in Critical Nursing Students during the Pandemic COVID-19.

Research Design uses Descriptive Analysis. The population was all professional nursing students. The sample size was 39 respondents using purposive sampling. Inclusion criteria are students who can complete the learning process for 2 weeks. The independent variable was JSCC. The dependent variable was primary assessment, diagnostic procedures, nursing care, Soft skills, and Outcome. Instrument use Edlink Application. Data analysis uses Partial Least Square (PLS).

The results showed that the variable The ability to explain theory had a positive relationship with The ability to make nursing care (ρ = 0,000), primary assessment with the ability to make nursing care (ρ = 0,000), The ability to explain diagnostic procedures with nursing care (ρ = 0,000), The ability to make nursing care with Soft skill (ρ = 0,000), and soft skill has with Outcome (ρ = 0,000) with t statistic> 1.96 in The ability to make nursing care (t statistic = 25,273), Soft skill (t statistic = 8,15), Outcome (t statistic = 9,267).

The innovation of learning method using e-learning journal sharing of critical care has a positive impact on explaining deeper cases, strengthening learning competencies, and critical thinking.

Keywords: e-hearing, critical nursing, journal sharing.

Introduction

Pandemic COVID-19 is an outbreak of coronavirus disease 2019 (COVID-19) which attacks many victims globally as well as in Indonesia1,2. The cause of the Plague was due to the rapid spread of COVID-19 to various countries and caused many deaths. The reason is because of the rapid spread of COVID-19 which is easily transmitted through saliva splashing or maybe also airborne. The plague is certain to continue to increase with the increase in COVID-19 victims, the Indonesian government in May 2020 issued a policy to work, worship, and study at home3. Local governments also follow the recommendations of the central government by making circulars related to physical distancing, using masks when leaving the house, washing hands with soap and running water, studying at home, worshiping at home, and working at home. The world of nursing education in Indonesia is also affected by government policy, so lecturers must innovate in the learning process at home for a long time. Nursing students who are currently going through the education process are also affected because of the COVID-19 Pandemic. The impact is felt by every student and lecturer in the learning process in Indonesia. The impact that is seen through the learning process is the change in learning method in nursing students who were initially conventional and are now fully engaged in using e-learning innovations. Nursing students are currently enrolled in critical nursing...
courses. Students have different challenges in 2020 in completing assignments and completing the existing learning process. Critical nursing students must also complete the workload they get during the COVID-19 Pandemic. If this pandemic is not finished soon, the learning process will be hampered and the need for learning innovations to find the best solution without leaving aside the competencies obtained by students.

WHO data on May 8, 2020, found COVID-19 cases in the world of 3,759,967 confirmed cases with 259,474 deaths. Data from the Ministry of Health on 9 May 2020 found COVID-19 cases in the Southeast Asia Regional of 86,294 confirmed cases with 3,075 cases died. WHO data on May 8, 2020, also shows that in Indonesia there were 12,776 confirmed cases of COVID-19 with 930 deaths with transmission classification as community transmission4,5. Whereas on May 11, 2020, COVID-19 cases in Indonesia found 14,032 confirmed cases with 1,176 deaths in 6. The health university in Kediri City has dismissed its students to study at home, but the learning process must still be carried out11. Some health schools in China formally cancel formal teaching in hospitals, have their exams suspended, and hinder the education of health students in the face of a pandemic, as well as in Canada, the effects of the Pandemic virus restriction cause cessation of clinical practice and choice for students for up to 6 weeks8. Cui’s research results in 2018 showed that the effectiveness of evidence-based nursing is superior to traditional teaching in students’ critical thinking9. Competence in practice using evidence-based practice or journal sharing is better than other method 10. The health university in Kediri City has dismissed its students to study at home, but the learning process must still be carried out11. STIKES Kediri Baptist Hospital has also closed students and carry out learning from home. The need for innovation related to the learning process of nursing students who are also supposed to practice in hosp. The role of lecturers in facing the challenges of using e-learning fully without using conventional method (lectures) during COVID-19 needs to make innovations that focus on student activity. The use of e-learning method, in full without any physical interaction (lecture method) requires a student-focused learning approach. The use of sharing journals can improve student self-efficacy, increase information literacy, improve perceptions of evidence-based practice (EBP), and intrinsic academic motivation to experience stimulation, and can predict the future implementation of EBP 7,12–14. Satisfaction increased significantly in satisfaction surveys that were routinely collected over one year related to the curriculum by providing material related to evidence-based nursing practice 15. The results of previous studies show that overall, there is no significant difference between groups with e-learning and conventional learning or face-to-face relating to the knowledge, skills, and satisfaction of nursing students, and also E-learning can be used in offering alternative education method15–17. The study uses an e-learning model with a journal sharing approach to work on nursing care reports, measure competence, and exam results in critical nursing periods. Students do a Journal Sharing or research results to students to be able to do in-depth analysis related to interventions or measuring tools obtained through journals and are expected to improve the quality of care and get the best means of intervention or measuring tools in carrying out nursing care in the critical nursing area. Implementation of Evidence-Based Practice Nursing must continue to be developed, implemented, and evaluated using validated method including the use of best practice standards 18. Learning to students using method like this needs to be developed to improve the quality of applications of research results in the area of health services. Learning method don’t have to be classed, can also use online media through e-learning to apply evidence-based practice using JSCC. Traditional learning in the class can be transferred to online media and is inseparable from the learning styles of students. Students feel that online programs can meet their needs in learning. Lecturers applying technological innovation in nursing education require an understanding of learning directly to students so they can satisfy and meet the needs of students.

Materials and Method

The study uses a descriptive-analytic research design. Descriptive Analytic Research was to use crosssectional research that analyses deeply related to several variables studied. The purpose of this study was to analyze the E-Learning Innovation: Journal of Sharing of Critical Care (JSCC) in Critical Nursing Students during the Pandemic Period of COVID-19. The study population was all final-year nursing students at STIKES Kediri Baptist Hospital. The research sample was nursing
students at the final level of Nursing at STIKES Baptist Hospital in Kediri using the Total Sampling Technique. Total Sampling is a sampling technique that uses the entire population as research respondents. The sample size of this study was 39 respondents. The independent variable of the study is critical nursing competency. Implementation of JSCC for 6 weeks, with a load of 6 critical nursing care. JSCC procedures namely 1) The learning process using paid edlink applications (https://edlink.id/login) 2) students get pseudo cases of critical patients through e-learning 2) students conduct critical nursing assessments based on case theory or diagnostic prognosis, primary assessment, and diagnostic procedures 3) students make nursing care through Main complaint assessment, problem priority analysis, outcome nursing care plan, nursing care plan, 4) students determine interventions by comparing interventions or measuring tools based on journals or research results and sharing them through video conversion with students and other lecturers 5) after students implement JSCC 6 months the students assessed Fatigue, competency and exam score scores. This research was conducted data collection from March to April 2020. Data collection using questionnaires based on Edlink Application and Google Form. The scoring technique uses an interval data scale from 0-10 (less to very good). The results of the study were tabulated and coded and then analyzed using Partial least square (PLS). The study has obtained a letter of ethics clearance from the Chakra Brahmanda Lentera Institute with letter number 001/25/V/EC/KEPK/Lemb.Candle/2020.

Results and Discussion

Results: Measurement of the outer reflective model using reliability and validity. Reliability using Cronbach’s alpha with a minimum value of 0.7, the value on the outer loadings obtained the latent variable value (the ability to explain the theory, primary assessment, diagnostic procedure, nursing care, soft skills, and outcome) ≥0.7. Convergent validity using the average variance extracted (AVE) value with a value of ≥ 0.5, which means that this value describes sufficient convergent validity and means that one latent variable can explain more than half of the variance of the indicators on the average. The results showed that composite reliability, which is a group of indicators measuring a variable, has good composite reliability because it has a composite reliability ≥ 0.7. The results showed that the Goodness of fit model was measured using the R-square dependent latent variable with the same interpretation as regression. Q-Square predictive relevance for structural models measures how well the observed value is generated by the model and also its parameter estimates. The value of Q-square> 0 indicates that the model has predictive relevance, otherwise, if the value of Q-square ≤ 0 indicates that the model lacks predictive relevance. The results showed that the results of T-statistics with α = 5% and t = 1.96, obtained a variable T statistic> 1.96 with a positive original sample estimate, so all variables have a positive relationship between variables (The ability to make nursing care with Soft skill; Soft skill with Outcome; Outcome with Soft skill).

![Figure 1. PLS E-learning “Journal Sharing of Critical Care (JSCC)”](image-url)
Discussion

The results showed that there was a strong relationship and validity and reliability were confirmed for each latent variable. The strong relationship between the ability to explain the theory to the ability to make nursing care, this explains that the ability of students to explain theory through e-learning using the edlink application in the journal sharing of critical care model in the practice of the nursing profession shows validity, reliability, and relationships strong and positive. The ability of students to explain the theory. Students can explain the concepts of medical diagnosis, etiology, clinical manifestations, pathophysiology \((p = 0.000)\). Students understand medical diagnosis in critical nursing using the JSCC E-learning model. Students demonstrate their ability to complete assignments, pre convergence assessment results, and video conferencing post conferences. Lecturers give questions related to cases theoretically and direct students in understanding the etiology of diagnostic problems, clinical manifestations to the course of the disease to have an impact on subsequent nursing care. Students can understand the signs and symptoms of the case and refer to it as major and minor data to establish a nursing diagnosis. Nursing care is inseparable from the ability of students to understand the basic medical diagnosis cases that arise, students can see the prognosis of the disease, and the direction of the disease will develop.

The results also showed that there was a close and positive relationship between the ability to explain the primary assessment and the ability to make nursing care. The ability of students in conducting critical nursing care assessments by conducting primary assessment studies including airway studies, breathing studies, circulation studies, disability studies, and exposure studies. Critical nursing students must be able to perform competencies or actions for each primary assessment carried out, this is important because it deals with critical conditions in patients. A close and positive relationship based on statistics shows that students studying during the Pandemic COVID-19 period were still able to have the standardized abilities of higher education in health Baptist hospital health colleges in Kediri. Students learn from home but they can carry out assignments and achieve predetermined primary assessment competencies. Teaching online research does not improve attitudes toward research, but nursing students report an increase in understanding of research terminology 19–21. Critical care nursing research tends to increase collaboration with patients and families, illustrating the shift towards user values 22–24. Students in conducting nursing care also focus on the primary assessment that has been done. Nursing care plans made by students must be based on a journal or research results. Students use evidence-based practice and are directed as needed for each primary assessment that has been obtained. JSCC allows students to analyze journals using PICO (population, intervening, control, outcome) data extraction and is compared to each nursing care plan that will be provided.

The results showed that there was a relationship with a strong and positive relationship between the ability to explain diagnostic procedures and the ability to make nursing care \((p = 0.000)\). Students get pseudo cases through e-learning media with the method of journal sharing for critical care. Students analyze laboratory and diagnostic results to analyze the relationship with problems that occur in patients. Students connect the
problem of abnormal conditions related to the diagnostic results obtained and finally determine the problems in nursing care. Students make follow-up plans for nursing care based on evidence-based practice following the problems found. Educational interventions to improve the competence of mentors must be designed \(^{16,25,26}\). Evidence-based practice is very important for nursing education because Florence Nightingale is a pioneer of evidence-based practice and technology is a key component of the evolution of evidence-based practice \(^{27,28}\). Diagnostic procedures that were analyzed included abnormal values of cardiac output, fluid balance, acid-base, blood chemistry, IWL, mean arterial pressure, fluid balance, and CBC.

The results showed that the ability to make nursing care with soft skills had a strong and positive relationship \((P = 0,000)\). Sub variables that are in it indicate that there are a high validity and reliability related to the making of nursing care with the ability of students in the realm of soft skills. The ability of students in making nursing care has sub-variables as a measuring tool including the meaning of the main complaints, analysis of priority problems, the objectives of nursing care, and planning of interventions based on evidence-based practice. Students can also achieve their soft skills in the form of clinical reasoning skills, patient safety, self-development, and self-actualization. Students plan critical nursing care in a structured manner with an evidence-based practice approach from sharing journals that have been made previously. E-learning based learning method for students of the critical nursing profession with a journal sharing of critical care approach in the area of intensive care to improve evidence-based understanding based on practice must be carried out due to the existence of Pandemic COVID-19 which makes students unable to achieve their competence in the practice field and have an impact on learning conditions \(^{22,29}\). This learning method shows the existence of learning preferences, interactive learning, course design, patient safety, and future learning needs. The e-learning program captures the learning styles and needs of students. Evidence-based practice underscores the modern approach to nursing to ensure the provision of safe, up-to-date, and person-centered care in a developing clinical environment.

Professional students at the critical nursing stage carry out nursing care with secondary and primary data. Students generally do nursing care without using research or journal results when doing nursing care. But at this time because there is a Pandemic, students use secondary data and the use of journals without doing practice. Students are more focused on conventional nursing care in general, which makes sharing information related to research results less. Journal sharing is expected to increase knowledge and information related to new things from information that can be applied to nurses based on evidence. Critical nursing care by sharing journals with students, students can be more exposed and easier to understand in doing nursing care with the best action on patients. Evidence-based practice can support the nursing profession to ensure the provision of safe, current, patient-centered care \(^{15,30}\). The nursing curriculum includes this as a good learning method for students and easy internet access in implementing it. Lecturers and students are connected in a flow and can discuss well related critical care to be provided. Professional students will further enhance the understanding between evidence and clinical practice and will ultimately increase self-confidence in students when students take care of patients in clinical settings. The learning method for professional students is by sharing a journal of Critical Care (JSCC). In the condition of Pandemic COVID 19 online student learning method based on professional profession. Digital learning innovation method with online media can be used. The method of the Sharing Journal of Critical Care (JSCC) can still be used with students conducting a journal analysis and making nursing care based on evidence-based practice.

The results also showed that the ability of the student soft skill to influence the outcome was in the form of the final score of the critical nursing competency test and the level of student fatigue. Higher education bridges the practice gap in increasing knowledge, through learning method using journal sharing of critical care based on evidence-based practice to remind knowledge of college students. Findings from small-scale research studies also indicate that e-learning does meet a variety of learning styles and the needs of nursing students, but we all also understand that online learning alone is not enough nor should a mixed approach to learning also be adopted to meet and bridge the gap in theoretical practice which supports the integration of knowledge into clinical practice. The application of the Journal of Sharing of Critical Care needs to also understand changes to research ideas that have been formed beforehand into something accessible and useful, clear links between research and clinical and professional nursing practice, comments on subject and learning formats, improved
skills in search and exploration effective evidence, and improvement for the future. The evidence-based practice supports nursing to ensure the provision of safe, current, and patient-centered care. The critical nursing curriculum includes evidence-based research but students often have difficulty understanding the relevance of research. Making the connection between research and clinical practice open to students increases their overall satisfaction. Improving understanding between clinical evidence and practice increases student confidence in questioning the clinical practice.

Models based on sharing journals or based on evidence in nursing care offer academic support and coping strategies in advanced nursing programs. (Cantwell et al., 2020). The American Association of Colleges supports active learning strategies and strategies must also use student-centered strategies. Although the surveyed nursing students reported moderate ability beliefs, their intention to adopt and integrate EBP in their future nursing practices was relatively high (Labrague et al., 2020). Evidence-based nursing is an important competency for nurses to provide high-quality care. Various educational efforts to improve the evidence-based practice of nurses are ongoing internationally. An evidence-based practice curriculum can be combined and integrated with core nursing courses. Implementing blended learning in EBP education among nursing students is effective.

**Conclusion and Acknowledgment**

**Conclusion:** The ability to explain the theory, the ability to explain primary assessment, the ability to explain diagnostic procedures have a strong and positive relationship to the ability to make nursing care. Students can make nursing care that has a positive impact on Soft Skills, and Outcome.

Regional Exposure to Air Pollution and Health Behaviors as a Risk Factor for Suicide Attempt: The Seventh Korean National Health and Nutrition Examination Survey (KNHANES), 2016-2017, Korea Centers for Disease Control and Prevention

Jung Nam Sohn
Professor, Department of Nursing, Hanseo University, Republic of Korea

Abstract

Background/Objectives: The purpose of this study is to identify the influencing factors of fine particle concentration level by region and health behaviors on suicide attempts.

Method/Statistical Analysis: This study used the 7th (2016-2017) primitive data disclosed by the National Health Nutrition Examination Survey. Considering the design features of the sample data, it is analyzed with a complex sampling method by reflecting stratas, clusters, and weight. The data were analyzed using logistic regression analysis of the complex sample using the SPSS/WIN 18.0 program.

Findings: As a result of logistic regression analysis, the provability of suicide attempt was 12.32 times (95% CI 5.33-28.49, \( p < .001 \)) higher in depression diagnosis group, 5.55 times (95% CI 1.87-16.46, \( p = .002 \)) higher in 10 or more drinks in single session group, 2.48 times (95% CI 1.07-5.73, \( p = .003 \)) higher in high perceived stress group, and 0.1 unit increase in Health-related Quality of life (\( \beta = -2.35, p = .030 \)) resulted in 0.79 times factor on suicide attempt rate.

Improvements/Applications: This study can provide basic data to develop an intervention program that can reduce suicide attempt rate by analyzing environmental and health related factors affecting suicide attempts.

Keywords: Air pollution, health behavior, suicide, depression, quality of life.

Introduction

Korea’s suicide rate was 24.3 per 100,000 in 2017\(^{[1]}\) and it is very high compared to 11.58 people per 100,000 population, which is the average suicide rate in OECD countries in 2015, second only to Lithuania\(^{[2]}\). Suicide is an important indicator of the mental health of the general public and plays an important role in identifying the weaknesses of the nation’s mental health system.

Suicide is caused by multiple causes, including various physical, mental, and sociocultural factors. Recently, some studies on environmental factors related to suicide-related behaviors were conducted\(^{[3]}\). Among the various air pollution materials, ultrafine particle, due to its small size, affects the central nervous system and induces an inflammatory reaction, which is considered to be highly likely to have a neurobehavioral effect\(^{[3]}\). In addition, when the concentration of fine particle PM10 increased by 1 \( \mu g/m^3 \), the probability of death due to suicide was significantly increased by 1.008 times compared to the probability of death by other factors\(^{[4]}\), and from 2002 to 2013, in the results of a long-term follow-up study of the National Health Insurance Corporation sample cohort data, the risk of suicide by region increased over a long period of air pollution exposure as suicide increased more than 4
times according to air pollution in the highest level (4th quartile) from the lowest level (1st quartile)[5]. Therefore, it is necessary to study how environmental factors such as air pollution are related to suicide attempts.

Other health behavior factors such as health-related quality of life, perceived stress, depression, and drinking have been reported to be related[6-9]. It has been reported that the risk of suicidal thought is low when health-related quality of life is good[6]. Depression is reported as the riskiest factor among suicide-related behaviors[7-8]. In addition, studies on the relationship between environmental factors and suicide attempts among suicide-related factors have not been conducted. In recent years, the global environmental pollution problem has become serious and the damage to the health is expected, but the result is difficult to predict. Therefore, research on the relevance of health effects such as suicidal behavior of environmental factors is needed. Therefore, by analyzing the relevant data on the fine particle concentration by region of the Ministry of Environment and data from 2016 to 2017 out of the 7th National Health and Nutrition Examination Survey, the aim is to determine the effect of fine particle concentration by region and health behavior on suicide attempts.

Method

Subjects: This study used the 7th (2016-2017) primitive data disclosed by National Health and Nutrition Examination Survey[9] and the annual air pollution level provided by the Ministry of Environment[10]. The National Health and Nutrition Examination Survey used a two-stage stratified cluster sampling method, with each sample’s enumeration district and household as primary and secondary sampling[9]. In this study, a total of 16,277 people aged 19 and over were the final subjects for this study.

Instruments:

Suicidal attempt: The suicide attempt was determined by whether or not a suicide attempt was made in the last year[9].

Regional exposure to air pollution: For the fine particle exposure, the average PM10 (fine particle) concentration data of the year was used for the annual air pollution level of the Air Korea’s annual report[10] on air quality for the subject’s residence area. In this study, the PM10 4th quartile of the year was calculated and analyzed.

Health behavior: Health behavior was measured by health-related quality of life, depression diagnosis, perceived stress, and amount of drinking. Health-related quality of life was measured by EQ-5D is calculated by multiplying each score in five dimensions by weight value, and closer to 1, the higher the health-related quality of life[9]. Perceived stress is the stress perception rate, and the numerator were the number of respondents who felt stress “less” or “strongly” during their daily life[9]. Depression diagnosis was measured by whether or not a depression was diagnosed[9]. The amount of drinking was the average amount of alcohol consumed when drinking[9].

Data collection: This data was surveyed from January to December 2016-2017[9] and annual air pollution level change measurement data by region provided by the Ministry of Environment[10].

Ethical consideration: As of 2015, the National Health and Nutrition Examination Survey conducted the research conducted by the state for public welfare without being reviewed by the Research Ethics Review Committee in accordance with the Bioethics Act and Enforcement Rules[9].

Data analysis: In order to establish the representativeness of the sample to the population, the complex sampling method was used by reflecting strata, cluster, and weight in consideration of the sample design characteristics of the data[9]. The data were analyzed using descriptive statistics of the complex sample and logistic regression using the SPSS/WIN 18.0 program.

Result and Discussion

General characteristics of subjects

The suicide attempter’s mean health-related quality of life was 0.81 (±2.69) and the mean health-related quality of life of non-suicide attempter was 0.95 (±0.001), indicating that the suicide attempter had a low health-related quality of life. There was no significant difference in the proportion of suicide attempts according to the 4th quartile of PM10 concentration of fine particle(F=0.36, p=.972). The rate of suicide attempt was significantly
different according to depression diagnosis (F=112.70, \( p<.001 \)), level of perceived stress (F=33.19, \( p<.001 \)), and degree of amount of drinking (F=18.50, \( p=.005 \)). Among the general characteristics, there was a significant difference in the proportion of suicide attempts according to income level (F=42.79, \( p<.001 \)) and economic activity (F=37.94, \( p<.001 \)) [Table 1].

Factors affecting suicidal attempt of subjects:
To identify exposure to fine particle concentrations and health behavior factors affecting suicide attempts, a logistic regression analysis was performed by adjusting the income level and economic activity, which differ in general characteristics. As a result of the analysis, there was no significant difference in suicide attempt according to the 4th quartile of fine particle concentration (PM10). Among health behaviors, factors affecting suicide attempts were depression diagnosis (\( \beta = 2.51, p<.001 \)), health-related quality of life(\( \beta = -2.35, p=.030 \)), amount of drinking (\( \beta = 1.71, p=.002 \)), and perceived stress (\( \beta = 0.91, p=.033 \)). The group diagnosed with depression was 12.32 times more likely (95% CI 5.33-28.49, \( p<.001 \)) to undergo suicide attempt than the group not diagnosed with depression. Compared to the group with low perceived stress, the group with high perceived stress showed 2.48 times more susceptibility (95% CI
In amount of drinking, compared with the group with 1 or 2 drinks, the group with 10 or more drinks was 5.55 times more likely to attempt suicide (95% CI 1.87-16.46, \( p = .002 \)). In health-related quality of life (\( \beta = -2.35, \ p = .030 \)), a 0.1-unit increase equated to 0.79 times the suicide attempt rate. In other words, the suicide attempt rate increased by 1.11 times as the health-related quality of life decreased by 0.1 units [Table 2].

**Discussion**

In this study, to determine whether air pollution and health behavior affect suicide attempts, the National Health and Nutrition Examination Survey and the Ministry of Environment’s atmospheric environment concentration data were used. In Korea, a policy is in place to establish a national suicide prevention action plan since 2018, to eliminate suicide risk through active intervention and management of suicide, and reduce the suicide rate to 17 by 2022\(^{[11]}\). Recently, on the basis of the results that systemic inflammatory marker (C-reactive protein) has been changed due to environmental pollution, that this is related to suicide risk\(^{[12]}\), and in addition to the existing biological and socio-cultural causes, the relationship with environmental pollution as a cause of suicide has been raised. As a result of designing and analyzing the study based on the results of these previous studies, it was found in this study that it does not affect the suicide attempt according to the annual PM10 concentration exposure by region. This is similar to the result that there was no association between PM2.5 and 29,939 suicides in Japan\(^{[13]}\). However, this is contrary...
to the result that there is a correlation between suicide mortality rate and 5 pollutant concentrations during the week, and a reported result of a 3.2% increase in suicide mortality according to weekly PM10 concentration\(^{[14]}\), and the study of suicide deaths in Korea which found that the odds of deaths due to suicide increased 1.008 times as PM 10 concentration increased \(^{[4]}\). In this study, the annual average observed concentration of fine particle concentration by region was applied, and various factors such as temperature that could affect fine particle concentration were not considered. Therefore, in the next study, it is necessary to make a model for predicting the atmospheric environment for pollutant concentration.

In this study, the factor that had the greatest influence on suicide attempts after adjusting income and economic activity was depression. Post-mortem investigations showed that almost all suicide attempters had mental health problems and high levels of depression\(^{[15]}\). In a study in Taiwan, the risk of suicidal thought was 15.5 times higher compared to the group without depression\(^{[7]}\). In this study, the group diagnosed with depression was 12.32 times higher in suicide attempt than the group not diagnosed with depression, which is similar to the results of the previous studies.

The second influencing factor was amount of drinking. In the risk factor analysis of suicide attempters, drinking status was 51.5% during suicide attempt, and drinking was found to be a risk factor affecting suicide attempts\(^{[17]}\). In this study, people with a large amount of drinking were 5.55 times higher than those with a small amount of drinking\(^{[17]}\). In a drinking state, it makes it difficult to control the negative emotions of people who have thoughts of suicide, and the ability to judge is also reduced by paralyzing rational thinking. This condition can easily lead to suicide attempts or suicide\(^{[17]}\).

The third influencing factor was perceived stress. Stress is shown to be a major influencing factor in suicide related behavior \(^{[7, 17]}\). In this study, it was found that a person with a lot of stress is 2.48 times more likely to attempt suicide, and it is similar to the result that stress is a major influencing factor of suicide related behavior\(^{[7]}\), or the result that a person who has a lot of stress thinks suicide 3.5 times more than a person who feels less stress\(^{[17]}\). People with suicide attempt experiences can lead to suicide related behaviors due to inability to address stress well.

The fourth influencing factor was health related quality of life. The health-related quality of life was 0.95 for those who did not attempt suicide, similar to the results for men and women in their 40s, which was 0.95 and 0.92 for 50s \(^{[18]}\), but suicide attempters were as low as average 0.81. This is because health-related quality of life is negatively correlated with suicidal thoughts \(^{[19]}\) and when health-related quality of life is low, suicidal thoughts are 2.5 times \(^{[17]}\) higher than in the high health-related quality of life group.

As a result of this study, air pollution concentration exposure level, which is an environmental factor among the risk factors of suicide attempt, did not appear as an influencing factor of suicide attempts. There should be contributions to reducing suicide attempts by mediating depression, amount of drinking, perceived stress, and health related quality of life which were found to be health behavior related factors affecting suicide attempts.

**Conclusion**

Factors influencing suicide attempts were depression, amount of drinking, perceived stress, and health related quality of life. Therefore, a program to mediate these factors should be developed and applied, and repetitive studies should be attempted to confirm the impact of environmental factors on suicide attempts. Therefore, in order to investigate the short-term and long-term effects of air pollution on suicide-related behaviors, a predictive modelling research on air pollution exposure should be conducted, and corresponding research on risk factors should be conducted.

Tuberculosis in Baghdad, Iraq 2012-2016: Retrospective Study

Ali Kareem Durib1, Ekterina Valerievna Blinova2

1Lecturer, Medical Institute Baghdad, Middle Technical University, Baghdad, Iraq, 2Faculty Surgery Department, National Research Mordovia State University, 68 Bolshevistskaya, Saransk, Russia, 430005, Operative Surgery Department, Sechenov University, 8, Trubetskaya Street, Moscow, Russia, 119991

Abstract

Objective(s): The present study intended at examining the prevalence of tuberculosis in Baghdad City, Iraq for the period of 2012-2016.

Methodology: A descriptive “retrospective” design was applied throughout the present study from the period of November 12th 2017 to February 13th 2018 in order to detect the tuberculosis cases with regard to patients’ demographic characteristics in Baghdad City, Iraq for 2012-2016. A total of (11680) registered patients with tuberculosis are selected. An instrument was constructed for the purpose of the study. Data were collected from the health records at the National Tuberculosis Center, State TB center, and district TB center for the period of 2012 to 2016 with the use of the study instrument. Data were analyzed through the application of descriptive statistical data analysis approach of frequency, percent and total scores.

Results: The study findings revealed that there was a significant difference among them pairwise from this point of view; i.e., the number of married people is more than single, more than divorced and more than a patient with a dead spouse the literacy level of TB patients is significantly different, with (59.77%) of illiterate patients, (2.27%) of elementary education, (18.30%) of secondary education, (19.04%) of secondary education and diploma and (0.61%) university degree. Most of the patients had experienced Extra-pulmonary Tuberculosis (52.36%).

Conclusion: The study concluded that the gender ratio was accounted for the most (2.14:1) in the year of 2015. The urban zone the incidence rate was greater than that of the rural zone.

Keyword: Tuberculosis, retrospective study, prevalence, Baghdad City, Iraq.

Introduction

Tuberculosis, or TB, is a bacterial infection that can spread through the air. It is most often found in the lungs, but can exist in any organ in your body. When a person coughs or sneezes, they can transmit so-called “active” TB. However, many people are also infected with an inactive form of TB, known as latent TB. The bacillus that causes the disease is called Mycobacterium tuberculosis (M.tb). M.tb’s unique cell wall, which has a waxy coating primarily composed of mycolic acids, allows the bacillus to lie dormant for many years. The body’s immune system may restrain the disease, but it does not destroy it. While some people with this latent infection will never develop active TB, five to ten percent of carriers will become sick in their lifetime(1).

The incidence of TB varies with age. In Africa, TB primarily affects adolescents and young adults (WHO, 2011a). However, in countries where TB has gone from high to low incidence, such as the United States, TB is mainly a disease of older people, or of the immunocompromised(2,3).

The limited availability of data on health status is a major constraint in assessing the health situation in developing countries. Surveillance data are lacking for many major public health concerns. Estimates of prevalence and incidence are available for some diseases but are often unreliable and incomplete. National health authorities differ widely in capacity and willingness to collect or report information. To compensate for this and improve reliability and international comparability, the
World Health Organization (WHO) prepares estimates in accordance with epidemiological models and statistical standards\(^{(4-12)}\).

Based on the early stated facts, the present study ought to carry out a retrospective study to investigate the detected cases of tuberculosis in Baghdad, Iraq for 2012-2016 with respect to its demography.

**Method**

A descriptive “retrospective” design was employed throughout the present study from the period of November 12\(^{th}\) 2017 to February 13\(^{th}\) 2018 in order to detect the tuberculosis cases in Baghdad City, Iraq for 2012-2016. A convenient sample of (11680) registered patients with tuberculosis in Baghdad, Iraq for the period of 2012-2016. These patients were males and females and they were one year to over than 65 year of age. An instrument was constructed for the purpose of the study. It is comprised of items that focused on patients’ characteristics of age, gender and type of Tuberculosis. A pilot study was conducted for the determination of the study instrument’s content validity, internal consistency reliability and adequacy. The study was carried out for the period of December 10\(^{th}\) -20\(^{th}\) 2017. Content validity of the instrument was determined through panel of (15) experts. These experts were (5) faculty members at the College of Nursing University of Baghdad, (5) Faculty members at the College of Medicine University of Baghdad and (5) epidemiologists at the Ministry of Health and Environment. They were presented with copy of the study instrument and asked to review it and provide comments for its modification to be more appropriate measure of the study. They had reviewed the instrument and presented their comments with an agreement that the instrument is content valid. Internal consistency reliability was determined for the study instrument through the use of split-half technique and measurement of Cronbach alpha correlation coefficient. The result indicated that Cronbach alpha correlation coefficient was $r=0.85$ which adequately reliable measure for the problem underlying the present study. Data were collected from the health records at the National Tuberculosis Center, State TB center, and district TB center for the period of 2012 to 2016 with the use of the study instrument. Data were analyzed through the application of descriptive statistical data analysis approach of frequency, percent and total scores.

**Results**

Table 1a presents that female patients were slightly larger than male ones. Relative to the living place, this table depicts that patients living in the urban area were accounted for the most (91.85%) (Table 1b).

The results in the Table 1c reveal that 41.92%, 18.53%, 31.05% and 8.50% of the patients were married, single, divorced and patients with deceased spouses, and there was a significant difference among them pairwise from this point of view; i.e., the number of married people is more than single, more than divorced and more than a patient with a dead spouse.

The data show that the literacy level of TB patients is significantly different, with 59.77% of illiterate patients, 2.27% of elementary education, 18.30% of secondary education, 19.04% of secondary education and diploma and 0.61% university degree (Table 1d).

Table 1e indicates that most of the patients had experienced Extra-pulmonary Tuberculosis (52.36%).

Table (2) reveals that reported incidence rate of TB cases according to the geographically in Baghdad during 2012-2016. The rural area incidence rate was 66/100,000 per year and Urban area 166/100,000 per year. The incidence rate of rural area was almost same since 2012 to 2016. Among the urban zone the incidence rate was slightly decreasing during 2012- 2016.

**Conclusion**

Based on the interpretation of the study findings, the study can conclude that:

1. Female patients were slightly larger than male ones.
2. Most of the patients were married, urban area residents, illiterate and having Extra Pulmonary Tuberculosis.
3. The gender ratio was accounted for the most (2.14:1) in the year of 2015.
4. The urban zone the incidence rate was greater than that of the rural zone.
Recommendations:

Based on the early stated conclusion, the present study can recommend that:

1. Patients who were young males and females, married, illiterates and urban area residents can be provided with all means of treatment and preventive measures.

2. Further research with a large sample size and wide range of variables can be conducted.

Immediate Induction of Labour Versus Expectant Management (Waiting for 24 Hours Before Induction) For prelabour Rupture of Membranes at Term

Muna Kasim Mahmood¹, Batool Abdzaid Alsultany²

¹Assistant Professor in Obstetrics and Gynecology Karbala University College of Medicine,
²F.I.B.O.G. Senior Obstetrics and Gynecology in Karbala Maternity Teaching Hospital

Abstract

Background: Prelabour rupture of membrane occur when membrane ruptured without contractions in term pregnancy.

Objectives: To assess the effects of expectant management versus induction of labour in term prelabour rupture of membranes on maternal and fetal wellbeing.

Method: This study is carried out in kerbala maternity hospital from October 2018 till December 2019. (139) patients with rupture of membrane at term in latent phase of first stage of labor. These patient were divided into 2 groups; first group (62 pregnant) which was expectant management for 24 hours and a second group (77 pregnant) which was managed by active induction of labour by using either oxytocin infusion or prostaglandienes depending on Bi-Shop score of the cervix.

Results: 139 pregnant 50 (35.97%) primigravida and 89(64.03%) had at least one previous vaginal delivery. Term with membrane rupture and no uterine contractions. 77(55.4%) start active management of labor with either prostaglandins or oxytocin depending on Bi-shop score of the cervix and 66 (44.6%) start conservative management. Caesarean section was carried out in 24 (17.3%) of the female mostly due to fetal distress and arrest of cervical dilatation. Vaginal delivery occur in 115 (82.7%) . The active management group (19.48%) delivered by caesarean section and (80.52%) delivered vaginally. While the group that managed conservatively (14.52%) delivered by caesarean section and (85.48%) delivered vaginally and the P-value between both groups are not significant (0.593).Regarding the duration of labour we found that expectant management had a mean duration of labour of about 8 hours which is shorter than the mean duration of labour of active management which is 10 hour, but the P-value is statistically not significant (0.440). There are no maternal complications in the two groups of pregnant female, but there is one intrapartum fetal death with active management plane but the difference was statistically not significant. (P-value 0.811).

