**Discussion**

The results of the analysis of personality factors on the discipline of nurses in the Makassar City Barombong Health Center after being given a questionnaire showed a significant value of 0.827 > 0.05 which means that H\(_a\) was rejected and H\(_0\) was accepted. This shows that personality factors on discipline have no effect. An important factor in a person's personality is the value system adopted, the value system in this case is directly related to discipline. Values that uphold the discipline taught or instilled by parents, teachers, and communities are used as a frame of reference for the application of discipline in the workplace. The value system will be seen from one's attitude and attitude is expected to be reflected in behavior.

Research conducted shows that there is no meaningful relationship between motivation for working conditions and work discipline. That there is no meaningful relationship between work environment conditions and nurse performance. Other research
that is in line to conclude that there is no significant relationship between developing opportunities and work discipline. Thus it can be concluded that environmental factors have no influence on the discipline of nurses at the Makassar City Barombong Health Center (8, 9).

Efforts to instill discipline are basically instilling values in order to achieve the goals of the Puskesmas from within namely the morale or enthusiasm and awareness of the nurse of the importance of work discipline, discipline because of compliance with existing commitments, and compliance based on identification. The results of the analysis of environmental factors on nurse discipline at the Makassar City Barombong Health Center after being given a questionnaire showed a significant value of 0.827 > 0.05 which means that Ha was rejected and H0 was accepted. This shows that environmental factors on discipline had no effect.

This study is in line with research that analyzes the effect of work environment and work stress on employee performance with the conclusion that the positive influence of work environment with performance is rejected because a significant value of 0.102 is obtained. Results of analysis using chi-square obtained p value = 0.332 or p value > 0.05. Thus, H0 is accepted and Ha is rejected, so it can be concluded that there is no meaningful relationship between work environment and the performance of inpatients at Tugurejo Hospital Semarang (10).

This study is in line with the results that there is no relationship between education, work environment conditions and the quality of nursing services in the Emergency Room Installation of the Salewangan Maros Regional Hospital with p > 0.05, and there is a relationship between workload and the quality of nursing services in the Room of the Nursing Installation. Emergency Regional Hospital of Salewangan Maros with p = 0.003. There is a relationship between factors interpersonal relationships with the quality of nursing services in the Emergency Room Installation of the Salewangan Maros Regional Hospital with p = 0.004. Based on the results of this study it was concluded that the factors of work stress nurses with the quality of nursing services in the Emergency Room Installation of the Salewangan Maros Regional Hospital were workload factors and interpersonal relationships (11).

Contrary to the results of the study that the work environment has a positive but not significant effect on organizational commitment. Work discipline and work stress have a positive and significant effect on organizational commitment the work environment has a positive and significant effect directly on nurse performance without having to go through organizational commitment. Work discipline directly influences but not significantly to nurse performance, but indirectly work discipline has a positive and significant effect on nurse performance through organizational commitment. Thus it can be concluded that personality and environmental factors have no influence on the discipline of nurses in the Makassar City Barombong Health Center (12).

Conclusions

Based on research that has been done, it can be concluded that; there is no influence between personality and environmental factors on the discipline of nurses in the Makassar City Barombong Health Center. The results of this study can be used as a reference material for learning about the discipline of nurses for health workers so that this research input material to carry out their duties properly.

Conflict of Interest: There are no conflicts of interest between the authors.

Inhibition Activity of Lemongrass Extract (*Cymbopogon citratus*) to the Growth of Supragingiva Plaque Bacteria Colony

Wimardian, S.M.¹, Bargowo L.², Savitri I.J.²

¹Undergraduate Student of Dental Medicine Faculty, Universitas Airlangga, Surabaya-Indonesia, ²Researcher Departement of Periodontia Dentistry, Dental Medicine Faculty, Universitas Airlangga, Surabaya-Indonesia

Abstract

**Background:** Periodontal disease is multi-factor. It is caused by the interaction of microbes which accumulated into biofilms called plaques and increase the host’s inflammatory immune response. If plaque removal is not adequate, it causes gingivitis, and if it continues then it becomes a chronic infection and leads to attachment loss. The bacteria that colonize inside supragingival plaque can be inhibited with something that contains antibacterial, e.g. lemongrass (*Cymbopogon citratus*). Lemongrass contains many phytochemicals including alkaloids, flavonoids, tannins, and saponins which can be used as antibacterials.

**Objective:** The aim of this study is to determine the inhibitory power of citronella leaf extract against supragingival plaque bacterial activity.

**Method:** This study used extracts diluted with serial dilution method on BHIB media with concentration of 100%; 50%; 25%; 12.5%; 6.25%; 3.125%; 1.56%; 0.78% and bacteria are planted on MHA media. Then, bacterial colony was calculated.

**Results:** There are significant differences in the growth of supragingival plaque bacterial colonies in all concentrations.

**Conclusion:** Lemongrass leaf extract (*Cymbopogon citratus*) inhibits the growth of supragingival plaque bacterial colonies at a concentration ranging from 3,125%

**Keywords:** Supragingival plaque, antibacterial, *Cymbopogon citratus*, periodontitis.

Introduction

Based on 2007 Basic Health Research¹ the prevalence of the Indonesian population with dental and oral problems including periodontal disease was 23.4% and had increased to 25.9% in 2013. Periodontal diseases that are often found are gingivitis and periodontitis.²

Gingivitis is a condition of inflammation of the soft tissue that surrounds the teeth or gingiva. It can cause gingivitis if it is not well-treated and even can develop into periodontitis. Periodontitis is a dental connective tissue disease that causes progressive alveolar bone loss around the teeth and ultimately causes tooth loss.³

Periodontal disease is multi-factor, due to interactions between plaque, microbes, and hosts that encourage an increase in host’s inflammatory immune response.⁴ Dental plaque is a soft deposit in the form of a thin layer (biofilm) that attaches to the surface of the
tooth or other hard structures in the oral cavity. Plaques consist of microorganisms (bacteria) which number almost 70%, microorganisms (non-bacteria) such as microplasma, yeast, protozoa, viruses, leukocytes, macrophages and intracellular matrices.

Supragingival and subgingival plaques associated with teeth play a major role in calculus formation and carries root, whereas subgingival plaques are associated with tissues played a role in tissue destruction. Supragingival and subgingival plaques associated with teeth play a major role in calculus formation and carries root, whereas subgingival plaques are associated with tissues played a role in tissue destruction.

Efforts that can be made to prevent and control the establishment of dental plaques, including managing dietary habit, chemical actions against the bacteria and extracellular polysaccharides also doing a mechanical action in the form of clean up the oral and dental cavities of all the food scraps, bacterial and the metabolisms results.

At present, there are many studies using herbal ingredients as medicines, including in dentistry. One of the plants that can be used as an antimicrobial is lemongrass (Cymbopogon citratus). Lemongrass plants are annual herbaceous plants, originating from the Poaceae Tribe. Those are used as a generator of taste for food and are believed to also be used in traditional medicine. The chemical contents of lemongrass are essential oils, saponins, polyphenols, tannins, and flavonoids.

Based on previous research, it shows that the active compound content of citronella leaves has broad-spectrum antibacterial activity against gram-positive bacteria, gram-negative bacteria, and fungi. Therefore, the ability of lemongrass can be a basic consideration for researchers to make herbal mouthwash ingredients for there are no further studies reporting whether lemongrass leaf extract has the ability to inhibit supragingival plaque bacteria.

The aim of this study was to determine the inhibitory power of citronella leaf extract against supragingival plaque bacterial activity.

**Material and Method**

This type of research is a laboratory experiment with the design of The Post-Test Only control group design. This research was conducted in the Research Center Faculty of Dental Medicine, Airlangga University and Pharmacy Laboratory, Airlangga University, East Java.
After 24 hours, each tube is taken one by one and planted on Mueller Hinton Agar (MHA) media by strike move to check there is bacterial growth or not. Incubation again for 24 hours at 37°C. After the second incubation, we took 0.1 ml from the boundary tube between bacterial growths and the non-positive and negative control then planted on MHA media. After that, it was put into the incubator at 37°C for 24 hours. The number of bacterial colonies that grow on MHA media after the last incubation was calculated and the data analysis was done.

### Results

The results of this study can be seen from the number of supragingival plaque bacterial colonies growth.

**Table 1:** The number of supragingival plaque bacteria colonies given lemongrass extract (*Cymbopogon citratus*) at a concentration of 1.56%-100%

Based on the results of the study, it can be seen that there is no growth of supragingival plaque bacterial in groups of 100%; 50%; 25%; 12.5%, 6.25%, and 3.125%. The growth of supragingival plaque bacterial colonies was only seen at 1.56% concentration and increased the number of bacterial colonies at 0.78%.

**Statistical Analysis:** The measurement results are tabulated according to each group sample, followed by testing the normal distribution using the Shapiro-Wilk Test with Sig > 0.05. It can be concluded that the data are normally distributed, and the homogeneity testing using Levene’s Test with Sig. <0.05 can be concluded that the data is homogeneous. After that, statistical tests were carried out using One-Way Anova at the significance level of Sig. <0.05 and significant differences were obtained. It was continued by performing multiple comparisons using Post-hoc Tukey Anova which concluded that all groups had significant differences.

**Discussion**

Based on phytochemical tests and scientific research, it stated that extracts of lemongrass leaves contain several chemicals. These chemicals include alkaloids, flavonoids, and tannins that have biological activities such as antioxidants, antifungal, and antibacterial so that the extract of lemongrass leaves can inhibit bacterial growth and healing gingival inflammation.

The growth and proliferation of bacteria on media are influenced by various factors and environmental conditions, including temperature, pH, osmotic pressure, oxygen and chemicals present in the media. In this study, all the factors used in the growth, but only the chemicals in the extract of the lemongrass leaf were the
most appropriate in the growth of supragingiva plaque bacterial.

This research shows results in accordance with the research hypothesis that citronella extract (Cymbopogoncitrus) can inhibit the growth of supragingival plaque bacteria. It can be judged from the absence of growth of plaque bacterial colonies in the concentration groups of 100%, 50%, 25%, 12.5%, 6.35%, and 3.125%. However, the bacteria seen at a concentration of 0.78% showed a decrease in the colony from positive control and decreased the number of colonies again at a concentration of 1.56% before finally at a concentration of 3.125% there was no visible bacterial colony.

According to previous research, citronella leaf extract was effective against gram-positive bacteria (Staphylococcus aureus, Bacillus cereus, Bacillus subtilis) compared to gram-negative bacterial bacteria (Escherichia coli, Klebsiella Pneumoniae, Pseudomonas Auruginosa). This is because the active compounds of lemongrass leaves work together to kill pathogenic bacteria.

This research proves that the greater the concentration of citronella extract, the greater the antibacterial activity. This is in accordance with the opinion expressed by Pelczard and Chan (1988) that the higher the concentration of an antibacterial ingredient given, the greater the antibacterial activity.

The flavonoids contained in citronella extract have the most presentation compared to other active compounds, flavonoids can interfere with cell membrane permeability, so the pumping system Na+ and k+ cannot function resulting in retained sodium ions, fluid regulation is inhibited so that the volume in the cell increases and resulting in bacterial death. Saponin has the ability to interfere with surface tension on bacterial cell membranes, which makes the increase in permeability resulting in cell leakage and intracellular compounds will come out, and bacteria die. Alkaloids can cause cell membrane layers not to form intact so that cell leakage occurs and the release of intracellular compounds of bacteria that cause bacterial death. Tanin can reduce the work of endonuclease retention enzymes which results in RNA transcription that does not occur that will disrupt the permeability of bacterial cell membranes resulting in cell leakage and the release of intracellular compounds resulting in bacterial death.

**Conclusion**

Lemongrass leaf extract (Cymbopogoncitrus) effectively inhibited the growth of supragingival plaque bacterial colonies at a concentration ranging from 3.125%.

**Conflict of Interest:** There is no conflict of interest.

**Source of Funding:** This study is self-funded.

Knowledge Regarding COVID-19 Pandemic among Student Nurses: Online Cross-sectional Survey

Abirami P.,1 Suseelal T.,2 Jelin Elizabeth G.,3 Dr. C. Kanniammal3
1Professor, 2Asso. Prof., 3Asst. Prof. 4Dean, SRM College of Nursing, SRM College of Nursing

Abstract
COVID-19 pandemic it is a public health emergency declared by WHO and it is a major cause of concern for the healthcare profession. The present study is being conducted to assess the knowledge regarding COVID-19 Pandemic among student Nurses. A cross sectional survey by Using Online Google forms study was conducted. Non probability Convenient Sampling technique was used. The tool used for the study comprises of two sections. Section A comprises of demographic data and Section B comprises of structured questionnaire to assess the Knowledge regarding COVID-19 Pandemic among student Nurses which includes 25 questions. The data was collected and analysed by using descriptive and inferential statistics. A structured questionnaire comprised of 25 questions developed by investigators was administered to 213 student Nurses. Among the 213 student Nurses, majority 56.8% of them has adequate knowledge regarding the present global pandemic and 41.8% had moderately adequate knowledge. This study concludes that student Nurses adequate knowledge regarding COVID-19 pandemic.

Keywords: COVID-19 pandemic, Healthcare profession, Student Nurses.

Introduction
Coronaviruses are a large family of viruses that can cause illness ranging from the common cold to more severe diseases like Middle East Respiratory Syndrome (MERS) and Severe Acute Respiratory Syndrome (SARS). The 2019 novel coronavirus, called ‘SARS-CoV-2’ (previously referred to as 2019-nCoV), is a new strain that has not been identified in humans before. The disease that is caused by SARS-CoV-2 is called ‘COVID-19’.

On 31 December 2019, the World Health Organization (WHO) was informed of several cases of viral pneumonia of unknown cause detected in Wuhan City, China.

The outbreak has rapidly evolved, affecting other parts of China and many countries worldwide in Asia, Europe, North and South America, Australia and Africa. On 11 March 2020, WHO labelled the COVID-19 outbreak as a pandemic.

Typical symptoms of COVID-19 include fever, cough, difficulty breathing, muscle pain and tiredness. More serious cases can develop severe pneumonia, acute respiratory distress syndrome, sepsis and septic shock. Anosmia—loss of the sense of smell or sometimes the sense of taste – has also been reported as a symptom of COVID-19 infection.

Generally, older people and those with underlying conditions (such as hypertension, heart disorders, diabetes, liver disorders, and respiratory disease) are expected to be more at risk of developing severe symptoms.

The evidence from analyses of cases to date is that COVID-19 infection causes mild disease (i.e. non-pneumonia or mild pneumonia) in about 80% of cases and most cases recover; 14% have more severe disease and 6% experience critical illness.

COVID-19 is transmitted from human-to-human mainly via flu-like symptoms and respiratory droplets that people sneeze, cough, or exhale. These droplets land on objects and surfaces, and others can catch COVID-19 by touching these objects or surfaces, then touching their eyes, nose or mouth. People can also catch COVID-19
by breathing in droplets from a person with COVID-19 who coughs or exhales droplets.

The infectious period may begin 1–2 days before symptoms appear, but people are likely most infectious during the symptomatic period, even if symptoms are mild. The infectious period is estimated to last for 7–12 days in moderate cases and up to 2 weeks in severe cases.

The first case of COVID-19 in India, which originated from China, was reported on 30 January 2020. As of 15 June 2020, the Ministry of Health and Family Welfare (MoHFW) has confirmed a total of 332,424 cases, 169,798 recoveries (including 1 migration) and 9,520 deaths in the country. India currently has the largest number of confirmed cases in Asia, and has the fourth highest number of confirmed cases in the world with the number of total confirmed cases breaching the 100,000 mark on 19 May and 200,000 on 3 June. India’s case fatality rate is relatively lower at 2.80%, against the global 6.13%, as of 3 June. Six cities account for around half of all reported cases in the country—Mumbai, Delhi, Ahmedabad, Chennai, Pune and Kolkata. As of 24 May 2020, Lakshadweep is the only region which has not reported a case. On June 10, India’s recoveries exceeded active cases for the first time reducing 49% of total infections.

In response to this serious situation, the World Health Organization (WHO) declared it a public health emergency of international concern on January 30 and called for collaborative efforts of all countries to prevent the rapid spread of COVID-19.

Maharashtra and Tamil Nadu, has been seriously hit by the COVID-19 epidemic. Some unprecedented measures have been adopted to control the COVID-19 transmission all over India including the suspension of public transportation, the closing of public spaces, close management of communities, and isolation and care for infected people and suspected cases. Public were advised to just stay at home to avoid contacting with others.

The battle against COVID-19 is still continuing in India. To guarantee the final success, people’s adherence to these control measures are essential, which is largely affected by their knowledge, towards COVID-19 in accordance with KAP theory.

As with SARS and MERS, when dealing with patients who may have COVID-19, health professionals should follow airborne precautions and wear respiratory masks (N95 or higher) during intubation and when entering a negative pressure room. As a Health Care professionals and the Future Nurses are responsible to update the knowledge on COVID 19 pandemic so this study aims to Investigate regarding Knowledge on COVID 19 pandemic among student Nurses at SRM college of Nursing.

Materials and Method

A quantitative approach was utilised to achieve the objectives of this study. Non experimental. Descriptive research design was adopted. Sample size was 213 Student Nurses. Based on the Non probability convenient sampling technique, inclusion and exclusion criteria samples were selected. The study variable was Knowledge on COVID-19 Pandemic.

Participants: This cross-sectional survey was conducted from March to April among Student Nurses the week immediately after the lockdown in India. Because it was not feasible to do a direct structured Interview method during this special period, we decided to collect the data online through Google forms from the Student Nurses as they are the Future Nurses. This Google form contained a brief Introduction on the background, objective, procedures, voluntary nature of participation, declarations of anonymity and confidentiality, and notes for filling in the questionnaire, and agreed to participate in the study were instructed to complete the questionnaire via clicking the link by the student Nurses. After confirmation of the question, the participant was directed to complete the self-report questionnaire. Totally 213 student Nurses responded to the Questionnaire.

Measures: The questionnaire consisted of two parts: demographics and Structured Questionnaire to assess the Knowledge on COVID-19 pandemic. Demographic variables included age, gender, marital status, level of education, Type of Family, Family History of Covid-19, Source of information regarding Covid-19, Dietary Pattern and place of current residence. According to guidelines for the COVID-19 by the World Health Organisation, a knowledge questionnaire was developed by the authors. The questionnaire had 25 questions Overview, clinical presentations, transmission routes, prevention and control of COVID-19. These questions were created as Multiple Choice Question Method, a correct answer was assigned 1 point and an
incorrect/unknown answer was assigned 0 points. The total knowledge score ranged from 0 to 25. The Scoring Interpretation were 0 to 10 (Inadequate Knowledge), 11 to 20 (Moderately Adequate Knowledge), 21 to 30 (adequate Knowledge) The Cronbach’s alpha coefficient of the knowledge questionnaire was 0.75 in our sample, indicating acceptable internal consistency.

**Statistical Analysis:** The information collected from the study participants was scored and tabulated. The data were entered into the master coding sheet and saved in Microsoft Excel. Statistical analysis was conducted using Statistical Package for Social Sciences-16. Mean, percentage, and standard deviation were used to explain the demographic variables, and the Level of Knowledge on COVID 19 Pandemic among Student Nurses and Chi Square test to analyse the Knowledge on COVID 19 Pandemic among Student Nurses with their Demographic Variables.

**Discussion**

COVID-19 is a relatively new virus that has had devastating effects within the short time since it was first detected in December 2019. To date, there has been limited published data on knowledge regarding COVID 19 Pandemic. In this study predominantly we found an overall correct rate of 56.8% on the knowledge questionnaire, indicating that most respondents are knowledgeable about COVID-19. The finding of a high correct rate of COVID-19 knowledge among student nurses was unexpected, because this epidemiological survey was conducted during the very early stage of the epidemic. Because of the serious situation of the epidemic and the overwhelming news reports on this public health emergency, the student nurses would actively learn knowledge of this infectious disease from various channels of information. The p values corresponding to the demographic variable “Gender and knowledge level of COVID-19” and “Source of information regarding Covid-19 and Knowledge level of COVID-19”. The significant positive association between social Media and COVID-19 knowledge scores supports this speculation.

Similarly, the p value corresponding to the demographic variable “residential state” is less than 0.05 and is significant at 5% level hence we can say that there is significant association between “residential state and knowledge level of COVID-19”.