Conclusion: Conservative or active management of labour are effective as a treatment for term prelabour rupture of membrane, but active management of labour need close monitoring and associate with more complications.

Keyword: Prelabour rupture of membrane, expectant management of labour, active management of labour.

Introduction

Prelabour rupture of membrane occurs in about 10% of all pregnancies, 80% of them occur in term pregnancies.¹ Rupture of membrane occur due to many causes such as over distended uterus (polyhydramnio, twin pregnancy or uterine fibroid), congenital uterine anomaly or cervical incompetence, inflammatory process due to cervicitis or amnionitis or due to smoking and nutritional deficiencies.² Complications of prelabour rupture of membrane include cord prolapsed, cord compression, placental abruption, maternal and neonatal infection and increase incidence of caesarean...
section and operative vaginal delivery\(^2\). Pregnant women with term pregnancy and rupture of membrane without contractions had 2 main management options; conservative management in which we can wait for 24-48 hr with the hope of starting spontaneous contractions and labor (mimic the spontaneous labor) which may cause chorioamnionitis, prolonged labor and active management in which we can initiate the contractions by using prostaglandins or oxytocin infusion to shorten the duration of labor and lower incidence of infection but increase the incidence of fetal distress and caesarean section. \(^3\)\(^4\) Prostaglandin E1 analogue (Misoprostol) can be used for induction of labour as an oral tablet, sublingual, vaginal or rectal which can cause uterine contractions and cervical ripening and is a drug of choice for induction of labour because it is cheap, easily to be administer and no need special temperature for it is use.\(^5\)\(^6\)\(^7\) The recommended dose of oral misoprostol for induction of labour between 50-100 micrograme can be repeated every 4 hours.\(^8\)

**Materials and Method**

139 pregnant female included in the study, who are attained Karbala maternity hospital from October 2018 till December 2019. All these women are in latent phase of first stage of labour (cervical dilatation ≤ 4 cm). Inclusion criteria: Single cephalic presented fetus, Term (37-41 weeks) gestation and had spontaneous rupture of membrane without abdominal pain. Exclusion criteria; Previous caesarean section, Fetal macrosomia, Preterm pregnancy, Signs and symptoms of chorioamnionitis, Signs and symptoms of fetal distress (decrease movement, abnormal Doppler, meconium stained liquir), Maternal medical disease (hypertension, diabetes.), Malpresented fetus, Women in active labour and any contra indications for induction of labour such as placenta praeavla. History taken from these female and general abdominal examination (presentation, contraction, fetal heart rate). Pelvic examination confirmation of rupture of membrane and assessment of cervical dilatation was done. After that these female divided into 2 groups. First group was conservative management (for 24 to 48 hours) and the second group were actively management (induction of labor by prostaglandins or oxytocin depending on Bishop score of the cervix). Women are followed during the whole period of their hospital stay (duration of hospital stay, mode of delivery, route of delivery, maternal and neonatal complications), both groups receive prophylactic antibiotics (oral amoxicillin). Caesarean section was indicated for fetal distress, arrest of cervical dilatation or descend of fetus. After delivery neonates were monitored for early signs of infection or neonatal care unite admission and the females were monitored for any signs of endometritis or bleeding that necessitate blood transfusion.

**Results**

139 pregnant female were included in this study, 50 female (35.97%) were primigravida and 89(64.03%) had at least one previous vaginal delivery. They were term pregnancy between 37 weeks to 41 weeks (mean 39.37). Duration of membrane rupture prior to admission was between one to 24 hours prior to admission with average about 4.67 hours. All female was in latent phase with cervical dilatation of (1–4) centimeter with average 3 centimeter. 77 of these female (55.4%) start active management of labor with either prostaglandins or oxytocin depending on Bi-shop score of the cervix and 66 female (44.6%) start conservative management. Rupture of membrane to delivery time was calculated between 1 to 48 hours with mean of 9.34 hours. Caesarean section was carried out in 24 (17.3%) of the female mostly due to fetal distress and arrest of cervical dilatation. Vaginal delivery occur in 115 (82.7%). No maternal complications were occur in both groups, But there is one intrapartum fetal death in the active management group. Mean hospital stay was about 12.19 hours (2-52 hours) as shown in table (1).

</table>

Table (3) showed that 19.48% of female with active management delivered by caesarean section compared to 14.52% of patients with expectant management that need immediate caesarean section. 80.52% of pregnant female delivered vaginally with active management compared to 85.48% of pregnant female with expectant management, but the P-value was 0.593 which is statistically not significant.

Table (4) showed the relationship between mean duration of labour and management plane of labour, which showed that expectant management had a mean duration of labour of about 8 hours which is shorter than the mean duration of labour of active management which is 10 hour, but the P-value is statistically not significant (0.440).

Table (5) shows the relationship between maternal active (-), expectant (-), P-value () and fetal complications active (1 dead baby (0.7%), expectant (-), P-value (0.811) . There are no maternal complications in the two groups of pregnant female, but there is one intrapartum fetal death with active management plane but the difference was statistically not significant. (P-value 0.811)

**Discussion:** Management options for prelabour rupture of membrane at term are either conservative or active induction of labour. Induction of labour is the most option applied nowadays because of maternal preference this modality of management(9), but induction of labour need close monitoring of uterine contractions and fetal heart rate as it may cause hypertonus uterine contractions, fetal distress, fetal death and rupture uterus. Most female with prelabour rupture of membrane can delivered spontaneously if managed conservatively 24-48 hr in 75-80% of these female(10). In our study we found that both planes of management (expectant or active by induction of labour) had no statistically significance difference regarding maternal, fetal complications, mode of delivery and duration of labour in contrast to study done by Jagrati Kiran in 2015 who found that active management of labour is superior to expectant management regarding maternal and neonatal morbidities and mortalities(11) while similar to the result.
of study done by A. Shetty in 2002\(^{16}\) and Shafqat Fatimain 2015 who also found no statistical significant between the two modalities of management\(^{12}\). There is a study done by Shah Krupa in 2012 who found that the period between rupture of membrane to the delivery was significantly lower in active management unlike our result we found that there is no statistically significant between the two groups\(^{13}\). In our study there was no statistically significant in the incidence of caesarean section in both groups (P-value 0.593) in contrast to study done by da Grace Krupa in 2005 which found higher incidence of caesarean section in conservative management group\(^{14}\). In a study done by Mansi in 2017 found higher incidence of fever and wound infection in women treated conservatively (P-value 0.006 for maternal fever and 0.003 for wound infection)which was statistically significant while in our study maternal and fetal complications between the two groups was not significant\(^{15}\).

Effects of E. Coli Infection on Kidney Function Tests in Experimentally Inoculated Rats

Mundher Jabbar Irsan AL_Okhedi¹, Thaar Mohammed Najim², Bahjat Fakhri Mahmood Al-shammari¹, Mustafa Salah Hasan², Marwa Raad Jead⁴

Abstracts

The aim of this study was to evaluate the kidney function tests in rats experimentally infected with E. coli with monitoring signs of UTI. Forty female rats were divided into two groups, infected (20 rats) and control (20 rats). The infected group were inoculated intraurethral by 10⁸ suspension of E. coli. The animals were monitored for presence of signs. E. coli urine bacterial demonstration were done at 1 week before infection and 24hrs., 48hrs, 96hrs, 6 days, 12 days and 24 days after infection. Blood samples were collected at zero, 24hrs, 3 days, 6 days, 14 days and 24 days. Blood samples for serum BUN and creatinine were collected. The findings suggested that the E.coli isolation has been continuous 24 days since experimentation started. After 24 hrs. post infection, infected rats were suffering from UTIs sings, including frequent urination, pain on urination, foul smelling, diarrhea, poor appetite, and fever. Also, the current results showed that at zero time, all rats present normal value of serum urea and creatinine, Post-infection with E. coli, A significant increase in BUN and creatinine was shown by the infected group at 24 hours, 3 days, 6 days, 14 days and 24 days, as opposed to the control group.

In conclusion, E. coli can induce UTI in rats manifested by increase BUN and Creatinine.

Keywords: Rat, BUN, Creatinine, E. coli, Kidney, UTI.

Introduction

Escherichia coli has been implicated to causes disease in human(1) as well as animals (2,3,4,5,6,7,8).

In addition to gastrointestinal effects, it can cause UTI, meningitis in neonates and humans septicemia(9).

The presence of a specific virulence factors, adaptations of the microbial, encouraging urinal tract achievement, distinguishes E.coli which is a source of UTI and another uropathogens from associated memberships of their genus and species(10). Escherichia coli are the most common organism causing Lower (UTI). Although not all strains of E. coli are pathogenic to the urinary tract which suggested that the infective E. coli strains are a selected group with special properties enabling them to survive and multiply in the host tissue(11).

Creatinine is generated as the final result of muscle metabolism, creatinephosphate is excreted primarily by the kidneys and then mostly through glomerular filtration. Blood creatinine assays are most specific clinically important renal function calculation(12).

The Urea of Blood Nitrogen (BUN) is the protein breakdown product cause acute kidney dysfunction and kidney hypoperfusion incidence(13,14).

An experimental infection of EHEC conducted on New Zealand rabbits by(15) they showed an increase in

BUN level on the eighth day after infection as compared with control group.

Mohawk et al. (16) Managed E. coli O157: H7 was found to have elevated blood urea nitrogen levels in moribund animals, for mice orally.

This study aimed to estimate the kidney function tests in rats experimentally infected with E. coli with monitoring signs of UTI.

**Materials and Method**

Forty female rats were classified into two groups, infected (20 rats) and control (20 rats). The infected group were inoculated intraurethral by $10^8$ suspension of E. coli according to (17).

The animals were monitored for presence of signs. E. coli urinbacterial demonstration were done at 1 week before infection and 24hrs., 48hrs, 96hrs, 6 days, 12 days and 24 days after infection.

Blood samples were collected at zero, 24hrs, 3 days, 6 days, 14 days and 24 days. The blood samples were collected for estimation the serum BUN and creatinine which were done according to manufacturer instructions.

All data were analyzed statistically as described by (18).

**Results and Discussion**

The isolation of the E. coli was continuous for 24 days from starting the experiment, while no bacterial isolation was appeared before infection (Table 1).

These result in agreements with (19,20) who indicated that before the outbreak was triggered there had been a large rise in bacterial counts of infectious groups relative to their bacterial counts.

All rats included in this study had normal yellow urine before the infection was induced, after 24 hrs. post infection, infected rats were suffering from UTIs sings, including frequent urination, pain on urination, foul smelling, diarrhea, poor appetite, and fever.

Infection led to a strong loss-related anorexia body weight in both categories contaminated (21). The renal excretions of arginine vasopressin byendotoxin of E. coli as well as IL-1recovery. Bacterial endotoxin injections or IL-1 can induce fluid intake changes indicating increasing of fluid and water intake (22). The increased consumption of water in an infected group can contribute to body temperature increasing and diarrhea, resulting in loss of fluid as well as dehydration (23). Anorexia occurrence with an infection indicates that anorexia may be an integral part of the process reaction. It seems like the diet, the intake of food might be suppressed when the metabolic rates for each body temperature degree can go up by 10 - 13 percent. Anorexia caused by infections is believed to be the major factor in the negative balance between nitrogen and weight loss of the body (10). This theory has been tested by injection E.coli. Endotoxin bacteria in rodents, culminating in a rise in body temperature and a decrease in the consumption of food (24).

Appetite loss in infected rats is a vital factor for the hosts defence in the deliberate redistribution during infection of nutrients that contribute to “nutritional immunity.” Evidence now shows that suppression of food consumption in both E and fasted rabbits can be due to endogenous cytokines. E.coli and interleukin-1 have been shown to inhibit the consumption of food.

Also, the current results showed that at zero time, all rats present normal value of serum urea and creatinine, Post-infection with E. coli, the infected group displayed a significant increase ($P<0.05$) in BUNas well as creatinine at days 24 hrs, 3 days, 6 days, 14 days and 24 days as relating with control group (Table 2).

BUN’s and creatinin’s increased may be attributable to the consequence of micro-organisms and their toxins on the kidneys, also the results is completely agreed with (25,26,27) have all decided thoroughly to disclose this development. Increased amounts of creatinine and urea for kidney failure, the results of the present research in agreement with (28) who noticed that serum creatinine was higher in contaminated rabbits with pathogenic E. Coli and the animal found in many kidney areas that...
suffered severe destruction. Al-Taae(29) reported a substantial rise (P<0.05) in serum creatinine and urea on day 30 after *E. coli* infection. In comparison with the control group, *E. coli* O157: H7 in rabbits.

The Effectiveness of Audio-Visual Education on Lactation Management and Chocking in Mother with Baby in Pandemic Time Covid-19

Heru Suwardianto¹,²,³, Rimawati³

¹Associate Lecturer, Certified Expertise Critical Care (CECC), ²Indonesian Critical Care Nurses Association (ICCNA), ³Baptist Hospital Health Collage in Kediri, Jl, Mayjend Panjaitan, No. 3B Kediri City, Jawa Timur Indonesia

Abstract

Many mothers with babies who do not give exclusive breastfeeding and do not understand prevention efforts when the baby is choking, so that mothers need to understand lactation management to optimize the purpose of exclusive breastfeeding, and need to equip themselves in preventive management when the baby is choking. The research objective was to determine the effectiveness of lactation management education and management of choking in mothers with babies in East Java Indonesia.

The research method was a pre-experimental pretest-posttest design. The population was all mothers with babies in Kediri City East Java Indonesia. The sample consisted of 30 respondents using the incidental sampling technique. The independent variables were lactation management education and the choking in babies. The dependent variable was Knowledge and Skills. The research instrument used a questionnaire to use google form and Youtube. Data were collected and statistical tests were performed using the Wilcoxon test with α <0.05.

The results showed that most respondents were infants aged 11-15 months (40%), maternal age was 23 years old (30%), had two babies (60%), body weight 10-11 Kg (30%), complete immunization (90%), but 10% of infants are not immunized. All infant respondents receive exclusive breastfeeding and also regularly attend Posyandu. The results of the Wilcoxon statistical test on the knowledge variable obtained a Z value of -4.8 (> 1.96) with a P-value = 0.000 and the choking treatment variable with a Z value of -4.6 (> 1.96) with a P-value = 0.000 which means there is a significant effect of Audio-Visual Education on Lactation Management and Chocking in Mothers with Babies during the Covid-19 Pandemic on the knowledge and improvement of choking management skills in respondents.

Effective education is provided to increase knowledge and skills in the management of choking in infants. Prevention is more important in reducing the morbidity of cases related to nutrition and the incidence of choking in infants.

Keyword: Audio-visual Education, Lactation, Chocking, Mother with baby.

Introduction

Lactation management is an effort or means made to achieve successful breastfeeding. One of the successes of breastfeeding is breastfeeding techniques. Incorrect breastfeeding techniques cause pain and blisters on the nipples because the baby does not feed until the breast areola, if he only feeds on the nipples, the baby will get a little breast milk. After all, the gums do not press on the lactiferous and the mother will feel pain due to blisters on the nipples ¹. Mothers can study lactation management as part of an effort to prepare for labor and breastfeeding so that complications and things that hinder the breastfeeding process can be prevented². A mother after giving birth is obliged or expected to
breastfeed her baby, this is also believed by the existing culture in the community that it is perfect to be a mother if she can conceive, give birth and breastfeed. Obstetricians must take action to safeguard perinatal mental health. The ability to provide support and to protect our breastfeeding mothers becomes extremely difficult where the virus is rampant. Mother’s milk is the best life fluid that is needed by babies. Mother’s milk contains various substances that are important for the growth and development of babies and according to their needs, but not all mothers want to breastfeed their babies for various reasons, for example, fear of fat, busyness, saggy breasts, and so on, some mothers want to breastfeed their babies, but there are many obstacles, usually, breast milk does not want to come out or the production is not smooth. In the Covid-19 pandemic phenomenon that is often found in the community when breastfeeding mothers often have more severe problems due to the mother’s lack of knowledge in proper breastfeeding techniques, this can affect the fulfillment of baby nutrition because they do not get optimal nutrition and can also cause pain, blisters, and redness in the mother because the baby is not feeding using improper technique.

The Pandemic COVID-19 is spreading throughout the world and has increased sharply in the number of infections, the number of pregnant women and children with COVID-19 continues to rise. Maternal age at the time of COVID-19 in Wuhan was between 29-34 years, with clinical manifestations of fever (86%), cough (14%), and shortness of breath (14%) According to a study in Dhaka Bangladesh on 1,667 infants for 12 months, the results showed that exclusive breastfeeding can reduce the risk of death from acute respiratory infections and diarrhea. Providing exclusive breastfeeding for 6 months is recommended by international guidelines which are based on scientific evidence about the benefits of breast milk for babies, mothers, families, and country. Based on the results of research by Susan Narula, (2015) on the Relationship between Knowledge Level and Mother’s Work with the Success of Lactation Techniques in Breastfeeding Mothers, it shows that most (80.4%) breastfeeding mothers fail to perform lactation techniques, (64.7%) breastfeeding mothers have a low level of knowledge and most (80.4%) breastfeeding mothers have jobs. The COVID-19 has ramifications for the delivery of newborn nutrition. The factors that influence the process of breastfeeding mothers with infants aged 0-6 months, it is shown that 47% of mothers show poor breast conditions, 55% of mothers show poor breastfeeding techniques. Based on the results of observations on breastfeeding mothers on February 10, 2020, at Puskesmas Pesantren Kediri City, the results obtained from 10 breastfeeding respondents, 6 respondents were not capable of breastfeeding techniques by 60%, and 2 respondents who were less capable in breastfeeding techniques by 20%, as well as 2 respondents who are capable of breastfeeding techniques by 20%. The results of the pre-study showed that the problems that occurred in breastfeeding mothers were a pain in 40% for 4 respondents, 10% blisters in 1 respondent, and 10% redness in 1 respondent, and without complaint 40% in 4 respondents.

Mothers who have babies aged 0-6 months are obliged to provide exclusive breast milk. Exclusive breast milk is that babies are only given breast milk, without additional fluids such as formula milk, oranges, honey, tea water, water, and without additional solid foods such as bananas. papaya, milk porridge, biscuits, rice porridge, and team. Breastfeeding on time is not enough, not infrequently, failures in breastfeeding, one of which is due to lack of or absolutely no experience and knowledge about how to breastfeed properly. The ability and willingness of a mother to breastfeed are based on a level of knowledge which is a learning process that can produce the expected behavior changes. Giving breast milk alone without any complementary food until the baby is six months old will have tremendous benefits for the development and growth of the baby in addition to increasing the bond of affection between mother and baby. When breastfeeding in public amenities, mothers can wear masks or cloth face coverings to protect themselves, while their infants cannot wear any respiratory protection to avoid direct exposure to the indoor air. The fulfillment of breast milk for infants aged 0-6 months is less effective. This is influenced by the lack of knowledge of mothers in breastfeeding techniques for their babies. Breastfeeding techniques are a way of providing ideal food for the growth and development of the baby, if the mother does not provide proper breastfeeding techniques then the impact on the mother is such as pain, blisters or redness caused by the baby not feeding until the breast areola, while the impact that can occur if babies do not get optimal nutrition from breastfeeding, including the baby’s weight does not increase, and babies often whine because they are not satisfied.

The correct breastfeeding technique is necessary
so that both the baby and the mother feel comfortable and the baby can get the most from breastfeeding. Management of Choking also needs to be properly educated for mothers with babies. Correct breastfeeding techniques can also be useful in reducing infant mortality due to improper breastfeeding positions. Every mother who has a baby needs to know about the correct breastfeeding technique to achieve optimal baby nutrition. Support from nurses and families is very influential in giving breast milk. Nurses can put more emphasis on counseling about correct breastfeeding techniques to prevent common problems that arise such as blisters, pain, and mothers are reluctant to breastfeed because breastmilk does not come out using leaflets and questions and answers so that families and patients can know the importance of breastfeeding in babies.

**Method**

Method were a pre-experimental pretest-posttest design. This research provides visual education through google form and also videos embedded in Youtube by researchers. The questionnaire is also placed on the google form, the assessment uses the Linkert scale. The independent variables of the study were lactation management education and the management of choking babies. The dependent variable of this research is Knowledge and Skills. The study population was all mothers with babies in the Pesantren District of Kediri City. The research sample consisted of 30 respondents. This research uses the incidental sampling technique. Incidental Sampling in the technique of determining the sample based on chance, that is anyone who accidentally meets the researcher can be used as a sample if it is considered that the person who happened to be met is suitable as the data source. How to collect research data using a google form link containing video and uploaded to Youtube. Respondents by accessing Google Form received audio-visual education and were also able to directly evaluate their understanding of lactation management and management of choking in infants. The questionnaire link is given to cadres to be continued and given to mothers with babies. The questionnaire contains videos of lactation management and management of choking infants. The sample size obtained was 30 respondents. This study has a permit from the agency and got an Ethics Clearance. Data were collected and statistical tests were performed using the Wilcoxon test with $\alpha < 0.05$. Ethical Clearance in Chakra Brahmanda Lentera Institute Indonesia with Number 010/09/VII/EC/KEPK/Lemb.Candle/2020.

The results of the study were obtained from 30 respondents of mothers with babies who were respondents during the COVID-19 Pandemic. The results showed that most respondents were infants aged 11-15 months (40%). The results showed that most of the mothers were 23 years old (30%). Most of the respondents had two babies (60%). Respondents Babies weigh at most 10-11 kg (30%). Respondents Babies have the majority have complete immunization (90%), but 10% of infants are not immunized. All infant respondents receive exclusive breastfeeding and also regularly attend Posyandu.

Based on the results of the study, it was found that the average knowledge before the Audio-Visual Education on Lactation Management and Choking in Mothers with Babies during the Covid-19 Pandemic, it was 5.1 and after education, it was 8.8. Based on the results of the study, it was found that the average choking treatment before the Audio-Visual Education on Lactation Management and Choking in Mothers with Babies during the Covid-19 Pandemic was 4.8 and after education was 6.7. The results of the normality test using Shapiro-Wilk showed that all data <0.05, which means that all data groups are not normal, so the statistical test is reduced to Wilcoxon. The results of the Wilcoxon statistical test on the knowledge variable obtained a Z value of -4.8 (> 1.96) with P-value = 0.000, which means that there is a significant effect Audio-Visual Education on Lactation Management and Choking Baby Management in Mothers with Babies during the COVID Period 19 towards increasing knowledge of respondents. The results of the Wilcoxon statistical test on the choking management variable obtained a Z value of -4.6 (> 1.96) with P-value = 0.000, which means there is a significant effect Audio-Visual Education on Lactation Management and Choking Baby Management in Mothers with Babies during the COVID Pandemic Period 19 towards the improvement of choking management skills in respondents.

### Discussion

Lactation management is an effort or method made to achieve breastfeeding success. One of the successes of breastfeeding is breastfeeding techniques. Incorrect breastfeeding techniques cause pain and blisters on the nipples because the baby does not feed until the breast areola, if he only feeds on the nipples, the baby will get a little breast milk. After all, the gums do not press on the lactiferous and the mother will feel pain due to blisters on the nipples. Breastfeeding technique is a way that is second to none in providing ideal food for healthy growth and development of infants and has a unique biological and psychological impact on the health of mothers and babies. Breastfeeding techniques are needed so that babies and mothers feel comfortable and that babies can get the most benefit from breastfeeding. The correct technique of breastfeeding is how to give breast milk to the baby with the correct attachment and position of the mother and baby. Breastfeeding is a way that is second to none in providing the ideal food for the growth and development of a healthy baby.

Based on the results of the study, it was found that Audio-Visual Education on Lactation Management and Management of Choking Babies in Mothers with Babies during the Covid-19 Pandemic had an impact on choking management skills in infants. The baby was associated with increased risk of choking and the highest frequency of choking on finger foods occurred in those who were given finger foods the least often15–17. This shows that the education provided can be used as a preventive in management efforts if choking occurs in infants18,19. Based on the results of the study, most of the mothers who had fewer breastfeeding techniques were mothers who did the breastfeeding technique where the steps were partially carried out and some steps were not carried out. The steps that are not taken by the mother are that the baby is not stimulated to open the mouth by touching the cheek with the nipple after the baby is fed, the suction is not released in the right way, namely by inserting the mother’s little finger into the baby’s mouth, after breastfeeding, milk The mother did not remove a little which was then smeared on the nipple and areola, and the mother also did not check the condition of the breast for injuries or cracks after breastfeeding. In breastfeeding techniques with steps that are not taken by the mother, the mother may have become accustomed to not doing it because the breastfeeding time is not right, and the baby often cries20,21,30,31,22–29. The steps taken in part are that the mother does not wash her hands before the act of breastfeeding, the mother does not sit or lie...
Sufficient breastfeeding technique for mothers is mothers who do the technique with the right steps, and do the technique with partial steps, where the steps are taken correctly are the mother washing her hands before feeding, the mother looking at the baby with great affection, after the baby opens his mouth, quickly the mother brings the breast closer and most of the serial enters the baby’s mouth, the baby is slung in the right way, that is, the baby is held upright against the mother’s shoulder then the mother gently pats the baby’s back. However, it was also found that several techniques were not used, namely, the mother did not stimulate the baby to open his mouth when he was going to be breastfed, the mother did not release the baby’s suction with her little finger after breastfeeding, and the mother did not check the condition of the breast after breastfeeding. This can be proven in terms of the existing phenomena or problems if the respondent has problems with pain and blisters. After all, the baby does not breastfeed until the breast is acerola, if he only feeds on the nipple then the baby will get a little breast milk because the gums do not press on the lactiferous and the mother will feel pain due to blisters on the nipple. Insufficient breastfeeding techniques, the results show that working mothers do breastfeeding techniques in the right steps, it does not rule out that working mothers will affect the time of breastfeeding given to babies, a work schedule that cannot be controlled by the respondent. There are several views from experts on the family. A family consisting of individuals who are joined together by the bonds of marriage, blood, adoption, and live in the same household. While on the other hand, the family is defined as a part of a society whose role is very important to form a healthy culture. In the research results, it was found that most of the breastfeeding techniques lived together with husband and family so that living together in one house with the husband and the respondent’s family would feel psychologically supported to help and support in the act of breastfeeding so that the respondent had sufficient knowledge about the position of breastfeeding, adequate nutritional status, how to stimulate breast milk and care for breasts, so that respondents have confidence, are relaxed in breastfeeding and are not stressed. Family social support provides physical and psychological comfort, reducing the tendency for events that can cause stress.
Conclusion

Based on the results of the study, it was found that the mean of knowledge before the Audio-Visual Education on Lactation Management and Management of Choking Babies in Mothers with Babies during the Covid-19 Pandemic which means that there is a significant effect Audio-Visual Education on Lactation Management and Choking Baby Management in Mothers with Babies during the COVID-Pandemic Period 19 towards increasing knowledge of respondents. The results of the Wilcoxon statistical test on the choking management variable which means there is a significant effect Audio-Visual Education on Lactation Management and Choking Baby Management in Mothers with Babies during the COVID Pandemic -19 towards the improvement of choking management skills in respondents.

Analysis of Worring among Lecturers of Indonesian Bethel Theology on Covid-19

Gernaida K.R. Pakpahan
Lecturer of STT Bethel Indonesia

Abstract

The purpose of this research is to analyze the worry among the lectures of Bethel Theological Seminary concerning Covid-19. The research is using mixed method, which is combination of both qualitative and quantitative method. It employs both descriptive quantitative and phenomenological investigation approaches. The results of quantitative method is triangulated with the qualitative results. The results show that the lecturers of Bethel Theological Seminary do not worry about Covid-19. However, in the future, they may worry, especially if information concerning Covid-19 is spreading uncontrollably. Therefore, the researcher suggest that the stakeholders filter the information regarding Covid-19, so that it may not raise anxiety among those lecturers.

Keywords: Covid-19, worrying, spreading, anxiety.

Introduction

Beginning in 2020, the world was rocked by the spread of co-19 from Wuhan which infected many people in many countries. Covid-19 is a humanitarian pandemic that has caused many victims to be positively infected. Among those infected, some recovered, but many also died. The pandemic covid-19 issue is an interesting phenomenon that is studied and analyzed. That is what encourages scientists, economic practitioners, leaders in various fields of life, and including the general public to give their views on this virus. His views and analysis cover health, social, economic and even political aspects. Pandemic covid-19 has a significant impact on the conditions of human life in general, including the emergence of anxiety, fear, concern and anxiety which then affects humans both physically and psychologically.

Research results show that computer anxiety impacts on a person’s poor skill, performance, and efficacy in using computers. So the results of previous studies indicate that concerns are strategic issues that need to be addressed immediately. But apparently there is no specific research that addresses the concerns of co-19 in the world of education. Based on the explanation above, it appears that research on STTBI lecturers’ concerns about co-19 is an important thing to do. The research was intended to study and analyze the extent to which the impact of co-19 influenced the concerns of STTBI lecturers. From the results of the aforementioned research, it is expected to be a reference for treatment for lecturers who are worried because of co-19.

Materials and Method

The method used in this research is mixed method or combination research that combines quantitative research method and qualitative research method. Conceptually, anxiety is a universal human experience that impacts on the physical, mental, social and spiritual conditions of humans. Operationally, anxiety is a condition in which a person experiences anxiety, fear, tension, anxiety, anger that affects his whole life. The focus of this research (ie worries) can not only be seen and/or discussed positivistically from the outside, but it also needs to be seen and examined more deeply. In the context of such understanding, combination research is a method that can accommodate these needs.

The combined strategy that will be carried out in this study is concurrent triangulation. In this case, the data generated from quantitative research is triangulated with data generated from qualitative research. When the data
from both studies are well confirmed, the research data can be declared valid. For this reason, it is necessary to explain the specifications of both studies.

Quantitative research method were carried out using a descriptive qualitative approach (1 variable and 1 sample group). The variables studied were worries, while the sample group studied was STTBI lecturers. The number of STTBI lecturers is 60 people. Sampling is done randomly using the help of Nomogram Herry King at an error rate of 0.1 which results in a sample of 30 people.

![Figure 1. Calculation of the Number of Research Samples](image)

Research data is measured on an interval scale, and collected by a questionnaire in the form of a statement with a choice of answers on a Likert scale. The questionnaire was arranged based on 3 indicators: feelings, experience, and fear of impact. The questionnaire was tested for validity and reliability then used to collect data. The collected data were analyzed by descriptive t-test. Qualitative research is used to test natural subjects. In this study, the qualitative research approach used is phenomenology. Researchers become the main instrument in research, and collect data with in-depth interview techniques and Focus Group Discussions. The research informants were taken by purposive technique and followed by snow ball sampling. Data validation was done by triangulation, and analyzed using the Spradley model of taxonomic analysis techniques. The results to be sought in the form of meaning is not just a conclusion. In this case what is being sought is the meaning of the level or hierarchy of STTBI lecturers’ concerns for Covid 19.
Results

Quantitative Research Results:

Instrument Validity and Reliability: This test is a indicator of anxiety. Thus there are 3 test results in accordance with the number of indicators of this study. There are 3 instruments with each instrument having as many as 6, 6, and 4. The following are the results of testing the instruments that have been carried out.

Table 1. Indicator Reliability Test Results

<table>
<thead>
<tr>
<th>Reliability Statistics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cronbach’s Alpha</td>
</tr>
<tr>
<td>.860</td>
</tr>
</tbody>
</table>

The instrument for this indicator has a Cronbach’s Alpha coefficient of 0.860. This value is higher than the value that becomes the reliability standard that is 0.6. Thus, this instrument has good reliability.

</table>

Of the 4 questions in this instrument, all of them had a Corrected Item-Total Correlation coefficient above 0.3. Thus, all question items are valid.

### Description of Worry Variable Data

The values in the anxiety variable are obtained by averaging the values of each instrument on the three research indicators. There are 33 respondents who answered as many as 15 instrument items. In accordance with the instrument that has been developed, the range of lecturers’ anxiety values is from 1 to 4. In fact, the lowest concern that lecturers have is 1, and the highest concern is at the level of 3.47 as shown in the following table.

### Descriptive Statistics Calculation Results Table

<table>
<thead>
<tr>
<th>Descriptive Statistics</th>
<th>N</th>
<th>Minimum</th>
<th>Maximum</th>
<th>Mean</th>
<th>Std. Deviation</th>
</tr>
</thead>
<tbody>
<tr>
<td>Kekuatiran</td>
<td>33</td>
<td>1.00</td>
<td>3.47</td>
<td>2.378</td>
<td>.50295</td>
</tr>
<tr>
<td>Valid N (listwise)</td>
<td>33</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The average lecturer concern is 2.37 in the range 1-4. In this case, on a scale of 1-4, the boundary between worrying and not worrying is at 2.5. Thus, while it can be said that the lecturer is not worried about the existence of Covid-19 because worries are only worth 2.37 (less than 2.5). The distribution of lecturer worries is shown in the following histogram.
Image of Distribution of Lecturers’ Concerns:
Based on the histogram above, it appears that although the average lecturer worries are 2.37, there are quite a number of lecturers who have worries. In this case, as many as 14 lecturers had worries above 2.5. For this reason, the average value (2.37) needs to be tested with one sample t-test.

Uji One Sample t-test:

<table>
<thead>
<tr>
<th>Table of results One Sample t-test</th>
</tr>
</thead>
<tbody>
<tr>
<td>One-Sample Test</td>
</tr>
<tr>
<td>Test Value = 2.5</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>t</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td>Kekuatiran</td>
</tr>
</tbody>
</table>

Based on the above table, it appears that the difference between lecturer worries (2.37) with limitation worries (2.5) is -0.12 which means lecturer worries are below the limit. Furthermore, the value of t is -1.39 which is accepted at the error level 0.172.

Qualitative Research Results
The concerns of STTBI lecturers on Covid-19 are in varying degrees of severity. However, this research found that there is something that equates one lecturer with another lecturer, namely the mechanism of the anxiety formation itself.

1. In December 2019, the world was shocked by the presence of a new virus, namely covid-19 or corona that occurred in Wuhan, China. At this
stage, lecturers who already know this information feel normal. This happened to all lecturers. There are several reasons they are not worried about this, namely the distance between China and Indonesia which is quite far, and there have been efforts to localize this incident so that it does not spread outside.

2. In January 2020, Covid began to spread outside of China and new cases occurred in other countries. At this stage, the lecturer has begun to be divided in terms of his worries.

3. In March 2020, the first Covid case occurred in Indonesia. At this stage, the gap between lecturers has begun to increase. Some lecturers who were not yet worried, are now starting to have worries. This is indicated by feelings such as panic, confusion, “parno”, and fear. While the lecturers who were still feeling normal, at this stage some began to be vigilant and guarded even though they did not panic.

4. In April 2020, Covid-19 infected students at the Bethel Petamburan Seminary. At this stage, some lecturers who had been panic-d, now become dizzy and stressed. While the lecturers who felt normal were no longer there.

Concrete Triangulation Results: The findings obtained in quantitative research are then triangulated with the findings in qualitative research. The process of matching data produces validated data, and data that is not validated. Validated data alone is the final result of this study.

Concrete Triangulation
Lecturers’ concerns are divided into 4 phases:
- Phase 1 (normal)
- Phase 2 (be on guard, just in case)
- Phase 3 (panic, fear, confusion)
- Phase 4 (stress, dizziness)

On the results of quantitative research, it is known that there is 1 lecturer who is not worried at all (worries of 1). When this was confirmed in qualitative research, there were no lecturers who were not worried at all. So this data is not confirmed. While lecturers who are in the category of not worrying (scores below 2.5) were found to be in the anxiety phase 2 and 3. Furthermore, lecturers who had worries (more than 2.5 worries) were found to be in the worry phase 3 and 4. Nevertheless, it is true that in general lecturers are not worried (as evidenced by the results of quantitative and qualitative research).