All other p values are not significant at 5% level since they are not less than 0.05 hence we can say that there is no significant association between “Age, Marital Status, Level of education, Types of family, Residence, Family History of Covid-19 and Dietary pattern” and “Knowledge level regarding COVID-19”.

The present study was able to provide a comprehensive examination of the knowledge toward COVID-19. The findings suggest that student Nurses have an acceptable level of knowledge on COVID-19 and are generally positive in their outlook on overcoming the pandemic. Even so, consistent messaging from the government and/or health authorities are key to aid their knowledge and understanding of COVID-19. Additionally, to update the Knowledge webinar on COVID 19 pandemic is conducted Continuously to improve the knowledge because the fact that Nurses are at risk of infection in the epidemic chain is a critical issue because Nurses help in controlling the outbreak.

**Acknowledgement:** The author acknowledges Dr. C. Kanniammal Dean, SRM College of Nursing for constant guidance. We would like to thank study participants for their constant support.

**Conflict of Interest:** Dr. Abirami P., Dr Suseelal T., Mrs. Jelin Elizebath G. and Dr. C. Kanniammal declares that no conflict of interest in addition, this study was not funded.

**Statement of Human and Animal Rights:** All procedures followed were in accordance with the ethical standards of the responsible committee on human experimentation (institutional and national) and with the Helsinki Declaration of 1975, as revised in 2008

**Statement of Informed Consent:** Informed consent was obtained from all the study participants for being included in the study.

Salivary Levels of Interleukin-6, Interleukin-8 and Tumor Necrosis Factor-alpha in Smokers Aged 35-46 Years with Dental Caries Disease

Bayan Jebur Hussein1, Hawraa Noori Atallah2, Najlaa Abdulameer Ali AL-Dahhan3

1Lecturer, Department of Oral Pathology, College of Dentistry, University of Kufa, Al-Najaf, Iraq. 2Lecturer, Department of Oral and Maxillofacial Surgery, College of Dentistry, University of Kufa, Al-Najaf, Iraq. 3Assist. Prof., Department of Basic Science, College of Dentistry, University of Kufa, Al-Najaf, Iraq

Abstract

Introduction: Dental caries is one of the most common infectious diseases prevalent in the oral cavity, and it is an inflammatory disease with a multi-factor etiology. IL-6, IL-8, and TNF-α are two types of cytokines that are major mediators of acute inflammation, and are necessary for the development of specific immune responses.

Objective: The present study aimed to assess the level of pro-inflammatory cytokines (IL-6, IL-8, and TNF-α) in the saliva of smokers with dental caries and the control (non-smokers) according to different age, BMI, and sex.

Materials and Method: Whole saliva from 32 smokers aged 35-46 years with dental caries and 16 healthy subjects, to measure IL-6, IL-8, and TNF-α levels by enzyme immunoassay (ELISA).

Results: The mean BMI, age, and sex between the experimental group and the control group were similar, were not statistically significant (p=0.466, p=0.240, p=0.455), respectively while, there were a significant difference in CRP between the two groups (p=0.037). Concentrations of salivary IL-6, IL-8 and TNF-α were not affected by periodontal health. No statistically significant difference in periodontal health, assessed by CPITN, were observed between the groups (p=0.413). Salivary levels of IL-6 and IL-8 were significantly higher in smokers with dental caries compared with control (p<0.05). Salivary levels of IL-6 and IL-8 were increased significantly in smokers with dental caries compared with control (p<0.05). No significant differences in salivary TNF-α in dental caries patients compared to control (p=0.063). The correlation between TNF-α, CRP, age, sex, and BMI with IL-8 were positive and statistically significant (p=0.01, p=0.036, p=0.009, p=0.007, and p=0.005), respectively. There was no significant correlation between IL-6 and TNF-α cytokines and other parameters, except for a positive association with CRP levels (p=0.006, p=0.043), respectively.

Conclusions: These data indicate links between production of tumor necrosis factor-alpha (TNF-α), interleukin-6 (IL-6), and Interleukin-8 (IL-8) in smokers’ saliva and dental caries disease. Also, the existence of a statistically significant positive correlation between TNF-α, age, gender, and BMI with IL-8.

Keywords: Dental caries, saliva, inflammation, interleukin-6, interleukin-8, tumour necrosis factor.
phase, and belongs to the pentraxin family. Its levels are elevated in cases of inflammation, injury or infection(3).

Cytokines play a major role in modulating the immune response, and are either proinflammatory (IL-1, IL-8, IL-6, TNF-α and TGF-β), or antiinflammatory (IL-2, IL-4, IL-10, IL-12, and IFN-γ). The nucleus of any cell has the ability to secrete cytokines, but its main source is macrophages and helper T cells(4). Among the cytokines, interleukins have a crucial function and are implicated in oral cancer.

IL-6 is synthesized in acute inflammatory responses that contribute to host defense. It is involved in the processes of controlling the immune response, inflammation, hematopoiesis, and tumorigenesis. Elevated IL-6 levels may lead to disturbances in immune responses. IL-6 is involved in the regulation of tracking of lymphocytes through the lymph node after developmental stimulation(5). Gabayn found that IL-6 contributes to the induction of the transition from acute to chronic inflammation through secretion of the monocyte chemoattractant protein-1 (MCP-1)(6).

IL-8 is an inflammatory stimulant cytokine, and is considered the prototype molecule in the chemokine class. IL-8 also plays an important role in the acute inflammatory response and persists for a relatively long time at the site of inflammation(3). IL-8 release from macrophages and neutrophils is activated by NF-κB. Its expression is modified by other different stimuli, such as hypoxia, inflammation or steroid hormones. IL-8 binds to CRCX-1 and CRCX-2 receptors that are identified on both inflammatory cells from tumor-associated infiltrate and tumor cells(7).

TNF-α is a protein with a role in host defense and in warning responses. It promotes cell proliferation in the white blood cell molecules adhere to endothelial cells and activate phagocytic killing mechanisms. Besides cytostatic and cytotoxic affecting neoplastic cells(8,9), TNF-α involves nuclear factor kappa B (NF-κB), caspase cascades, transcription factors and activating protein-1 (AP-1), and participation in signal regulation, inflammation, cell growth, and death(3). StJohn et al. indicated that IL-8, IL-6, and TNF-α were proven to be overexpressed in OSCC(10). The present study aimed to evaluate the levels of pro-inflammatory cytokines (IL-6, IL-8, and TNF-α) in the saliva of smokers with dental caries aged between 35-46 years and their relationship with BMI, age, sex and their correlation with each other.

Materials and Method

Study Population: Forty-eight subjects aged ranged from 35-46 years, were divided into two groups, the first group included 16 healthy and non-smoking (10 males and 6 females) as controls, while the second group included 32 smokers (18 males and 14 females) with dental caries enrolled at the Clinical Center at the College of Dentistry at Basra University. From January 2019 to September 2019, they were diagnosed under our supervision. Clinical evaluation procedures e.g. examination of teeth, periodontal, oral mucosal status, assessment of malocclusion and collection of saliva samples. The body mass index (BMI) of each individual was calculated in a standard manner. Informed consent was obtained from each participant prior to sample collection.

Salivary Samples Collection: Saliva was collected from patient and controls group by a standard method. After the participants were asked to refrain from eating, chewing and drinking at least one hour before the collection. Saliva samples were collected between 09:00-11:00 AM. Saliva was collected for 10 min in titration tubes by drooling method(11). The saliva samples were homogenized and clarified by centrifugation at 10000 g for 15 min at 4 °C. All samples were stored at -70 °C for analysis.

Detection of Salivary Levels of IL-6, IL-8 and TNF-α: After collecting salivary samples from non-smoking (healthy subjects), and smoking dental caries patients, specific cytokines IL-6, IL-8, TNF-α and C-reactive protein (CRP) were measured by human IL-6, IL-8, TNF-α and CRP ELISA kit (Elabscience, Korea). In order to assess the impact of periodontal disease on levels of salivary cytokines, Community Periodontal Index of Treatment Needs was measured in each patient after the collection of saliva(12). Patients with chronic inflammatory diseases i.e., (psoriasis, arthritis, Sjoegren’s syndrome, inflammatory bowel disease) that may affect levels of salivary cytokines were excluded.

Statistical Analysis: SPSS software 22 was used for statistically analysis. The data are expressed as mean±SD. Significance of the difference between the mean value of the measured parameters between groups were evaluated by Student’s t-test. And chi-square. Correlation was indicated by Pearson correlation tests and P<0.05 is considered significant.
Result

The mean BMI, age, and sex between the experimental group and the control group were similar, were not statistically significant (p=0.466, p=0.240, p=0.455), respectively while, there were a significant difference in CRP between the two groups (p=0.037). Concentrations of salivary IL-6, IL-8 and TNF-α were not affected by periodontal health. No statistically significant difference in periodontal health, assessed by CPITN, were observed between the groups (p=0.413)[Table 1]. Salivary levels of IL-6 and IL-8 were significantly higher in smokers with dental caries compared with control (p<0.05). No significant differences in salivary TNF-α in dental caries patients compared to control (p=0.063)[Table 2]. The correlation between TNF-α, CRP, age, sex, and BMI with IL-8 were positive and statistically significant (p=0.01, p=0.036, p=0.009, p=0.007, and p=0.005), respectively. There was no significant correlation between IL-6 and TNF-α cytokines and other parameters, except for a positive association with CRP levels (p=0.006, p=0.043), respectively [Tab 3].

Discussion

Cytokines regulate many aspects of the immune response, therefore, along with other factors, they will be useful tools for diagnosing and monitoring the oral cavity, and saliva can be used as diagnostic material to measure biomarkers released during disease onset and progression. IL-6, IL-8, and TNF-α immune cell products play an important role in oral mucosa diseases, but the exact role of cytokines in the etiology of dental caries is not well known. In the innate response, the
molecular phenotypes associated with oral pathogens bind to the receptors of the host cells, including dendritic cells, which then activate the inflammatory response by releasing the active of pro-inflammatory cytokines, i.e., IL-1β, IL-6, IL-8 and TNF-α(3). Initially, gingivitis may only develop, and if the immune response is successful, periodontitis will resolve; however, if the infection persists and more bacteria spread occurs, intensification of the warning response can damage gum tissue in infected subjects(13). The mean BMI, age, and sex between the experimental group and the control group were similar, not were statistically significant (p=0.466, p=0.240, p=0.455), respectively. While, there was a significant difference in CRP between the two groups (p<0.037). Concentrations of salivary IL-6, IL-8 and TNF-α were not affected by periodontal health. No statistically significant difference in periodontal health, assessed by CPITN, were observed between the groups (p=0.413) [Table 1]. These results are consistent with other studies(1, 14). One study indicated that elevated CRP levels were a risk factor for developing one type of cancer. High levels of CRP before surgery are an unwanted diagnostic indicator(15). Yadav and Prakash indicated that the pattern of dental caries varies with BMI, sex, age, race, food habits, socio economic status, geographical location and oral hygiene practices(16). There is a correlation between CRP levels and disease prognosis. In the study by Park et al., an increased CRP/albumin ratio was correlated with prolonged disease and decreased survival rate(17). Blatt et al. noted that CRP, ferritin, and hemoglobin can be used as biomarkers in diagnosis and disease progression(18). The same idea is supported by Tai et al. in patients with oral squamous cell carcinoma (OSCC), which they showed a positive association between high CRP levels and oral cancer, and revealed that CRP level was associated with invasion of localized lymph nodes(19). Relationship between cancer and inflammation is bidirectional. The tumor triggers an inflammatory response by increasing serum levels of CRP on the one hand, and chronic inflammation is involved in the development of a malignant process, on the other hand(3). On the other hand, Grimm et al. identified high levels of CRP, high number of total leukocytes, neutrophils, monocytes; and a low number of lymphocytes is correlate with a low survival rate in oral cancer(20). Salivary levels of IL-6 and IL-8 were significantly higher in smokers with dental caries compared with control (p<0.05) [Table 2]. The levels of salivary cytokines are elevated as a result of disturbances in the oral cavity, and these results are in line with previous studies(13, 14). Also, these results were confirmed by the Kurtis et al. where they found that high levels of IL-6 in dental caries patients lead to fewer broblasts and osteoblasts. It also supports demineralization of teeth and the development of cavities, especially in smokers(21). IL-8 play an important role in the acute inflammatory response and persists for a relatively long time at the site of inflammation(3). Garrido et al. showed significantly higher levels of CRP and IL-6 in subjects diagnosed with apical periodontitis compared to normal healthy teeth(22). Tumor can trigger an inflammatory response, triggering the release the cytokines i.e., IL-1β and IL-6. Márton et al. indicated that the specificity and sensitivity of IL-6 protein were less favorable than IL-6 mRNA, and the expression of salivary IL-6 mRNA was significantly associated with dental status and age(23). On the other hand, Gabay reported that interleukin-6, in addition to the presence of other cofactors, causes resorption of bones and stimulates synthesis of chemocines(6). Saheb Jamee et al. found significantly higher concentrations of IL-6 in patients with OSCC and in the saliva of chronic periodontitis compared to IL-8 and TNF-α levels(24). Gornowicz et al. reported significantly elevated salivary IL-6 levels in children with dental caries. Consequently, the researchers speculated that the dysfunction of the triangle oral mucosa, immune cells and saliva lead to the emergence of oral mucosa diseases i.e., periodontitis, leukoplakia, oral lichen planus and oral cancer(1). Our results differ from the Teles et al., on the one hand, as they reported lower levels of IL-8 and elevated levels of TNF-α(25). On the other hand, it is compatible, as they reported elevated levels of IL-6 in a healthy periodontally group compared with chronic periodontitis. IL-6 receptor stimulates the activation of signal transducers, Janus kinases (JAK), and activators of transcription (STATs), which then stimulate pathways that include mitogen-activated protein kinase (MAPK), which in turn supports cancer development. This may explain the reasons for the elevated levels of IL-6 in the saliva of smokers with dental caries and OSCC patients. Manifestations of IL-6 have been detected in tumor cells and tumor-infiltrating leukocytes, and this indicates the presence of a paracrine loop of stimulation. Colak et al., show that children who are frequently exposed to sugary fluids, formula milk, breast milk, fruit juices, etc. from sweet liquids for long periods are at risk of early childhood caries (ECC)(26). Consequently, Menon et al. concluded that the problems that children face especially ECC are not just pain and infection, but they also affect communication, speech,
eating, dietary nutrition, playing, etc\(^{27}\). No significant differences in salivary TNF-\(\alpha\) in dental caries patients compared to control \((p=0.063)\) [Table 2]. These results are consistent with other studies \((7, 28)\). Contrary to our findings, Kurtis et al. found that high levels of TNF-\(\alpha\) in the saliva of dental caries patients lead to fewer fibroblasts and osteoblasts, and aid in demineralization of teeth and the development or deepening of cavities, especially in smokers\(^{21}\). One study showed that TNF-\(\alpha\), which is produced by osteoclasts, is an important factor that regulates the spacing of these cells as well as is involved in the processes of resorption\(^{29}\). Ghallab et al., found a lower elevation of TNF-\(\alpha\) in erosive oral lichen planus (OLP) patients after treatment\(^{30}\). Mcleachlan et al., conclude that pro-inflammatory cytokine concentrations are also elevated within both gingival tissues and serum of persons with periodontal inflammation\(^{31}\). The DEATH protein bound to TNF-\(\alpha\) is encoded by the TRADD gene, which recruits TNF-\(\alpha\) receptor-associated factor-2, a protein is encoded by the TRAF2 gene and signaling molecule RIP which activates and stimulates the Nuclear Factor Kappa-light-chainenhancer of activated B cells (NF-\(\kappa\)B) pathway, and is involved in cell survival and proliferation and anti-apoptotic agents, and this explains why TNF-\(\alpha\) levels did not change in patients’ saliva. The correlation between TNF-\(\alpha\), CRP, age, sex, and BMI with IL-8 were positive and statistically significant \((p=0.01, p=0.036, p=0.009, p=0.007, and p=0.005)\), respectively [Tab 3]. These results have been confirmed by other studies\(^{1, 13}\). IL-8 is released by neutrophils and macrophages in response to various stimuli i.e., steroids, inflammatory signals, chemical environment, and environmental stresses that activate the nuclear factor-kappa-B(NF-\(\kappa\)B) pathway that activates the expression production of IL-8. IL-8 and TNF-\(\alpha\) play an important role in immunity of the oral cavity. It is possible that elevated levels of IL-8 lead to stimulation of TNF-\(\alpha\). These results have been supported by previous studies \(^{1, 13}\). IL-8 levels may change with lifestyle, ethnic differences, geographic distribution, genetic differences, and individual habits. Elevated IL-8 levels may be found in gingivitis and periodontitis. However, none of these cases can raise the levels to the extent seen in oral cancer\(^{7, 32}\). Punyani and Sathawane found that increased levels of IL-8 confirmed its role in angiogenesis and progression\(^{32}\). Therefore, large changes in IL-8 levels provide us with great potential for use as a single salivary biomarker. This could open new horizons for treatment plans from targeted leukotriene therapy\(^{31}\).

There were no significant correlation between IL-6 and TNF-\(\alpha\) cytokines and other parameters, except for a positive association with CRP levels \((p=0.006, p=0.043)\), respectively [Tab 3]. This conclusion was confirmed by a previous report\(^{39}\). Sugawara indicated that TNF-\(\alpha\) is an effective cellular compound and its production leads to oral diseases\(^{32}\). This means that the salivary level of cytokines may be increased as a result of disorders in the oral cavity. These results are consistent with other studies\(^{7, 33}\). Barnes et al., reported that IL-6 can be generated not only by activated macrophages/monocytes, but also by fibroblasts and activated endothelial cells in inflamed tissue, while TNF-\(\alpha\) is produced predominantly by activated macrophages at the site of infection/inflammation, and also by T cells. In turn, IL-6 production can lead to the inhibition of TNF-\(\alpha\) expression\(^{36}\). This finding supports our current results. On the other hand, Li et al. indicated that up-regulation of MUC1 expression in oral epithelial cells result from Porphyromonas gingivalis infection or increases in pro-inflammatory cytokines such as IL-1\(\beta\), IL-6, and TNF-\(\alpha\)\(^{37}\). Contrary to our results, Fine et al., reported that IL-6 can be generated not only by activated macrophages/monocytes, but also by fibroblasts and activated endothelial cells in inflamed tissue, while TNF-\(\alpha\) is known to be produced predominantly by activated macrophages at the site of infection/inflammation, and also by T cells\(^{36}\). Several studies have indicated the pivotal role of chronic inflammation in carcinogenesis by modifying inflammatory cells and cytokine production\(^{3, 37}\). This explains why cytokine levels are high in patients, and thus support our current findings. Also, the result of this study confirmed by Barnes et al., who stated that IL-6 can be generated not only by activated macrophages/monocytes, but also by fibroblasts and activated endothelial cells in inflamed tissue, while TNF-\(\alpha\) is known to be produced predominantly by activated macrophages at the site of infection/inflammation, and also by T cells\(^{36}\). In turn, IL-6 production can lead to the inhibition of TNF-\(\alpha\) expression\(^{39}\). Saheb Jamee et al. found significantly higher concentrations of IL-6 in patients with OSCC and in the saliva of chronic periodontitis compared to cytokine levels (IL-6, 8, and TNF-\(\alpha\))\(^{24}\). Data from this study indicate links between the production of inflammatory, and immunoregulatory cytokines and chemokines (IL-6, IL-8 and TNF-\(\alpha\)), and dental caries in smokers. Therefore these parameters can be used as biomarkers to indicate disease severity and progression.

**Conclusions**

The results indicate links between production of IL-6 and IL-8 in smokers’ saliva and dental caries.
Excretion of specific cytokines in patients’ saliva are useful tools for diagnosing and monitoring dental caries disease. Therefore, can be used saliva as a noninvasive diagnostic fluid to measure biomarkers released during disease onset and progression.

**Acknowledgment.** The authors are grateful to all the patients and healthy subjects who participated in this study. Also, the authors are grateful to the faculty in Preventive Dentistry, Department of Pedodontics, and Department of Biochemistry for their valuable support towards this clinical research.