Discussion

Worrying is a universal human experience, because it is certain that everyone must have felt anxiety. It is true that the level of concern for each individual is different. Anxiety is very closely related to anxiety. Anxiety according to McCroskey is a feeling that is owned by every individual. He considers that the emergence of anxiety involves negative thoughts and feelings so that the consequences lead to unusual behavior and responses. While T E Foose saw an anxiety relationship with phobias. Such conditions actually want to describe the phenomenon, epidemiology, genetics, neurocircuits, and training of any irregularities, to identify in general and different clusters. Each anxiety instrument is organized cognitively and psychologically to see the reaction it causes.

While in the New Testament, a prominent expression can be seen from the Greek word merimnai, which means “concerned, worried, anxious, and afraid.” If the focus on material concern shows weakness or lack of faith. For this reason, understanding the nature of life that depends on God is far more important in worrying about material things.

Another phrase that is used to describe the attitude of worry is the Greek word daag which, if translated
can be interpreted to be anxious, anxious, afraid, afraid. Referring to various notions of the word “worry” it actually shows clear evidence that humans are limited beings who need help\(^1\). Thus it can be said that someone who is anxious needs help that is able or able to free himself from being worried.

On the other hand, feelings of worry in humans is one proof of the need for a definite guarantee about the survival of his life. The guarantee covers, among other things physical, mental, spiritual and social health. It is believed that with this guarantee the level of anxiety that brings anxiety to a person can be reduced. Regarding anxiety, it is good to pay attention to what is expressed by McCroskey\(^1\) that anxiety is an integral part of worry. Anxiety exists in two things namely, state anxiety and trait anxiety. Anxiety in the category of state anxiety is an experience of anxiety that arises in certain circumstances. So, worrying about the category of state anxiety can occur because there are calamities that threaten humanity such as the corona virus case that is endemic globally.

First, individuals experience stress and illness. One important symptom that is easily identified in someone who is anxious in the severe category is stress\(^1\). Furthermore, according to Rita L. Alkitson et al, stress situations produce emotional reactions ranging from excitement to general emotions of anxiety, fatigue, disappointment, and depression (Hilgard, Atkinson, and Atkinson 1980). It can be ascertained that stress that is not resolved properly will ultimately cause greater pressure on a person and if the condition is getting worse then the next result is the emergence of various diseases.

Second, confusion or apathy. If worries are not managed properly, it will have a wide impact, including causing apathy and depression. In general, apathy is an act of withdrawing from the problem at hand. However, apathy that is not resolved can be fatal because it causes depression. For individuals who are unable to control stress or show powerlessness to solve problems, it will cause apathy\(^1\).

Third, anxiety. Mental health is a condition where there is no psychopathology, such as depression and anxiety. This is shown in the harmonious relationship between feelings of happiness and satisfaction in life, positive individual functions both towards themselves and the environment\(^1\).

Fourth, hopelessness or frustration. Feelings of frustration or hopelessness are responses to disappointment towards the failure to achieve targets or goals. It can also be said that frustration is an unpleasant tension, filled with an increasingly higher level of sense and nerve activity. In an effort to achieve something big, hard efforts were made. Frustration as a sense of disappointment with one’s failure to achieve a desired hope or ideal, or a sense of disappointment because the expectations and results achieved do not have a match\(^1\).

Fifth, kill yourself. A person who experiences prolonged depression can result in self-harming actions namely suicide. Depression is an emotional condition characterized by deep sadness, feelings of insignificance and guilt, withdrawal from others, unable to sleep, loss of appetite, sexual desire, and pleasure from what can be done. For people who can’t stand the pressure, anxiety can cause someone to commit suicide. The results of this study indicate that the concern that exists in STTBI lecturers is still at a low level. If related to the five indications above, lecturers’ concerns only reach the third level, which is anxiety. This is certainly in accordance with the results of quantitative research, namely lecturers do not have significant worries about co-19.

Conclusions

Based on the results of research that has been done, it can be concluded that it is true that the concerns of STTBI lecturers on Covid-19 still exist in the low category, namely anxiety. However, this concern can develop if information about Covid-19 continues to grow, and the lecturer pays attention to that information. This is consistent with the new findings in this study, namely concerns based on historical information.

Evaluation of Health Services System Process Based on Island Clusters (Case Study in Tanimbar Island District)

Juliana Chatarina Ratuanak1, Muhammad Alwy Arifin2, Darmawansyah2, Amran Razak2, Muhammad Syafar3, Muh. Yusri Abadi2, Anwar Mallongi4

1Master Program in the Department of Health Administration and Policy, Hasanuddin University, 2Assoc. Prof of Department of Health Administration and Policy, Hasanuddin University, 3Professor of Department of Behavioral Science and Health Promotion, Hasanuddin University, 4Professor of Department of Environmental Health, Hasanuddin University

Abstract

The Cluster Center in the island cluster strategy is a health facility that provides primary and secondary health efforts that oversee several sub-groups and/or satellite groups within an island group. The purpose of this study was to determine the process of the island cluster-based health service system in the Tanimbar Islands Regency. This type of research is qualitative research. There were 8 informants in this study, namely the head of health Office, and 7 Head of Public Health Center in the southern cluster of the Tanimbar Islands. Source of informants determined intentionally (purposive). The results showed that the planning process was still carried out by each health facility that was not following island cluster-based services. The organization is carried out by the head of the Public Health Center by monitoring the implementation including preparation and setting of strategies and evaluating the achievement of targets. The implementation of island cluster-based health services is divided into 2 systems, namely case referral and program referral. In the implementation of health services not yet running optimally. Supervision consists of internal supervision and off-site supervision conducted every three months. The evaluation was carried out to see the problems faced by the Public Health Center to be immediately handled, the evaluation showed several programs had not been implemented 100%.

Keywords: Evaluation, Process, Island Clusters, Health Services, Tanimbar Island.

Introduction

Healthy Indonesia 2025 contains the hope that the community can reach quality health services and obtain health insurance. Quality health services intended here are health services including disaster emergencies, services that meet the needs of the community, and are organized by professional standards and ethics. The achievement of UHC differs from country to country, depending on political will and state financial capacity. The richer the country, the easier the country is to ensure health services for its citizens1.

As an archipelago, there are many islands in the Tanimbar Islands, both inhabited and untouched with a total of 113 (one hundred and thirteen) islands. The Tanimbar Islands Health Service is a regional work unit that is the main health service in the Tanimbar Islands district. In charge of 13 Public Health Centers, 34 Pustu (Supporting Public Health Centers) and 19 Poskesdes (Village Health Post), 2 Public Hospitals, 1 Maternity Hospital, 1 RB, and 3 BP. The total number of employees is 437 spread across the health department, Public Health Center, Pustu, and Poskesdes. Conditions of a very wide range of control and frequent obstacles in service in various fields, more specifically in the health sector, have created a health service system known as the Cluster Island health services.

Looking at the condition of the Tanimbar Islands Regency which is also included in the DTPK BK area (Border Remote Areas and Health Troubled Islands) and bearing in mind the Maluku Governor Regulation on Island Cluster Health Services, West Southeast Maluku Regency Regulation number 9 of 2018 concerning Island...
Cluster-Based Health Services and Technical Guidelines for Maluku Island Group Health Services, the purpose of this study is to find out the process of island cluster-based health service systems in the Tanimbar Islands Regency.

**Material and Method**

The type of research used is qualitative research. There were 8 informants in this study, namely the Head of Health Office, and 7 Public Health Center Heads in the southern cluster of the Tanimbar Islands. Source of informants determined intentionally (purposive). The study was conducted by conducting in-depth interviews with informants with the help of interview guidelines.

**Results**

There are several processes in island group-based health services, including planning, organizing, implementing, monitoring, and evaluating. The following are the results of each research variable in the health service process.

Planning at the Public Health Center is carried out to determine how the service process will be carried out in the future Public Health Center. The following are the results of the interview with the informant about the planning process at the Public Health Center.

“Prepare a work plan and put it into program planning for 1 year and then submit it to the Head of the Public Health Center after it has been approved and submitted to the Health Office. The design is based on the coverage results that were not reached and the problems that occurred in the previous fiscal year were included in the current year’s program plan” (YYH, 39 Years Old).

“If for program planning we sit together (every month) and then each presentation program if there are obstacles or problems then we sit and discuss after that a new plan is made” (SP, 57 Years Old).

“The program manager draws up a plan of proposed activities for each program after that, prepares a plan for implementing activities from the program to the Public Health Center planning team and then consults with the health department for implementation” (VO, 41 Years Old).

Information on the suitability of planning at the Public Health Center with the strategic plan in the health department was obtained from the following informants

“Yes, it was stated in the strategic plan” (JCR, 46 Years Old)

“It is appropriate and stated in the work plan of the health service because if it is not there it will be rejected by the system” (DB, 48 Years Old)

“It’s appropriate, because always consult with the health department” (YYH, 39 Years Old)

Based on the results of the interview with informants, it is known that the planning carried out at the Public Health Center is in accordance with the health department’s strategic plan because in the preparation of the plan it always consults with the health department and all forms of service are contained in the health department’s work plan.

Organizing is done so that every plan that has been made to get arrangements so that it is ready to be implemented to achieve common goals. The results of interviews with informants regarding the organizing process at the Public Health Center are shown in the following excerpt.

“Before starting the program, the head of the Public Health Center gathers program holders to see the preparation and timing of the program. After the program in the field has been completed, a re-evaluation is made of the obstacles in implementing the program.” (LL, 39 Years Old)

“The person in charge of UKM (public health efforts) conduct briefing with program holders before going to the field ...” (VO, 41 Years Old)

“Based on management functions, ranging from planning, implementation to evaluation. The Head of the Public Health Center performs the function of direct control over the implementation of the program.” (SF, 46 Years Old)

Based on the results of interviews with informants about the organization conducted by the Head of the Public Health Center it is known that the head of the Public Health Center always monitors the implementation carried out at the Public Health Center including organizing by looking at the preparation and setting of strategies that will be used before the implementation of health services and re-evaluating after implementation health services to see the extent of achieving targets.
After the planning and organizing are done, then what needs to be done is to realize the plan by implementing or implementing it. Information about island group health services was obtained from the following informants.

“There are 2 systems, case referral and program referral ...” (JCR, 46 Years Old).

“Shortening the range of control in handling health care in the cluster area. The capabilities of health workers in the Public Health Center of the cluster center are the same as those in other Public Health Centers. The island cluster system is quite helpful in handling health problems.” (SOL, 45 Years Old).

“The island cluster is one of the solutions to complete the control range of health services in the Tanimbar Regency, both in terms of funding, logistics, and human resources.” (JK, 45 Years Old).

“The island cluster system has a very good purpose. But in the development of island cluster-based health services, only symbols and extinctions.” (IM, 44 Years Old).

Based on the results of interviews with informants it was noted that the implementation of island group-based health services was carried out with 2 systems namely case referral and program referral, where case referral was intended for those who were sick and then referred to health facilities with higher levels. While the program reference is a report that is carried out in stages. Supervision is one of the most important aspects when it is important to implement island cluster-based health services. Supervision is carried out so that early irregularities can be known so that they can be addressed as soon as possible. The following are the results of interviews with informants regarding the supervision process in the implementation of island group-based health services.

“Supervision is divided into two, namely Public Health Center internal supervision through an internal audit team and off-site supervision every three months by involving internal audit and program holders” (LL, 39 Years Old).

“Supervision every 3 months in the Pustu and also Posyandu independently and integrated with the team related to the performance of services in the pustu. Coordinate with the village head to monitor services in the pustu due to island-based service areas. In the supervision, if there are obstacles in service in the pustu such as lack of medicines or consumables, they will be funded with available funds.” (IL, 43 Years Old).

The interview results show that the supervision process by the health department for each Public Health Center is conducted by SIDAK (inspection) and conducts discussions about the problems being experienced by the Public Health Center, but the implementation of supervision is more often done in cross-sector mini-workshops. Whereas the supervision conducted by the Public Health Center is divided into two types namely internal supervision and off-site supervision which is conducted every three months in collaboration with the village head.

The following are the results of interviews with informants about the evacuation process carried out by the Tanimbar Islands Health Department on the Public Health Center in the southern cluster.

“The evaluation was carried out by first conducting a presentation from the heads of the Public Health Center related to the implementation of activities in the months that have not yet been evaluated, if non-budgetary activities can be completed as soon as possible. and then it is evaluated by telephone for an unreachable Public Health Center and then calls every three months for us to complete and discuss in evaluation meetings.” (JCR, 46 Years Old).

The evaluation process is carried out with a presentation related to the implementation of activities that are already running and for Public Health Centers that cannot be reached by evaluating via telephone. Then the problem is identified and made an effort as soon as possible to resolve the problem, but for problems that can not be solved is postponed for the following year. From the evaluation results, it was found that there are still some programs that are not 100% implemented.

Discussion

Program planning carried out at the Public Health Center is following the strategic plan of the health department and all forms of service are contained in the health service work plan. However, this planning process is not following the planning of the island cluster system where planning should be arranged together through one-door planning so that it can be properly accommodated.

Research conducted by Habibi et al. shows the
results that planning is arranged through the process of identifying problems, determining priority issues and formulating work programs in the P2M program at Tamangapa Public Health Center. Another study conducted by Setiowati and Budiono showed the results that the PMT Recovery program planning activities for toddlers in the work area of the East Tegal Public Health Center went well, there were no obstacles. Planning is considered important because it is the process of determining goals or objectives to be achieved and determining the paths and resources needed to achieve that goal as efficiently and effectively as possible.

The organizing process carried out at the South Cluster Public Health Center in Tanimbar Islands Regency is always monitored. Research conducted by Habibi et al., found that the division of tasks, determination of resources, and arranging workgroups in the Communicable Disease Eradication program at Tamangapa Public Health Center was determined based on the discipline or competency of each health worker. While research conducted by Abdullah et al. shows the results that the organization of workgroups was not arranged according to the SDIDTK activity guidelines, the division of tasks to teachers and cadres was still limited to height and weight measurements, the use of KPSP was still carried out entirely by officers.

Other research conducted by Arifuddinet al shows the results that the organization of Public Health Center employees refers to applicable government laws and regulations. Lembasada Public Health Center in the search for responsibility or authority is still not going well.

This study is in line with the study of Jambormias et al., which shows that the formation and implementation of island-based maternity hospital waiting policies is one form of innovation in an effort to shorten the range of control and affordability of health services for pregnant women. Access to health services for pregnant women will be easier to obtain because it is still in a single unit or group of islands.

Research conducted by Utami et al found that internal control functions in the HIV-STI LKB were carried out by the Head of the Public Health Center and service manager while for external supervision conducted by the Semarang City Health Office was carried out by direct field observation and checking monthly reports from Public Health Centers, hospitals, and NGOs. Research conducted by Habibiet al note that the leadership in conducting supervision is usually only via telephone.

There are several indicators of the health service program in the South Cluster of the Tanimbar Islands Regency Public Health Center which are not optimally realized. For programs that have not been realized, education is carried out by working across sectors and endeavoring to create regulations in the form of regulations or decisions by village heads. In line with the research conducted by Purnomo, the results show that hospitals have not been able to handle emergency cases with 100% live saving as standard.

**Conclusion**

This study concludes that the planning process is still being carried out by each health facility that is not compatible with island cluster-based services. The organization is carried out by the head of the Public Health Center by monitoring the implementation including preparation and setting of strategies and evaluating the achievement of targets. The implementation of island cluster-based health services is divided into 2 systems, namely case referral and program referral. In the implementation of health services not yet running optimally. Supervision consists of internal supervision and off-site supervision conducted every three months. Evaluation is carried out to see the problems faced by the Public Health Center for immediate treatment. Evaluation results show that some programs have not been implemented 100%. Planning should be adjusted to the guidelines for the implementation of island-based health services in order to achieve the desired goals of health services.

Analysis of Serum Vitamin D and Major Histocompatibility Complex Class I-Related Chain a (Mica) Levels in Patients With Breast Carcinoma

Asvin Nurulita¹, Budi Mulyono², UmiSolekhah Intansari², Mansyur Arif³

¹Clinical Pathology Department, Faculty of Medicine, Hasanuddin University, RSUP Dr. Wahidin Sudirohusodo Makassar; ²Clinical Pathology Department, Faculty of Medicine Gajah Mada University, RSUP Dr. Sardjito Yogyakarta

Abstract

Introduction: Breast carcinoma is the most deadly cancer in women worldwide, with an incidence rate of 26 cases per 100,000 women in Indonesia. Treatment and prognosis is very dependent on the stage of breast carcinoma. Vitamin D can inhibit proliferation and invasive cancer cells, induction of differentiation, apoptosis and promotion of angiogenesis. Major Histocompatibility Complex class I - related chain A (MICA) plays a role in reducing the expression of NKG2D receptors in breast carcinomas so that they can be targeted for treatment of breast carcinoma treatment. The aim of this study was to determine vitamin D and MICA levels in serum patients with non-metastatic and metastatic breast carcinoma.

Method: We examined 86 samples of breast carcinoma patients (44 non-metastatic samples and 42 metastatic samples) with a range of 29 - 68 years old. Vitamin D levels were examined by the Enzyme Linked Flourescent Assay (ELFA) method while the MICA levels were examined by Enzyme Linked Immunoabsorbant Assay (ELISA).

Result: There were significant differences in mean vitamin D levels in non-metastatic and metastatic breast carcinomas (29.88 ng/ml vs 19.06 ng/ml; \( p < 0.01 \)). Serum MICA levels in patients with non-metastatic breast carcinoma were lower (333.52 pg/ml) than in metastatic breast carcinoma (333.52 pg/ml vs 528.71 pg/ml; \( p < 0.01 \)). A negative correlation was found between vitamin D levels and MICA in both groups (Pearson correlation, \( p: -0.58 \)).

Conclusion: Metastatic breast carcinoma had lower vitamin D levels and higher serum MICA levels than non-metastatic breast carcinoma.

Keywords: Breast carcinoma, Vitamin D, MICA.
of breast carcinoma are metastasis, where 400,000 patients in the world died each year, the most common metastases are bone metastases (30-85%) with an mean life expectancy of only 25-72 months\textsuperscript{5}.

Major Histocompatibility Complex class I-related chain A (MICA) is a membrane-bound protein that functions as a ligand to stimulate receptor activation of Natural Killer Group 2 Member D (NKG2D). Major Histocompatibility Complex class I - related chain A includes MIC family members expressed in various types of malignant tumors such as breast, colon, liver and melanoma. MICA expression can be triggered by an active pathway in various pathophysiological conditions such as infection and oncogenic transformation (often expressed in epithelial tumors)\textsuperscript{6}.

Holdenrieder\textsuperscript{7} showed that serum MICA levels increased significantly in malignant patients (breast, lung, gastrointestinal, gynecological, kidney, and prostate carcinoma) compared to patients with benign tumors and healthy controls. Serum MICA levels in carcinoma patients are associated with stage and metastasis\textsuperscript{7}. Roshani\textsuperscript{8}in Iran showed that serum MICA has an important role in reducing the expression and presentation of NKG2D receptors in breast carcinoma patients and recommends that MICA be targeted for treatment of breast carcinoma.

Calcitrol inhibits the expression of cytokines IL-1, IL-6, IL-12, and TNF-α and inhibits the expression of Major Histocompatibility Complex (MHC) in both class I and class II Seydelfound that administration of Vitamin D2 was able to suppress MICA expression in hepatocellular carcinoma patients\textsuperscript{9-11}.

Research on serum vitamin D and MICA levels in breast carcinoma in Indonesia, especially in Makassar as long as the researchers’ knowledge has not been done so we are interested in conducting research on the analysis of serum vitamin D and MICA levels in metastatic breast carcinoma and non-metastatic breast carcinoma.

**Materials and Method**

A. **Study Design:** This study aims to find out the differences serum vitamin D and MICA levels in patients with non-metastatic and metastatic breast carcinoma. This study was a descriptive analytic study with a cross sectional approach.

B. **Place and Time of Study**

1. **Study Place**
   a. Outpatient Installation and Inpatient Installation of Surgical Oncology RSUP Dr. Wahidin Sudirohusodo Makassar and other networking hospitals for sampling.
   b. Installation of Clinical Pathology Laboratory RSUP Dr. Wahidin Sudirohusodo, and FKUH Research Unit/RSPHTN Hasanuddin University for examination of serum Vitamin D and MICA levels.

2. **Research Time:** The study was conducted from January-May 2019.

C. **Inclusion and Exclusion Criteria**

1. **Inclusion Criteria:**
   a. Research subject group: adult women (aged 20-70 years) who were diagnosed with breast carcinoma by the clinician in the Surgical Oncology Department based on history taking, physical examination, laboratory examination, radiological examination and/or histopathology and had never received chemotherapy, radiotherapy and surgery.
   b. Willing to participate in research by signing an informed consent.

2. **Exclusion Criteria:**
   a. Patients detected suffer from other primary malignancies.
   b. Breast carcinoma patients diagnosed with infectious diseases.
   c. Lipemic, icteric or hemolytic specimens.
   d. Insufficient sample volume.
   e. Incomplete data.

D. **Research Permit and Ethical Feasibility:**

Every action in this study was conducted with the permission and knowledge of the patients which were used as research samples through an informed consent sheet and stated to fulfill ethical requirements to be carried out from the Health Research Ethics Commission of the Faculty of Medicine, Hasanuddin University-Hasanuddin Hospital-RSUP Dr. Wahidin Sudirohusodo Makassar (KEPK FKUH-UH-RSWS).

E. **Research Process:**

a. Record identity of patients who meet the inclusion criteria and provide a complete explanation of what
will be done to them and if they agree they will fill out and sign an informed consent.

b. Subjects who fulfilled the inclusion criteria were sampling of 3 ml venous blood. The serum is obtained after a blood-filled tube forms a clot for 30 minutes at room temperature and then centrifuged for 20 minutes at 3000 rpm. Samples were collected enough, stored at 80°C for 12 months, when examined the samples were thawed at 25°C before analysis.

c. Laboratory examination:

1. Vitamin D levels were examined using the Vidas Biomerieux device in principle with the Enzyme Linked Flourescent Assay (ELFA) using the Biomereux reagent VIDAS 25OH Vitamin D.

2. MICA levels were examined using the Microplate Reader Multiscan FC Thermoscientific with the principle of an Enzyme-Linked Immunoabsorbant Assay test (ELISA) using the Human MICA ELISA reagent kit (Bioassay Technology Laboratory).

F. Analysis Method: Data distribution was tested for normality using the Kolmogorov-Smirnov test. If the distribution of data is normal, the serum vitamin D and MICA levels between the two groups (metastatic and nonmetastatic breast carcinoma) were tested using c. The difference was found to be significant if the value of \( p < 0.05 \). Correlation test between serum vitamin D and MICA levels was tested using the Pearson correlation test. Correlation was stated as significant if the value of \( p < 0.05 \).

Results and Discussion

The subject of this research was enrolled for 5 months, breast carcinoma patients who were treated at RSUP Dr. Wahidin Sudirohusodo Makassar and fulfilling the inclusion criteria were 88 patients. As many as 2 patients were excluded, due to incomplete data, so that the data included in the analysis were 86 samples. Patients with non metastatic breast carcinoma were 44 patients and metastatic breast carcinoma were 42 patients. The age of the subjects was 33-76 years, with a median of 50 years. Breast carcinoma patients aged <40 years are around 2.33%, and > 70 years are around 3.49%. This study showed that most breast carcinoma patients in RSUP Dr. Wahidin Sudirohusodo Makassar were in the age group 40-49 years (Table 1).

Source: Primary Data

Description: \( n \) = Number of samples; IDC = Invasive Ductal Carcinoma.
Hadi\textsuperscript{12} found that breast carcinoma patients in developing countries were found in a younger population than in western countries with a majority of productive age (20-50 years). According to the CDC, breast carcinoma at \(< 45\) years can be caused by several risk factors such as a history of breast or ovarian carcinoma, genetic factors and a positive family history.\textsuperscript{13}

The serum vitamin D levels obtained were normally distributed by the Kolmogorov-Smirnov test. The mean serum vitamin D level in patients with non metastatic breast carcinoma is 29.88 ng/ml, with a value range of 9.7-33.7 ng/ml. The mean serum vitamin D level in patients with metastatic breast carcinoma is 19.06 ng/ml with a value range of 10.5 - 58.7 ng/ml. Comparison of mean vitamin D levels between the two groups was tested using the t-test. There were significant differences in the mean vitamin D levels in the non metastatic and metastatic breast carcinoma groups with a value of \(p < 0.01\) (Table 2).

**Description:** * Independent t-test

The difference in mean serum vitamin D levels in both groups can be seen in Figure 1, where the mean vitamin D level in the nonmetastatic carcinoma group was higher than metastasis.

![Figure 1. Comparison of mean serum vitamin D levels between nonmetastatic and metastatic breast carcinomas. (source: primary data)](image-url)
Alco\textsuperscript{14} found a median level of 25-OHD 19.76 in patients with breast carcinoma, and a serum 25-OHD level was lower in breast carcinoma patients who died than those who were still alive. Janbabai’s study in 2016 found an association between 25-hydroxyvitamin D levels and metastatic breast carcinoma. Patients with distant metastatic breast carcinoma had lower vitamin D levels (12.22 ng/ml) than patients without distant metastasis (23.7 ng/ml)\textsuperscript{15,16} showed that there was a relationship between vitamin D deficiency and breast carcinoma, where serum vitamin D levels are significantly lower in breast carcinoma (85.7%) than in control group (55.8%). White\textsuperscript{17} found that giving vitamin D can inhibit the progression of breast carcinoma. This further affirm that vitamin D has an antitumor effect that can inhibit proliferation and invasive cancer cells, induction of differentiation and apoptosis, anti-proliferation and antiangiogenesis\textsuperscript{18}.

The dysregulation of vitamin D metabolism in metastatic breast carcinoma is thought to be due to the effects of tumor paracrine and dysregulation of the 24-hydroxylase enzyme that plays a role in serum vitamin D homeostasis. In addition, microarray analysis shows the relationship of vitamin D with Cyclin-dependent kinase inhibitor P21, which plays a role in controlling the cell cycle. Beckett also found an association of vitamin D levels with overexpression of miR-26 and miR200 associated with increased motility, adhesion and invasion of EMT in metastatic breast carcinoma\textsuperscript{19}.

Data distribution of serum MICA levels was found to be normally distributed when tested by the Kolmogorov-Smirnov test. The mean serum MICA level in patients with metastatic breast carcinoma is 333.52 pg/ml, with a value range of 177-552 pg/ml. The mean serum MICA level in patients with metastatic breast carcinoma was 528.71 pg/ml with a value range of 364-694 pg/ml. Comparison of mean serum MICA levels between the two groups was tested using the t-test. It was found a significant difference in serum MICA levels in nonmetastatic and metastatic breast carcinoma groups with a value of \( p < 0.01 \) (Table 3).

Description: * Independent t-test

The difference in mean serum MICA levels in both groups can be seen in Figure 3, where the mean serum MICA level in the metastatic carcinoma group was higher than nonmetastasis.

Major Histocompatibility Complex Class I - related Chain A can be detected in Leukemia patients and tumors in epithelial cells including breast, lung, colon, kidney, ovarian and prostate malignancies\textsuperscript{20-21}. Recent study showed that the expression of MICA is limited to the proliferation of epithelial cells but is not expressed in quiescent cells. It has been reported that over-expression of several oncogenes can induce MICA expression independently\textsuperscript{22}. Increased MICA soluble is detected in patients with pancreatic adenocarcinoma, various gastrointestinal malignancies, hepatocellular carcinoma, pulmonary carcinoma, malignant melanoma and various types of leukemia.

The initial stages of tumorigenesis begin with the loss of tumor suppressor gene function (gatekeeper) and activation of oncogenes, resulting in hyperproliferation. At this stage the active E2F transcription factor is needed for the cell cycle to take place, but it can also activate MICA transcription. Some findings indicate a direct relationship between the stages of tumor cell proliferation and MICA induction. Strong proliferative signals can cause DNA damage which results in an upregulation response of MICA and PI3K known to increase proliferation which indirectly also increases MIC transcription\textsuperscript{23}.

Table 3. Comparison of serum MICA levels in nonmetastatic and metastatic breast carcinoma groups.
The study by Cascone\textsuperscript{24} in patients with Non Small Cell Lung Carcinoma (NSCLC) found an increase in MICA expression associated with prognosis. MICA overexpression is closely related to DNA damage. The MICA-NKG2D bond can be a NK cell antitumor response costimulator. Tumor cells will protect NK cells through several mechanisms, namely MICA release, proteolytic action of metalloprotease, and suppression of NKG2D regulation on the cell surface.

Correlation of vitamin D and MICA levels in patients with breast carcinoma, followed by the Pearson correlation test. It was found that there was a significant negative correlation between Vitamin D and MICA levels in breast carcinoma patients ($p < 0.0001$) with strong correlation strength ($r = -0.58$), as seen in table 4. This indicates that the lower the vitamin D level then the higher the MICA level and the risk of metastasis in breast carcinoma will increase.

Description: * Pearson Correlation Test

Vitamin D can inhibit the expression of Major Histocompatibility Complex (MHC) molecules, both MICA and MICB, costimulatory molecules (CD40, CD80, and CD86), inhibition of dendritic cell maturation and inhibition of proinflammatory cytokines (IL-1 and TNF). In addition, Vitamin D is also able to
increase chemotaxis and phagocytosis of monocytes, is cytotoxic to tumor cells and bacteria, and many other effects\textsuperscript{10}. The interaction of MICA and NKG2D plays an important role in NK cell activation and tumor immunosurveillance. Chitadze\textsuperscript{23} found that NKG2D deficiency was associated with EMT which increased tumor invasion and metastasis.

**Conclusion**

a. Vitamin D levels in patients with metastatic breast carcinoma are lower than vitamin D levels in non metastatic breast carcinoma.

b. Serum MICA levels in patients with metastatic breast carcinoma are higher than serum MICA levels in non metastatic breast carcinoma.

c. Vitamin D levels were inversely correlated with serum MICA levels in patients with breast carcinoma.

Critical Overview of Adolescent Suicides in India; A Public Health Concern

Ashwin Mathew¹, Suja M.K.², V. Priya³

¹Ph.D. Scholar, ²Associate Professor, ³Assistant Professor, Department of Social Work, Amrita School of Engineering, Coimbatore, Amrita Vishwa Vidyapeetham, India

Abstract

Suicide is the second most leading cause of death among the 15-29 age group (adolescent). The World Health Organization statistics indicate that 8, 00,000 people suicide annually. The National Crime Records Bureau records indicates that suicidal deaths in 2014 is 15.8% more than 2004, 17% of the suicides worldwide happens in India. Suicides is a contingency that affects the victim’s family community and nation at large and has a long lasting effect on the people left behind. The adolescents often don’t get help when needed which leads to suicides. Sustainable Development Goals 3 intents to promote healthy lives and promote wellbeing for all.

Aim: To understand; 1) the percentage increase of suicide in India, difference between male and female suicides, 2) identify states with maximum number of suicides, 3) identify states with maximum number of student suicides, 4) Major Causes for suicide among adolescent male, female and trans gender and to study 5) Major means adopted for suicides in India, 6) Understand the significance promoting wellness addressing adolescent suicides.

Results: there is significant increase in number of suicides form 2013 to 2016 and it affects the nation’s economy. The states with maximum number of adolescent suicides are 1) Maharastra, 2) Tamil Nadu, 3) West Bengal, 4) Madhya Pradesh and 5) Karnataka. The major Causes for suicides among adolescents male, female and trans gender were identified. The most common means adopted for suicide among adolescents have been identified and listed.

Conclusion: The adolescent and student suicides in the nation are increasing rapidly causing serious economic burden to the nation. Hence a comprehensive suicide prevention plan must be developed, the policy should individually target the states with highest number of adolescent and student suicides, access to the most prominent means of suicides must be limited. A national suicide prevention help line and community based access points could be created to provide mental health first aid to the vulnerable adolescents and students.

Keywords: Adolescent Suicides, Student Suicides, Economic Burden of Suicides, Suicide Prevention Policy, Adolescent Wellness, Adolescent Suicides in India, Suicides in Indian States.

Introduction

WHO recognizes suicides as a public health priority and plans to increase the awareness regarding suicide and suicide attempts and intents to make suicide prevention as global public health priority. The Sustainable Development Goals (SDGs) 3 is to ensure healthy lives and promote wellbeing for all.¹ The WHO statistics indicate that 8, 00,000 people attempt suicide and many more attempt suicide suicides. Suicide is the
second most leading reason cause of death among the age group 15-29 age group (adolescent), 79% of the suicide worldwide happens in lower middle income country and hence India is at greater risk.\(^{(2)}\) The National Crime Records Bureau reports indicate that the suicides rate has increased 15.8% from 2004 to 2014\(^{(3)}\), this significantly impairs the nation’s development the government and parents of the adolescents spend considerable amount of money in their upbringing.

Suicidemental health problems and depression has high correlation especially in developed nations. Suicide occurs impulsively at crisis situations as the victim is not able to deal with the life stress in situations such as; financial problems, relationship issues and chronic diseases. The most significant factor for suicide is a previous suicide attempt. The crucial aspect in suicide risk reduction is to identify the Causes for suicide and address them and to limit access to the means of suicides.\(^{(4)}\)

Research studies indicate that; indicate that suicide victims and inpatients showed similarly high rates of affective disorders. The suicide victims with family history of affective disorders and suicidal tenancies are more vulnerable to suicide. Four significant risk factors identified are 1) Bipolar Disorders, 2) Affective disorders with comorbidity, 3) Lack of previous mental health treatment and 4) availability of fire arms which accounted for 81.9% of cases.\(^{(4)}\) Prevention programs including Peer Educators (PEs) have been found useful in helping young people in school especially the adolescents going through heavy psychological burden. The results indicate that that the mindfulness and Support, Appreciate, Listen, Team (SALT) using Peer Educators (PE) have enhanced the PEs broad emotional intelligence and PEs expressed increased ownership of life, taking actionand seeking support when needed. Research studies also suggest that future research should be carried out in developing nations to understand the knowledge regarding suicides especially in the adolescent age group\(^{(5)}\). WHO further emphasizes that India develop a comprehensive suicide prevention plan and integrate it with the mental health act to contain the growing threat of adolescent suicides.\(^{(1)}\)

**Method**

This study is based on the secondary data available from the official government websites. The adolescent suicides related data from 2013 to 2016 has been used in the study. The basic statistical analysis was done using Microsoft Excel 2013.

The rationale behind this study is to understand 1) National adolescent suicide rate and difference between male and female suicides, 2) States with highest number of suicides, 3) States with highest number of student suicides and rate of student suicides, 4) Major Causes for adolescent suicides 5) Major means adopted by adolescent suicides and 6) Understand the significance promoting wellness addressing adolescent suicides. The researcher would also attempt to identify future research areas and try to lay down a comprehensive suicide policy guidelines keeping in mind the recommendations of WHO and UNICEF and relevant research studies.\(^{16}\)

**Results**

1. **Total Suicides among 15-29 Age Group (Adolescent) in India; Years 2013, 2014 & 2015\(^{(6),(7),(8),(9)}\):** The number of suicide in 2013 is 46,368, in 2014 it has raised to 54,100. The percentage increase of suicides form 2013 to 2014 is a whopping 16.675 % which is a matter of concern when we compare this data with the National Crime Records Bureau report stating that “suicidal deaths of 2014 is 15.4% higher than that of 2004”, we can understand the rapid increase in adolescent suicide in India which is a public health concern. The increasing number of suicides is a threat to the nations GDP, it’s estimated that death of one adolescent between the 15-29 years cost approximately 70 lakhs. The economic loss in 2014 alone would account to 70 lakhs × 54100 adolescent suicides which equals to 378.7 billion rupee, this significantly affect the nation’s economic progress and the public health initiatives.