Pandemic Corona Virus and Policy of Forest Resources Conservation

Aries Isnandar¹, Absori², Harun³, Natangsa Surbakti⁴

¹Doctoral Student of Faculty of Law, Universitas Muhammadiyah Surakarta, ²Professor, Universitas Muhammadiyah Surakarta, ³Professor of Law, Universitas Muhammadiyah Surakarta, ⁴Lecturer of Faculty of Law, Universitas Muhammadiyah Surakarta

Abstract

These brief highlights some of the identified and perceived impacts of the COVID-19 crisis on development aspects interconnected with the forest sector, with a particular emphasis on the impacts on the production and trade of forest workers. It proposes a series of recommendations as a basis for policy development in the aftermath of the crisis, and highlights potential opportunities to leverage the progress achieved so far, to ensure that decades of advances are not reversed. Forest products, including non-wood forest products continue to support livelihoods throughout the crisis while delivering essential items, such as hygiene and sanitary products, biomass for heating, ethanol forsanitizer, respirator paper and packaging for parcels. Forest preservation is currently a concern of many countries, including Indonesia, Basic policies are needed so that the problem of forest destruction can be overcome. Furthermore, in order to achieve the objectives of forestry policy, there are several conditions after pandemic Covid 19 outbreaks, one of which is that there must be an active involvement in conserving forest resources.

Keywords: Policy, forest preservation, Covid 19, pandemic.

Introduction

Pandemics are hazards related to large-scale outbreaks of infectious diseases that can greatly increase morbidity and mortality over a wide geographic area and cause significant economic, social, and political disruption. The consequences of a pandemic, affecting people on a worldwide scale, with expected long-term impacts and consequences on the coupled socio-ecological systems, can be described as a disaster. On 13 March 2020, the World Health Organization (WHO) declared the novel coronavirus disease (COVID-19) a pandemic pushing humankind into an ongoing global crisis, which is unique in the recent history, at least by its spatial extent, rapid onset and its complexity of consequences.¹

Based on observations conducted by the researcher, in the conservation area of natural resources in Wonogiri, located in Gendol hill forest nature reserve in Dali Village, Geneng Village and Conto Village, Bulukerto Sub-District, Wonogiri Regency, which is located exactly at the foothill, there are 650 families in these villages that are very dependent on the existence of clean water from the Gendol Hill river, as said by Sadiman in a conversation (December 2017). In other areas, approximately 20 km to the south-west side, there is Donoloyo teak forest, Watusumo Village, Slogohimo Sub-District, Wonogiri Regency, which covers 8300 m² area. According to the provision, that area must be preserved and maintained in harmony and balance, taking into account the preservation of the ecosystem, said Totok a Forest Ranger, Person in Charge of BKSDA Wonogiri (May 2017).

Ministerial Regulation of Environment and Forestry of the Republic of Indonesia Number P.6/Menhk/ Setjen/ot 1.0/1/2016 concerning Organization and Work Procedure of Forest Area Stabilization Center
and Law No. 5 of 1990 concerning Conservation of Biological Natural Resources and their Ecosystems are the provisions that provide a basis for ideas in general which has to be adjusted with the actual condition, said Hidayat, W (May 2018), Secretary of the Wonogiri Environmental Office.

Sadiman said that “if I have helped the community including the government, does the government intend to pay attention to my wishes?” Sadiman himself wants the area to become a tourism area that will later be monitored and maintained. This also includes sedimentation condition that occurs in Gajah Mungkur Wonogiri Reservoir and not-maintained Donoloyo teak forest, Watusumo Village, Slogohimo Sub-District, Wonogiri Regency, which until now require attention from the government, especially concrete maintenance follow-up plans, which of course must be preceded by development-oriented policies, which are mainly based on local wisdom, as stated by Bintoro, T, an activist and an observer of forestry (October 2019).

Besides that, the researcher tried to meet with policy makers who in this case were responsible informants namely Mr. Edi Santoso (Deputy Regent of Wonogiri) said that there are 2 forms of conservation policy currently running after the pandemic in Wonogiri namely forests within the area and forests outside the area. If we talk about forests in the area I can say one hundred percent has nothing to do with the Wonogiri Regency government policy, because the management of conservation issues, and production management, etc. are all the authority or authority of Perhutani. For those outside the area or community forest (forest on community-owned land) the Wonogiri Regency government has the authority to determine policies. Teak Forest Donoloyo including Alas Gendol is fully the authority of Perhutani (forest within the area). The regional government of Wonogiri Regency in accordance with the regional autonomy law number 23 of 2014 in its policy does not include forests in the area which means that even though its geographical location is still within the Wonogiri regency area, the regional government of Wonogiri Regency is not entitled to forest policies in the area.

Based on the aforementioned description, the Policy of Forest Resources Conservation after the Covid 19 outbreak needs to be reviewed in order to comprehensively understand the overview of conservation towards forest resources in Wonogiri Regency area.

Method

This research uses normative and empirical research method. As a result, the observations conducted are in accordance with the required needs.

Results and Discussion

a. Definition of Policy: The term policy as referred herein is equated with the word policy which is distinguished from policy (wisdom) and policy (virtue). Winarno and Wahab agree that the term ‘policy’ is often used interchangeably with other terms such as goals, programs and grand design. For policymakers and people engaged in the field of policy, the use of these terms may be confusing.

Basically, there are many restrictions or definitions regarding the meaning of policy. Each of these definitions gives different emphasis. This difference arises because every expert has different backgrounds.

A writer said that policy is the principle or way of acting chosen to direct decision making. According to Ealau and Kenneth Prewitt quoted by Charles O. Jones, policy is a standing decision characterized by behavioral consistency and repetitiveness on the part of both those who make it and those who abide it. The United Nations (UN) states that a definition of policy is a guide for action. This guideline can be very simple or complex, general or specific, broad or narrow, vague or clear, loose or detailed, qualitative or quantitative, public or private. Policy with this definition may be in the form of a declaration about a program, regarding certain activities or plans.

Based on the discussion above, we intend to formulate a definition of public policy as a response to a political system, through government power, towards the problems of society. In other words, public policy is the government’s decision to solve public problems. Such decision can implied actions or not actions, the word “public” can mean both community and company, it can also mean the state-political system and administration. Meanwhile, “government” is a person or group of people who are mandated by all members of a political system to make arrangements for the entire system. It can be RT, RW, village, regency, province, State, between countries (ASEAN, EU) and the world (WTO, UN).
b. **Power manifestation of community influence in its care for forest conservation and resources:**

In the first research, based on observations and involved directly into the field conducted by the writer by using the methodology of sociological approach about the forestry conservation after pandemic Covid 19 outbreak, the overview of resources conservation that have been carried out apparently is not as expected.

The second research was located in Donoloyo teak forest, Watusumo Village, Slogohimo Sub-District, Wonogiri Regency, which covers an area of 8300 m². According to the provision, that area must be preserved and maintained in harmony and balance, taking into account the sustainability of the ecosystem. The forest is historically a forest that is located on the banks of the upper reaches of Bengawan Solo.

The covid 19 outbreak benefits the conservation and natural resources agency (*Balai Konservasi dan Sumber Daya Alam*, BKSDA) and until now, the forest has been preserved since people will not dare to take the slightest element related to the teak trees because of the pandemic. From the description above, it turns out that the forest ranger as well as the head of BKSDA can take advantage of this situation so that the forest rangers can internally make a policy that can be used in the context of awareness to the surrounding community for the maintenance of the Conservation and Natural Resources Agency (BKSDA).

c. **Bottom up policy model before the pandemic outbreak:** Policy implementation is an activity that can be seen after the issuance of valid direction from a policy that includes efforts to manage inputs in order to produce outputs or outcomes for the community. The stage of policy implementation can be characterized and distinguished from the policy making stage. Policy making on one hand is a process that has a bottom-up logic, in the sense that the policy process begins with the delivery of aspirations, requests or support from the society. On the other hand, policy implementation has a top-down logic, in the sense of decreasing abstract or macro alternatives policy into concrete or micro actions. Grindle stated that implementation is a general process of administrative action that can be examined at a particular program level. Meanwhile, Van Meter and Van Horn stated that policy implementation is an action carried out by the government and private sector both individually and in groups with the intention of achieving purposes. Grindle added that the implementation process will only being when concrete goals and objectives have been determined, an activity program has been arranged and funds are ready and submitted in order to achieve the goals.

d. **Typology of policy resolution:** In this research, the writer must obtain the overview of the conservation of forest resources in the Wonogiri Regency area in accordance with the researched object. It is done in order to obtain a typology of each researched area, as the resolution of problems arising from each of researched area is not the same. Based on the aforementioned matter, in accordance with the arising problems, the forestry policies should change for the better. The policy enforcers should consider giving incentives to the affected people.

The work of the forest apparatus is lighter because the forest looting perpetrators are scared of the pandemic, thus the condition of the forest is more maintained. The policy makers should apply the health protocol in making policies. Complete a workplace risk assessment including, creating a day-to-day plan that follows the guidelines Develop a COVID-19 Infection Prevention and Control Protocol (Protocol) based on the risk assessment on the forestry policy. Implement and enforce the Protocol to help prevent and control the transmission of COVID-19. Reducing the number of social interactions between state apparatus in the forestry and people and nearby communities. Physical distancing or enhancing protection via masks where physical distancing is not practical Good hygiene practices on forest inspection. Cleaning and disinfecting high touch point areas at the start and end of each day

From the aforementioned events, the Forest Ranger and the head of BKSDA, Totok, can take advantage of the occurring situation and condition so that the story can be used as materials for awareness to the community for the preservation of BKSDA during pandemic, this kind of policy model must be heard and considered by related officials from the local to the center in order to be used as a reference material in the framework of determined policy during pandemic.
Therefore, if we compare the costs incurred with the benefits in the sense there is neither profit nor loss from it. However, if the reservoir is functioned as its original function, then the cost is very high and it seems impossible to be conducted seeing our current economic condition. Also, with regards to green belts planted, apparently it was not carried out in accordance with the protocols during pandemic. This matter must be heard by the concerned officials from the local to the center to be used as materials in determining actions in making policy.

From the problem that arises as the research object, which is regarding the matter of policy decided by the government, in this case the Ministry of Environment, it is still not aspirational. This can be proven by the case of Forest Conservation both in terms of its management or the rights and obligations of each party between the community and the government as occurred in several places.

**Conclusion**

Firstly, we must optimize the pandemic gave a security sense in the forest. BKSDA need to give autonomy in addressing environmental issues that are related to policies that favor the community during pandemic by using the potential strengths of local communities and combining them with the strength of interest groups in the community in order to carry out communication to provide data that is true and can be accounted for in order for it to be used as consideration by relevant officials in making policies related to forest resources. Secondly, by using the health protocols during implementation of the policy in the field that occurs and a human relation approach that is combined with the sociological process occurring in public life, by way of emphasizing the formal and logical approach, so that it tends be creative and rejects the routine logic regulations, this is where the enlightenment policy lies on safety of the people and the forest.

Abstract

The spread of the COVID-19 pandemic has led to widespread concerns internationally and among the members of the public health community including dental health professionals. The dental health care professionals are at higher than usual risk due to the proximity to the patient’s face, direct contact with the body fluids such as saliva and blood. The objective of this article is to provide an overview of the symptoms, modes of transmission of the COVID-19 infection, triaging of the dental patients, specific recommendations for the management of the dental patient, infection control modalities with an emphasis on dental specialties, global outlook on the pandemic by dentists, and implications on the patients and dentists. A literature search was performed and articles about the symptoms and modes of transmission of the COVID-19 infection, management of COVID-19 diffusion in dental practice were retrieved. The articles were then reviewed and infection control measures for various dental specialties as well as patient management strategies were also outlined in the results. The dental team has to implement measures to provide care and treatment to the patient as well as prevent the spread of the infection.

Keywords: COVID-19, Dental Practice, Cross Infections, Patient Management, Risk stratification, Dental Triaging.

Introduction

The prevailing COVID-19 pandemic in the world is caused by a virus named SARS-CoV-2 (severe acute respiratory syndrome coronavirus 2). SARS-CoV-2 belongs to a large family of viruses called the Coronaviruses (CoVs).[1] The China health authority informed the World Health Organization of multiple cases of pneumonia of unknown etiology in the Wuhan province on December 31st, 2019. Most of the patients lived or worked around the Huanan local seafood wholesale market.[2] On January 7th, 2020, the WHO abbreviated the new pathogen discovered from the throat swab of one of the patients as 2019-nCoV.[3] The Coronavirus Study Group renamed the pathogen as severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). There was no evidence of human to human transmission in the first two weeks of detection of the disease, and it was considered to be a normal flu consisting of acute respiratory problems with a common cold. A severe outbreak of the virus happened in China.

in the third week of January 2020, followed by spread throughout the globe\[4\]. As on September 3, 2020, the total number of laboratory-confirmed cases in the world are 26,182,709, of which 18,446,689 have recovered, and the number of deaths is 867,362.\[5\] An extensive search was carried out on COVID-19 and dental health professions on the internet to obtain literature. Gaps and areas of wealth in the literature were identified.

**Symptoms of Covid-19:** A patient infected with COVID-19 may present with mild, moderate, or severe illness. Patients suffering from mild illness present with upper respiratory tract infection, mild fever, dry cough, sore throat, nasal congestion, headache, muscle pain, or malaise. Ageusia or loss of taste and/or anosmia or loss of smell, diarrhea, and vomiting have also been observed. Cough and shortness of breath without signs of severe pneumonia are seen during the phase of the moderate illness. Fever with severe dyspnoea, respiratory distress, tachypnoea (> 30 breaths/min), and hypoxia (SpO$_2$ < 90% on room air) is seen in severe illness. Children present with mild cyanosis, too.\[6\]

**Modes of spread and risk associated with COVID-19 in dental clinics:** COVID-19 can be transmitted from one person to another directly through respiratory droplets, with recent studies suggesting that transmission may occur via contact and could be fomite borne.\[7\],\[8\] The asymptomatic incubation period for infected individuals has been reported to be approximately 1 -14 days, but asymptomatic individuals could spread the virus after 24 days.\[9\],\[10\],\[11\] The presence of the live virus in the saliva of the infected was demonstrated by To et al.\[7\] The virus binds to the human ACE -2 (angiotensin-converting enzyme 2) receptors, which are present in high concentrations in the salivary glands.\[12\],\[13\]

The dental care setting carries an increased risk of transmitting infection due to the procedures carried out that involve close facial communication with the patient, multiple, often long exposure to body fluids such as blood, saliva, sweat, etc. as well as sharp instruments and armamentarium. Transmission of the virus may be due to direct inhalation of microbe, which is airborne and could remain suspended for long duration in the air; due to direct contact with patient materials, contact with the conjunctival, nasal, or oral mucosa with droplets and aerosols containing the virus. Cough from an infected individual may propel the virus a short distance in the form of droplets.\[15\],\[16\] Contact with contaminated instruments and surfaces can also lead to the spread of the infection.\[17\]

However, among the modes mentioned above, droplet and aerosol transmission of the virus are of utmost concern in the dental clinic as it is tough to avoid generating a massive quantity of aerosol as well as droplet containing the patient’s saliva and blood during dental practice. The dental instruments such as hand pieces use gas to drive the turbine to rotate at high speeds and work with running water and generate aerosols and droplets mixed with the patient’s saliva and blood which could stay airborne for a while and further settle on surfaces or enter the respiratory tract.\[15\] Besides, dental professionals and other patients have likely contact of conjunctival, nasal, or oral mucosa with droplets and aerosols containing microorganisms generated from an infected individual and propelled a short distance by coughing and talking without a mask. Effective infection control strategies are needed to prevent the spread of 2019-nCoV through these contact routines.\[18\],\[19\].

Cough or sneeze by an infected person can render the virus and infect individuals within a radius of approximately 2 meters, thus forming the basis for the social distancing measures among the community to decrease the spread.

Inanimate objects located close to an infected individual or touched by him/her could be a source of spread.\[20\],\[21\]. Handwashing and disinfection play a key role in stopping the spread of this disease.\[22\].

**Tele dentistry and messaging services during the COVID-19 pandemic:**

- Tele dentistry can be a practical approach during the COVID-19 pandemic to decrease the number of patients visiting the dental clinic and thus limiting the visits to emergency and urgent dental care.
- WhatsApp Messenger, owned by Facebook Inc., California, is a text messaging service that can be used for communication between the dentist and the patient. Members of the dental health team should be appropriately taught to use these internet-based communication tools with an assessment of indications and contra indications. Virtual assistance in the form of photographs, short video clips, or video calls can be of great use for communication between the patient and dentist to evaluate the need of the patient to visit the dental clinic.\[23\],\[24\],\[25\].
**Triaging of Dental Patients:** The patients visiting the dental clinic can be segregated based on the criteria mentioned in Table 1.

**Table 1: Criteria for segregating the dental patients in dental clinic**

**Management of a patient with symptoms of COVID-19:** If a patient has symptoms of COVID-19, then the patient needs to be categorized as a high-risk patient and may be managed as stated in figure 1.
There is no standard protocol for the various specialties of dentistry as well as general dentistry on the approach to management of a patient during and post the Covid-19 pandemic. This discussion lays down the guidelines for the management of a dental patient with prevention of nosocomial infection as well as guidelines of individual dental specialities.

a. Management of a dental patient and prevention of hospital-acquired/nosocomial infection

- Elective procedures to be deferred and only urgent/emergency procedures to be performed
- Standard, contact, and airborne precautions to be followed by the dentists, which include the use of personal protective equipment (PPE) as well as following hand hygiene practices\[26\]
- Use of mouth rinse before the procedure: SARS-CoVIs known to highly susceptible to topovidone mouth rinse.\[27\] Rinsing can be advised before the procedure, and 0.2% povidone-iodine may be used. This could help in the reduction of the virus in the saliva.\[28\],\[29\]
- Some of the dental instruments used in the clinic, such as mouth mirrors and syringes, should be disposable or single-use, which prevents prevent cross-infection.
- Extraoral radiographs \{OPG & CBCT (Cone beamcomputed tomography)\} should be recommended to avoid gagging or initiation of the cough reflex, which is frequent during intraoral imaging. If an IOPA or any other intraoral imaging procedure is mandatory, then the sensorsshould be double barriered.\[30\]
- Rubber dam minimizes splatter generation.
- The use of ultrasonic armamentarium, as well as high-speedhandpieces and 3-way syringes, should be reduced to decrease the generation of contaminated aerosols.
- Negative-pressure treatment rooms or \(ff2\) and well ventilated operating rooms (AIIRs) to be used to treat a suspected laboratory confirmed COVID-19 positive patient rather than in a routine dental clinic setting.\[31\]
- Disinfection of the inanimate surfaces with chemicals as the SARS CoV-2 virus could survive and stay viable in aerosols for 2 to 3 days at room temperature on inanimate objects or surfaces.\[31\]

b. Patient management by certain individual dental specialties

Oral and maxillofacial surgery:

Outpatient:

- Minimum patients to be entertained as no elective surgery to be performed
- Consultation on the phone/video call to be held before face to face meeting with documentation of the telehealth procedures
- Minimum number of patients to be present in the waiting room; contact time to be shortened
- Risk assessment of the patient to assess the possibility of having contracted the infection to be done by recording the body temperature and evaluation of the respiratory symptoms
- Evaluation of the contact and clinical history – contact with a patient with respiratory problems and fever in the previous 2 to 3 weeks.

Inpatient Care:

- All the inpatients to undergo a swab test for COVID-19 as a routine.
- New patients to be separated from the rest of the patients until a negative result is obtained.
- PPE to be used by the medical staff as a mandate.\[26\]
- Mask and gloves to be used in case of asymptomatic patients to avoid droplet infection

Operating Room:

- Test for COVID-19 to be performed before shifting the patient into the operating room
- FFP2 (Filter face piece) respirator without valve and a gown to be worn by the patient
- FFP2 respirator with a valve and a gown and gloves to used by the staff
- Negative pressure to be established in the operating room
- PPE to be worn by every staff member with a watertight sterile gown over it
- Face shield to be worn by the operating doctor and the assisting team member
- Members of the surgical team to be outside the room during intubation and extubation
• Extraoral approach to be used if possible
• Use of osteotome to be considered wherever possible
• Minimum aerosol formation to be a priority
• Use of electric cautery to be avoided and if used should be with a smoke evacuation machine
• The operating room to be cleaned and disinfected 15 minutes after the patient has left the room[32],[33].