**Male and Female Suicides among the Adolescent Age Group in India; Years 2013, 2014 And 2015\(^{(6),(7),(8),(9)}\):** There is significant difference between male and female suicides. The number of male suicides is significantly higher than that of the female suicides. The difference between male and female suicide in 2013 is 7,064 suicides, in 2014 the difference between male and female suicides is 9,950 suicides, and in 2015 the difference between male and female suicides is 9,435 suicides.

2. **Suicide Rate amongst Adolescents in India 2013-2015\(^{(6),(7),(8),(9)}\):** States with Highest Number of Suicides: The states with highest number of suicides
in 2013, 2014 & 2015 are 1) Maharashtra, 2) Tamil Nadu, 3) West Bengal, 4) Madhya Pradesh, 5) Karnataka and 6) Andhra Pradesh. Specific strategies must be formed to address suicides in these states as they contribute to the majority of the adolescent suicides in India.

3. Total Number of Student Suicides in India 2013-2016; States with Highest Number of Suicides: The states with maximum number of student suicides in India in the years 2013, 2014, 2015 and 2016 are; 1) Maharashtra, 2) Tamil Nadu, 3) West Bengal, 4) Madhya Pradesh, 5) Karnataka, 6) Chhattisgarh, 7) Andra Pradesh.

The percentage increase in student suicide from 2013 to 2016 is an alarming 18.31%. The government and parents spend a lot of time and effort in developing the career and character of a student and hence the rapid increase in student suicides significantly affects our nation’s developmental gains.

4. Causes for Suicide amongst Adolescent Age Group in India 2013 & 2015; Male, Female & Transgender

Male: Figure No. 1, Causes for Suicide amongst Adolescent Age Group in India 2013 & 2015; Male (Suicide rate in percentage).

The most common Causes for suicide among male in 2014 and 2015 are: 1) Other Causes, 2) Other Family Problems, 3) Causes not known, 4) Illnesses, 5) other prolonged illnesses, 6) love affairs, 7) Insanity/Mental Illnesses, 8) Failure in examination, 9) Marriage related issues, 10) Unemployment, 11) Drug Abuse/Addiction

Female: The Figure No. 2, Causes for Suicide amongst Adolescent Age Group In India 2013 & 2015; Female Illustrates that:

The most common Causes for death among adolescent female in India in 2014 and 2015 are; 1) Other Family problems, 2) Other Causes, 3) Marriage related issues, 4) Illnesses, 5) Causes not known, 6) Other Prolonged Illness, 7) Love affairs, 8) Dowry Related Issues, 9) Insanity/Mental Illness, 10) Examination Failures.

Transgender: The Figure No. 3, Causes for Suicide amongst Adolescent Age Group in India 2013 & 2015; Transgender illustrates that:-

The most common Causes for adolescent transgender suicides in 2014 and 2015 are; 1) Other Causes, 2) Illnesses, 3) Other Prolonged illness, 4) Suspected/illicit relation, 5) Professional/Career Problem, 6) Other family problem, 7) Insanity/Mental illnesses:-, 8) Drug Abuse Addiction, 9) Causes not known.

5. Means of Suicide Adopted by Adolescent Age Group in India; Male, Female and Transgender in 2013 and 2015;

Male: The Figure No. 4, Means of Suicide Adopted By Adolescent Age Group in India 2013 & 2015; Male illustrates that:-

The most common means adopted by adolescent male in 2013 and 2015 in India are; 1) Hanging, 2) Poisoning, 3) consumption of insecticides, 4) fire/self-immobilization, 5) consumption of other poison, 6) other means, 7) drowning, 8) coming under running trains, 9) jumping, 10) overdose of sleeping pills.

Female: The Figure No. 5, Means of Suicide Adopted By Adolescent Age Group in India 2013 & 2015; Female illustrates that:

The most common means adopted by women in the adolescent age group for suicide in the years 2013 and 2014 are 1) Hanging, 2) Poisoning, 3) consumption of other poison, 4) fire self-immobilization, 5) consumption of other poison, 6) other means 7) drowning, 8) coming under running vehicles/trains, 9) Jumping and 10) over dose of sleeping pills.

Transgender: The Figure No. 6, Means of Suicide Adopted By Adolescent Age Group in India 2015; Transgender illustrates that:-

The most common Causes for suicide among transgender suicides in India are; 1) by fire/self-immobilization, 2) by hanging, 3) Jumping and 4) jumping of moving trains/vehicles.

Discussions and Conclusions

The percentage increase in adolescent suicide in India from 2013 to 2014 is 16.67% is higher than the records published by the National Crime Records Bureau 15.4% in increase from 2004 to 2014. The economic loss caused by adolescent suicides in 2014 accounts to 378.7 billion rupees which seriously affects the nation’s developmental gains. The priority should be to prevent male suicides which is significantly higher than that of female suicides in India. The government and NGO’s must individually target the states with
The maximum number of suicides in 2013, 2014 and 2015 were in: 1) Maharashtra, 2) Tamil Nadu, 3) West Bengal, 4) Madhya Pradesh, 5) Karnataka and 6) Andhra Pradesh.

The percentage increase in student’s suicide from 2013 to 2016 is 18.31% is alarming. The states with the maximum number of student suicides should be individually targeted and suicide prevention strategies involving student volunteers and teachers could be introduced in the educational institutions to address student suicides.

The best way to prevent adolescent suicides is to understand the Causes for suicides and to take appropriate measures to address them states the WHO, hence the suicide prevention policy could try and target people who are vulnerable to; other causes, other family problems, causes not known, love affairs, illnesses, other prolonged illnesses, insanity or mental illness, failure in exams, marriage related issues, dowry problems, drug abuse/addiction, unemployment, suspected/illicit relations and professional and career problems.

Preventing access to the means of suicide helps in reducing the number of suicides as per WHO guidelines and we suicide prevention policy could try and limit access to the most common means of adolescent suicides; Hanging, poisoning, consumption of insecticides, consumption of other poison, other means, drowning, coming under running vehicles/trains, jumping, jumping of moving vehicles, overdose of sleeping pills, fire/self-immobilizing.’

Further research must be done to understand: 1) high number of male suicides, 2) high number of student suicides, 3) high student and adolescent suicides in certain states, 4) the leading causes of adolescent suicide other family problems and other problems, 5) the actual number of transgender suicides in India.

The government should try and develop a suicide prevention policy considering the recommendations; 1) the states with highest number of adolescent and student suicides should be targeted individually, 2) student volunteers should be trained in educational institutions to give support to the students, 3) the adolescents who are vulnerable to common means of suicide should be assisted, 4) Access to the common means of suicide should be reduced 5) government should try and start a suicide prevention helpline, computer based and mobile based chat support to help adolescents 6) community based access points to give mental health first aid 7) Community mental health volunteers could be trained and employed in the PHC-SHC-CHC respectively. The primary focus should be to reduce the adolescent suicides and to foster their growth for the betterment of the nation.

How are Government’s Liability in Indonesia and Netherland?: Juridical-Normative Study with a Comparative Approach

Firzhal Arzhi Jiwantara¹, Karmal Maksudi²

¹Law Faculty of Muhammadiyah, University Mataram,  
²Law Masters Program 42 Seventeen August 1945 Surabaya

Abstract

Indonesian liability is included as the Government’s responsibility, namely as a compulsory compliance obligation of the state or government officials or other who carry out government’s functions as a result of an objection, a law, a judicial review, which is submitted by a person, the community, an entity civil law either through court settlement or out of court. The purpose of this study was to compare the responsibilities between Indonesia Government with Netherlands. The study used juridical-normative with a comparative approach based on the statute approach as the object of discussion. This case as a form of Governments’ responsibility both in civil and administrative cases. While accountability of the Government in Netherlands (civil law system) are known with several teachings regarding civil liability, namely: Accountability based on mistakes (schuldaansprakelijkheid), liability based on an error with an inverse proof load (schuldaansprakelijkheid met omkering van de bewijslast), and liability based on risk (risicoaansprakelijkheid). In the Dutch legal system, the equivalent of strict liability is risk-aansprakelijkheid. Responsibility based on risk is a form of responsibility that is not based on the elements of error for the following activities: hazardous material management; waste management installation; and drilling mining activities. The Defendant is free from responsibility based on risk, if: loss arises as a result of war; losses due to extraordinary natural events; losses due to obeying authority orders; losses due to victim’s actions; losses due to third party actions.

Keywords: Comparison, Government Liability, Indonesia, and Netherlands.

Introduction

Government as implementing the legislation certainly has the main task and function for ensuring the creation of public welfare based on the established rules and assignment of bestuurzorg or tasks in the form of public services. State government based on the constitution is a reflection of the rule of law. The concept of a prosperous and society are a concept that includes responsive justice values, which support the objective of the rule of law. The government as the organizer is also demanded to be more flexible towards the problems that occur in the community so that the result of legal products do not harm and guarantee fairness. Furthermore, regarding the state’s liability in the air navigation implementation, the state’s liability could be divided into two, namely liability under the administrative law and liability under the international law.²³ That article said: “Delegation is the delegation of authority from a higher Government Agency and/or Government Officer to a lower Government Agency and/or Government Officer with responsibilities and accountability is fully transferred to the recipient of the delegation”. Even though UUAP distinguishes into two, it does not try to determine the definition of the two. Responsibility is paired with another responsibility while the equivalent responsibility is a liability. It turns out, that there are also those who equate the notion of accountability with accountability which implies the understanding: willingness to sue the responsibilities that have been given to those who accept and are willing to carry out certain tasks. Understanding Accountable means the same as responsible, answerable. Furthermore, the meaning of word accountable, according to the
Contemporary English-Indonesian Dictionary, is responsible. As in writings relating to the contractual relationship between the nurse and her client, many contain a charge of accountability that is equated with accountability. Based on the description above, the researcher will discuss the Liability of the Government in Indonesia and compare it with the Liability of the Government in Netherlands 4,5.

**Material and Method**

Type of research used in this study is juridical-normative research, which is scientific research procedures in finding truth based on the study of legal science in terms of normative which is focused on analyzing the application of norms in positive law 2,3. The approach used is a Comparative Approach, which compares the accountability of the Indonesia Government with Netherlands and the statutory approach, which is used in the contents of legal regulations to examine existing problems. Legal research 3 is a distinctive character of jurisprudence 3,4, to address legal issues that are studied in this research. In legal research, we need a method that is related to the problem to be examined. Source and Type of Data Material: Primary Data, which is legal material that consists of laws and regulations relating to issues raised regarding the comparison of government responsibilities in Indonesia and Netherlands. Secondary data, namely legal material obtained from books, journals, opinions of scholars, and symposiums conducted by experts related to issues raised in research on comparative accountability of governments in Indonesia and Netherlands. Tertiary Data, i.e. legal materials that provide meaningful instructions or explanations for primary and secondary legal materials, such as legal dictionaries in the fields of Administrative Law and Constitutional Law.

Finding: Responsibility in the sense of liability is defined as accountability which is a translation of liability/ aanspralijkheid, a specific form of responsibility. Peter Mahmud Marzuki’s opinion is related with the civil law experts’ opinion in the early 20th century, namely JH Niewenhuis, said that accountability is an obligation to bear compensation as a result of violating the norm. Violating actions of these norms can occur due to: first the act against the law, secondly the interpretation. Furthermore, Nieuwenhuis explained that accountability was based on two pillars, namely violation of law and error. Referring to Niewenhuis 5’s opinion, an understanding can be drawn that the accountability can occur because First of the Law; it means that a particular person/party is declared liable not because of his mistake, but he issued because of the provisions of the law. This kind of accountability is called a risk liability. The primary data used by the Swiss Reinsurance Company is compiled by governments or insurance associations in individual countries.

**Discussion**

The concept of this accountability can we examine based on Peter Mahmud Marzuki’s opinion. He said that the definition of responsibility in the sense of liability is defined as accountability which is a translation of liability/ aanspralijkheid, a specific form of responsibility. According to him, the definition of accountability refers to the position of a person or legal entity deemed to have, to pay a form of compensation after a legal event or legal action. A person, for example, must pay compensation to another person or legal entity for having committed an unlawful act (onrechtmatige daad) which causing harm to that person or other legal entity. The term of accountability is within the scope of private law 5,6,7,8. Peter Mahmud Marzuki’s opinion is related with the civil law experts’ opinion in the early 20th century, namely JH Niewenhuis, said that accountability is an obligation to bear compensation as a result of violating the norm. Violating actions of these norms can occur due to: first the act against the law, secondly the interpretation. Furthermore, Nieuwenhuis explained that accountability was based on two pillars, namely violation of law and error. Referring to Niewenhuis 5’s opinion, an understanding can be drawn that the accountability can occur because First of the Law; it means that a particular person/party is declared liable not because of his mistake, but he issued because of the provisions of the law. This kind of accountability is called a risk liability. The second mistake was caused by an agreement between the parties that harmed one of the parties as regulated in Article 1365 of the Civil Code (unlawful acts). This kind of liability is known as accountability based on the element of error and in its development also because the proof is a liability based on the presumption of guilt. The responsibilities and accountability of government positions in the public sector are outlined in the legislation form (regulation), policy regulations (beleidsregel), and state administrative decisions (beschikking), as well as factual actions (feitelijke hendeling), in the form of government actions that are resolved through institutions different courts, if the government’s actions cause harm to citizens.
According to Toshiro Fuke, from the historical aspect of the development of accountability to the state, there are 6 (six) development phases mentioned as follows: since the liberation theory, state liability, non-authoritative activities, the welfare state, the case of compulsory acquisition of property (land in particular), and loss/injury that caused by natural distoter. In a broad sense, state liability is that the state will compensate for any loss that arises and occurs, which is caused directly or indirectly, materially or mentally to the citizens, as a result of using public authority. Premiums are disaggregated into two broad classes: life and property-liability insurance.

The primary data used by the Swiss Reinsurance Company is compiled by governments or insurance associations in individual countries. Recognizing the different valuation bases adopted in different countries, the Swiss Reinsurance Company adjusts the primary data to attain consistency. In particular, an attempt is made to produce premium figures that are gross of reinsurance and gross of commissions. Even though such a valuation basis more closely reflects the demand for insurance rather than the supply, the researcher ensure that data are consistent enough to justify the international comparative analysis adopted in this paper. The definition of criminal liability is proposed by Simons as a psychic state so that the application of a criminal code from a public and private point of view is considered appropriate. Still, according to Simons, the basis of responsibility in criminal law is a certain psychic circumstance in the person committing a criminal act and relationship between the circumstances and the deeds that have been done in such a way that person can be reproached for doing the deed. So it can be deduced that the core of accountability in criminal law as proposed by Simons is: the first one, a person with psychic or mental condition; and second one about the relationship between psychological condition likely stress and self esteem and actions. The term of Governmental Liability is often interchangeable with the term State Liability, for example, JJ Van Der Gouw, et al. (1997) entitled Government Liability in Netherlands said that both the states, central and regional governments, the officer council and other subordinates that have governmental duties which are classified as legal persons who can be held accountable both in civil law and law administration if unlawful actions. Acts of public law (for example in the form of dismissal) article 131 were used, according to him because the use of Article 839 of the German Civil Code which is the personal responsibility of officials (official personality) is often unsatisfactory, so that in turn can lead to public distrust of the government. In general, the definition of Government Responsibility is the compulsory compliance obligation of the state or government or government officials or other officials who carry out government functions as a result of an objection, lawsuit, judicial review, which is submitted by a person, the public, a good legal entity through court settlement or out of court for fulfillment in the form of (a) payment of a sum of money (subsidies, compensation, benefits, etc.); (b) issue or cancel/revoke a decision or regulation, and (c) other actions that fulfill their obligations, for example, to carry out more effective and efficient supervision, prevent danger to humans or the environment, protect citizens’ property, manage and maintain public facilities and infrastructures, impose sanctions for violations and so on. The understanding is clear that governmental liability is more emphasized on civil and administrative liability, while criminal liability is attached to the personal acts of the officials concerned, for example, corruption, murder, adultery, etc. by criminal provisions. In the context of governmental liability, in the field of civil law is generally based on an action against the law committed by the authorities (onrechtmatige overheidsdaad or unlawful acts of the government) as determined in Article 1365 of the Civil Code.

The settlement of this civil action can be done through the court or outside the court, namely through the ADR mechanism (al: mediation and arbitration) The procedure for civil litigation pursuant to Article 1365 of the Civil Code is intended for the government to be civilly responsible in the form of compensation payments, so it must be proven: (a) the government’s actions are against the law; (b) truly guilty; (c) the claimant (community/private legal entity) did indeed suffer a loss; (d) the loss is the result of government actions. Governmental responsibility in the scope of administrative law is based on unlawful acts of the government caused by the actions of the government in the form of State Administration Decree made in violation/contravention, at first the laws and the prevailing regulations, the second is contrary to the general principles of good governance as stipulated in Law No. 28 of 1999 concerning Administration of a Country that is Clean and Free of Corruption, Collusion, and Nepotism.
Conclusion

The definition of accountability refers to the position of a person or legal entity deemed to have, to pay a form of compensation after a legal event or action. The liability in Indonesia is included as the Government’s responsibility, namely as a compulsory compliance obligation of the state or government or officials government who carry out government functions as a result of an objection, suit, judicial review, submitted by a person, community, body civil law either through court settlement or out of court.

Mediating Effect of Self-Leadership in the Relation between Job Commitment and Job Competence among Care Workers in Korea

Hee Kyung Kim

Professor, Department of Nursing, Kongju National University, Gongju, South Korea

Abstract

Background/Objectives: The purpose of this study is to provide basic data for nursing intervention development that enhances the job competence of care workers by exploring the mediating effect of self-leadership in the relationship between job commitment and job competence.

Method/Statistical analysis: Data were collected using a questionnaire targeting 96 care workers belonging to 5 home-based elderly welfare centers in D city. Data were analyzed by descriptive statistics, Pearson correlation coefficients, multiple regression and Sobel’s test.

Findings: The care workers’ job commitment scored 3.99 points, self-leadership scored 3.82 points, and job competence scored 3.95 points out of 5 points. The job competence of subjects was a high positive correlation with job commitment (r=.78, p<.001), and self-leadership (r=.86, p<.001). The main factor influencing the subject’s job competence was self-leadership (β=.75, p<.001), and 74.9% of job competence was explained. In addition, self-leadership had a complete mediating effect in the relationship between job commitment and job competence.

Improvements/Applications: Job commitment and self-leadership showed a high correlation with job competence, self-leadership had a complete mediating effect. Therefore, the directors should place importance on job-related factors of care workers. It is necessary to develop and operate a leadership improvement program to foster self-leadership.

Keywords: Job commitment, Self-leadership, Job competence, Care workers, Mediating effect.

Introduction

The influence of the elderly in Korean society is increasing continuously. More than half of the elderly in Korea evaluate their health as average or bad, and are suffering from the disease for more than 3 months, 89.5% of the elderly responded that they had chronic diseases diagnosed by a doctor, and the entire population of elderly people have an average of 2.7 chronic diseases, and 83.5% of elderly people have taken prescription drugs prescribed by doctors for more than 3 months. In addition, the physical and cognitive function of the elderly also has a higher rate of restriction as the age increases, and 71.4% of the subjects with reduced physical function appear to be receiving care[1]. Overall, there is a need for a systematic care service policy for the elderly.

76.3% of the elderly in Korea currently live separately from their children, so the demand for home-visit care services provided by care workers is expected to continue to increase[1] and the elderly prefer to receive care at home, and the family is hoped that caregivers will visit home and provide services. Accordingly, the care
service providers for the elderly under the long-term care insurance for the elderly in Korea are care workers, and the job competence of care workers can be evaluated in terms of service quality. Job competence is an action that leads to successful outcomes through interaction with behavioral characteristics observed from those who generate high performance, that is, knowledge, skills, attitudes, and values. In particular, in the case of care workers since their competence plays an even more important role in the health and well-being of the subject.

According to the research to date, it has been said that if care workers have excellent competence, expertise and skill, they can satisfy the needs of recipients and provide quality services. In the case of 123 care workers job competence was about 3.66 out of 5 points, and as a result of measuring the job competence of 116 care workers, it was 3.79 out of 5 and it needs to be made so that they have higher job competence. In order to increase the job competence of these care workers, it is necessary to analyze the factors that affect job competence improvement.

In this study considers the results that the degree of commitment to one’s job affects job performance, and leadership affects job competence and performance. Job commitment means that one’s job becomes the center of one’s life, the desire to actively participate in the job becomes stronger, and the job is the standard in the process of establishing and realizing the concept of self and it is the degree to which he is immersed in his current job based on specific beliefs about the relationship between himself and his current job. Immersion is a result of the ability to experience and this level of job commitment appears more strongly in performance-related situations and situational characteristics.

On the other hand, self-leadership can be said to be able to exercise leadership by controlling and managing thoughts and actions with one’s own autonomy. According to a study, the self-leadership of 311 daycare center teachers was a major factor influencing teacher competency and as it was found that childcare teachers with high self-leadership have higher awareness of expertise and more positive verbal interactions, it is inferred that it will have a major impact on enhancing the job competence of care workers.

Therefore, the purpose of this study is to empirically test the mediating effect of self-leadership in the relationship between job commitment and job competence and provide basic data for developing strategies to increase the job competence of care workers.

**Method**

1. **Subjects:** The subjects of this study were 96 care workers in charge of home-visit care belonging to 5 home-based elderly welfare centers of D city, who were adult men and women who understand the purpose of the study and voluntarily expressed their willingness to participate and gave written consent, who were care workers with more than 6 months of job experience. The number of subjects was calculated using the G-power 3.1.9.4 program. The number of samples required to maintain 2 predictors, effect size of .15, significance level of .05, and power of .90 was 88, and 96 people were surveyed considering the dropout rate of 10%.

2. **Instruments**

   2.1. **Job commitment:** A job commitment tool revised by Park was used. This tool has a total of 9 questions, and on a Likert 5-point scale, the higher the score, the higher the degree of job commitment. In the study by Park, the reliability was Cronbach’s α=.92. In this study, it was .90.

   2.2. **Self-leadership:** A self-leadership tool revised by Koh was used. There are 20 questions. On a Likert 5-point scale, the higher the score, the higher the degree of self-leadership. In Koh’s study, the reliability of the sub-area was Cronbach’s α=0.78~0.86. In this study, it was .94.

   2.3. **Job Competence:** A tool reconfigured by Lee from National Competency Standards for care workers was used. There are 24 questions. On a Likert 5-point scale, the higher the score, the higher the degree of job competence. In Lee’s study, the reliability Cronbach’s α=.85. In this study, it was .94.

3. **Data collection:** Data collection was from July to August 2020. Researchers and research assistants visited 5 home-based elderly welfare centers in D city, and after receiving permission by explaining the research purpose and method to the center director, after meeting, the research purpose was explained directly to the nursing care provider and received a written consent with the help of a research assistant, especially in the data collection method. After that, data was collected through completing...
questionnaires. The time required to complete the questionnaire was 15 minutes.

4. **Ethical consideration:** This study was approved by the institutional review board of K University after submitting a proposal for ethics of the subject for deliberation (KNU_IRB_2020-44). The code of ethics was followed.

5. **Data Analysis:** Using the SPSS Window 23.0 program, the degree of variables of care workers was calculated by descriptive statistics, the correlation between job commitment, self-leadership and job competence was calculated using Pearson’s correlation coefficients, and the mediating effect was obtained using multiple linear regression, and the significance test for the mediating effect size was analyzed with the Sobel’s test.

**Result and Discussion**

1. **General characteristics of subjects:** The subjects of this study were care workers in charge of home-visit care (100%), and the age ranged from 32 to 76 years old, with an average of 57.78±8.89 years old, with age over 60 years accounting for 44.8% (44) over 60 years old. Most (96.9%) were women, and the most frequent education level was high school graduate with 48.9% (44), and the average work experience as a care worker was 42.59±31.82 months, ranging from 7 months to 11 years. It was found that more than half (69.4%, 77) had no other licenses other than the care worker license. Most of them (74.4%) received less than 1 education session during the past year, and for the monthly income, 0.51-1 million won accounted for more than half (55.2%).

2. **Degree of Job commitment, Self-leadership and Job Competence in Care workers:** The care workers’ job commitment scored 3.99 points out of 5 points, self-leadership scored 3.82 points out of 5 points, and job competence scored 3.95 points out of 5 points [Table 1].

4. **Mediating effects of self-leadership in the relation between job commitment and job competence in subjects:** As a result of examining the multicollinearity, the Durbin-Watson index for autocorrelation was 1.96, which was close to 2, which was independent. The multicollinearity between the independent variables was less than 10 with a VIF (Variance Inflation Factor) index of 3.90, and the tolerance was 0.26, which was higher than the standard value of 0.1, indicating that there was no multicollinearity, so this data was suitable for regression analysis.

Self-leadership, a parameter between job commitment and job competence, had a significant influence in the regression analysis in step 3.

As a result of the regression analysis of step 1, job commitment, an independent variable, had a statistically significant effect on self-leadership, a mediating variable (β=.86, p<.001), and the explanatory power to
explain self-leadership was 74.4%. In step 2 regression analysis, job commitment, an independent variable, had a significant effect on job competence, a dependent variable ($\beta=.78$, $p<.001$), and the explanatory power to explain job competence was 60.4%. To test the effect of self-leadership as an intermediary variable on job competence as a dependent variable in step 3, as a result of regression analysis with job commitment and self-leadership as predictive factors and job competence as the dependent variable, job commitment ($\beta=.13$, $p=.211$) was not significant, but self-leadership ($\beta=.75$, $p<.001$) was a significant predictor of job competence.

As a result of comparing the $\beta$ values, it was found that self-leadership was completely mediated since .78 in step 2 was greater than .13 in step 3, and job commitment in step 3 was not statistically significant. The degree to which self-leadership explains job competence was 74.9%. As a result of conducting Sobel’s test to confirm the significance of the mediating effect coefficient, it was statistically significant ($Z=7.14$, $p<.001$) [Table 3].

**Discussion**

This study was attempted to understand the mediating effect of self-leadership in the relationship between job commitment and job competence.

The job commitment of this study was 3.99 out of 5 points, which was higher than the level of job commitment of 3.82 points [6] as a result of a survey of employees who received job training in securities companies. The life of care workers serving and providing care to others can be regarded highly as a desirable job in the profession and needs to be supported so that it can be further improved. The self-leadership score was 3.82 out of 5, somewhat higher than the self-leadership of the daycare center teachers which was 3.75 [7]. Self-leadership is a way of thinking about yourself and your role in what you’re doing, and care workers have a professional sense of duty to take the lead in helping the vulnerable subjects and it is judged that they have the ability to perform their role as a leader. In the future, if education to improve such leadership is given, it can be further improved. Also, the job competence of care workers was 3.95 out of 5, which was slightly higher than that of 3.68 points of job competence of 217 care workers who provide home-visit care services with more than 1 month’s experience [15]. The results of this study are considered to be the result of having subjects with higher job competency as they were subjects who provided nursing services for more than 6 months.

The relationship between the subject’s job competence, job commitment, and self-leadership showed a high positive correlation. This was similar to the result [16] showing a positive correlation between the job commitment of the cabin crew of a low-cost airline and 3 sub-areas of job competence. In addition, the self-leadership of daycare center teachers showed a positive correlation with the teaching competence, which is consistent with the result [7] that the higher the self-leadership, the higher the teaching competency. Therefore, it is recommended to consider job commitment and self-leadership in education and activities to increase the job competence of care workers. Also, in the relationship between job commitment and job
competence, self-leadership had a complete mediating effect. This was similar to the result of a study of care workers [17] showing that self-leadership improves the service quality and productivity of the organization. Self-service is a decisive factor for care workers to demonstrate job competence, and self-leadership with expertise and autonomy can help provide quality services and increase productivity. Therefore, it is recommended that home-based elderly welfare center directors develop and apply a self-leadership improvement program as a way to improve the job commitment and job competence of care workers in charge of home-visit care.

Based on the results of this study, it is necessary to increase self-leadership in order to increase the job competence of care workers in charge of home-visit care. In order to do that, one must control oneself and increase self-motivating autonomy, and knowing one’s role and abilities with thinking and action strategies, setting goals and putting them into practice, one should make an effort to take responsibility for the results. Ultimately, these efforts can increase the influence of care workers, and it is thought that they can improve their job competence and increase the satisfaction of the care recipients. Therefore, it is suggested that a leadership improvement program be developed and actively used as supplementary education for care workers.

Periodic Acid Schiff (PAS) Staining: 
A Useful Technique for Demonstration of Carbohydrates

Swapna Shedge A., Priya Roy, Ajay Shedge, Megha A. Doshi

Abstract
The term mucosubstances is used to denote all tissue components other than glycogen, rich in carbohydrates, which are present in connective tissue or as secretion of certain epithelial structures. Connective tissue mucosubstances are called “mucopolysaccharides”, while those secreted by epithelia are referred as “mucins”.

Objectives: To show the usefulness of PAS staining in identification of carbohydrates in normal and malignant lesions of mammary gland and endocervical gland.

Methodology: This is a retrospective, observational, analytical, case control study aimed to evaluate mucin histochemical pattern in normal and diseased lesions of mammary and endocervical glands. Twenty five histologically proven blocks of normal and Intraductal carcinoma of mammary gland, normal and adenocarcinoma of endocervical glands were taken. Tissue sections were stained by PAS technique.

Results: Results were tabulated according to colour intensity into different grades ranging from + to ++++. PAS staining of normal endocervical glands showed presence of PAS +ve substances like carbohydrate & mucins. PAS stain for adenocarcinoma cervix gave mild reaction with focal magenta shade, suggestive of presence of few neutral mucosubstances. PAS staining of normal mammary gland and of Intraductal carcinoma showed similar results. Ducts and lobules stained with magenta showed the presence of PAS positive substances like carbohydrate and neutral mucins.

Conclusion: Mucin histochemical patterns serve as valuable, cost-effective tool for diagnosis in histopathology and for the researchers in histology, where a slight change in the mucin pattern may help in the early diagnosis of disease process. PAS technique is perhaps the most versatile and widely used of techniques for the demonstration of glycoproteins, carbohydrates and mucins.

Keywords: Mucins, PAS stain, Normal, Adenocarcinoma, Intraductal carcinoma.

Introduction
Special stains belong to a diverse family of slide-based stains that rely on basic chemical reactions for microscopic visualization and general identification of various tissues, structures, cells, organelles, carbohydrates, minerals and micro-organisms. Introduced to all college biology students through the simple bacterial test known as the Gram stain. Special stains use both, science and art to provide valuable and cost-effective information for pathology laboratory.\(^1\)

Periodic acid (HIO\(_4\)) is an oxidizing agent used initially by Jackson and Hudson (1937) for the chemical estimation of polysaccharides.\(^2\) “McManus” (1946)
was the first to apply Periodic acid to the histological demonstration of mucin, whereas Hochkiss (1948) emphasized the legitimacy of Periodic acid as a special histochemical reagent. Dr. Joseph Forde Anthony McManus (1911-1980) was a Canadian pathologist who is best known for his formulation of one of the most frequently used stains in histopathology; the McManus Periodic-acid Schiff stain. Periodic acid acts upon the 1,2 glycol linkage of carbohydrates in tissue sections to produce aldehyde which can be colored with Schiff’s reagent. The method can be used in paraffin sections or frozen sections and is useful as a reaction for carbohydrates of tissue: i.e glycogen (in paraffin sections only) mucin, basement membrane, reticulin, colloid of thyroid and pituitary stalk, granular cells of renal arteriole etc.

Chemistry
PAS reaction demonstrates aldehyde groups formed by the oxidation of certain tissue carbohydrates and glycogen. The oxidation of the tissue sections is performed using periodic acid. After oxidation, tissue sections are treated with Schiff’s reagent, a colourless mixture of basic fuchsin, HCl and sodium metabisulfite. During incubation, basic fuchsin binds to the newly formed aldehyde groups in the tissue. Rinsing the sections in running water after the Schiff reagent incubation causes the bound basic fuchsin molecules to assume a pink to red color due to molecular changes. Several counterstains may then be used to visualize other tissue elements. Hematoxylin counterstaining is very commonly used to demonstrate cell nuclei, although other counterstains may also be used. Some older method include treating the sections in a sulfurous rinse solution before running water wash. This can serve to reduce background staining by removing excess Schiff’s reagent from the tissue.

Material and Method
The present study was conducted in the Department of Anatomy, Krishna Institute of Medical Sciences University, Karad from May 2010 to June 2018. The type of study was observational, analytical and case control. Work protocol was submitted to the protocol and ethical committee for approval and necessary permission was taken.

Sample size was twenty five blocks of histologically proven normal and Intraductal carcinoma of mammary gland, normal and adenocarcinoma of endocervical glands. The tissues were fixed in 10% formal saline with 2% calcium acetate and a pinch of phosphotungstic acid to help for preservation of mucins. The tissues embedded in paraffin blocks were prepared by histopathological technique and cut at 5 – 6 microns. Sections were stained with Hematoxylin and Eosin for identification of the tissue and special stain PAS for identification of carbohydrates and results were interpreted. PAS-Periodic acid Schiff reagent stains all carbohydrates including mucosubstances. Therefore mucosubstances are PAS positive. All the results obtained were tabulated according to colour intensity into different grades ranging from + to ++++. 

Observations and Results
All the results were tabulated according to colour intensity into different grades ranging from + to ++++. 

Colour Index:

++++ : Very strong positive reaction.
+++ : Strong positive reaction.
++ : Moderate reaction.
+ : Weak reaction.
- : Negative reaction.

Inference: Regarding special stains – PAS stain was used to assess presence of neutral mucosubstances. PAS stain for normal endocervix gave magenta colour with strong reactivity suggestive of presence of netural mucin. Epithelium and glands, both gave moderate to strong reactivity. PAS stain for adenocarcinoma cervix gave mild reaction as focal magenta staining, suggestive of presence of minimal neutral mucosubstances as compared to normal endocervix.

Sections of normal mammary gland stained with PAS showed the ducts and lobules stained magenta, confirming the presence of PAS positive substances like carbohydrate and neutral mucins. For Intraductal carcinoma breast, PAS stain gave moderate reaction as focal magenta staining, suggestive of presence of neutral mucosubstances. However the colour intensity was more than that of normal breast tissue.

Discussion

Worldwide, cervical cancer is the fifth most deadly cancer in women. It affects about 16 per 100,000 women per year. It accounts for 20-25% of all the cancers and 85% of all the female genital tract malignancies. Primary adenocarcinomas make 5-10% of all cancers of the cervix. Invasive breast cancer is the most common carcinoma in women, accounting for 23% of all cancers in women globally and now the most common cancer in Indian women, having recently overtaken cervical cancer in this respect.

The term “mucosubstances” is used to denote all tissue components, other than glycogen, rich in carbohydrates which are present in connective tissue or as secretion of certain epithelial structures by Spicer et al.

Numerous types of mucins occur depending on the
Examples of connective tissue mucins are chondroitin sulphate, heparin sulphate, keratin sulphate and hyaluronic acid. Epithelial mucins may be neutral or acidic. Neutral mucins are hexosamine units which may be associated with glucoronic or sialic acid; the reactive group being carboxyl. In sulphated mucins this group is blocked by a sulphate group which becomes the active group. Strongly sulphated mucins are of connective tissue type; the weakly sulphated groups are of epithelial type. The non-sulphated mucins are sialic acid and hyaluronic acid (carboxylated D-glucoronic acid). These can be enzymatically digested, though enzyme resistant forms do occur.