Endodontic Practice:

• Dilution of sodium hypochlorite to a concentration of 1% to extend the supply with no compromise on the quality of the treatment
• Rubber dam usage to minimize generation of splatter. Care must to taken to place the rubber dam to cover the nose for an advantage to decrease the spread of the infection.[26]

Pediatric Dental Practice: Riccardo Castagnoli et al.[34] studied COVID-19 positive pediatric patients in China over three months and concluded that children acquired the viral infection from their family members but presented with less severe symptoms than in adults. The prognosis was also better with recovery in 1 to 2 weeks after the onset of the disease.

• Preventive dental behaviors should be promoted

Orthodontic Practice:

• Postpone routine orthodontic appointment as per guidelines of the single Nations
• Follow up of patients experiencing discomfort or problems concerning the orthodontic appliance they are using.[23] Table II below shows the followup procedure for dental patients.

Table II: Orthodontic followup for dental patients

| In case of pain/swelling/severe discomfort – visit an emergency dental clinic. |

Discussion

Dental practice: Global outlook during the COVID-19 outbreak: The dental clinic setting increases the risk of cross-contamination and infection between the dental health care worker and the patient. Stern and effective infection control procedures are to be followed by the dental practitioners and hospitals in the countries affected/potentially affected by COVID-19.
After the outbreak of the disease in China in late 2019, routine dental treatment was suspended in January 2020. After three months, the situation is limping back to normalcy\[35]\[36]. Countries closely linked to China, which include Hong Kong, Taiwan, and Singapore, imposed travel restrictions, quarantines, social distancing measures, self-isolation, and heightened hygiene to decrease the arrival of new cases among the community and prevent silent community spread of the pandemic. Routine dental care was closed down just as in China.

The UK NHS’s was of the view that dental practitioners should continue to provide routine dental care for patients who are asymptomatic with no contact history. The general dental practitioners were not comfortable with this advice. They felt that they were morally obliged to reduce routine dental care to decrease the spread of COVID-19 among patients and further into the community. However, the financial consequences of the self-employed dentists were also understandably of concern\[37]. The British Dental Association (BDA) has informed the BBC(British Broadcasting Corporation) that dentists in the united kingdom have been receiving multiple calls from patients who are believed to be in real agonizing pain, with no option of sending them anywhere. As per the British Dental Association, there are a large number of patients who are going untreated; it also says that some of the untreated conditions such as abscesses could lead to facial space infections and thus end up being life-threatening. Patients have been asked to call their local practitioners and seek prescriptions on the phone and obtain them from the pharmacy in case of serious symptoms. Numerous patients are not able to receive emergency appointments as practices are not allowed to see the patient face to face.

Dentistry has been termed as the riskiest of professions in relation to COVID-19 by The New York Times\[38]. The American Dental Association (ADA) has urged the US Department of Health and Human Services to federally recognize licensed dentists to administer point of service COVID-19 tests to test a patient before the procedure henceforth decrease the risk of exposure to the entire dental team.

The ADA has made recommendations for the reimbursement for costs incurred due to the procurement and use of Personal protective equipment(PPE) as well as payments for temporary procedures.\[40] Teledentistry facilities are being made available to the dentists in certain states of USA.\[41]

The dental clinics across the Indian subcontinent have been asked to suspend all non-essential procedures since March 31st, 2020. The Indian Dental Association(IDA), in its bulletin released on March 17th, 2020, titled “Be prepared … but don’t panic” directed the dentists in India to concentrate on emergency dental care and to make a well-informed decision about the patient and their practice.\[42]

COVID-19: Implications faced by patients, dentists, and dental businesses: North American Dental Group (“NADG”), a leading U.S. Dental Service Organization, has reported that a considerable number of Americans have raised significant concerns about seeking dental treatment during the current COVID-19 pandemic. Seventy-one percent of the patients were uncomfortable visiting the dental clinic and wanted to postpone an elective procedure. Only 42 percent of the Americans were confident that their dentist was prepared to prevent the spread of the COVID pandemic.

Dental treatment is expensive and not entirely covered by insurance. A patient to whom oral health has always been of utmost importance is likely to return to the clinic and also bear the costs. However, there will be many who would postpone their visit to the dental beyond the lockdown due to fear or due to economic effects due to job losses, salary cuts, etc. Patients residing in countries who have the lockdown are finding it tough to reach a dentist even in case of emergencies such as broken teeth as a result of biting onto something hard\[43].

The overhead expenses of the dentists in developing and undeveloped countries is expected to rise as the dentist has to procure PPEs. There has been an acute shortage of as well as unclear guidance on PPEs in the United Kingdom.\[44]

There have been severe financial problems faced by dental offices, health care operators, and hospitals as well as insurance companies. As dental treatments are limited only to emergency treatments, the management of patients has become expensive. One of the very adverse impacts of the dental practices being shut down is on the salaries of the dental staff. Unemployment insurance in developed nations could partially cover their requirements.\[45]\[46]

Conclusion

Dentistry: The way ahead

• Change in the approach by the dentist, patient as
well as the government.

- Use of teledentistry to minimize the footfall at the dental clinic.
- Only emergency procedures to be performed.
- Changes in the infrastructure of outpatient and inpatient units, as well as the operating room.
- Adequate supply and use of personal protective equipment by the dental health care team.
- Permission to allow the dentists to take nasal and throat swabs of the patients for the coronavirus.
- Low-interest loans for dental practices.

Prevalence of Hearing and Vision abnormalities in School Children in Udupi District Karnataka

Vasanthalaxmi K.¹, Manjula S.D.¹, Benita², Sindhu², Suchetha P.K.³

¹Associate Professor, ²Postgraduate Student, ³Selection Grade Lecturer, Department of Physiology, Kasturba Medical College, Manipal Academy of Higher Education, Manipal-576104, Karnataka

Abstract

Background: Preschool screenings are recommended for early detection and treatment of childhood visual and hearing disorders.

Objective: To evaluate the prevalence of hearing abnormalities, visual impairments and correlate its association with consumption of vitamin A rich food and usage of electronic devices in school going children in Udupi district, Karnataka

Method: Rinnie’s test and Weber’s tests was done by using tuning fork method for hearing, Snellen’s chart for distant vision, Jager’s chart for near vision, Ishiara chart for colour vision and confrontation test for field of vision. Questionnaires were used to get the detailed informations regarding consumption of vitamin A rich food and usage of electronic devices,

Result: Screening test for hearing and vision conducted on 250 students. There was no significant hearing abnormality was found out of 250 students, there was hearing impairment in 1.6% of the children due to ear infection. In vision screening, 12.8% of children having visual abnormalities like myopia, hyperopia and color blindness. The total prevalence of vision abnormalities was 32(12.8%) 95% CI: 11.924-13.676.

Conclusion: Vision and hearing screening is very essential in school children to recognize the visual impairments or hearing abnormalities at earliest which will be helpful for further treatment. This study should be conducted in large sample size.

Keywords: Preschool children, vision, Hearing, screening.

Introduction

The auditory and visual impairment often has an important impact on the physiological as well as psychosocial development of a child; it may also affect their socioeconomic status as they grow older.¹ It is important for the development of sense of hearing, oral language acquisition, verbal capability, reading and writing and for good educational grades.²⁻⁴ Some children with visual defects have much poor academic performance in school. Sometimes this underlying visual defect can cause behavioral impairments like learning disabilities, dyslexia and attention deficit disorder. The major eye problems including refractive errors, color blindness can occur in school children.⁵

The primary need for awareness about Hearing Loss in children is lacking in many parts of the world, it is unnoticed by parents and teachers.⁶ The early identification and rehabilitation of hearing impairments provide great benefits for the child, besides reducing educational and physiological consequences: Hence, a
consensus should be made that the hearing assessment and monitoring should not be carried out only in newborns, but also during the school life. The hearing loss in children can be due to genetic disorders, some viral infectious diseases like swelling of the parotid glands, and meningitis, mechanical injuries. Usage of mobile phone and ear phone in incorrect way causes incurable damage to hearing. It is required to conduct routine clinical examination for hearing abnormality in school children. In initial evaluation of hearing loss cases, audiology estimation may not be readily available for all patients, in such conditions, tuning fork test was done for initial identification which was easily available, inexpensive and easy to use.

The visual requirements in a class room are essential for child’s study as well as for their achievement. The visual efficiency impairment that may impact on learning potential includes eye discomfort, inattention, and task avoidance etc. Most of the time, small children may not be knowing about their visual problem as they are not able to explain their simultaneous associated symptoms. One of the most frequent visual impairments that might occur in early school age children are the refractive errors. Visual impairments left untreated can lead to both short- as well as long-term physical and psychological problems, including physical and verbal bullying, depression, anxiety, poor visual motor skills, low self-esteem, problems in school as well as work site, and accidents and injuries.

One of the most important causes of preventable blindness in young children is Vitamin-A-Deficiency (VAD), because vitamin A is important for the synthesis of pigment of rods and cones. As per the recent World Health Organization (WHO) estimation, VAD has medium and high public health significance in 45 and 122 countries all around the world, respectively.

Extensive use of computers and other electronic devices in children’s may make them more susceptible to the development of visual problems compared to that of adults. It may cause eye discomfort, fatigue, blurred vision, headaches, dry eyes and other symptoms of eyestrain. These symptoms may be due to poor lighting, glare, an improper work station set-up, or vision problems.

Therefore, the aim of the present study is to assess the hearing sensitivity, the prevalence of vision abnormalities and its association with the consumption of Vitamin A rich food and usage of electronic devices among school children in Manipal, Udupi district, Karnataka.

Materials and Method

Ethical approval for conducting the study was obtained from Institutional Ethics Committee of Kasturba Medical College and Kasturba Hospital, Manipal. (IEC/103and 127). Before doing the study, the permission from the school principal were taken. The consent forms and questionnaires were collected from the parents enrolled to ask for their permission to assess their child’s hearing and vision and to allow their children to participate in the study. The accepted parents written consent were taken, then the procedure and tests were explained to the children. In our cross sectional study total two hundred and fifty primary and higher primary school children both male and female within the age group of 9-12 years, were screened.

Materials required: Tuning Fork (265 cycles/sec), Snellen’s chart, Jaeger’s chart, Ishihara chart and Questionnaires

Method

Tests for Hearing:

Weber’s test: Identifies asymmetry of hearing.