With the development of new histochemical method by special stains, specific chemical composition of mucosubstances is documented by various scientists. But there have been very few studies on human endocervical mucosubstances such as by J. N. Bulmer et al (1988), Vatsala Misra et al (1997), Zhao Shumei et al (2003) and Hayashi, Isamu M.T et al (2003) in the histochemical study of normal and adenocarcinoma of endocervix gland. In the histochemical study of normal and neoplastic breast, the present study correlates well with workers, Luciano Ozzello and Speer (1958), D J Cooper (1974), Muaz Osman Fagare (2015) and S S.Spicer et al (2016). The PAS reaction is an useful indicator of the presence of tissue carbohydrates, and particularly so for glycogen when the technique incorporates a diastase digestion stage.

**Summary and Conclusion**

Mucin histochemistry of normal and malignant endocervical glands, normal and Intraductal carcinoma of breast was undertaken in the department of Anatomy at Krishna Institute of Medical Sciences University, Karad from 2010 to 2018.

In the present study, Haematoxylin and Eosin was used as routine stain for identification and confirmation of the tissue and special staining with PAS was carried out for presence of carbohydrates.

- In the present study mucin histochemistry of normal endocervical glands showed mixture of mucosubstances, both neutral and acidic.
- Histochemical results for malignant endocervical glands showed very few mucins. Mixture of both neutral and acidic were found. Neutral mucins were in trace amounts. So there is a shift in mucin pattern as compared to normal.
- Mucin histochemistry of normal breast tissue showed that neutral as well as acidic mucins were present.
- Histochemical results for IDC breast showed a mixture of both neutral as well as acidic mucins, with predominance of neutral mucins.

Abstract

Wine is called as a functional fermented food as it shows several health benefits. This fermented undistilled alcoholic beverage is produced by anaerobic fermentation of grape sugars to ethanol by the wine yeast. In this study, roselle (*Hibiscus sabdariffa*) and peppermint (*Mentha piperita* L.) extract were used for making the wine along with main ingredients to obtain nine variations of wine. All the ingredients are best known for their medicinal and nutritional benefits. Baker’s yeast (*Saccharomyces cerevisiae*) was used for the fermentation process. Each variation along with the standard red wine (control) was fermented for 28 days. Characterization properties like pH and Total Soluble Solids were measured and observed weekly. After 28 days, sensory evaluation was conducted for the developed variations. The results showed that the variations with 10% of roselle were found to be the most accepted and amongst them, red wine with 10% roselle and 6% of peppermint extract (V2T3) was the best selected one by sensory panelists. The final products for all the variations and control were tested to measure their pH, specific gravity, alcohol content and vitamin C. The pH, specific gravity and alcohol by volume (%) of the most accepted variation (V2T3) were 2.96, 1.006 and 10.73% respectively. The results indicate developed red wine was accepted by the panelists.

Keywords: Fermentation; Sensory; Roselle; Peppermint; Wine.

Introduction

Grapes have been widely used as a prime raw ingredient for production of making wines over a long period of time. Traditionally, red wine is produced from grape varieties that have black or red color and the fermentation is carried out on the skin using standard wine yeast. Despite that, studies have investigated the suitability of other fruits, vegetables, edible flowers or combination of two or more substrates can be used to produce wine for example mango wine, roselle wine, banana wine etc. Edible flowers have traditionally been used in different cultures, such as European and Asian, to improve the appearance (colour, odor and flavour) and nutritional value of food. Flowers are served as a salad, as a snack and as a side dish. For example, roselle, otherwise called Indian sorrel belongs to the *Malvaceaeae* family and develops in the tropic and sub-tropical locales of the world. It is an erect, extended sub-woody yearly bush that bears alternate leaves and blooms that are borne with leafy large calyces. It is popularly recognized as ‘mesta’ or ‘chukur’ in Indian subcontinent including Bangladesh. Roselle calyces are palatable and the traditional use of roselle calyces (fresh or dried) extends from its use in remedies for various diseases to food uses such as sauce or filling for tarts or pies; and also to jam, jelly, syrup, wine, ice cream and flavours. The nutritional composition of fresh calyces varies from study to study, probably due to various varieties, genetic, environmental, and ecological and plant harvesting. In early studies, protein (1.9 g/100 g), fat (0.1 g/100 g), carbohydrate (12.3 g/100 g) and fiber (2.3 g/100 g) were reported. They are rich in vitamin C (14 mg/100 g), calcium (1.72 mg/100 g), beta carotene (300 μg/100 g) and iron (57 mg/100 g) [1]. Peppermint or mint (*Mentha piperita* L.), a perennial aromatic herb belonging to the *Lamiaceae (Labiatae)* family, is
a natural hybrid between spearmint (*Mentha spicata* L.) and water mint (*Mentha aquatic* L.). Fortification of wines is common but doing the same to improve its beneficial health properties is still less explored. A study has been done where orange wines were fortified with herbal extracts like holybasil, lemon-grass, peppermint and ginger were chosen which are known for therapeutic and medicinal applications. These herbal extracts impart their beneficial properties to the fortified wines and hence, consumption of such fortified wines would give tremendous health benefits than regular wines [2].

**Materials and Method**

**Sample collection and preparation:** Fresh grapes were purchased, destemmed, soaked in warm water and salt (NaCl) for 10 minutes, washed with clean water, dried in a clean muslin cloth and sorted. Grapes were weighed accurately and crushed and mashed by a clean wooden muddler in a clean and dry vessel. Dried Roselle petals were purchased from market and weighed accurately according to the calculated concentration of the respected variation and it is crushed and mashed along with the grapes nicely with the help of the muddler. Sugar (75g) and sterilized warm water (500ml) were added to the mixtures after this. Thus the total soluble solids (TSS) of the mashes were adjusted.

Before inoculation, Potassium metabisulfite was added in the mashes to reduce the bacterial contamination. Commercially available baker’s yeast (*Saccharomyces cerevisiae*) suspension (1g/l) is added to it and mixed well. The wine must was filled into sterilized fermentation jars and sealed airtight and left to incubate for 28 days at room temperature. After 28 days the filtration was done of each variation and the amount of extract obtained from each variation was measured by measuring cylinder. Peppermint extract was made from fresh peppermint leaves which were purchased from the market and destemmed, soaked in warm water and salt for 5 minutes, washed with clean water, dried in a clean muslin cloth and sorted. For each variation apart from control, around 10 gm leaves were measured and taken for crushing. The leaves were crushed uniformly by adding water. Afterward, it was added to 200 ml distilled water and boiled. It was separated with the assistance of filter paper. The extract was thus prepared and could now be included. The extract was made just before adding to wine to guarantee it was included when fresh.

**Pasteurization and bottling:** The clear wine was transferred into covered steel pots and pasteurized by heating to 70°C for 15 minutes and cooled to room temperature (25°C). No chemical was added for the clarification of wines. Cold wines were filled into pre-sterilized bottles and kept in room until needed for further analysis.

**Determination of the physiochemical properties:**

*Determination of pH and total soluble solids (TSS), specific gravity (SG) and alcohol by volume % (ABV%):* The pH and TSS were measured according to the AOAC method[3]. Specific gravity (SG) of different wine versions was determined according to the procedure of Balogu and Towobola, 2017[4] and ABV% was then calculated based on specific gravity chart given by American Society for Brewing Chemists [5].

**Sensory evaluation:** Each panelist received the wine sample in a random presentation order, a glass of water for rinsing consumption between samples. Coded samples were assessed organoleptically using a 9-point hedonic scale.

**Results and Discussions**

**Physicochemical Properties:** *pH:* The pH of wine is important to know as it plays a critical role in many aspects of wine making, in particular wine stability. pH influences microbiological stability, influences the solubility of proteins and affects red wine colour and oxidative and browning reactions. Table 2 shows the weekly data of the pH for developed wines and it was observed that the wines are on acidic side (below 7) and in the variations the pH ranges from 2.8-3. The significant trend which was observes here was the pH was decreasing gradually throughout the fermentation.
period. Due to the low pH values, the wines gave a crisp tart taste to the product and it also enhances the microbial resistance of the product. The values are comparable with the pH values on the final day were 3.0 and 3.07 at 20 °C and 30 °C respectively in roselle wine [6]. The pH of 3 varieties of Zobo drink ranges from 2.5-2.67 [7].

**Total soluble solids (°Brix):** TSS measures the sugar content of present in the wine. This is measured using a refractometer, and is referred to as the degrees Brix (°). This influences the conversion of sugar to alcohol by yeast strain during fermentation period.

Table 3 shows the initial and final total soluble solids (TSS) of the developed wines. The initial brix(°) of the wines were to check the total soluble solids present in the wine musts before fermentation. The standard (T0) showed the highest initial brix of 21.54 followed by variation 3, variation 2 and variation 1. The final TSS of the wines has come down drastically in the final wines. The addition of sugar at the beginning of fermentation is necessary to provide suitable conditions for the growth of yeast and fermenting the sugar into ethanol [8].

**Specific gravity and Alcohol by Volume % (ABV%):** Table 4 shows the data for specific gravity (SG) of the developed wines. Final specific gravity is observed to be on a lower side than the initial specific gravity which is taken from the initial wine must. There is no significant trend observed in the specific gravity of wine. The standard wine had the highest initial SG of 1.09 amongst all the developed products, followed by variation 3 (1.087), variation 2 (1.085) and variation 1 (1.08). Thetable also depicts alcohol by volume % (ABV %) of the developed wines. The standard (T0) has showed to obtain the highest % of alcohol by volume % (ABV %) having an ABV of 11.27% which is almost near to the variations V3T2 (11.005%) and V3T3 (11.14%). This value is comparable with the wine produced from a blend of pawpaw and roselle extracts with a value of 10.5% (w/v) alcohol [9].

Sensory score analysis: Table 5 depicts the product wise mean sensory scores. While considering the mean sensory score with respect to taste, the highest score (8.04 ± 0.94) was obtained by V2T3, followed by standard (T0) which obtains a mean score of 7.48 ± 1.64. V3T2 got the minimum mean score with respect to aroma (4.60 ± 1.26). The statistical f-test indicates that the mean sensory scores with respect to aroma were found to be statistically significant at 5% level (p<0.05, 20.64*). While considering the mean sensory score with respect to mouthfeel, the highest score (8.12 ± 0.83) was obtained by V2T3, followed by standard (T0) which obtains a mean score of 7.44 ± 1.53. V1T1 got the minimum mean score with respect to mouthfeel (4.04 ± 1.48).

*Significant at 5 % Level, SEM: Standard Errors of mean, CD: Critical Difference
The statistical f-test indicates that the mean sensory scores with respect to aroma were found to be statistically significant at 5% level (p<0.05, 22.35*). While considering the mean sensory score with respect to colour and appearance, the highest score (8.24 ± 0.93) was obtained by V2T3, followed by standard (T0) which obtains a mean score of 7.84 ± 1.18. V1T3 and V3T2 got the minimum mean score with respect to colour and appearance (6.84 ± 1.28 and 6.84 ± 1.21). The statistical f-test indicates that the mean sensory scores with respect to aroma were found to be statistically significant at 5% level (p<0.05, 5.01*).

Appearance, colour, aroma, taste and subtle taste factors like flavour of wine constitute the quality. Aroma and taste of wines are very complex and depend on number of factors such as cultivar, vinification practices, fermentation and maturation[10].

</tbody>
</table>

*Significant at 5 % Level, SEm: Standard Errors of mean, CD: Critical Difference

The table 6 depicts the overall mean acceptability scores with respect to the products. The findings show that the highest overall mean acceptability score was found to be higher in V2T3 (8.092±0.84), followed by T0 (7.512±1.38). However, the least accepted product with minimum mean sensory score was found to be V3T2 (5.444±0.90). The data subjected for statistical tests reveals the difference in overall acceptability. The scores between products were found to be statistically significant at 5% level (p<0.05, 20.30*).

From the sensory scores it can be concluded that V2T3 was the best acceptable variation in all the attributes and panelists liked the product more than the standard (T0). The bitterness imparted by the 10% roselle in the product was well balanced by the addition of 6% peppermint extract with its cooling effect. In variation 1 the proportion of 5% roselle, grapes and peppermint extract was not well balanced which made the product less acceptable to the panelists and in variation 3 use of 15% roselle in the product showed reduced acceptance by the panelists as it imparted bitterness which made the variation unacceptable.

**Conclusion**

There are plenty of fruits, vegetables and edible flowers which are still underutilized though they can show positive health effects when consumed as it contains plenty of vitamins, minerals and also shows antioxidative properties. This study proves that acceptable wines can be prepared by addition of roselle and peppermint extract in the normal red wines if added in specific amount. The high acidity of the wines indicated that microbial spoilage resistance and storability can be improved when roselle is added to wine. Further studies are needed to check the proximate analysis and mineral compositions of wine and also to check the parameters of the wine when aged for a longer time.

Analysis of Injury Pattern & Forensic Medicine Management in a Case of Bomb Blast Injury

Toshal Wankhade¹, Deepak Bhagwat², Ambedkar Ranjan³, B.H. Tirpude⁴, P.N. Murkey⁴, I.L. Khandekar⁴

¹Senior Resident Dept of Forensic Medicine, AIIMS, Nagpur; ²Assistant Professor, Dept of Forensic Medicine, Govt. Medical College, Gondia; ³Senior Resident, Dept of Forensic Medicine, Banaras Hindu University; ⁴Professor, Dept of Forensic Medicine, MGIMS, Sevagram.

Abstract

Background: In 2016 midnight of summer a bomb blast occurred at ammunition depot Pulgaon. Blast was so severe that villagers in the radius of 10km witnessed the blast wave. It had killed 19 people which included Army officers, soldier & fire brigade men. As per police inquest & alleged history given by eyewitness, an authority of Central Ammunition Depot at Pulgaon noticed fire at ammunition store of the depot. For this reason emergency task force team of the depot got activated and few army personnel including fire brigade personnel rushed to the spot to control the fire. But unfortunately large amount of ammunition blasted suddenly as the fire spread inside the ammunition storage. Because of this 19 parsons were died on the spot & many were injured. To tackle the disaster civil authority were informed. When it was noted that total 19 personnel were died in the mishap, the District civil authority approached to Mahatma Gandhi Institute of Medical Sciences, Sevagram to send forensic medicine expert team to do spot Post Mortem (PM) examination. The main challenge before the forensic team was to establish the identity of the unidentified body apart from doing PM examination, so that the body can be handed over the kin as early as possible to end the uncertainty of their loved ones.

Aims & Objective: Forensic casework was carried out with aim to study the pattern of injuries in the bomb blast cases, and to assess forensic management done in mass disaster.

Material and Method: Study was carried out on 15 dead bodies involved in the bomb blast injury. It includes observation based on post mortem examination and assessment of forensic management done by our team.

Result: Bomb blast injury includes complex of injuries like burn injury(100%), decapitation (33%), injury of internal abdominal organs (40%) & chest organs (80%), fracture of bones (46%), Amputation of limbs (33%), and external mechanical injuries like contusion, abrasions and lacerations (100%). Due to destructive injuries identity of the victim gets obscured (40%).

Conclusion: Medicolegal postmortem, sample preservation and humanitarian action of establishing the identity of victims are the forensic management in bomb blast injury.

Keywords: Bomb blast, Mass disaster, Forensic Humanitarian action.

Introduction

Bomb blast is a kind of mass disaster. The WHO has defined disaster as an occurrence that causes damage, ecological disruption, loss of human life and deterioration of health and health services on a scale sufficient to warrant an extraordinary response from outside the affected community. A “Mass Disaster”
is considered to have occurred when the number of casualties occurring in a single event exceeds twelve\(^1\). Management of disaster is multifaceted. It includes involvement of various agencies like law enforcement, safety & Health care services. Forensic medicine role in the mass disaster includes

1) To retrieve and reconstruct bodies and fragmented bodies decently. 2) To establish personal identity. 3) To conduct autopsies on some or all of these bodies. 4) To establish the cause of death in same or all.

Apart from the routine forensic work forensic experts also has Humanitarian character in their task. This is known ‘humanitarian forensic action’\(^2\). Mass disaster is not uncommon in India. Hence preparedness should be there for such action. \(^3\). Present study involves handling of Bomb blast case by forensic expert.

**Aims & Objectives:** Forensic casework was carried out with aim to study the pattern of injuries in the bomb blast cases, and to assess forensic management done in mass disaster.

**Material and Method**

Mass casualty due to bomb blast occurred at Army Ammunition depot in summer 2016. Present study was cross-sectional in design and included deceased succumbed to blast injuries. Total 19 casualties were reported. Post mortem examination was conducted on 15 bodies out of total 19 bodies. 4 bodies were referred to another agency for administrative purpose, and are excluded from present study. Each team consists of one forensic expert, one junior resident & one mortuary attendant. Total 4 teams were formulated by MGIMS, Sevagram. Police officials collected the bodies and body parts which were submitted for postmortem examination. Bodies were categorised in two parts i.e. 1) Deceased of which facial structured was intact and identity could be established and 2) Deceased wherein identity from facial features was not established due to its complete destruction.

Injuries were noted by proper examination of the dead body and samples are preserved in order to establish identity of unidentified bodies. Cause & manner of the death of each person was determined based on observed trauma. Pattern of the injury is analyzed by comparing the existing injuries with the data from available literature. Standard Disaster Victim Identification (DVI) protocol\(^4\) was employed like visual identification, identification by interviews of next of kin and peer group and DNA analysis. Data was compiled and analysed with regards to trauma pattern and identification techniques involved.

**Observation:** Significant trauma was observed in almost all of the dead bodies with multiple body regions were involved. All the body areas had external mechanical injuries like abrasion, lacerations, contusions of various sizes and severity. Various major injuries observed amongst the bodies were as under.

**Burn Injury:** All 15 bodies have burn injuries these varied in extent and depth. Burn varies from superficial burn to complete charring of the body. (Fig.1). Inmost of the cases the blast had ripped off the clothing. Out of 15 bodies only 2 bodies was having minimal burn (up to 10%) & rest all of the cases were having severe burn injury starting from more than 50% to complete charring.

**Head & Neck Injuries:** 13 out of 15 (86%) of the victims had head & neck injury. Out of these 13 cases 5 cases had decapitation. (Fig 2 & 3). In remaining 8 cases, skull bone was fractured. The fracture skull varied from small fractures involving the base of the skull to major fractures of the vault. Decapitation injury ranged from level of lower jaw to transaction at the level of nipple in chest (1 case Fig.3). Brain injury involves laceration, oozing of brain matter & intracranial hemorrhages which included extradural, subdural and subarachnoid hemorrhages.

**Upper Trunk Injury (Thoracic Injury):** Injuries on the upper trunk involve external injuries such as pressure abrasion, abrasions, contusions, laceration in almost all the cases. Most of the bodies were having both external as well as internal trauma of chest. In 12 out of 15 cases (80%) internal chest trauma was present which included various injuries like hemotherax, hemorrhages, contusions & lacerations of lungs. Hemocardium, contusions & lacerations of heart was also appreciated. In 3 out of total 15 (20%) cases chest cavity was opened and charring of internal organs took place.

**Lower Trunk (Abdominal Injury):** Injuries on the lower trunk varied from external injuries such as pressure abrasion, abrasions, contusions, laceration in almost all the cases. 6 out of 15 cases (40%) show intrabdominal trauma which include hemorrhages in abdominal cavity, contusions & lacerations of abdominal organs. In 3 cases (20%) abdominal cavity was opened and viscera were charred.
Limb injury: Almost all the bodies had various kinds of injuries on limb varied from external mechanical injury such as abrasion, laceration, and contusions, fracture of bones or amputation of the limbs. Fracture of limbs was seen in 7 out of 15 (47%) bodies out of these 5 (33% of total) bodies had amputation of the limb.

Identification data: As all the deceased were serving personnel of the Ammunition Depot, list of missing personnel was provided by Depot Authority as they were deployed as a fire fighting team. 9 out of total 15 (60%) persons were identified by facial features and body was handed over to relative after post mortem examination. Body was first identified by Depot authority and later on by relatives of the deceased. In 6 bodies (40%) identity from facial structures could not be made out as body had decapitation injury as described earlier or their facial features unable to makeout due to extensive trauma. Among these 6 bodies, identity card of the deceased was found in two bodies (fig. 4). Still to confirm the identity of these bodies, sample was taken for DNA Analysis. Sample taken were blood on cotton cloth, the cloth was air dried and sealed in paper envelope. Sternal bones along with ribs were taken from all the 6 bodies for DNA analysis. On same day blood sample from parents of the missing persons was taken for matching the DNA profile with unidentified bodies. All samples are immediately forwarded to Regional Forensic Science Laboratory, Nagpur (RFSL). DNA analysis report was received within 48 hours and bodies handed over to relative by the police authority

To establish the identity following stepwise measures were taken.

1. Duty roster from the ammunition depot authority was taken.
2. Number of the missing personnel was identified by taking the roll call by the depot authority.
3. Relatives of the all missing personnel informed regarding the incident and they all were called at the site for identification of the bodies.
4. Depot officer and relatives of the deceased identified 9 bodies whose facial structure was intact.
5. To confirm the identity by DNA fingerprinting sternal bone & rib bones were preserved; blood was taken on cotton cloth. All these sample air dried and handed over to police as per norms.
6. Regional forensic lab, Nagpur was contacted by police authority and they were agreed to do DNA analysis within 2 days. Blood samples from the relatives were taken for the matching.
7. After the result of DNA analysis identity of all the deceased is established and bodies were handed over to police for further handover to relatives.
Discussion

Burn Injuries are commonly observed in blast injury. As per study by Water worthTA\textsuperscript{5} 19 out of 21 (90%) victims was having burn injury. In present study all 15 cases (100%) were having burnt injury. In study T A water worth most of the burn injury was superficial type but some injury were more extensive and charring of the tissue occurred due to flash. In present study also the burn pattern varies from superficial to deep and charring observed. However number of cases involved more in our study as large amount of ammunition store blasted at single time.

In the study by KahanaT\textsuperscript{6} 73 of 171 (43%) of cadaver is identified by visual method and in remaining cases scientific method are used for the identification before burial of the body. In our study, 9 cases out 15 (60%) had identified with facial characters. However to identify the unknown cases DNA analysis was performed. Differences in finding between these two studies may be due to less number of cases involved in current study and list of missing persons was known. However, the study done by water worth\textsuperscript{5} shows similarity with findings in our study pertaining to number of unidentified persons.

In present study 13 out of 15 (86%) cases suffered head, neck & face injury. This varied from skull fracture to complete decapitation of the head. Our findings matches with the study by T A Waterworth\textsuperscript{5} where 15 out 21 cases (70%) cases have the head injury in varying severity. However our findings differs with the study by Yogender Malik\textsuperscript{7} where 33% cases involved with injury at head region. This variation may be due to the variation in severity and amount of ammunition blast in these studies.

As per study of waterworth\textsuperscript{5} out of 21 bodies (43%) person suffered limb amputation. These findings are similar to our study where amputation of limb is seen in 5 cases (33%). Extremities injuries are one of the commonest involvements in bomb blast incident. In study by sue Mallonee\textsuperscript{8} .75% of the victims suffered with the limb injury. In our study all the (100%) victims were having various kinds of injuries on limbs ranging from abrasion, laceration, fracture to amputation of limbs. Fracture of the bone is noted in 7 out of 15 cases. (46%)

All the bodies were having external injuries over upper & lower trunk. In our study 12 (80%) individuals were having internal chest trauma that includes contusions & laceration of the lungs and hemorrhages in chest cavity & 3(20%) person were having open chest wound. 6 (40%) cases were having contusion and laceration of various abdominal organs out of which 3 (20%) bodies were having open abdominal wound. Similar finding was seen in study by waterworth\textsuperscript{5}.

Conclusion

Team work is must in mass disaster. It includes proper coordination between investigating agency, administration authority & medical team. In current case District authority advised for formation of medical team, the team examined the bodies and collected the proper samples, police agency done their inquest formalities quickly and liaised with RFSL for quick analysis of sample and due to this team work situation was handled on fast track.

Inclusion of forensic expert is must in this kind of situation. Due to involvement expert proper sample collection, their preservation, performing the autopsy and establishing the identity of unknown victim was done with great proficiency.
DNA typing allows the identification of individual, as long as sufficient DNA can be recovered from the sample(s). This is true even when the conditions are such that the victims’ remains are fragmented.

Regarding injury pattern complex nature of the injuries is present in case of bomb blast. Establishing the identity remains the main challenge due to severity of injury.

The common conception of forensic medicine is that they are involved with gathering evidence against crime. That is, they are focused on assignment of criminal responsibility. However, there has always been a humanitarian character to forensic medicine. ‘Managing the dead, including protecting their dignity but also helping to identify them to prevent and resolve the tragedy of people missing’ is the humanitarian forensic action is evident in present study.

An Autopsy Study of Brought Dead Cases at a Tertiary Care Hospital in Port Blair, Andaman and Nicobar Islands

Udayashankar Yadiyapur¹, A.K. Malle², Deepak H.D’ Souza³

¹Associate Professor, ²Assistant Professor, ³Professor & HOD, Dept. of Forensic Medicine & Toxicology, Andaman Nicobar Islands Institute of Medical Sciences (ANIIMS), Port Blair, A & N Islands.

Abstract

Introduction: Brought dead cases are considered as Medico-legal Cases which require investigation by law enforcing authorities, to know the cause of death and then decide whether it is a Natural/Unnatural death. The doctor’s post mortem report gives direction to the police in their investigation.

Method: All cases during the study period i.e. from 1st Jan 2019 up to 31st Dec 2019 were that were brought dead to GB Pant Hospital (GBPH), which is a tertiary care hospital attached to ANIIMS were included. All these cases were retrospectively analysed under various parameters.

Results: The present study reveals that out of 223 cases, 58 were brought dead to GBPH. Out of these in 57 cases the death was due to a Natural cause and in only one case it was due to an unnatural cause.

Keywords: MLC case, Medico-legal Case, Natural deaths, Unnatural deaths, Criminal Justice System, Brought Dead cases.

Introduction

After the birth of a person, death is sure and certain. This is the universal law of existence. Because of the complexities of life, factors like socio economic conditions, thoughts, habits, behaviours, physical and mental health- affect the life span of a person. Any death which is suspicious, and where there is some foul play, disturbs the peace of the family, community and ultimately the society.

Natural death means death occurring due to some natural disease or pathological condition, old age, or devitalisation; here the death is not intended or attempted and also does not occur accidentally⁽¹⁾. Deaths other than due to natural causes- Suicides, homicides, accidental deaths- are termed as ‘Unnatural Death’. This division of death into ‘natural’ and ‘unnatural death’ is very crucial for the police. Naturally, the police will need to investigate all the unnatural deaths to bring the case to a logical conclusion and thereby apprehend and punish the criminals and protect the innocents; thus maintaining law and order in the society and bring peace and prosperity.

Criminal Justice System comprises of the police, the judiciary and corrective system [prison department]. Although society maintains other forms of social control such as family, school, religious institutions, they are designed to deal with moral, and not legal mis-behaviour. Only Criminal Justice System has the power to control crime and punish criminals. And the doctor being in a responsible position in the society, shall support the system while discharging his duties.

The brought dead case or dead on arrival is such a situation that the attending doctor cannot certify whether it is natural death or unnatural death. If he satisfies himself, that it is due to some natural cause he will

Corresponding Author:
Dr. AK Malle
Assistant Professor Dept. of Forensic Medicine & Toxicology, ANIIMS, Port Blair, Andaman & Nicobar Islands
e-mail: mak101282@hotmail.com
issue the death certificate and if he suspects some foul play, he will make it a medicolegal case and informs the police. Thereafter, the police will hold the inquest and if the investigation officer of the case, finds any suspicion in the causation of the death, he will send the body for medicolegal autopsy, during which the cause of death, time since death, manner of death – natural or unnatural are opined.

Therefore, the cases which are brought dead are routinely registered as medicolegal cases and police are informed and death certificate is not issued and the body is not released to the relatives\(^{(2)}\).

The present study is aimed to analyse the brought dead cases in terms of natural and unnatural; sex & age incidences; and the cause of death.

**Materials and Method**

In the present study we retrospectively assessed all cases that were brought dead to GB Pant Hospital. Relevant data was extracted from the Post-mortem reports. Out of the total 223 cases subjected to post mortem examination 58 were brought dead to GBPH Casualty department and tabulated into MS Office Excel Sheets and later tabulated using SPSS Version 21.

**A. Criteria for case selection**

1. Both male and female victims were taken into consideration
2. All age groups are included in the study
3. All types whether natural or un natural are included in the study

**B. Collection of data**

1. Inquest report of police- address, age, sex, religion, place, time and date of occurrence of death.
2. Previous history of the case- from the relatives/ friends/co-workers of the deceased.
3. Medical documents – old case sheets, medication history & date and time of declaration of death.
4. During autopsy- whether the findings corroborates with apparent cause of death or not. External and internal findings are considered.

Discussion and Analysis

In the present study (Figure 1) out of all 223 post mortem examination cases conducted at GBPH, 58 cases were brought dead to the Casualty Department of GBPH which is 26%. This closely correlates with the study conducted by N. L. Disania et al, who reported that 31.70% cases were brought dead and much higher than reported by B. D. Gupta et al who reported that 10.7% cases were brought dead. It is much lower than the study conducted by Apurba Biswas et al who reported 58.33% of all cases were reported brought dead. Age wise distribution (Figure 2) of the brought dead cases and reveals that, the number of brought dead cases in the extremes of age are less and age group of 51-60 has maximum number of deaths i.e. 25.86% (n=15), this differs from N. L. Disania et al who reported that age group of 3rd decade had maximum deaths 27.27%, while Gupta et al reported that 31-50 age group topped at 48.89%

Sex wise distribution (Figure 3) of the brought dead cases, reveals a male to female sex ratio of 4.88:1, while N. L. Disania et al reported 1:0.18; Gupta et al reported it at 5.92:1 and Apurba Biswas et al reported it at 4.40:1.

In this study (Figure 4) Natural Deaths were 98.27% (n=57) vs Unnatural Deaths is 1.72% (n=1). This differs from Disania et al, who reported Natural Deaths at 21.9% and Unnatural Deaths at 78.1% and Apurba Biswas et al who reported Natural Deaths at 9.76% and Unnatural Deaths at 88.92%.

Figure 5 depicts distribution of deaths due to CVS and GIT disease. In this study deaths due to cardiovascular deaths in females were prevalent only in the age group of 61-70 years (females 6; males only 1 n=7). Similarly deaths due to cardiovascular diseases in males was prevalent mostly in the age group 51-60 (n=7). Deaths due to GIT diseases were prevalent in males only.

Table 1 depicts different causes of natural deaths; the CVS contributes more numbers (n=22), followed by GIT (n=21) in which all deaths are due to chronic liver disease. Out of these in 5 cases, viscera has been sent for chemical analysis for the confirmation of alcohol these showed features of chronic liver disease also and therefore included in GIT category. All these cases had a history of chronic alcoholism. RS, CNS and Infectious disease (in this case it was Falciparum malaria which was proved by lab investigation).

Research shows that almost every system in the body can be influenced by chronic stress. When chronic stress goes unreleased, it supresses the body’s immune system and ultimately manifests as illness. Fight or flight is the response to the stress. During this time heart rate, blood pressure, breathing, muscle tension, digestion, metabolism will all increase. Normally it should return to normal within 3 minutes. But because of faulty conditioning, this will continue leading on to chronic stress. To combat stress, person will resort to alcohol or tobacco which both are in high prevalence in Andaman.

Coronary Heart disease has long been regarded as a classical psychosomatic illness. There is a strong evidence that psychological stress is a significant risk factor for coronary heart disease and mortality. Tennant found that a positive relationship between life stress and cardiac infarction and sudden death; while study by Rosengren et al reported that mortality was increased two folds for men for experiencing 3 or more antecedent life stressful events. The INTERHEART study revealed that people with myocardial infarction reported higher prevalence of 4 stress factors: stress at work and at home, financial stress and major life events in the past year.

Conclusion

The present study reveals that almost all the brought dead cases are Natural Deaths. Diseases of the cardiovascular system and gastrointestinal system are major contributors. With respect to GIT, all deaths are due to Alcoholic Liver Disease and all are males. Both tobacco and alcohol addiction being high in Andaman’s Port Blair are major contributors to these natural deaths.

Efficacy of Neural Mobilization and Cervical Stabilization in Cervicobrachial Pain: A Randomized Controlled Trial

V. Rajalaxmi¹, R. Lavanya², K. Kirupa³, S.M. Divya Mary³, M. Yuvarany³

¹Professor, ²Internee, ³Assistant Professor, Faculty of Physiotherapy, Dr. M.G.R. Educational & Research Institute University, Velappanchavadi, Chennai - 600 077

Abstract

Objective: To analyze the efficacy of neural mobilization technique in cervicobrachial pain. To analyze the efficacy of cervical stabilization exercise in cervicobrachial pain

Background of the Study: Cervical radiculopathy is a pathological process of involving the cervical nerve root as a result of compression and inflammation of the nerve root near the cervical neural foramen. Cervicobrachial pain syndrome is term that describes pain and stiffness of the cervical spine with symptoms in the shoulder girdle and upper extremity.

Methodology: This was conducted in the Outpatients Physiotherapy department in ACS medical college and hospitals. Group A Received Neural mobilization technique and Group B Cervical stabilization exercise for 12 weeks. Pre and post-test taken by using primary outcome measure such as Pain DETECT Questionnaire, Disability of arm shoulder and hand DASH Questionnaire, Fear avoidance beliefs Questionnaire and cervical ROM.

Results: The comparison revealed that neural mobilization group A had a great increase in cervical range of motion flexion and extension (P ≤ 0.001), Decreasing pain intensity (P ≤ 0.001) and also shows significant decrease in the neural mobilization (P ≤ 0.001) than the cervical stabilization exercise. The significant difference between Group A seems to be more effective than Group B.

Keywords: Cervicobrachial pain, neural mobilization, cervical stabilization exercise, Fear avoidance beliefs questionnaire, Disability of arm, shoulder and hand dash.

Introduction

Cervicobrachial pain (CP) is defined as the presence of upper-quadrant pain associated with cervical spine pain. CP can therefore be referred to the arm from somatic structures or radiate to the upper limb through neuropathic mechanisms. Numerous classifications have been reported, including cervicobrachial pain syndrome, cervical radiculopathy and neck and arm pain. For this study, CP is defined as “the presence of arm pain associated with cervical spine pain” as described by Salt et al¹

Reddy et al states that Cervical spondylosis is a common degenerative condition of the cervical spine in the general population with incidence rate of 83 per 100,000 populations and prevalence of 3.3 cases per 1000 people and occurs mostly in fourth and fifth decades of life.²

Basson et al concludes that Neck pain is often associated with headache upper back and shoulder arm pain and cervical radiculopathy. Diagnosis of
cervicobrachial pain is made by a clinical process and there is often no overt neural involvement can be assumed if a cluster of clinical finding is present such as an active and passive movement dysfunction, adverse response to neurodynamic testing and evidence of local cause of neuropathic pain.3

Pierre Langevin et al states Cervical radiculopathy (CR) is an important subgroup of neck disorders. Although less prevalent than mechanical neck pain, CR leads to more severe pain and disability. In fact, individuals with combined axial and radicular symptoms have been shown to present higher functional limitations than those with either isolated axial or radicular pain.4

Schoenfeld AJ et al states Cervical radiculopathy was 107.3 per 100,000 for men and 63.5 per 100,000 for women. A more recent study from the US military found an incidence of 1.79 per 1000 person –year (50-54 years) the incidence of cervical radiculopathy seems to peak in the fourth and fifth decades in life.5

Levels of involvement is most typically the C7 (39.3%-46.3%) and C6 (17.6%- 42.6%) nerve roots. Bilateral involvement is reported in 5-36% of cases. The inter vertebral disc has been found to be causative in only 22% of cases, while 68% of cases appear to arise from a combination of discogenic and spondylotic causes. Cervical radiculopathy is one of the most health-related complaint. Cervical radiculopathy is common clinical diagnosis classified as a disorder of a nerve root and most often is a compression or inflammatory pathology from a space occupying lesion such as spondylotic spur, disc herniation as explained by Rajalaxmi et al.

Sharma et al states Neural mobilization can be used for both evaluation and treatment purposes, when it is used in the treatment; its main purpose is to reestablish the dynamic equilibrium of the neural tissues, normalizing its physiologic function. The nervous system can be effectively and safely mobilized, the ultimate aim of treatment is to restore the patient’s range of nervous system movement & stretch capabilities and to normalize the sensitivity of the system.6

Apoorva Sunil Likhite et al states the neurodynamic provocative tests used for the upper quadrant disorders, Upper Limb Neurodynamic Test 1 (ULNT-1) is reported to be evaluating most roots of brachial plexus and nerves of upper limb, with more emphasis on the median nerve.8

Rodriguez-Sanz D reports that The median nerve

neural mobilization (MNNM) and relieve CP, but through different mechanism and with a different onset of side effects MNNM is a specific physical therapy technique for the treatment of CP described by Butler, Coppieters, and Elvery –hall that achieves pain relief through mechanical stimulation of the median nerve and the brachial plexus.9

Jinyeol Jeon et al argues The recent therapeutic exercise there is increasing interest in, understanding the effect of cervical stabilizing exercise, not only to prevent neck disorder, but also reduce chronic cervical pain. These exercises induced cervical vertebra to maintain a neutral position by strengthening the deep muscles play a major role in maintaining spinal stability. Patient with cervical pain show reduced strength and endurance in deep muscles, as well as ability to retract the lower jaw compared to normal people, according to many studies. Moreover, there is a report there is report that stabilizing exercise is very effective at reduce chronic cervical pain and improving neck function.10

Gummesson et al reports The 30-items disabilities of the arm, shoulder and hand (DASH) questionnaire which has been assessed recording reliability, cross-sectional validity and longitudinal validity in a variety of arm disorders.11

Padua R et al states that The FABQ2 (Fear avoidance beliefs about physical activity) showed little or relationship with VAS (p = 0.26, p<0.001). The coefficient of r = 0.808 was estimated for the total questionnaire as an indicator of excellent reliability of the Persian FABQ.12,13

Sunnia Chandan et al reports that the pain DETECT questionnaire (PDQ) is one of the screening tools of neuropathic pain, which was published by Freynhagen et al., from Germany they established the usefulness and validity of this brief, self–administered questionnaire in identifying neuropathic components of pain in patients with chronic lower back pain.14 The use of these tools in different language and cultures could contribute to increase the recognition of neuropathic pain.15

**Materials and Method**

This was a comparative study with pre-post type. This was conducted in the Outpatients Physiotherapy department in ACS medical college and hospitals and took nearly 3 months to complete the study (January 2019-April 2019). 30 samples were selected from 40
volunteers based on the inclusion and exclusion criteria, Cervicobrachial pain of both gender aged between 30 to 60 years. Sufficient cooperation and to participate and able to communicate and follow the instructions and able to perform Neural mobilization and Cervical stabilization exercise according to Cervicogenic pain, Arm and hand pain, Neck distraction, Upper limp tension test, non-traumatic pain, Involved side cervical rotation less than 60 degree ROM and excluded those with Negative neurodynamic test, Neck and upper extremity surgery, Medical red flag suggesting a non-musculoskeletal origin, Vertebral instability, Vertebral spine infection, Neurological disease of genetic, infection, or neoplastic origin, Inflammatory or systemic disease, VBI symptoms, Rheumatoid arthritis.

Once the study gets approved from Institutional Review Board 30 samples were divided into two groups by random sampling method. The samples will be fully explained about the study and the questionnaire to be filled. They were then asked to fill the constant form it acceptance to participate in study, which is duly signed by the samples and therapist. Initially demographic details like age, gender, height, weight were collected assuring confidentiality of the same. Group A Received Neural mobilization technique and Group B Cervical stabilization exercises for 5 repetition/one sessions per day for 4 days a week for 12 weeks. Pre and post-test taken and before and after the study of 3 months, by using primary outcome measure such as Pain DETECT Questionnaire, Disability of arm shoulder and hand DASH Questionnaire, Fear avoidance beliefs Questionnaire and cervical ROM.

Data Analysis: The collected data were tabulated and analyzed using both descriptive and inferential statistics. All the parameters were assessed using statistical package for social science (SPSS) version 24. Paired t-test was adopted to find the statistical difference within the groups & Independent t-test (Student t-Test) was adopted to find statistical difference between the groups.

Results

On comparing the Mean values of Group A & Group B on Disability Arm Shoulder and Hand Questionnaire Score, both the groups showed significant decrease in the post test Mean values but (Group A - Neural Mobilization) shows 49.86 which has the Lower Mean value is effective than (Group B -Cervical Stabilization Exercises) 71.66 at $P \leq 0.001$.

On comparing the Mean values of Group A & Group B on Fear Avoidance Belief Questionnaire Score, both the groups showed significant decrease in the post test Mean values but (Group A - Neural Mobilization) shows 21.23 which has the Lower Mean value is effective than (Group B -Cervical Stabilization Exercises) 37.73 at $P \leq 0.001$.

On comparing the Mean values of Group A & Group B on Pain Detecting Questionnaire Score, both the groups showed significant decrease in the post test Mean values but (Group A - Neural Mobilization) shows 17.00 which has the Lower Mean value is effective than (Group B -Cervical Stabilization Exercises) 25.06 at $P \leq 0.001$.

On comparing the Mean values of Group A & Group B on cervical range of motion (Flexion & Extension), both the groups showed significant increase in the post test Mean values but (Group A - Neural Mobilization) shows 37.6 & 38.6 degrees which has the Higher Mean value is effective than (Group B -Cervical Stabilization Exercises) 29.0 & 29.6 at $P \leq 0.001$.

On comparing Pre-test and Post-test within Group A & Group B on DASH,Fear Avoidance Belief Questionnaire, Pain Detecting Questionnaire and Cervical Range of Motion (Flexion & Extension) showed highly significant difference in Mean values at $P \leq 0.001$.

Discussion

The present study was concluded to determine the effectiveness of neural mobilization and cervical stabilization exercise in cervicobrachial pain. About 30 subjects were selected. The 30 subjects were selected into group A 15 and group B 15. Group A Received Neural mobilization technique and Group B Cervical stabilization exercise for 5 repetition/one sessions per day for 4 days a week for 12 weeks of treatment. It was noticed that there was improvement the above parameters in all the two groups. In many studies it has been proved that neural mobilization technique has the greater impact on decrease in pain, strengthening of muscle and increasing in range of motion.

The statistical reports reveal that there is no significant difference in pre-test values of PDQ, FABQ, DASH and GONIOMETER ROM score in group A and group B. But there is statistically highly significant difference in post-test values of PDQ, FABQ, DASH and GONIOMETER ROM score in group A and group B. Both the groups show significant decrease in the post test values group A is more effective than group B. this shows both groups are significant in reducing pain, increasing in range of motion in cervicobrachial pain but Group A (neural mobilization technique) is more significant when compared to group b (cervical stabilization exercise).

Neural mobilization is used to affect the neural structures in conditions with signs of neural involvement or neural mechano sensitivity. It is said to have an impact on the axoplasmic flow, movement of the nerve and its connective tissue, the circulation of the nerve by alteration of the pressure in the nervous system, Dispersion of the intraneural oedema and can also decrease the excitability of dorsal horn cells.

Anupama prabhu et al (2017)The study aimed at VT for median nerve was reduced for the intervention group and for ulnar nerve it was reduced in both the groups with the mobilization of the neural tissue, there could be a better reception and faster conduction of these impulses and hence, increase in sensitivity of the nerve and reduction in pressure.

Kikukawa et al (2003) reported that microtubules were depolymerized by stretching, which can affect axonal transport. When nerve fascicles are stretched, its cross-sectional area is reduced interfascicular pressure increase, nerve fibers are compressed and microcirculation is compromised and pressure received by nerve will affect the edema and demyelination.

Rajalaxmi Gopala Krishnan al (2015) Suggested that the patients who meet the diagnostic classification for cervical radiculopathy might benefit from a multimodal treatment that includes interferential therapy, neural mobilization and conventional therapy. Rather it involves all the surrounding nerves and tissues whereas neural tissue mobilization specifically targeted the neural structure involved.
The present study attempts to identify the efficacy of two active manual therapy techniques in case of subject with cervicobrachial pain syndrome. One technique followed the principles of neural mobilization technique by utilizing neural tissue mobilization for median and radial nerve and other technique focused on cervical stabilization exercise. The study revealed that each of the approach (neural tissue mobilization and cervical stabilization) resulted in overall improvement in disability and pain but the neural tissue mobilization is more effective than the cervical stabilization.

Conclusion

This study confirmed that neural mobilization technique had better carryover effect as compared to cervical stabilization exercise and also it showed steady improvement in the pain and disability so subjects showed much faster improvement. That neural tissue mobilization for median and radial nerve as a treatment technique is much more effective than cervical stabilization exercise, thus the neural mobilization technique is effective in regard to increasing function as well as active ROM, while decreasing level of cervicobrachial pain and disability.

Abstract

Aim: To compare the effectiveness of sensori-motor training and balance exercise in subjects with neck pain.

Background: Impaired cervical joint position sense, sensorimotor and balance are associated with neck pain. The presence of cervical musculoskeletal impairment was not specific to cervicogenic headache but was present in various recurrent headache types.

Methodology: This study was a comparative study design with pre and post type, 50 samples were selected based on the inclusion criteria. Group A received balance exercise and Group B received sensorimotor training. Both groups received exercises for 40 mins/session per day for 5 days a week for 12 weeks. Pre and post test measures taken using visual analogue scale, Ammer dizziness diagnostic scale, patient specific functional scale, Tinitee balance scale.

Result: On comparing the mean value of group A and group B on values, it shows significant difference between group A and group B. Group A Seems to be more effective than Group B.

Keywords: Neck pain, balance exercises, Sensorimotor.

Introduction

The neck pain is a common musculoskeletal disorder and a costly public health issue. The pain is often persistent or recurrent in nature. The underlying mechanisms for recurrence or persistence remain unclear but could be associated with altered proprioception from the neck muscles. Some patients usually have impaired proprioception and postural instability which account for these symptoms and the impairments can lead to decreased physical performance and increased concerns of falling, particularly the elderly. Dizziness and unsteadiness have been shown to be predictors of both poorer recovery and poorer response to musculoskeletal treatment. Thus it is important to address such symptoms and disturbances in patient with neck pain not only to gain symptomatic relief but also it reverse the impairment to improve physical performance and function. In people with neck pain, coordination of head movements, intersegment coordination of the vertebrae of the cervical spine, and postural balance were show to be impaired. There is an abundance of receptors in the cervical muscles, and there are multiple cervical central and reflex connections to the vestibular, visual, and
postural control systems. In particular, the deep portions of the suboccipital muscles have the highest cervical receptor density and are known to have a specific role in these reflex and central connections.

It is estimated that between 10-40% of persons sustaining neck trauma as a result of a motor vehicle crash will go on to have chronic persistent problems. After pain, dizziness and unsteadiness are the next most frequent complaints in those with persistent problems following a whiplash trauma, with up to 70% reporting this complaints.

Cervicogenic dizziness is often related to upper cervical degeneration or a neck injury, such as whiplash. It is thought to result from a perturbation in sensory information from the upper cervical spine. Neck pain has been shown to be associated with balance disturbances and gait speed are also known to decline with ageing. Neck pain is related to impaired postural balance among patients and is highly prevalent among workers with high postural demands. Dysfunction of the cervical receptors in neck disorders can alter afferent input subsequently changing the integration timing and tuning of sensorimotor control.

Disturbances of balance have been found both in patients with whiplash associated disorders and idiopathic neck pain, neck pain precipitated by trauma resulted in greater or different balance impairments. Impaired cervical joint position sense is commonly argued to rely on abnormal cervical input if true muscle vibration, alternating afferent input, but not in mental interventions should have an effect on head repositioning acuity and neck pain perception. The role of deep cervical flexor muscles in postural support and the knowledge of impaired activation of these muscles in people with neck pain. The deep portions of the sub occipital muscles have the highest cervical receptor density and are known to have a specific role in these reflex and central connections. We found that greater and lesser dysfunction likewise was not related to headache classification or length of headache history. A chance in the nature of headache with age plays an important role in the choice of treatment.

Reduced cervical range of motion is one of the main complaints from patients showing cervical dysfunction and seeking help from therapists. The persistence of nonspecific neck pain may have a significant impact on patients with health status, activity of daily living, and work-related activities resulting in poor quality of life. Cervical afferent information is important to the control of posture, spatial orientation and coordination of the eyes and head.

Sensorimotor training emphasizes postural control and progressive challenges to the sensorimotor system to restore normal motor programmes in patient with neck pain. The balance training can effectively improve cervical sensorimotor function and decrease neck pain intensity.

**Material and Method**

This comparative study was conducted in the physiotherapy department took nearly 3 months to complete the study (January 2019-April 2019). 50 samples were selected from 70 volunteers based on inclusion criteria of age group of 45 to 65, insidious neck pain for at least 3 months and headache associated with neck pain, able to follow the instructions and spondylolisthesis and the excluded those with previous history of neck and head trauma or surgery, known vestibular pathology, vertigo or dizziness from ear to brain disorders, sensory nerve pathways. Inflammatory joint disease, cerebellar dysfunction. Both the group received exercise for 40mins/session for 5 days a week for 12 weeks the pre and post-test measurement will be taken before and after 3 months by using VAS, patient specific functional scale, Ammer dizziness diagnostic scale, Tinetti balance scale. Group A received balance exercises and group B received sensory motor training.

**Data Analysis:** The collected data were tabulated and analyzed using both descriptive and inferential statistics. All the parameters were assessed using statistical package for social science (SPSS) version 20.0. Paired t-test was adopted to find statistical difference within the groups & Independent t-test (Student t-Test) was adopted to find statistical difference between the groups.

Results

On comparing the mean values of VAS, both the groups have showed improvement in the post test mean values although the group-A post test mean value (5.0) showing lesser mean value is more effective than Group-B post test mean value (5.40).

On comparing the mean of PSFS, both the groups showed increased PSFS in the post test mean values. But the Group A post test mean value (16.08) showing the higher mean value is more effective than Group B post test mean value (15.28). On comparing the mean of ADDS, both the groups showed increased ADDS in the post test mean values. But the Group A post test mean value (31.09) showing the higher mean value is more effective than Group B post test mean value (33.04).

On comparing the mean of TBS, both the groups showed increased TBS in the post test mean values. But the Group A post test mean value (12.6) showing the higher mean value is more effective than Group B post test mean value (12.1).

Discussion

The present study was conducted with the sample size of 50 subjects to find out the efficacy of sensorimotor and balance exercise in subjects with neck pain. The present data indicates that balance exercise were indeed
efficient in reducing the neck pain, dizziness and in improving the functional activities of the subjects.

In a previous study by Revel et al, evaluated slow motion proprioceptive exercise which mainly concerned with eye-neck coordination for 8 weeks resulted in reduction in neck pain significantly when compared to other training group. Furthermore, Gosselin et al, demonstrated that body performance can be deteriorated by fatiguing on vibrating the neck muscles. Moreover, Roijezon, et al reported conversely improved balance performance was reported after neck coordination exercises.

Some evidence suggests that conventional treatment of manual therapy and specific therapeutic exercise directed towards neuromuscular impairments are effective interventions for relieving neck pain and dizziness symptoms and they improve cervical joint mobility and neck muscle performance. However, these interventions are not specifically directed towards impaired cervical proprioception and balance. The effects of exercise and manual therapy on proprioception (joint reposition sense) and balance remain uncertain. However, so far, all previous interventions were specifically targeting the neck muscle and postural control was assessed as the outcome measure. In contrast, additionally in this study, the exercise programs are individualized according to ongoing progress monitoring. It is expected that the findings of this trial will lead to improved clinical practice guidelines for persons with neck pain with impaired joint position sense and balance.

Endurance training has also showed a statistically significant improvement, however lesser the significant than the motor control exercise group. The study concludes that there seems to be evidence that endurance exercise are more beneficial in general exercise program in reducing neck pain and seems to be advantageous. The study concluded that samples in neck stabilization and postural correction showed better significance than stretch and strengthening exercise in reducing pain and disability and improving posture and breathing patterns. This systematic review maximum studies showed that there was some improvement in neck functional abilities and reduction in neck pain in the endurance training group. The study concluded that the postural alignment achieved from schroth method is better than that achieved by yoga.

**Conclusion**

The present study concludes that balance exercise were indeed efficient in reducing the neck pain, dizziness and in improving the functional activities of the subjects. Although, In the post treatment analysis, both the groups showed significant change in the outcome measures of VAS, tinetti balance assessment tool, dizziness scale, and patient specific functional scale, the group A has significant changes than the group B.

**Conflict of Interest:** None

Considerations Related to Safe Handling of Dead Bodies of Deceased Persons with COVID-19: Issues and Review of Guidelines

Vaibhav Anjankar¹, Ashish Anjankar², Anil J. Anjankar³

¹Associate Professor of Anatomy, ²Associate Professor of Biochemistry, ³Professor of Forensic Medicine & Toxicology, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences (DMIMS)

Abstract

The Novel Corona Virus (COVID-19) earlier known only as the Wuhan virus, expanded its circle and finally spreading its routes to India. The guidelines/considerations published by various government organizations for management of dead bodies in context of COVID-19 were reviewed.

The problem arrived when experts found some loopholes in government guidelines and other social issues were raised in different parts of country regarding the final rituals of deceased died due to suspected or confirmed cases of COVID-19. Some cases were also observed in neighboring countries also.

In this article, light was thrown on utility of body bags for handling dead bodies, environmental cleaning, autopsy & embalming related issues, precautions in case of community deaths etc. We tried to discuss the issues in light of available guidelines by government of India and other international guidelines.

Keywords: COVID-19, cremation, decontamination, funeral, decomposition.

Introduction

Some of the recent viral outbreaks showing the involvement of respiratory system include severe acute respiratory syndrome (SARS)¹ in 2002-03, Middle-East respiratory syndrome (MERS)² in 2012 etc that lead to life threatening illness. In December 2019, the world was introduced to a novel coronavirus severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2; formerly called 2019-nCoV) causing coronavirus disease 2019 (COVID-19)³ after the outbreak of pneumonia in Wuhan, a city in Hubei Province of China⁴. The Novel Corona Virus (COVID-19) earlier known only as the Wuhan virus, expanded its circle and finally spreading its routes to India⁵. The first case of COVID-19 in India was reported on 30 January 2020 originating from China⁵. The World Health Organisation (WHO) declared the COVID-19 outbreak a Global Health Emergency on January 30, 2020³, and pandemic on 11 March 2020³. As per the data provided by Ministry of Health and Family welfare, Govt. of India, till 19 May 2020, in India⁶ total active cases are 77103, cured or discharged patients and death toll reaching to 402.

COVID-19 pandemic have crossed the death records all over the world including European countries whose health system is considered one of the best in the world. Even the superpower America is struggling to curb the death rate. India being densely populated, the risk of spread is more. The guidelines/considerations of various government organizations for management of dead bodies in context of COVID-19 were reviewed. Certain issues published in media regarding dead body management due to COVID-19 are also discussed.

Present available guidelines for safe disposal of dead bodies: Various organizations/government bodies
have put forward their respective guidelines for safe management of a dead body in the context of COVID-19. Some of the major guidelines across the globe available for the same purpose are mentioned below.

- ‘COVID-19: Guidelines on Dead Body Management’- by Director General of Health Services (DGHS), MOH & FW, GoI published on 15.03.2020
- ‘Infection Prevention and Control for the safe management of a dead body in the context of COVID-19’ by World Health Organization (WHO) – Interim guidelines published on 24.03.2020
- ‘Considerations related to the safe handling of bodies of deceased persons with suspected or confirmed COVID-19’ by European Centre for Disease Prevention and Control (ECDC), Stockholm.
- ‘Dead body management in the context of the novel coronavirus (COVID-19)’ by Pan American Health Organization (PAHO) – Interim recommendations published on 18.03.2020
- ‘COVID-19 – Handling of bodies by funeral directors’ by State of New South Wales NSW Ministry of Health, Govt. of Australia released on 02.04.2020

The Concern: In spite of above mentioned available guidelines, some issues were observed.

1. Lacunae in guidelines: Anadolu Agency report mention about experts’ belief that Health Ministry’s guidelines regarding the handling of infected dead bodies have huge gaps. The seven-page guidelines issued by the Health Ministry do not specify the method of cremation or the plastering of graves. No clear guidelines are written in report about the body bags used.

2. Social issues: The controversies were published in certain media reports about cremation of lady in Delhi who died after corona virus infection following co-morbidity. The staff from Delhi’s two crematoriums allegedly denied last rites, fearing the spread of virus. Similar news came from Mumbai where cemetery at Malad denied burial of dead body of corona victim, fearing spread of coronavirus.

3. A heartbreaking tragedy published in The Hindu-Chennai, where an orthopedic surgeon of Nellore died due to COVID-19 after contracting infection from his patients. The local residents, ignoring prohibitory orders, protested the cremation of a doctor with apprehension that the cremation of the body could result in the spread of novel Coronavirus in the area.

Before handling the dead body: The most important task is to impart training of persons involved in handling the dead body. This include:

- infection control procedures
- hand hygiene
- how to put on and remove personal protective equipments (PPE)
- safe handling of sharps
- regular environmental decontamination including all surfaces and equipments with disinfectant
- disinfect the bag housing dead body; instruments and devices used on the patient
- ensure that any body fluids leaking from orifices are contained
- avoid unnecessary manipulation of the body that may expel air from the lungs

Utility of Body bags: WHO guidelines say that body bags are not necessary, although they may be used for other reasons (excessive fluid leakage) and further it is mentioned to wrap the body in cloth. Interim recommendations of PAHO also recommend that body bags are not necessary for packing the body. But factsheet issued by NSW, Australia writes that body should be transported and stored in a two leak proof body bags (double bagged). The outer body bag should be clearly and permanently labeled, such as: “COVID-19 – Handle with care”. Used body bags should be disposed of in clinical waste streams. MOH & FW guidelines mentions about using of leak proof plastic body bag but
thickness is not mentioned. Precautions issued by dept. of health, Govt. of Hong Kong recommend robust and leak-proof transparent plastic bag of not less than 150 μm thick, and should accompany with another layer of a mortuary sheet or opaque bag. It should be zipper closed; Pins are not to be used. Dr. T. Jacob John, a former head of the Virology Centre at ICMR said the plastic bag covering the body should be at least 100 microns thick, so it does not tear off easily.

**Environmental Cleaning:** Environmental Cleaning is the key stone procedure to curtail the spread of infection. It should be part of Standard Precautions, which should be applied to all patients in all healthcare facilities.

MOH & FW guidelines quoted to wipe all surfaces with 1% Sodium Hypochlorite solution with contact time of 30 minutes and then allowed to air dry. Hospital Infection Control Committee of AIIMS, New Delhi advocated the use of freshly prepared 1% Sodium Hypochlorite for a contact time of at least 10 minutes as a disinfectant for cleaning and disinfection. Alcohol (e.g. isopropyl 70% or ethyl alcohol 70%) can be used to wipe down surfaces where the use of bleach is not suitable, e.g. metals. JIPMER recommended use of 0.5% Hypochlorite with contact time of 10 minutes.

WHO- Interim Guidelines recommended disinfectant with a minimum concentration of 0.1% (1000 ppm) sodium hypochlorite (bleach), or 70% ethanol for at least 1 minute. PAHO advised surface disinfection with 0.1% sodium hypochlorite or 62-71% ethanol. ECDC mentioned use of hospital disinfectants active against viruses. Decontamination may be performed with 0.1% sodium hypochlorite.

**Autopsy related guidelines:** MOH & FW guidelines clearly mention to avoid autopsy. If autopsy is to be performed for special reasons, infection prevention and control practices should be adopted. The lungs and other organs may still contain live virus and additional respiratory protection is needed during aerosol generating procedures like use of power saws, washing of intestines etc. Airborne precautions include fluid resistant & long sleeved gown, P2/N95 masks, face shields or safety glasses etc. Number of staffs should be kept to minimum; round ended scissors & appropriate PPE should be used. Only one body cavity should be opened at a time. Negative pressure should be maintained in mortuary. Mortuary should be adequately ventilated.

After autopsy, body must be disinfected with 1% Sodium Hypochlorite and covered by a body bag. The exterior of body should also be decontaminated with 1% Sodium Hypochlorite solution.

DMER, Mumbai issued medical guidelines for death declaration on 09 April 2020 which mentions about no postmortem examination in suspected COVID-19 deaths.

**Embalming:** All major guidelines mentions that embalming should not be performed on dead bodies of COVID-19. This minimizes excessive manipulation of body. If embalming is must, embalmer should be certified and trained in the use of PPE for contact and airborne precautions. This includes P2/N95 respirator which has been fit checked, gown, gloves and eye protection.

**Community Deaths:** The present guidelines of MOH & FW are limited to hospital deaths only. MOH & FW guidelines lack the guidelines for such home deaths. Interim guidelines of WHO mention about these.

- Staff that will manage dead bodies, such as ambulance staff, police and general practitioners, should use PPE compulsorily.
- Person preparing dead body for last rites (e.g. washing, cleaning or dressing body, tidying hair, trimming nails or shaving) should wear gloves, eye and mouth protection (face shield or goggles and medical mask). Clothing worn to prepare the body should be immediately removed and washed after the procedure or an apron or gown should be worn. Washing of hands with soap and water is to be followed.
- Children, elderly people (>60 years old), and anyone with underlying illnesses should not be involved. Number of people involved in preparations should be kept to minimum.
- Nobody should touch/kiss the body and should wash their hands thoroughly with soap and water or alcohol based hand rub to minimize the risk of transmission; physical distancing measures should be strictly applied (at least 1 meter between people). Physical distance should be maintained.
- Those involved with placing the body in the grave, on the funeral pyre, etc. should wear gloves and wash hands with soap and water.
• Funeral should not involve more than five people. Participants should observe social distancing plus respiratory etiquettes and hand hygiene.

• No need to burn or dispose of the belongings (cloths, utensils etc) of the deceased. However, they should be handled with gloves and cleaned with a detergent followed by disinfection with a solution of at least 70% ethanol or 0.1% (1000 ppm) bleach.

**Transportation:** WHO guidelines mention that no special transport equipment or vehicle is required. Standard precautions (surgical mask, gloves, etc) must be followed by the personnel handling the body to minimize exposure to infected bodily fluids, contaminated objects and other contaminated environmental surfaces.

The body, secured in a body bag, exterior of which is decontaminated poses no additional risk to the staff involved in dead body transportation. During transport, direct contact with human remains or bodily fluids should be avoided. The vehicle should be decontaminated with 1% Sodium Hypochlorite after transportation.

**Cremation or Burial:** WHO interim guidelines clearly mention that people who died from COVID-19 can be buried or cremated. MOH & FW guidelines and PAHO recommendations also mention about the both.

In another instance, directions issued by Municipal Commissioner of Municipal Corporation of Greater Mumbai on 30.03.2020 quoted that all dead bodies of COVID-19 should be cremated at the nearest crematorium irrespective of religion. The reason being existing burial grounds are in highly dense locality with high chances of contamination. Further burial should not be allowed as procedure of packing the body in plastic bag and burying same prevent early decomposition and risk continuing the virus for future spread. The same circular was then revised and the BMC has allowed burial within Mumbai provided the burial ground is large enough to ensure there is no threat of transmission to the area’s residents.

Department of Forensic Medicine at the AIIMS, New Delhi has released its specific protocol, mentioning about points missed in the guidelines issued by the Health Ministry. Head of Forensic Medicine dept of AIIMS New Delhi also clarified that cremation of dead body of person died due to corona virus has no side effects by any method using fire or electrical or gas or by burial.

New protocol described that cremation should be preferred for the complete elimination of chances of infection in either electric or gas crematorium in a zipped body bag. If the burial of the body is requested, then it should be assured that the body is buried in a thick, airtight coffin. Dead body needs to be buried at a depth of 4-6 feet and should be cemented immediately as an additional precautionary measure.

Director AIIMS New Delhi, Dr. Guleria clarified that corona virus can not spread through dead bodies. It spread from respiratory secretions. Coughing is necessary for spread of virus. So there is no risk in cremating the infected dead bodies.

**Conclusion**

Considering the huge impact caused by COVID-19 pandemics on Global health care systems, it is important to reduce its transmission and prevent the number of deaths. It can spread through nasopharyngeal secretions but care should also be taken while contacting body fluids of deceased persons of suspected or confirmed case of COVID-19.

Guidelines issued by various government authorities should be meticulously followed and utmost care should be taken while handling the dead body by the concerned.

Age Estimation by Different Techniques of Dentin Translucency: A Literature Overview

Vidhya A., Nagabhushana Doggalli, Sushma Rudraswamy

1Post Graduate Student, 2Reader, Dept. of Oral Medicine and Radiology, 3Senior Lecturer, Dept of Public Health Dentistry, JSSDC & H., JSS Academy of Higher Education and Research (JSSAHER), Mysuru, Karnataka

Abstract

Background: Human Dentition presents as the most durable and resilient part of the skeletal system in the body subjected to wide range of physiological changes with increase in age such as attrition, cemental apposition. Among several functional changes dental root translucency is often considered to be more reliable parameter for estimation.

Methodology: The literature search for articles written in the English language in PubMed, MEDLINE, Embase and Google Scholar database by using MeSH terms “Dentin Translucency”, “Age Estimation”, “Forensic Method” “Dentin in Forensics”, “Digital Method of Age Estimation”, “Dentin Age estimation” was retrieved. The present evaluation is to provide a broad literature review on “Dentin translucency” as a tool in age estimation with emphasis on the most substantial method obtainable for identification.

Observations: It was observed both traditional and digital method are significant and reliable for identification of age by root dentin translucency. The custom built software program is commercially available and extensively used image editing software program. Moreover, digital method is easy to use, precise and less time consuming. Considering these benefits, the present study recommends the use of digital method to assess root dentin translucency for age estimation.

Conclusion: Though conventional sectioning of teeth with observation using caliper or under microscope was gold standard, due to advancement in technology and more precise results digital method could possibly serve as more reliable where estimation of age plays a vital role in identification process in the field of forensics.

Keywords: Dentin Translucency, Forensic science, Image software, precise age, Physiological Method.

Introduction

Age assessment by dental examination is one of the most reliable method of chronological age estimation used for criminal or illegal responsibilities, judicial punishment, medical, employment, execution of minority and anthropological purposes[1,2]. Eruption of teeth, tipping, later or horizontal movement through maxilla or mandible, mechanical or physiological attrition, periodontal disease, secondary dentine or cemental apposition, root resorption, dentin translucency and changes in color are substantial features that increases or changes with age. Physical or morphological, histological, physiological, radiological, chemical method were developed to evaluate dental age[3].

Once dental growth in association with or without skeletal growth is complete, developmental stages could not be used for age estimation instead the indicators such as attrition, loss of periodontal attachment, coronary secondary dentin formation, resorption of
root, transparency of root undergo changes through life are being used[4]. These Morphological or Physical method are based on assessment of ex-vivo teeth for age estimation in younger as well as adult population. The samples of the extracted tooth can be sectioned or unsectioned and observed with the eye or with microscope[5].

Gustafson[6], Solheim[7], Bang and Ramm[8], Lamendin et al[20] supported the assessment of dentin translucency at the tooth root as a reliable morphological parameter for age estimation by using calipers. Tomes, the first investigator described the translucent dentin as the affinity of root dentine to appear transparent in the transmitted light in dense section from the apex upwards as a result of the merging of the dentinal tubules[21, 22]. Conversely, numerous attempts were made to measure translucency using computer-based customized software[14]. The present evaluation is to provide a broad literature review on “Dentin translucency” as a tool in age estimation with emphasis on the most substantial method obtainable for identification.

**Methodology**

The literature search for articles written in the English language in PubMed, MEDLINE, Embase and Google Scholar database by using MeSH terms “Dentin Translucency”, “Age Estimation”, “Forensic Method” “Dentin in Forensics”, “Digital Method of Age Estimation”, “Dentin Age estimation” was retrieved. The present evaluation is to provide a broad literature review on “Dentin translucency” as a tool in age estimation with emphasis on the most substantial method obtainable for identification.

**Review of Literature: Bang and Ramm in 1970** presented a simple and accurate method for age estimation by sectioning of the teeth based on the measurement of the apical translucent zone length using incisors and cuspids. The zone length was measured buccally from the cementoenamel junction to the root apex. It was concluded

\[
\text{Age} = B_0 + (B_1 \times X) + (B_2 \times X^2)
\]

formulae is used for <9mm translucent zone and if translucent zones > 9 mm age is estimated by using \(\text{Age} = B_0 + (B_1 \times X)\)(where X stands for Translucent zones) formulae. The teeth were sectioned. In this study transparent root dentin zone was measured halfway between the pulp chamber and the root margin where the translucency is nearly horizontal[8].

**Nicolas et al in 1993** evaluated the image analysis systems for digital root dentin translucency. The study showed measurements obtained by Computer based translucency in compared to the conventional caliper method prove to be the reliable precise method for age estimation[9].

**Thomas et al in 1994** investigated the apical translucent dentine distribution among 49 vital and 55 non-vital teeth by using sectioned teeth. Freshly extracted teeth were sectioned longitudinally in the buccolingual plane to a thickness of 150um. Sections were photographed in polarized light at a standard magnification. Black-and-white prints of translucent apical dentine under standard magnification obtained were plotted using an Apple II digitizer. Regression analysis performed by using formulae derived as

\[
L\% = \frac{L}{L \times 100}, \quad A\% = \frac{S}{D \times 100}
\]

where \(L\) = length, \(A\) = area, \(S\) = area of translucent dentine and \(D\) = area of root dentine. The study concluded increased in apical translucency present in non-vital teeth when related with vital teeth at any specified age[10].

**Amariti et al in 1999** suggested different techniques for determining the age of a subject by means of the analysis of microscopic and macroscopic structural modifications of the tooth with ageing. Determination of age was performed by using regression formulae of

\[
\text{Age} = \text{RST} \times 5.3 - 2.28 \quad \text{by ratio of dentinal sclerotic (RST) or tubule thickness},
\]

\[
\text{Age} = \text{Secondary dentin} \times 0.20 + 20.35 \quad \text{by deposition of secondary dentine ratio},
\]

\[
\text{Age} = \text{Cemental apposition} \times 9.19 + 6.74 \quad \text{by using cemental apposition ratio.}
\]

The study stressed that dense sclerosis or dentinal tubule thickness provides more precise results for estimation of age than secondary dentine and cementum thickness[11].

**Valenzuela et al in 2002** presents three multiple regression models for age estimation from fresh extracted teeth. Model I for manual morphologic analysis using dentin color, attrition and cementum apposition, Model II for computer morphologic analysis using pulp and translucency width and area, Model III including both manual and computer morphologic analyses by attrition, color and translucency width. The study recommended image analysis of root dentin translucency width on freshly extracted teeth as a significant method for estimation of age[12].

**Singh et al in 2013** used a simple digital method
on 50 extracted permanent teeth sectioned to 250 μm to measure root dentin translucency and compared digital measurements to conventionally obtained dentinal translucency measurements. Assessment was made by using the formulas as

\[ \text{Age} = 32.3103 + (2.9452 \times \text{translucency length}) \]

by conventional method and

\[ \text{Age} = 32.0417 + (2.8151 \times \text{translucency length}) \]

by digital method. Application of these methods revealed a similar reliability of both the methods to assess age to within ±5 years of the actual determined age\[13\].

Acharya in 2014 proposed a new digital method with the help of commercially accessible computer hardware and software. Root dentin translucency area and length were measured on 100 sections of 250 μm thickness. Regression formulae derived using translucency length and area measurements showed

\[ \text{Age} = 29.91 + (7.45 \times \text{ATL}) + (-0.44 \times (\text{ATL} \times \text{ATL})) \]

by average translucency length, \n
\[ \text{Age} = 28.61 + (5.50 \times \text{MTL}) + (-0.24 \times (\text{MTL} \times \text{MTL})) \]

by maximum translucency length and

\[ \text{Age} = 31.75 + (2.97 \times \text{TA}) + (-0.07 \times (\text{TA} \times \text{TA})) \]

by translucency area. The study revealed smaller mean difference and larger frequency of errors for area in compared to length by digital method\[14\].

Chopra et al in 2015 use a digital method to estimate dentinal translucency on sectioned teeth and compared digital measurements by using computer based hardware and image analysis with a scanner followed by analyzing using American Board of Forensic Odontology (ABFO) no. 2 scale on the scanner platen by plotting axis method to conventionally root dentin translucency measurement method. Age estimation was performed by conventional method using

\[ \text{Age} = 29.720 + (4.102 \times \text{translucency length}) \]

and by digital method using \n
\[ \text{Age} = 29.823 + (3.930 \times \text{translucency length}) \]

The study concluded that the results obtained by both the methods are similar and constant with findings of various previous similar studies\[15\].

Bommannavar and kulkarni in 2015 measured root dentin translucency on 50 single rooted teeth sectioned longitudinally to obtain 0.25 mm uniform thickness manually and using a custom built software program Adobe Photoshop 7.0 version. The study illustrated age estimation using linear regression equations showed better efficiency of the digital method using regression formulae of

\[ \text{Age} = 22.809 + (5.364 \times \text{translucency length}) \]

when compared with the caliper method using regression formulae of \n
\[ \text{Age} = 25.874 + (5.597 \times \text{translucency length}) \]

for assessment\[16\].

Narayan VK et al in 2017 assessed whether physiological changes of the teeth allow probable correlation for age estimation using conventional caliper method. Root dentin translucency of unsectioned tooth was observed under stereomicroscope by modifying Johansson and Lamendin method. Age was derived by using

\[ \text{Age} = 0.2 \times X1 + 1.1 \times X2 + 0.3 \times X3 + 0.7 \times X4 + 17.9 \]

where \n
\[ X1 – \text{Root dentin translucency; } X2 – \text{Root dentin color; } X3 – \text{PDL attachment; } X4 - \text{Attrition}. \]

The study showed root dentin translucency evaluated by using stereomicroscope and Vernier caliper produced the strongest correlation to actual age when compared to other morphological features\[17\].

Gupta et al in 2017 conducted a study to measure translucency on sectioned teeth using digital hardware or software and to correlate degrees of root dentin translucency length with age by using

\[ \text{Predicted Age} = 25.28 + 1.81 \times \text{TD} \]

(Translucent Dentin length). 62 freshly extracted single-rooted permanent teeth were sectioned to 250μm thickness and scanned by flatbed scanner using digital software. Each tooth section was positioned next to an ABFO No. 2 scale on the platform and scanned at a resolution of 600 dpi. The images were obtained in Adobe Photoshop 7.0.1 image software followed by measurement of translucency length of the scanned images by using guides\[18\].

Bhardwaj et al in 2019 performed an investigatory study to compare the effectiveness of conventional, stereomicroscopic and digital method for age estimation by measuring root dentin translucency. Buccolingual sections of 30 freshly extracted permanent teeth were made of thickness 250μm by using micro motor and Arganksa stone. Analysis was performed by obtaining linear regression formula of

\[ \text{Age: } -9.947 + (8.610 \times \text{translucency length}) \]

by conventional method, \n
\[ \text{Age: } -7.797 + (8.742 \times \text{translucency length}) \]

by stereomicroscopic method and
Age: -8.9+ (8.430 x translucency length) by digital method derived. The author observed Digital method using image analysis software is statistically significant method followed by Conventional with the least being the Stereomicroscopic method[19].

Discussion

Physical or somatic changes, secondary sexual features, radiological examination of primary or permanent teeth eruption sequence, ossification centers are various significant approaches of age estimation. There is progressively strong evidence that dentine transparency is directly proportional to the increase in age and hence serves as a consistent tool to aid the determination of age estimation in both living and the deceased[23]. Many studies have used custom-made software American Board of Forensic Odontology No. 2 scale on the scanner platen, stereomicroscopy and digital Vernier caliper measurements to measure the root dentine transparency level. Conventionally, root dentin translucency was measured microscopically using calipers on sectioned teeth. The Translucency also can be assessed macroscopically on intact unsectioned teeth by using digital calipers but tooth sections offer improved results. In recent times, the use of custom fabricated software programs have been recommended owing to its accuracy and reliability[24].

Over the years root dentin translucency was measured using a digital caliper on the teeth sectioned using a hard tissue microtome. The major shortcoming using this method was that the sectioned teeth could not be properly stabilized and thus increasing the risk of damage or fracture by the pointed beaks of the caliper scale. Also, the magnifying glass could not enhance the exact clarity between the translucent and the opaque zone[10].

The improvement of the digital method is that the translucency measurements obtained were magnified at ×3 magnifications using the Zoom Tool, which permitted better visualization of the junction between the opaque and transparent zone. This could not be accomplished by the caliper method; hence that amount of magnification necessary for accurate age estimation can be determined[9,19]. However, the values of the root dentin translucency obtained by conventional and digital were very analogous, with no clear superiority of one method over the other by various studies. Furthermore, translucency can be measured by tooth sections provide better detail irrespective of the section thickness. Combination of sectioning of teeth followed by digital image analysis is often recommended.

Conclusion

Though conventional sectioning of teeth with observation using caliper or under microscope was gold standard and accurate, it is a more time-consuming destructive approach and is significant often for postmortem cases where utilization of numerous tooth is possible but less practical for living individual where tooth has to be extracted for such identification method in case of medico legal conflicts. Due to advancement in technology and more precise results digital method could possibly serve as more reliable where estimation of age plays a vital role in identification process in the field of forensics. Hence, further studies on a large scale are necessary to determine reliability of digital approach method without sectioning or compromising the tooth to estimate the age without damaging the integrity of tooth.

Study of Fingerprint Pattern: A Cross Sectional Study

Vijay Kumar Ag1, Suresh J.2

1Associate Professor, Department of Forensic Medicine & Toxicology, Adichunchanagiri Institute of Medical Sciences, 2Associate Professor, Department of Forensic Medicine & Toxicology, J.J.M Medical College, Davangere

Abstract

A fingerprint is an impression left by the friction ridges of a human finger. The recovery of partial fingerprints from a crime scene is an important method of forensic science. Moisture and grease on a finger result in fingerprints on surfaces such as glass or metal. Objective: To determine the predominant fingerprint pattern in and around Mandya district. The present study was conducted at department of Forensic Medicine Adichunchanagiri Institute of Medical Sciences, Mandya from 1st January to 31st January 2019. Total subjects included were 50 Male and 50 Female students. Subjects who were healthy and having normal hands were included in the study. In present study the Ulnar loop was the most frequently observed pattern followed by Plain whorl, in the total subject population in all ten digits. The least frequently observed pattern in the total population were Simple arches, twinned loops, tented arches, radial loops, accidental types and Exceptional arches both in Male and Female. Fingerprints can be captured as graphical ridge and valley patterns. Because of their uniqueness and permanence, fingerprints emerged as the most widely used biometric identifier in the 2000s.

Keywords: Finger Prints, Loop, Whorls, Arches, Composite, Biometry.

Introduction

A fingerprint is an impression left by the friction ridges of a human finger. The recovery of partial fingerprints from a crime scene is an important method of forensic science. Moisture and grease on a finger result in fingerprints on surfaces such as glass or metal. Deliberate impressions of entire fingerprints can be obtained by ink or other substances transferred from the peaks of friction ridges on the skin to a smooth surface such as paper. Fingerprint records normally contain impressions from the pad on the last joint of fingers and thumbs, though fingerprint cards also typically record portions of lower joint areas of the fingers.

Human fingerprints are detailed, nearly unique, difficult to alter, and durable over the life of an individual, making them suitable as long-term markers of human identity. They may be employed by police or other authorities to identify individuals who wish to conceal their identity, or to identify people who are incapacitated or deceased and thus unable to identify themselves, as in the aftermath of a natural disaster.

In the Henry Classification System there are three basic fingerprint patterns: loop, whorl, and arch, which constitute 60–65 percent, 30–35 percent, and 5 percent of all fingerprints respectively. There are also more complex classification systems that break down patterns even further, into plain arches or tented arches,[5] and into loops that may be radial or ulnar, depending on the side of the hand toward which the tail points. Ulnar loops start on the pinky-side of the finger, the side closer to the ulna, the lower arm bone. Radial loops start on the thumb-side of the finger, the side closer to the radius. Whorls may also have sub-group classifications including plain whorls, accidental whorls, double loop whorls, peacock’s eye, composite, and central pocket loop whorls.1,2

Fingerprint identification, known as dactyloscopy,3

e-mail: drsureshjfm@gmail.com
or hand print identification, is the process of comparing two instances of friction ridge skin impressions (see Minutiae), from human fingers or toes, or even the palm of the hand or sole of the foot, to determine whether these impressions could have come from the same individual. The flexibility of friction ridge skin means that no two finger or palm prints are ever exactly alike in every detail; even two impressions recorded immediately after each other from the same hand may be slightly different. Fingerprint identification, also referred to as individualization, involves an expert, or an expert computer system operating under threshold scoring rules, determining whether two friction ridge impressions are likely to have originated from the same finger or palm (or toe or sole).

**Objective:** To determine the predominant fingerprint pattern in and around Mandya district.

**Methodology**

The present study was conducted at department of Forensic Medicine Adichunchanagiri Institute of Medical Sciences, Mandya from 1st January to 31st January 2019. Total subjects included were 50 Male and 50 Female students. Subjects who were healthy and having normal hands were included in the study.

**Results**

In present study the Ulnar loop was the most frequently observed pattern followed by Plain whorl, in the total subject population in all ten digits. The least frequently observed pattern in the total population were Simple arches, twinned loops, tented arches, radial loops, accidental types and Exceptional arches both in Male and Female.

**Discussion**

In present study the Ulnar loop was the most frequently observed pattern followed by Plain whorl, in the total subject population in all ten digits. The least frequently observed pattern in the total population were Simple arches, twinned loops, tented arches, radial loops, accidental types and Exceptional arches both in Male and Female.

In 1823 Jan Evangelista Purkyně identified nine fingerprint patterns. The nine patterns include the tented arch, the loop, and the whorl, which in modern day forensics are considered ridge details. In 1880 Henry Faulds, a Scottish surgeon in a Tokyo hospital, published his first paper on the usefulness of fingerprints for identification and proposed a method to record them with printing ink. Returning to Great Britain in 1886, he offered the concept to the Metropolitan Police in London but it was dismissed at that time. Up until the early 1890s police forces in the United States and on the European continent could not reliably identify criminals to track their criminal record. Francis Galton published a detailed statistical model of fingerprint analysis and identification in his 1892 book *Finger Prints*. He had calculated that the chance of a “false positive” (two different individuals having the same fingerprints) was about 1 in 64 billion.

Gangadhar. M.R, Rajashekara Reddy. K (1983) reported in a study that the basic finger pattern type loops (57.11%) were common followed by whorls (27.89%) and arches (15.00%) in the general population with significant sex difference and insignificant bilateral difference.

Purkait R, (2003) observed in his comparative study on frequency of fingerprint patterns and variation in the ten digit classification on males (454 samples- 227 from each tribe) of Mundas and Lodhas, a tribal group of Midnapur district in West Bengal where Mundas exhibit higher frequency of whorl and loop patterns while loops are more frequent among Lodhas.

Nithin V (2009) reported in his study on 250 males and 250 females of south Indian population most frequent fingerprint pattern as ulnar loop in the total population as well as in the sex wise distribution.

Arabindbasu (1976) reported distributional trend oft he three principal pattern types having high frequency of loops, moderate whorls and low arches.

**Conclusion**

Fingerprints can be captured as graphical ridge and valley patterns. Because of their uniqueness and permanence, fingerprints emerged as the most widely used biometric identifier in the 2000s. Automated fingerprint verification systems were developed to meet the needs of law enforcement and their use became more widespread in civilian applications. Despite being deployed more widely, reliable automated fingerprint verification remained a challenge and was extensively researched in the context of pattern recognition and image processing. The uniqueness of a fingerprint can be established by the overall pattern of ridges and valleys,
or the logical ridge discontinuities known as minutiae. In the 2000s minutiae features were considered the most discriminating and reliable feature of a fingerprint. Therefore the recognition of minutiae features became the most common basis for automated fingerprint verification. The most widely used minutiae features used for automated fingerprint verification were the ridge ending and the ridge bifurcation.

A Study to Re-Design the Lay Out for Tertiary Level Health Care Mortuary

Vishva Deepak Bijawat¹, Ankit Kumawat², Vipin Gupta³

¹Assistant Professor, Forensic Medicine, Medical College, Barmer, ²Resident in Physiology, J.L.N. Medical College, Ajmer, ³Resident in Forensic Medicine, J.L.N. Medical College, Ajmer

Abstract

Autopsy, post-mortem examination or necropsy is the synonyms used for the examination of the dead body after death to collect all the necessary medicolegal evidences. The post-mortem examination is usually conducted in place which is called mortuary. The mortuary conditions in India are very bad in terms of infrastructure and facilities so they are not suitable to carry out scientific examination which results into post-mortem artefacts. Lack of instruments, facilities like electricity, water and antiseptic agents poses health hazards to mortuary attendant and doctors’ working in mortuary. This paper is aimed at describing the required facilities in a scientifically designed mortuary along with modification in building designs of a district hospital mortuary which is going to become a mortuary of new medical college to serve the purpose of post-mortem examination along with teaching of doctors and nurses.

Keywords: Autopsy complex, mortuary lay out, requirements in mortuary, teaching mortuary.

Introduction

With this modernization era and increased craving of society to deliver speedy and prompt services, much neglected part in healthcare system brings attention of mankind to modernise the infrastructure and staffing of mortuary to give a human touch on handling and disposal of dead bodies for their legal proceedings. The proper and decent modern facilities in mortuary complex will dispel the atmosphere of dislike, fear and hatred associated with mortuary complex in general individual of this country and this will allow the reluctant visitor to visit the mortuary.

In India most of places including secondary and tertiary(medical college) care level mortuaries have primitive facilities for body preservation as well as for autopsy examination, Even some of them deprived of basic necessity like electricity and water supply, Which needs urgent attention and redressal. The concept of a modern mortuary in a hospital, regards the mortuary as a culturally sensitive area in terms of public relation of the hospital¹.

When a patient dies during the course of treatment or receives as brought dead to institution the post-mortem care starts in form of various procedures like washing of body, plugging of body orifices with cotton plug and covering in white cloth which imparts a Respect to Dead body as well as retards the decay of body. When body is required to be preserved for some time and then is dissected to find out the cause of death. This is called an autopsy or post-mortem examination in laymen’s language. Post mortem examination is conducted to find out the cause of death may be for legal or scientific requirement depending on the circumstances leading to the death. The area where such procedure is carried out is called a Mortuary (Or Post-Mortem/Autopsy Room). On certain occasions, the body is also required to be preserved, till disposal arrangement is made either by the relative of the patients or the hospital authority.
Role of an ideal mortuary complex:
The various services provide includes:\(^2\):
- Documentation of incoming and outgoing bodies from Hospital to mortuary complex and their disposal and for identification of the body.
- Postmortem examination of the dead body to find out cause of death by forensic autopsies and pathological autopsies as well.
- The demonstration of Post Mortem findings for teaching purposes to undergraduates as well as post-graduates.
- To provide space for forensic evidence collection and storage until they are suitable for transport to FSL or Pathological Laboratories.
- To provide space for Family/police viewing and facilities for other specialised procedures like mobile Radiography, Photography and video recording etc.

General guidelines for mortuary designs

Every mortuary should have following minimum facilities:\(^3\):
- Suitable arrangements for receiving the dead bodies from the hospital or outside, with separate arrangements for keeping decomposed and infectious bodies (known HIV/hepatitis death cases)\(^4\) etc.
- Requisite space for post-mortem examination as well as to accommodate learning student, nurses or investigation officer.
- Other basic essential amenities like office, reception, toilets, Cold room, changing room, waiting room etc
- There should be fresh air and natural light to be available in each room of the mortuary with cleanliness & hygiene.
- The mortuary complex must be located at a short distance from the hospital preferably away from the general traffic routes used by the public. It must have a separate entrance for visitors and dead bodies.
- There should be a direct link between the hospital and the mortuary to Facilitate easy delivery of the dead bodies for autopsy from the wards. It should have adequate parking space.

MCI guideline of Mortuary complex for 100 MBBS students intake per year: Autopsy Block—there shall be an Autopsy room (approx. 400 sq. mt. area) with facilities for cold storage, for cadavers, ante-rooms, washing facilities, with an accommodation capacity of 20-25 students, waiting hall, office etc. The location of mortuary/autopsy block should be either in the hospital or adjacent to the hospital in a separate structure and may be shared with the department of Pathology\(^5\).

Staffing: The requirement of staff in the mortuary differs from place to place and depends on the type and quantum of work undertaken, the type of institute whether teaching or a Non-teaching hospital. The Sub-Committee Report (Bureau of Police Research and Development of 1975) laid down the staffing pattern and this has been accepted in principle by the government.

I. For initial 100 autopsies per year: (i) Specialists- Two (ii) Post mortem technician-One. (iii) Post mortem Assistant- One. (iv) Clerk/Steno-One. (v) Chowkidar- One. (vi) Peon- One (vii) Sweeper/Morgue attendants-4 (Three sweepers for shift duty round the clock and one as a reliever)\(^6\).

II. For every additional 100 autopsies per year, following additional staff is required: (i) Specialist- One. (ii) Post mortem assistant - One. (iii) Technician- One (for teaching institutions). (iv) Assistant - (300-500 autopsies/yr)-One,(>500 autopsies/yr) Two.

In addition these staff mortuary should require (I) Photographer - One. (II) Dark room attendant- One (on big centres, personnel for photographic work)

Equipments: The equipments required in mortuary vary widely. Only those equipments that are of certain significance related to the mortuary complex are listed as under: (as per the recommendation of Survey Committee Report on Medico-legal Practices in India, 1964)

(i) Basin E. I 12”-2

(ii) Weighing machines 3 No. For weighing bodies, organs and foetus with top loading tray up to 500 gram and up to 5kg.
   a. Platform scale for weighing the whole body - 1
   b. Balance to weight 100gms to 10 kg - 1
   c. Balance to weigh 0.2 gms to 10gms - 1

(iii) Cutting instruments-stainless steel:
   a. Skull cutter (electrical) - 1
b. Organ knife 10” blade, solid forged - 1

c. Organ knife 6” blade, solid forged - 1

d. Caltin solid forged -

e. Cartilage knife 5-1/2” blade solid forged - 2

f. Rib cutter

g. Cartilage knife 4” blade/solid forged - 2

h. Brain knife 10” blade, solid forged - 1

i. Resection knife 3” blade, solid forged - 2

j. Scalpels, BP Handle with blades - 1 Set

k. Bistoury, probe pointed solid forged - 1

(iv) Scissors (stainless steel)

a. Scissors; blunt sharp 8” - 1

b. Scissors; blunt/sharp 6” - 1

c. Scissors; dissecting 5” with one probe point for coronary artery - 1

d. Scissors; bowel, Bernard 11” -

(v) Forceps (stainless steel)

a. Bone cutting forceps 10” straight - 1

b. Bone cutting forceps 10” angled - 1

c. Rib-shears 9-1/2” - 1

d. Dissecting forceps 6” - 1

e. Dissecting forceps 8” - 1

f. Dissecting forceps 10” - 1

g. Toothed and un-toothed forceps - 6 each

(vi) Post-mortem Scissors:

a. Saw, Bernard 11” stainless steel Blade - 1

b. Saw, Bernard 9” stainless steel Blade - 1

(vii) Straight and curved Enterotome, viscrotome - 1 each

(viii) Miscellaneous:

a. Coronet stainless steel - 1

b. Needles, post-mortem half curved & double curved - 1 dozen

c. Probes silver with eye 10” - 1

(d. Chisel, straight 3/4 “ blade - 2

e. Chisel, spine with locating point (stainless steel) - 1

f. Gouge, 3/4” blade, stainless steel - 1

g. Hammer with wrench stainless steel - 1

h. Measures 12” stainless steel - 1

i. Mallet, boxwood with metal bands - 1

j. Small table 20” × 24” × 12” for dissection of organs - 1

k. Measuring jug (one litre) - 1

l. Metal/steel scale - 2

m. Magnifying glass - 3

n. Instrument trolley - 3

o. Cabinet - 1

p. Wooden boards - 3

q. Rubber gloves - Adequate quantity

r. Aprons - Adequate quantity

This list covers almost the entire range of equipments for post-mortem examination. However the following additions are also recommended by some of the authorities:

(viii) Suction Pump & Aspirators - 1 each

(ix) Body Scale - 1

(x) Repairing materials like: Thread white, cotton wool (absorbent), wool waste, a variety of discarded clothes, malleable wire, Polythene bags, Gloves, Masks, and Aprons etc.

(xi) Plastic Bins: For fixing large specimens.

Chemical and Reagents: There should be provisions for following chemical articles.

(i) Bleaching powder for cleaning mortuary table floors, etc.

(ii) 2% Glutaraldehyde for cleaning instruments.

(iii) Formative for sending specimens needing his to pathology.

(iv) Rectified and Methylated spirit as preservative

(v) Thymol crystals
(vi) Common salt
(vii) Sodium fluoride
(viii) Potassium oxalate
(ix) EDTA vials and tubes
(x) Sterilized glass tubes (plain).
(xi) Sterilized glass tubes with swabs
(xii) Liquid paraffin
(xiii) Sealing wax etc.
(xiv) Big size envelope, plain papers etc.

Universal Precaution: Eye protection (Goggles and face shields), Plastic Gowns, Personal protective equipment (PPE) & Puncture resistant hand protection (plastic or steel gloves)-prevent blood borne transmission.

Material and Method

A yearlong data from April 2017 to March 2018 collected from morgue register of District hospital, Barmer which showed total 268 dead bodies arrived at morgue among which 7 bodies are highly infectious (hepatitis -2, HIV-Aids-1, MDR-TB-1 and decomposed bodies 3). There is tendency of faster disposal of dead bodies to relatives on receiving the requisition of non-postmortem from I.O. The usual average stay of dead body in mortuary remains around 6 hours particularly due to frequent power cuts and interrupted power supply. There were nine unidentified dead bodies disposed from mortuary fairly within 48-72 hrs. There was maximum intake of four dead bodies at a time reported with maximum two dead bodies retained overnight in the mortuary. The space around the fixed cemented mortuary table found inadequate to accommodate 20-25 persons.

Situation of Mortuary Complex:

X: Proposed post mortem viewing gallery, Y: Proposed sample handling room etc.

Conclusion

As usual in the secondary care level hospital the condition of mortuary is worse since basic facilities like regular electric supply and water for cleaning dead bodies is not available. Due to lack of facilities there are chances of producing post mortem artefacts and missing out valuable findings. Provisions of mortuary facilities and services in a tertiary care hospital have an important bearing in terms of public relation of the hospital. To convert this mortuary into a teaching mortuary a post-mortem viewing gallery should be incorporated to accommodate the 20-25 students and a specimen handling room required as extension.

Determinant Analysis of Factors Influencing Tuak Consumption Culture on Guardian Earth Through the Leininger Model Sunrise Approach Theory

Wahyu Tri Ningsih¹, Titik Sumiatin¹

¹Lecturer Department of Nursing Tuban Campus, Polytechnic of Health Ministry Surabaya

Abstract

People who consume alcoholic drinks in various regions in Indonesia, if viewed through the Sunrise Model approach, is influenced by several things, including technological factors, religious and philosophy of life factors, social and family relationships factors, cultural and styles life factors, policy and regulatory factors, economic factors and educational factors. The purpose of this research is to know the determinants of factors that influence the Culture of Tuak Consumption on Bumi Wali Tuban through the Leininger Model Theory Approach. The research design used in this study was analytic with a cross sectional approach. The population in this study are all residents in the area of Tuban Regency with a total of 1,291,665 people with a sample size of 400 taken using cluster sampling. Data was collected by using a questionnaire. The collected data was tabulated, analyzed using frequency distribution and percentage and presented in the distribution table. Analysis of bivariate and mutivariate data used logistic regression to find factor determinants. The results show that cultural values and lifestyle are the factors that most influence the culture of tuak consumption with p value 0.000 (p <0.05) and OR 23.11. This means that cultural and lifestyle factor have a chance of 23,11 times for someone to drink tuak. Tuak consumption in Tuban Regency is a culture that has declined and become a characteristic. This drink is “obligatory” and serves as a banquet for traditional events or traditional rituals in Tuban.

Keywords: Consumption of tuak, Leininger’s Sunrise Model Theory.

Introduction

As one of the drinks that contain alcohol, palm wine is also a favorite drink in various regions in Indonesia, especially in areas where Lontar trees grow, sap trees which are usually called sap can be processed into drinks which became known as “Tuak”. Apart from Tuban, other areas that also have an old habit of consuming Batak, specifically the North Tapanuli region, Bali, South Sulawesi Toraja Tribe and Madura.

The results of the Demographic and Population Survey of Indonesia (IDHS) in 2012 also provided information that the percentage of alcohol drinkers in men aged 15-19 years was 30.2% and those aged 20-24 years was 52.9%, while the percentage of women aged 15-19 years by 3.5% and aged 20-24 years by 7.1%(1). Data on the number of consumers of Tuak and other types of alcoholic drinks in Tuban according to the District Health Office of Tuban is not clear. But in general, if we look at the daily life of the Tuban community, tuak has become a chatting partner for them. Every afternoon and evening the Tuban community has a habit of gathering, talking in groups, accompanied by a drink of wine. And it has become a hereditary culture in the city of Tuban since long ago.

The number of people who consume alcoholic beverages/palm wine in various regions in Indonesia when viewed through the Sunrise Model theory approach, namely the Transcultural approach, is influenced by several factors, including technological factors, religious...
factors and philosophy of life, social factors and family relationships, cultural factors and lifestyle, policy and regulatory factors that apply, economic factors and educational factors. From a health point of view the consumption of alcoholic drinks can also cause various diseases, and one of the diseases that often arise due to consuming alcoholic drinks/Tuak is Hypertension. Sesso also mentioned that there is a positive relationship between alcohol consumption and hypertension in both men and women(2).

According to the Regional Regulations of Tuban No. 9 2016, alcoholic drinks are classified into three groups, namely: Group A is a drink with an ethyl alcoholic or ethanol content of up to 5%, Group B is a beverage with an ethyl alcohol or ethanol content of 5% to 20%, Group C is drinks with 20% to 55% ethyl alcohol or ethanol content. Tuak is an alcoholic beverage with 4% content. Based on the decisions and regulations that have been set, then tuak can be classified as one type of liquor class A.

In Tuban Tuak comes from sap of sap which is tapped from a siwalan tree or palm tree, which is accommodated in a bamboo “Bumbung” 40-50 cm long, and is stored for several days. The longer the storage, the higher the alcohol content it contains(3). Diseases that can be caused by excessive alcohol consumption include: 1) Heart and blood vessel disease(4), 2) diabetes mellitus, 3) kidney disease(5),(6); 4) liver disease; 5) psychological disorders(7).

The tradition of drinking palm wine has become a tradition of hereditary in Tuban. This drink is “mandatory” to exist and is a banquet at traditional events or traditional rituals in Tuban. It is not uncommon for Tuak to be a feast for young people when guests arrive from areas outside of Tuban. At the gathering we often encounter wine drinks in it, and also in Tuban there are not a few shops that sell this drink.

Material and Method

The research design used in this study was analytic with cross sectional approach. The population in this study were all residents in the Tuban Regency area with a total of 1,291,665 people. The sample in this study was a portion of the population in the Tuban Regency area. The inclusion criteria in this study were: population recorded in population data, male sex and adult age. The sample size in this study was 400 respondents. The sampling technique in this study was carried out by cluster sampling.

The dependent variable in this study is the culture of drinking wine. The independent variable in this study was taken from Leininger’s Sunrise Model Theory, namely technological factors, religious and philosophical factors, social factors and family attachment, cultural and lifestyle factors, policy and regulatory factors, economic factors, Education factors. The instrument used in data collection was a questionnaire created by the researcher by developing the Sunrise Model theory. Statistical test uses logistic regression to analyze dominant factors.

Result

Respondent characteristics showed that all respondents were male, in the age range of 40 - 59 years (66.50%), and most worked in the private sector (41%) (table 1).

The results of the analysis using the logistic regression test showed that the technology variable obtained a regression coefficient of -0.038 with a significance level (r-value) of 0.998> 0.005. Technological factors do not significantly influence the culture of palm wine consumption in Bumi Wali Tuban. Religious variables obtained a regression coefficient of 1.069 with a significance level (r-value) of 0.344> 0.005. Religious factors do not significantly influence the culture of palm wine consumption in Bumi Wali Tuban. Family variables obtained a regression coefficient of 19.030 with a level of significance (r-value) of 0.996> 0.005. Family factors do not significantly influence the culture of palm wine.
consumption in Bumi Wali Tuban. Variable values of culture and lifestyle obtained a regression coefficient of 3.150 with a significance level (value-value) of 0.000 <0.005. Lifestyle factors significantly influence the culture of palm wine consumption in Bumi Wali Tuban. The policy variable obtained a regression coefficient of 20.662 with a significance level (r-value) of 0.993 >0.005. Policy factor does not significantly influence the culture of palm wine consumption in Bumi Wali Tuban. Economic variables obtained a regression coefficient of 0.227 with a level of significance (r-value) of 0.620 >0.005. Economic factors do not significantly influence the culture of palm wine consumption in Bumi Wali Tuban. The education variable obtained a regression coefficient of -1.641 with a significance level (r-value) of 0.000 <0.005. Educational factor significantly influences the culture of palm wine consumption in Bumi Wali Tuban. The factor of culture and lifestyle values is the most influential factor in the culture of drinking palm wine consumption with p value 0.000 (p value<0.05) and OR 23,111. This means that lifestyle has a 23,111 chance for someone to drink wine. (table 2)

**Discussion**

Research shows that almost all Tuban people are Muslim and religious factors do not significantly influence the culture of palm wine consumption in Bumi Wali Tuban. Adrianna Murphy in the article stated that Muslim women were less likely to drink alcohol than non-Muslims(8). Research conducted by Khusnaini, states that there are differences of opinion between community leaders and religious leaders in addressing the circulation of tuak in Kaba Tuban Regency. Community leaders argue that tuak is not intoxicating, contains many benefits and by selling tuak can increase income. While religious leaders forbid tuak to be traded because it is included in intoxicating drinks (khamr)(9).

The data states that the majority of Tuban residents are Muslim but the majority of them are palm wine consumers. They consume tuak for various reasons, among others, just because they want to drink, relieve stress, and to socialize when there are residents’ activities. The results of the study stated that family factors did not affect the culture of palm wine consumption in Bumi Wali Tuban. Sobhee, S et al., In their study stated that, people who live in one house do not influence individuals to buy alcoholic drinks and the greater the number of family members the smaller expenditure on alcohol(10). Research by Constantinescu, Maria, and Cornel Constantinescu, states that drinking alcohol behavior in addition to being influenced by personal choices is also influenced by the environment, for example legislation and friends(11).

According to this research, according to the results of the study by Sobhee, S et al., They are not influenced by the family in consuming tuak. They live in an environment where most of the people are consumers of palm wine, so they are influenced to consume it. Consuming palm wine is common and easy to find in
various places in Tuban. The factor of cultural value and lifestyle is the most influential factor on the consumption of palm wine in Bumi Wali Tuban. The study of Jennifer Ahern et al. States that environmental culture which is permissive to alcohol consumption influences individual alcohol consumption\(^{(12)}\). Research by Riskiyani et al. Shows that individuals understand tuak as a traditional alcoholic drink that has positive and negative effects on its consumption. Tuak is a beverage that can strengthen the brotherhood and is always served in celebration of traditional parties and daily activities, so that it has become a tradition in society. Residents present tuak as a typical drink to entertain visitors or guests, so that visitors or guests become accustomed to wine drinks\(^{(13)}\).

The tuak consumption culture is a culture that has gone downhill in the Tuban region. This drink is “mandatory” to exist and is a banquet at traditional events or traditional rituals in Tuban. This study is in line with the results of the study above, that environmental culture influences a person to consume alcohol. So although most people think that drinking wine is a negative habit, but the culture of drinking wine still persists in the community for the reasons stated above.

The policy factor does not significantly influence the culture of palm wine consumption in Bumi Wali Tuban. Research by Constantinescu, Maria, and Cornel Constantinescu, states that drinking alcohol behavior in addition to being influenced by personal choices is also influenced by the environment, for example legislation and friends. This study also states that to reduce the consumption of alcoholic beverages, several policies need to be carried out, including: 1) Limiting the number of days and hours of sale, the density of certain locations or places where alcoholic drinks are sold; 2) Limiting alcohol consumption in public places. Prohibition of alcohol in certain areas in the city and at certain times. Promote physical security and social order; 3) limiting alcohol marketing and promotional prices, especially marketing and promoting alcohol intended for young people; 4) Promote consumption of soft drinks, by setting prices lower than the cheapest alcoholic drinks; 5) restrictions on the sale of alcohol near schools\(^{(11)}\).

Explicitly, the regulation does not regulate traditional drinks containing alcohol such as wine. The Tuban District Government also does not prohibit the sale of palm wine. Because producing palm wine is one of the economic sources of citizens. To reduce the impact of excessive drinking there is an appeal from the government to sell wine in areas far from the crowd, so that people who are drunk do not make a fuss. Besides being a source of income, tuak is also a tradition that has been passed down in the community.

Economic factors do not significantly influence the culture of palm wine consumption in Bumi Wali Tuban. Rafferty, Ellen, in her study said that, as individual income levels increase, the estimated opportunities for engaging in alcohol consumption also increase. Individuals with higher incomes tend to drink more often than low income earners\(^{(14)}\). Sobhee’s research, S, also states that spending to buy alcohol by alcohol dependent individuals increases when income rises. Income is the main determinant of spending on alcohol by individuals who are alcohol dependent\(^{(10)}\).

The education factor significantly influences the culture of palm wine consumption in Bumi Wali Tuban. Rafferty, Ellen, in the results of the study stated that, individuals with less education than secondary school had a 1.09 times higher chance than individuals with education after secondary school\(^{(14)}\). Anamaria Ciubară’s research also states that the level of education also influences general attitudes toward alcoholism and alcoholism, subjects with higher education are far more aware of the negative effects of alcoholism than subjects with less educational levels\(^{(15)}\). Low education factor makes it difficult for someone to accept new information, in this case is information about wine and its effects, even though they argue that drinking wine is a negative habit.

**Conclusion**

The factor of cultural value and lifestyle is the most influential factor in the culture of consumption of palm wine, the cultural value and lifestyle has a 23.1 times chance for someone to drink wine. In accordance with Leininger’s Sunrise Model theory approach, what needs to be done is to help clients adapt to certain cultures that are more beneficial to health (negotiation) and cultural restructuring, namely by periodically providing counseling about the dangers of alcoholic beverages to the community in communities and adolescents in schools.

Personal Hygiene Relationship with Typhoid Fever Occurrence in Gowa Regency, Indonesia

Wahyuni Sahani¹, Syamsuddin S.², Inayah³, Muspida⁴, M. Askar⁵

¹Associate Professor, ²Assistant Professor, ³Assistant Professor, ⁴Graduate Student, ⁵Environmental Health Department & the Center of Excellent on Urban Health of Health Polytechnic of Ministry of Health in Makassar, Indonesia

Abstract

Objective: The objective of this study was to determine the relationship of individual hygiene with the incidence of typhoid fever in the working area of Pallangga Health Center, Gowa Regency.

Method: The type of study used was observational analytic with a cross-sectional approach. The population in this study were all cases of suspect typhoid fever in the health center of Pallangga in the last 3 months with 104 cases. Subjects involved in this research were 83 patients were taken by simple random sampling. Data obtained, then analysed using SPSS for Windows with the Chi-square test.

Result: The results of this study were good handwashing habits before eating found over 38 subjects (45.8%) and 45 subjects (54.2%) with poor habits, good handwashing habits after defecation showed by 55 subjects (66.3%) and 28 subjects (33.7%) were showing poor habits while frequent out-of-home eating habits found over 58 subjects (69.9%) and rarely eating out of home showed by 25 subjects (30.1%).

Conclusion: This research found that there was a significant relationship between handwashing habits before eating (p=0.01) and eating habits outside the house (p=0.02), and statistically no significant relationship between handwashing habits after defecation (p=0.16) with the incidence of typhoid fever in the Pallangga Community Health Center Gowa District.

Keywords: Personal Hygiene, Typhoid Fever, Health Center.

Introduction

Typhoid fever is an acute infectious disease that is always in the community (endemic) in Indonesia, ranging from the age of toddlers, children and adults, even the elderly. Typhoid includes a systematic infection with typical symptoms of fever. The disease is endemic and becomes global health matter¹ and a public health problem from case studies in major hospitals in Indonesia, the rare cases of typhoid tend to increase from year to year with an average illness of 500/100,000 people with mortality rate between 0.6-5%.²

Typhoid is one of the endemic diseases in Indonesia, the majority cases were school-age children and productive age groups. This disease causes a high rate of absent in class, on average it takes 7-14 days to treat if someone is typhoid. If the treatment is not complete, it can lead to a career which then becomes a source of transmission for others.³

Data obtained from the South Sulawesi provincial health office in 2012 recorded 24,998 cases positive with typhoid fever, in 2013 typhoid fever was recorded at 31,633 cases with an incidence rate (3.8). In 2014

Corresponding Author:
M. Askar
Environmental Health Department & the Center of Excellent on Urban Health of Health Polytechnic of Ministry of Health in Makassar, Indonesia
e-mail: askar@poltekkes-mks.ac.id
typhoid was recorded at 16,743 cases, patients were 7,925 men and 8,818 women with incident rates (2.07), with the highest cases being in Bulukumba Regency (3,270 cases), Makassar City (2,325 cases) Enrekang Regency (1,153 cases) and the lowest in North Toraja district (0 cases), Luwu Regency (1 case) and Tana Toraja District 19 cases.4

The transmission of typhoid fever occurs through fecal-oral route, hygienic procedures play main role in prevention and control of the infection.5 Based on disease data from Pallangga Health Center, the number of typhoid fever cases was 104 cases in 2018. It was allegedly caused by housing factors including lack of toilet facilities that did not meet health requirements.

Method

This study was led in the working area of Pallangga Community Health Center, Pallangga District, Gowa Regency, covered 4 villages and 4 sub-districts. The independent variables were the habit of washing hands before eating, the habit of washing hands after defecation and out home eating habits behavior. The dependent variable was the occurrence of typhoid fever patients in the working area of Pallangga Health Center, Gowa Regency.

The population in this study were all patients with typhoid fever as many as 104 patients in the working area of Pallangga Health Center, Gowa Regency. The number of samples in this study was taken from a portion of the population determined using Random Sampling which was taken randomly as many as 83 patients with typhoid fever in the working area of Pallangga Health Center, Gowa Regency.

Data analysis was performed by using Software SPSS for Windows with Chi-square test, Microsoft Excell for processing and creating master table and Microsoft word for reporting this research.

Discussion

Hand-washing habits before eating: Personal hygiene in this study was related to typhoid fever cases. These include the habit of washing hands before eating, using soap, and cleaning nails. The incidence of typhoid fever often occurs in slums, low socio-economic environments, unhygienic states and people with poor personal hygiene.

Based on crosstabulation among variables to find out the relationship between handwashing habits before eating and the incidence of typhoid fever in the working area of Pallangga Gowa Health Center, the results were 38 subjects who had good handwashing before eating seen 11 subjects who positive typhoid fever and 27 subjects who negative of typhoid fever. While from 45 subjects who had the habit of washing hands before eating less well, it was found that 30 subjects positive of typhoid fever and 15 subjects who negative of typhoid fever.

The results of bivariate statistic analysis using the Chi-square test obtained p-value=0.01<α=0.05 meant H0 was rejected and Ha was accepted implied that there was a significant relationship between handwashing habits before eating and the incidence of typhoid fever. This was in line with the research which states that there was a significant relationship between handwashing habits before eating and the incidence of typhoid fever in the working area of Tumaratas Health Center and research explaining that someone who practices hand washing before eating less well at risk 3 times to experience the incidence of typhoid fever.

It was also said that personal hygiene is one of the efforts that can prevent the occurrence of typhoid fever because the transmission media of germs that cause typhoid fever move and cause transmission could be directly or indirectly.

Based on the results of observations and interviews conducted in the working area of the Pallangga Community Health Center, Gowa Regency found that there were 45 subjects who had poor handwashing habits that only washed their hands before eating by water without soap and not rubbing their hands, between fingers, and nails. So this is what can lead to the development and as a source of transmission of typhoid fever.

The water source for hand washing before eating is the dug well, the results of observations of dug well water, which were tasteless, odorless, and colorless, when viewed from the results of physical observations
Personal health is a very important thing for someone to have a health condition, only each person can condition it. Healthy conditions can be obtained if each person behaves clean and healthy. For example, if a person is not clean in caring for his body, then his health will be disrupted and will cause illness. The participation of related institutions (health center) is also needed in order to foster good personal hygiene behavior for the subjects, the thing that can be done is to do empowerment, health promotion, and water quality checks.

**Hand-washing habits after defecation:** Based on crosstabulation to find out the relationship between hand washing habits after defecation and the incidence of typhoid fever in the work area of Pallangga Gowa Health Center, the results were 55 subjects who had good handwashing after defecation found 22 subjects positive of typhoid fever and 33 subjects negative from typhoid fever. While 28 subjects who had a poor habit of washing hands after defecation, it was found that 19 subjects positive of typhoid fever and 9 subjects negative of typhoid fever.

The results of the bivariate analysis using the chi-square test obtained p-value = 0.16 > α = 0.05 so H0 was accepted and Ha was rejected by the conclusion that there was no significant relationship between handwashing habits after defecation and the incidence of typhoid fever.

Poor hand washing habits after defecation are likely they are not attacked by typhoid fever because their stool does not contain Salmonella typhi, or there is Salmonella Typhi but is dead, or there are still living Salmonella Typhi but in insufficient amounts to infect, or there are Living Salmonella thypi in sufficient quantities to infect but not actually enter the body. This causes the habit of washing hands after defecation in this study is not a risk factor for the incidence of Typhoid Fever in the working area of the Pallangga Health Center, Gowa Regency. It’s very important to maintain the availability of water and soap for handwashing at the toilet after defecation for diminishing improper handwashing.8

**Outdoor Eating Habits:** In food handlers who do not pay attention to their personal hygiene, especially food handlers, they must always pay attention to and maintain their cleanliness. The incidence of typhoid fever often occurs because someone more often eats outside the house without us knowing the cleanliness of the food and food handlers who could suffer from typhoid fever which can transmit bacteria through these foods.

Based on crosstabulation to find out the relationship between eating habits outside the house and the incidence of typhoid fever in the Work Area of Pallangga Gowa Health Center, the results were 58 subjects who had the habit of eating outdoors often from 35 subjects who suffered typhoid fever and 23 subjects did not suffer from typhoid fever. Whereas from 25 subjects who have eating habits outside the house that are not often done it is known that 6 subjects suffered from typhoid fever and 19 subjects who did not suffer from typhoid fever.

Based on table 5.6 the results of the bivariate analysis using the chi-square test obtained a value of P = 0.02 < α = 0.05, so Ho was rejected and Ha value was accepted by the conclusion that there was a significant relationship between eating habits outside the home with the incidence of typhoid fever. This is in line with research9 who said that there was a significant relationship between eating habits outside the home with the incidence of typhoid fever in the working area of Tegal Pagiyanten Health Center and also in line with research10 found that there was a significant relationship between eating habits outside the home with the incidence of typhoid fever in the Ngemplak Community Health Center Working Area in Boyolali Regency. Stating that those who have eating habits outside the home are at a greater risk of 2,625 times getting typhoid fever compared to someone who has a good habit of eating and drinking at home.

It was also said that the transmission of typhoid fever can occur anywhere and anytime usually occurs through the consumption of food outside the home or in public places if the food and drink are consumed less cleanly. It can also be caused because the food is served by a typhus case who lacks hygiene while cooking and can also be caused by latent typhoid (hidden) patient who lacks cleanliness while cooking. A person can bring typhus in his digestive tract without pain, this is also called latent case. These cases can transmit typhus to many people, especially if he works in serving food to many people such as cooks in restaurants.

In addition, when eating outside, especially in public places there are usually flies that fly everywhere and even land on food. These flies can transmit Salmonella
Typhi by means of flies previously perched on feces or vomiting typhoid fever patients then perch on the food to be consumed.

Health efforts that must be done are to provide knowledge to the community by counseling the public about controlling the incidence of typhoid fever. One of them is not to get used to eating outside the house, which is the stalls/peddlers who are not guaranteed to be clean and provide advice to traders to always maintain the cleanliness of their merchandise both from washing tools, materials and up to the supply of food.

Typhoid fever is a disease caused by Salmonella Typhi infection in the small intestine and bloodstream. These bacteria mix in dirty water or milk and infected food.

Typhoid transmission can occur in various ways, known as 5F, namely food, fingers, fomites, fly, and feces. These germs can be transmitted contaminated drinks and through intermediates of flies, where flies will be eaten by those who are healthy.

Salmonella thypi from the newly infected human mouth goes to the stomach, some germs will be destroyed by gastric acid (HCl) and some pass through to the distal small intestine (the intestine can irritate) and release endotoxins causing the blood to contain bacteria (bacteremia) primary, then through the bloodstream and lymphoid tissue to the lymph and liver. In this lymphoid tissue germs multiply, then enter the bloodstream and reach other organs, especially the small intestine so that inflammation occurs which causes malabsorption of nutrients and intestinal hyperperistaltic resulting in diarrhea. Fever is caused by salmonella and endotoxin stimulates the synthesis and release of pyrogens by leukocytes in inflamed tissue.

**Conclusion**

Based on the study that has been carried out, we found that there was a significant relationship between handwashing habits before eating and eating habits outside the home with the incidence of typhoid fever. Even though, we fail to found a significant relationship between the habit of washing hands after defecation with the incidence of typhoid fever.

Based on the results of the conclusions above, the authors suggest that all people have to maintain a clean and healthy lifestyle in all fields, get used to washing hands before eating, after defecating and reducing outdoor eating habits. It is recommended for the health center to work with the people in optimizing The Clean and Healthy Behavior program to improve the optimization of personal hygiene behavior in order to create community health and well-being in the work area of the health center and provide health education to the community.

It is better for future researchers to conduct further research regarding other factors such as (knowledge, attitudes, sources of clean water, history of typhoid family members and individual characteristics) that are associated with the incidence of typhoid fever.

Abstract

Introduction: K4 achievement was referred to a specific coverage of pregnant mother who have achieved to antenatal service which according to the standard, at least four times in a region during particular period of time. In Bondowoso District, the achievement of K4 was 82.7%, thus, Bondowoso District has not fulfilled to the target plan achievement which has been established by East Java Government in about 88%.

Objective: To analyze effects of input and process to the achievement of K4 in Bondowoso District.

Method: Quantitative research and cross sectional approach. The sample of research was taken from all midwives who have implemented K4 achievement in Bondowoso District as many 190 midwifes. The data analysis was multiple linear regression. Findings: This research demonstrated to a significant effect between input and process to K4 achievement.

Conclusion: The variables of input (man, money, and materials) and process (organizing, actuating, and controlling) were factors which affected to the achievement of K4, therefore, it was suggested to the Office of Bondowoso District to concern more on the indicators of either input or process as knowledge on Human Resource, and facilities and infrastructures which were provided to the midwifes as the executor or implementer of K4 achievement.

Keywords: Input, Process, and K4 Achievement.

Introduction

The problem of health development in Indonesia was detected on the high rate of maternal mortality and infant mortality. Based on Khan’s Low birth weight remains associated with key indicators not just of maternal poverty (notably adequate maternal education) but also markers of structural poverty in health care (notably quality ANC)[6]. In Indonesia, this health problem was ranked on the second in Southeast Asia, specifically for the maternal mortality rate after Laos with the percentage 305 of 100 million in last 2015. A causal factor from this problem of maternal mortality rate was not maximal first screening and prevention attempt in the pregnancy complication during pregnancy test (ANC), particularly on K4 achievement which has not complied to the plan target 2017-2022. According to Department of Health of Republic Indonesia 2010, the pregnancy test (ANC) was a health service which given to pregnant mother during pregnancy period due to the established standard of pregnancy test service. The pregnancy test (ANC) could be exerted as the first screening to the baby condition. Based on the survey from Riskesdas 2018, the health service on pregnant mother in Indonesia has two indicators of SDGs which would be derived
from the achievement of ANC, as K1 (ANC1) and K4 (ANC 4). K4 was the fourth or more contact of pregnant mother to the health officer to get pregnancy test service according to the standard, in minimum of four times of pregnancy test service with the frequency of once visit in first trimester (14 weeks), once visit in second trimester (in range of 14-28 weeks), and two times visit in third trimester (in range of 28-36 weeks)\[12\]. The achievement of K4 in Indonesia has not fulfilled to the plan target in 2018, 2,1% from the target of strategic plan in 2018 78%, while the achievement of K4 in Indonesia has reached to 75,9% in 2019. The achievement of K4 in East Java has reached 90,5%\[3\]. In Bondowoso District, K4 achievement 83,5%, therefore, Bondowoso District has not complied to the target of strategic plan which has been established by the Government of East Java in about 88%. Bodowoso District has target of K4 strategic plan 95%, and in fact, Bondowoso District has not fulfilled the strategic plan target as many 11,5% in 2018. From the total of 25 puskesmas in Bondowoso District, there were no one which could comply the achievement target of strategic plan K4 in Bondowoso district\[4\].

The factor which could affect the success of strategic plan achievement of K4 was aspect of input, man (human resource). The variable of man which was referred by the researchers, the midwife who have implemented K4 achievement which considered from aspects of age, educational background, period of service, knowledge, and training\[7\]. Money or fund source (material) in this context was facilities and infrastructure as supporting tool and material availability which could be very influential to the success of K4 achievement program. Next, the process also has a significant role to follow up the input, thus, the process has some indicators which could affect this research, as organizing, actuating, and controlling. Besides those three indicators, another factor which could affect the research problem was environment which was influenced by level of education, occupation, social economic, and social characteristics of society which was influenced by family support, role of health officer, village apparatus support, public figure, and religious figure\[12\].

This research aimed to analyze the effects of input and process to the achievement of K4 in Bondowoso District.

Method

This research exerted design of analytic observational and method of cross sectional approach. This research employed multivariate method in medium of SPSS 22. The population of this research was 190 midwives who have practiced K4 achievement program in Bondowoso District. The technique of data sampling in this research was total sampling. The total sampling referred to a technique of data sampling where the total of sample was similar to the population\[9\], therefore, the sample of research were all the midwives who have implemented K4 achievement in Bondowoso District as many 190 midwives. The variable of research was consisted of independent variable as input and process and dependent variable as K4 achievement. The instrument of data collection in this research was questionnaire. Next, the collected data would be analyzed through multiple linear regression method.

Research Findings: The result of analysis exerted multiple linear regression in this research would be presented into three sections, the first was respondent characteristic and the second was validity and reliability test, while the third one was analysis result.

Respondent Characteristics:

Table 1. Respondent Characteristics

<table>
<thead>

</table>
Based on the table 1 above, it was identified that from 190 respondents, as many 63.68% or 121 respondents from the graduate of DIII (Diploma Program) and 26.32% or 69 graduates of D4/S1 degree. The age of midwife in Bondowoso District who have implemented K4 achievement program, the respondents in age range 20-30 years old 17.89%, or approximately 34 respondents, age range 31-40 years old 41.05% or approximately 78 respondents, age range 41-50 years old 29.47% or approximately 56 respondents, and age range 51-60 years old 11.58% or approximately 22 respondents. The majority of respondents were the midwives who have work experience along 1-8 years as many 55 midwives or 28.95.

Validity and Reliability Test: The validity test was aimed to clarify how great the validity and accuracy of an instrument to employ its function. To test the validity of research, the researchers used instrument of product moment pearson’s correlation where they must correlate each statement to the total score, and then the correlation result was compared to the critical number 0.30[5].

Whilst, the reliability test was aimed to test how far the result of measurement was relatively consistent. The good statement referred to a clear statement which was easily understood and has similar interpretation, although it was conveyed to the respondents in different way and different period of time. Further in this research, the reliability test was employed through Cronbach Alpha and this research instrument was considered as reliable, since it delivered to Cronbach Alpha value more than 0.60[8].

</table>

Based on the table 2 above, it was referred that each indicator has $R_{cal}$ value which was greater than 0.30. It indicated that the indicators which were used in this research variables were said as reliable or valid to collect the data. Moreover, the testing result showed that each variable has Cronbach Alpha value more than 0.60. Thus, it was concluded that all variables in this research were reliable.
Analysis Result

a. T Test (Partial Hypothesis Test): The hypothesis of input and process in this research was tested its validity through partial test. This type of testing was aimed to see significant level (p-value), if the result of significance level from the calculation was fewer than 0.05, then, the first hypothesis was approved, on the other hand, if the result of significance level was greater than 0.05, thus, the hypothesis was disapproved.

According to the result of hypothesis testing on input variable, it was indicated that t cal value 6.472 and significance level 0.021. This significance level was fewer than 0.05, which referred that the variable of input has positive effect to the achievement of K4 in Bondowoso District. The variable of process indicated t cal value 9.346 and significance level 0.013. This significance level was fewer than 0.05, which referred that it has positive effect to the achievement of K4 in Bondowoso District.

b. F Test (Simultaneous Hypothesis Test): To test the independent variable simultaneously, the researchers tested through F test. Next, the result of statistic calculation who wed that F cal value = 153.474. By exerting the significance level 0.05, it was derived that the significance level was fewer than 0.05. It referred that the hypothesis has stated that the variable of input and process have effects simultaneously to the achievement of K4 in Bondowoso District.

c. Determinant Coefficient (R): The determinant coefficient was a scale which indicated the variation size of dependent variable which could be explained by the independent variable. The value of determinant coefficient was determined by the value of adjusted R square.

The result of regression calculation showed that the determinant coefficient (adjusted R2) 0.792 or 79.2%, which referred that the variable variation of K4 achievement in Bondowoso District could be explained by the variable of input and process. While, the rest 20.8% was explained by other variables which were not submitted in this research.

Discussions

Based on the research finding, it showed that the majority of midwives as the implementers of K4 achievement program have age, educational level, and service period which were categorized into stable and consistent stage of career development, besides, the indicators as input (man, money, and materials) and process (organizing, actuating, and controlling) have positive effects to the achievement of K4[1]. K4 achievement was referred as a form of assessment on the level of health development which must be implemented by Health Office of Bondowoso District as an attempt to improve K4 program achievement through visit service ANC 1 (K1) and visit ANC 4 which was optimally according to the minimum standard of service. The indicators of K4 achievement was the implementation of ANC 4 (the fourth pregnancy test by health officer). Moreover, the continuous treatment must be conducted by identifying the variable of input (man, money, and materials) and process (organizing, actuating, and controlling) which was executed by the service provider in order to realize the achievement of K4 which complied the strategic plan target in about 95%[11].

This research finding was in line with the theory stated by Tampubolon, the implementation of health program was not apart from its health management system, as input, process, and output. The administration input was valued as all things that were needed to implement administration task[10]. Within this input, it required to management unsure: 4M (Man, Money, Material, and Method)[2]. Next, process was referred as steps which must be taken to achieve goals. According to G.R Terry in Satrianegara (2014), there are four functions of administration in the process, but the researchers only employed three functions of administration in this research, as organizing, actuating, and controlling[1]. The organizing step was identified from the availability of implementer or midwife and organizational structure who perform K4 achievement. Actuating was seen from the implementation of K4 visit according to the standard operational of implementation.

The research done by Sulistiyani (2016) has supported to this research finding that the evaluation of implementation of K4 achievement service in Puskesmas Jakenan was due to the system approach and covered to human resource, thus, the implementation of K4 achievement service was less and output was not achieved[12]. Moreover, the research done by Titiwiarti 2013 has also demonstrated that the scope of antenatal visit (K4) was caused by lack of facilities and infrastructures, fund availability which has not fulfilled to the service need, not maximal recording and reporting which caused to not optimal visit achievement[14].
Based on the result of statistic testing, it was clearly identified that the independent variables were related to the dependent variable. The relation which given by the independent variables was positive, which referred that the relation of both variables was in the same direction. Therefore, the relation was positive as long as the independent variables were increased, the dependent variable would also increase as well. In short, the better variable of input and process would affect to the higher achievement of K4 program in Bondowoso District.

Next, the main problems which could emerge during the implementation of K4 in Bondowoso district was the limited resource, from either the aspect of facility and infrastructure or funding that have been established by Puskesmas or Health Office of Bondowoso District. Moreover, the geographical aspect of Bondowoso District where was surrounded by hills was also the problem for the health officer or midwife to conduct socialization concerning to K4 achievement. Further, the signal trouble of difficulty which was experienced by midwife who was on duty in the suburbs of district, for instance Sub-district of Ijen, Tlogosari, Wringin, and Tamankrocok.

It was also suggested to the Health Office of Bondowoso District to conduct monitoring and evaluation to the implementation of K4 in suburbs of district, in order to get the problems of health officer including to the provision of facility and infrastructure which functioned to support the health officer to provide service. In addition, it also needed to some trainings in continuous by the officer of K4, especially in particular regions which did not comply the strategic plan target of Health Officer of Bondowoso District and Government of East Java.

Conclusions

Based on the result of data analysis, this research showed that the variable of input (man, money, and materials) and process (organizing, actuating, and controlling) affected positively and significantly to the achievement of K4 in Bondowoso District. However, based on the report of K4 achievement in Bondowoso District, it has not fulfilled yet to the strategic plan target in the district level or East Java Province. Although, all inputs and processes have obeyed to the standard operational of service according to Permenkes 97. This condition was not referred to bad capability of human resource to serve the clients according to the standard operational, but there were some external factors that could affect to K4 achievement, so it could not fulfill yet to the target of strategic plan. The external factor was geographical problem which was mostly found by the health officer or midwife in suburbs as well as mountain area in Bondowoso District. Moreover, the limited access of signal or network in some regions might also cause to the lateness on process of information reception and submission of activity report.

Abstract

Aim: This study aimed to quantify the effectiveness of bonded Calcium oxide (CaO)-nanoparticles as a demineralisation inhibitor.

Methodology: Twelve specimens of enamel were subjected to demineralisation-remineralisation cycles following the application of a bonding agent with or without CaO-nanoparticles. Calcium (Ca), and phosphorus (P) contents were evaluated utilising energy-dispersive X-ray spectroscopy (EDS). An independent sample t-test was performed to examine the statistical difference between CaO group and control one.

Results: The CaO group showed higher Ca wt% (67.59 ± 1.68) than the control group (65.22 ± 0.47) with significant difference (p = 0.017).

Conclusion: Application of bonding agent containing CaO-nanoparticles could enhance the enamel resistance against cariogenic challenge.

Keywords: Enamel, CaO-nanoparticles, bonding agent, recalcification.

Introduction

Enamel is the most mineralised and hardest tissue of the human body. Its hardness is mainly attributed to its composition. It is composed essentially of inorganic materials; approximately 95-98% of it is Ca and phosphate (PO₄³⁻) ions that form hydroxyapatite crystals. Organic materials are roughly made up 1-2% of enamel composition, containing enamel-specific protein named enamelin, which possesses a pronounced affinity for hydroxyapatite crystals binding. The reminder composition of enamel is made up of water, which accounts for about 4%. Enamel constituents are highly organised; millions of hydroxyapatite crystals are organised in thin, elongated structures (4-8 µm) called rods. The number of rods ranges from 5 million to 12 million. Each rod is surrounded by a sheath made up of protein[1-3]. The area between rods (inter-rod enamel) has the crystal of different orientation from that of enamel rods. Small spaces free of crystals exist between rods, called pores. They contribute to the permeability of enamel that allows diffusion and fluid movement to occur, but also varies the density and hardness of tooth, which can produce vulnerable sites which are more susceptible to demineralisation where pores enlarge and crystalline structure shrink in size[3,4].

Dental demineralisation and remineralisation are dynamic processes coexisted in a balance throughout life. When the demineralisation outweighs remineralisation, the mineral contents of the dental tissue dissolve, starting...
When the remineralisation outweighs demineralisation, the caries is reversed, and the demineralised tissue is remineralised\[^{5,6}\]. A dental filling has been applied to repair dental caries. Nevertheless, secondary caries frequently developed at the restoration tooth interface. Moreover, tooth restoration might need to be changed due to material deterioration, crack, or fracture. Therefore, it is a significant challenge for preventive and operative dentistry to induce the remineralisation of hypomineralised caries lesion. The remineralisation of demineralised dental tissue is the process of mineral restoration\[^{7}\]. Remineralising agents are available in many forms, such as fissure sealants, restorative materials, mouth rinses, chewing gums, and dentifrices\[^{8,9}\].

With the invasion of nanotechnology, some researchers have examined the application of nanoparticles in preventive and restorative dentistry. Recently, the application of nanotechnology in the science of dentistry has grabbed significant attention. Nanoparticles are materials with particles size ranging between 1 and 100 nm, possessing special physicochemical features and a wide range of uses encompassing pharmaceutical applications. The nanoparticles-based formulation for localised delivery in the oral cavity can be existing as aqueous suspensions, or it could be incorporated into the constituents of a gel or paste\[^{10-12}\].

Calcium is the most significant natural constituent of teeth. Thus, many calcium derivatives have been expressed great potentials to be applied in teeth related disorders due to their biocompatibility and biodegradability\[^{13}\]. Calcium, fluoride, and phosphorus ions play a vital role between remineralisation and demineralisation processes and subsequently modify the progression of dental caries\[^{14}\]. Adhesive systems containing calcium compound as calcium chloride or calcium phosphate were previously investigated. Shinkai et al. examine the effect of adding calcium chloride on microtensile bond strength, where an adverse effect was recorded\[^{15}\]. In another study, Shinkai added calcium phosphate to a bonding agent with a non-significant effect for the addition on the result\[^{16}\].

Calcium oxide is a significant inorganic material with a variety of employments across industrial\[^{17}\] and dental application\[^{18}\]. To date, no researches have been performed to study the synthetic CaO-nanoparticles as demineralisation inhibitor. Thus, the aim of this study was to investigate the effectiveness of bonding agent containing this nanoparticles preserve the surface mineral content against cariogenic challenge. The null hypothesis was: there would be no statistically significant effect for CaO-nanoparticles on the mineral contents of enamel.

### Materials and Method

**Calcium oxide-nanoparticles suspension preparation:** Calcium oxide nanoparticles were prepared according to a method described by Al-Shaibani et al.\[^{19}\]. CaO suspension was prepared by adding 10 ml of distal water to 50 mg of CaO-nanoparticles powder, and it was shacked very well prior to the using. A good mixing was achieved before using for the two suspensions.

**Artificial cariogenic solution and saliva preparations:** An artificial cariogenic agent of 4.6 pH, and a solution of artificial saliva containing remineralising agents were prepared according to the procedure described by Ou et al.\[^{20}\].

**Sample preparation:** Twelve enamel samples were prepared from anonymised impacted third molars to be used in this study. Ethical approval for this study was performed by the Ethical Committee of University of Kufa (reference number 7 in 05/03/2018) which was obtained according to the ethical standards and Declaration of Helsinki placed in the 1964 and its later amendments. Any specimens with crack, a sign of hypocalcification or defect were discarded.

All the crowns were sectioned coronally at the cemento-enamel junction. Each crown was positioned into moulds with the buccal surface facing down (base) and fixed in place with sticky wax to be mounted in an acrylic resin. After setting, the blocks were removed from the moulds, and each base was ground and polished to create a flat enamel surface. The selected specimens were randomly divided into two groups according to the received treatment:

**Control group:** The samples were treated with 37% phosphoric acid and after that were coated by bonding agent (Tetric N-Bond, Ivoclar Vivadent, Switzerland).

**CaO group:** The samples were treated with 37% phosphoric acid followed by a coating material composed of a combination of one drop from each of CaO suspension and Tetric-N bonding agent.
All the coating materials were cured by light cure device for 10 s, then subjected to demineralisation-remineralisation cycles. Each cycle involved sample immersion in the artificial cariogenic solution for 1 h, followed by immersion in the artificial saliva for 11 h. The two solutions were changed daily. Throughout the period, samples were at 37 °C under 100% relative humidity.

**SEM-EDS examination:** Post-treatment mineral contents of the enamel samples were measured as wt% of Ca and P. The samples were dehydrated with a series of ethanol concentrations: 50%, 75%, 90% and 100% respectively, for 20 minutes for each concentration, to remove any remnant of water.

Then, they were coated with 24 nm gold layer using Sputter Coater (Quorum technologies Ltd, Laughton, East Sussex, England). The elemental analysis was accomplished using SEM-EDS (Inspect S50, Netherland) at 12 kV accelerating voltage, 10.0 mm working distance and 5000x magnification. Four spectrums were taken for each sample, and then the average of the readings was calculated. During the elemental analysis, the incoming kV must be at least 2 times higher than any peak of a measured element [21]. The accelerating voltage in this study was 12 kV, which is larger than the energy of the electron shells of the measured elements.

**Statistical analysis:** Mean and standard deviations were calculated, and the data were checked for normal distribution by Shapiro-Wilks test. The effect of mineralising agents on the chemical composition of enamel (Ca%, and P%) was analysed by Independent Sample t-test using SPSS version 22.0 (IBM Corp., Armonk, US) at a confidence level of 95%, and \( p \leq 0.05 \).

### Results

The result of the data analysis obtained by EDS for two groups is summarised in Table 1. Mean and standard deviation for the enamel surface elemental analysis of experimental groups. A significant increase in Ca contents of CaO group compared to the control group was reported (\( P\)-value = 0.017). For CaO group, the relative content of P was lower than the control group. However, the difference was statistically non-significant (\( P\)-value = 0.129).

### Discussion

This study has quantitatively evaluated the remineralisation potential of CaO-nanoparticles on enamel surface subjected to cariogenic challenge. SEM-EDS was utilized to record the structural changes of enamel surface (Ca wt%, and P wt%). This methodology was similar to that used by previous studies [22, 23]. In the current experiment, the impacted third molars were used for the aim of standardisation and to avoid the effect of variation in the teeth chemical composition.

Remineralisation is a repair process for non-cavitated lesions. For the remineralisation enhancement, the increase of Ca concentration in the oral fluids would seem reasonable. Calcium containing compounds rather than phosphate were widely used as a remineralising agent like calcium silicate [24] and Calcium carbonate [25]. In fact, Ca considered as one of the key minerals for remineralisation process [26].

The present *in-vitro* study mainly demonstrated a remineralising potential of CaO-nanoparticles. A significant increase in the relative amount of surface Ca content as a result of the application of CaO-nanoparticles was reported in this study. These results were logical, and the rationale for that is CaO-nanoparticles possess Ca in its chemical composition. Mixing of CaO with water resulted in the production of calcium hydroxide [27], which was proved to be an effective remineralising agent [28]. It was stated that, in the presence of biological fluid, the calcium hydroxide permitting the development of biological apatite [24]. On the other hand, the use of a bonding agent may be an effective method to fill porous spaces in demineralised tissue and enhancing remineralisation by containing CaO-nanoparticles.
The Ca-rich media would enhance Ca enamel uptake, rise chance of remineralisation. The increase in Ca wt% in the CaO group reflect the incorporation of the Ca and regrowing of the hydroxyapatite crystals. It was reported that during the demineralisation process, the Ca loss preceding that of P \[29\]. Therefore, using of Ca-rich agent for the demineralisation suppression would be efficient. According to the present result, the applied null hypothesis was rejected.

One of the limitations in the current study is the expected differences in the mineral contents of the samples, which might have referred to differences in original contents. However, the selection of teeth of similar criteria with random allocation of the samples to groups makes sure these differences had a minimal effect.

**Conclusion**

Despite the limitations, and depending on the data obtained from the current study, we able to demonstrate that the CaO-nanoparticles could enhance enamel resistance to cariogenic attack.

Abstract

Introduction: Discipline is a benchmark to find out whether the role of a manager or leader as a whole can be implemented well or not.

Method: This research is a quantitative study supported by qualitative data with cross-sectional study design.

Results: The test with the chi-square test of personality and environmental factors obtained a p-value of 0.827 that Ha was rejected and H0 was accepted so that there was no influence between personality and environmental factors on the discipline of nurses in Barombong Public Health Center, Makassar.

Conclusion: There is no influence between personality and environmental factors on the discipline of nurses in the Makassar City Barombong Health Center. This research can be used as a reference material for learning about nurse discipline and is expected for health workers to be used as input for carrying out their duties.

Keywords: Discipline, Personality, Environment.

Introduction

World Health Organization (WHO), that in order to improve the performance of nurses both in the enforcement of discipline of nurses must be able to provide comfort and satisfaction to nurses as an appreciation for the performance they do. Based on medical record data obtained at the Makassar City Barombong Health Center, that the total number of nurses is 124 people(1,2).

Nurses as one of the important assets in the management of health facilities in hospitals and health centers have a very important role, other than as paramedics to treat patients, because of these very important tasks, nurses should have a high work discipline, for example about work discipline is associated with risks that may occur, for nurses who are not disciplined delays in handling patients (even in seconds) will greatly jeopardize the safety of patients’ lives(3).

Discipline is a matter of benchmarks to determine whether the role of a manager or leader as a whole can be implemented properly or not. Nursing is one of the professions in hospitals and dipuskesmas that plays an important role in the implementation of efforts to maintain the quality of health services in health centers and hospitals. Health services at puskesmas are a form of service provided to clients, by a multi-disciplinary team including the nursing team. The nursing team is a member of the health team that faces client health problems for 24 hours continuously(4).
Public health center has a role in efforts to improve the highest public health. In an effort to achieve the degree of public health, Public health center and hospitals organize affordable and quality health services for the community\(^5\). To improve services, one important factor that must be considered by hospitals and health centers is Human Resources (HR). Explain that the success of an institution is determined by two main factors, namely Human Resources or Labor and supporting infrastructure or work facilities. People who work or become members of an organization called personnel, employees, employees, workers, labor, and others\(^6,7\).

**Material and Method**

This study uses quantitative research method supported by qualitative data with a cross sectional or cross sectional research design, where the independent variable (the influencing variable) and the dependent variable (the affected variable) are measured and observed at the same time. The sample in this study amounted to 50 respondents. with cross sectional or cross sectional research design, using non-rundem sampling method with criteria determined by researchers.

**Findings:**