Tuning fork was struck and placed high on the forehead in the midline. The subjects were asked whether the sound was louder in one ear or equally heard in both ears.

Rinne’s test: It identifies the presence of conductive hearing loss.

This test compares patient’s Air conduction (AC) hearing with his Bone conduction (BC). Hearing light vibrating tuning fork was placed on the mastoid bone, behind the ear. When the patient can no longer hear the sound, quickly place the fork close to the ear canal and asked whether he could hear the sound or not.

Questionnaires: A detail history of each subject is carried out by questionnaire (Figure-1), The questionnaire had 12 YES or NO questions which are suitable for this study and easy to understand. The parental questionnaire had questions related to the children’s audiology related problem.
1. Did your child ever have any hearing abnormality? ( ) Yes ( ) No
2. Do you think your child hears well? ( ) Yes ( ) No
3. Does your child seem to hear better on some days rather than other days? ( ) Yes ( ) No
4. Does anyone in the family present hearing impairments? ( ) Yes ( ) No
5. Was there any complication during pregnancy or birth? ( ) Yes ( ) No
   If yes, which one? _______________________________
6. Did your child ever have ear infections or other ear problems? ( ) Yes ( ) No
   If yes, which one? _________________________________
7. Did your child ever have any ear surgery? ( ) Yes ( ) No
8. Does your child use cotton swabs to clean his/her ears? ( ) Yes ( ) No
9. Does your child have any health problem? ( ) Yes ( ) No
   If yes, which one? _________________________________
10. Does your child present learning difficulties in school? ( ) Yes ( ) No
11. Does your child respond soon whenever you are calling him/her? ( ) Yes ( ) No
12. Does your child present language or speech problems? ( ) Yes ( ) No

Adapted from Guerra-silva and Lacerda(3)

Test for visual acuity-distant vision and near vision.

Distant vision-subjects were seated at a distance of 6 meter from the snellen's chart and were asked to read the chart with each eye separately till the line where he/she were able to read comfortably.

Near vision- subjects were asked to read the jaeger’s chart from each eye separately, holding the chart at a distance of 10-12 cm from them.

Test for Color vision- the subjects were asked to read the ishihara chart by each eye separately. Field of vision was tested by using finger confrontation method for both the eyes separately.

**Questionnaires:** The questionnaires related to the consumption of vitamin A rich food and the usage of electronic devices were included.

**Questionnaires**

**Section--A**

1. What is your child like to have more frequently (Fruits/Vegetables)
   If fruits what kind ……………
   If Vegetables what kind ……………
2. Do your child is taking meals with Carrots? (Yes/No)
   If yes how frequently? (Daily/Twice in a week/Weekly once/Monthly twice)
3. Do your child is taking meals with Green leafy vegetables? (Yes/No)
   If yes, how frequently? (Daily/Twice in a week/Weekly once/Monthly twice)
4. Do your child taking meals with Sweet potatoes? (Yes/No)
   If yes, how frequently? (Daily/Twice in a week/Weekly once/Monthly twice)
5. If your child is non-vegetarian, Please answer the following questions?
   A. Do your child is taking meat? (Yes/No)
      If yes, how frequently? (Daily/Twice in a week/Weekly once/Monthly twice)
   B. Do your child is taking Poultry (egg)? (Yes/No)
      If yes, how frequently? (Daily/Twice in a week/Weekly once/Monthly twice)
   C. Do your child is taking seafood’s (fish)? (Yes/No)
      If yes, how frequently? (Daily/Twice in a week/Weekly once/Monthly twice)
6. Are you aware of Vitamin A deficiency (Yes/No)
7. Do you think that your child take regularly Vitamin A foods based on the daily need of Body? (Yes/No/Not sure)
8. Did you visit any doctors for nutritional disorder for your child? (Yes/No)
   
   If the previous answer is yes, answer the following questions:
   
   • What kind of deficiency/disease? ______________
   
   • Taking any kind of supplement ______________

Section-B

9. Which of the following electronic devices your child using regularly?

   () Television
   () Mobile
   () Laptop

The questionnaires were given to the child and parent.

**Statistical Analysis:** The data was analyzed using IBM SPSS statistics 15 data editor. Descriptive statistics such as frequency and percentage were used at 95% of confidence interval for 250 samples. The level of significance was set at 5% absolute precision and 95% confidence interval for vision. The confidence interval for hearing was estimated to be +1.96.

**Result**

In our study, the hearing test was conducted by Rinne’s test and Weber’s Test and questionnaires. There was no any significant hearing abnormality.

In weber’s test, all the 250 students could hear equally on both the ears. There was no lateralization.

The data collected from the parental questionnaire about child hearing reported that, out of 250 students, 1.6% of parents said that their child heard better on some days as compared to other days, 4% presence of hearing impairments in the family, 1.6% of the children had ear infection, 0.4% had difficulty in learning. No student has undergone ear surgery.

In our study, the data collected by the questionnaire, related to the ear hygiene and use of ear phones has reported that, Out of 250 students 2% of students reported ear problem, 95.2% of the students cleaning their ears regularly. Out of which, 24% cleaning the ears once in a week, 67.6% once in two weeks, 8.4% once in a month and 4.8% are not. 7.2% of the students are using ear phones, range of volume 0.8% ‘mild’, 98.8% ‘medium’ and 0.4% ‘high’.

In vision screening, out of 250 students, 12.8% children having visual abnormalities includes myopia, hyperopia, color blindness. 4.4% children, were already wearing glasses having Myopia or Hyperopia were also included in this study. 7.2% of the children had myopia 4.8% of color blindness, 0.4% had hyperopia. Field of vision for all the 250 children was normal. (Table 3).

In our cross sectional study, The prevalence of myopia was 7.6% (95% CI: 6.72 – 8.46), hyperopia was 0.4% (95% CI: 0.476 – 1.276), and color blindness was 4.8% (95% CI: 3.924 – 5.676). The total prevalence of vision abnormalities among three school children in Manipal, Udupi District, Karnataka was 32(12.8%) 95%CI: 11.924 – 13.676.

The Consumption of vitamin A rich foods was collected by questionnaires method. Among 250 children, 240(96%) children were taking carrot, two hundred and nineteen (87.6%) children taking green leafy vegetables, one hundred and ninety-nine (70.6%) were taking meat, two hundred and seventeen (86.8%) children were taking egg and one hundred and eighty (72%) children were taking fish.

The daily usage of electronic devices (television, mobile phones, computer or laptop) of children was collected by using questionnaires method. Among 250 children, 212 (84.8%) children were daily watching television, 115 (46%) children using mobile phone, and 8(3.2%) children were using computer or laptop.

Discussion

Normal hearing and vision are very essential in school children, as it affect their learning. The current study involved in assessing the prevalence of Hearing Loss and vision among primary and higher primary school children in Udupi district of Karnataka State.

The primary need for awareness about Hearing Loss in children is lacking in many parts of the world, it is unnoticed by parents and teachers. The early identification and rehabilitation of hearing impairments provide great benefits for the child, besides reducing educational and physiological consequences: Hence, a consensus should be made that the hearing assessment and monitoring should not be carried out only in new-borns, but also during the school life.

The most common hearing disorder is unilateral hearing loss, which is found approximately in 3% of school age children. Conductive hearing loss, which is more frequent in the month of fall and winter due to the weather, may be considered the most common cause in the school age hearing screening.

One of the study reported that the behaviour of students can give the hints about any issues with being non-responsive to name call, not attentive in class, frequently asking the other person to repeat the sentence or question, concentrating on the teacher’s lip movements and being inattentive in classroom, preferring social isolation being passive and easily getting tired, are due to hearing loss in children.

Sometimes, the results of the child being detected with hearing impairments can take a different dimension where the caretakers wrongly diagnose or classify these children as Inattentive or being hyperactive, or label them to have poor educational grades, which is another result of being unaware of the child’s hearing loss issues.

Studies have reported that, at the initial stages, it is difficult to detect any minor hearing loss without any additional audiology related clinical evaluation. The significant relationship between some of the answers from caregivers and the procedure performed in the school age hearing screening demonstrates that it is possible to associate the use of questionnaire along with the test in hearing screening, and had aim to analyse the effectiveness of a low cost screening instrument. Which further concludes that the questionnaires may be used to classify children as having normal hearing or hearing impairments. Furthermore, they pointed out that developing low-cost strategies can help in caring for children with hearing impairments in developing countries.
In our study, there was no hearing abnormalities observed. The reason for observing no hearing loss in these cases is that the occurrence of hearing abnormalities is very less and also factors such as, the child’s response being very casual, not relevant to the question, or just a simple lack of awareness about their own hearing sensitivity.

There was 7.6 % total prevalence of vision abnormality in 250 school children out of that major prevalence was due to myopia, which was lower as compared to other studies done on prevalence in India. Similar type of prevalence of vision abnormalities in children were reported in different studies in India like, 20.2% of refractive errors were found in rural area of coastal Karnataka, 27.1% of children having refractive errors in Pune, 5.22% of Prevalence were found in urban female school children in Surat, 4.3% of school children having refractive error in Maharashtra. In our study, 0.4% of children were having hyperopia 2.5% of hyperopia was reported in urban school children of low income families in Kolkata, 4.91% of school children in Madhya Pradesh.

Vitamin A deficiency (VAD) is an important cause of nutritional blindness in young children and VAD causes more than 250,000 children to go blind in Asia each year; 52,500 such cases per year are from India. A survey conducted in 1992, in 3 primary schools in a rural area of India’s southwest Maharashtra State, assessed the prevalence of vitamin A deficiency (9.8%) among children, 5-15 years of age. Around 72% of children were found VAD in urban school children of low income families in Kolkata, 4.91% of school children in Madhya Pradesh.

In our study, 4.8% prevalence of color blindness which is not significant. It was reported 2.3% children were having color blindness in Pune.

In our study, 0.4% of children were having hyperopia 2.5% of hyperopia was reported in urban school children of low income families in Kolkata, 4.91% of school children in Madhya Pradesh.

In our study, association of the visual impairments with the consumption of vitamin A rich food and electronic device usage in among school children cannot be analysed statistically, as the numbers of children who have vision abnormality in the sample are scanty.

**Conclusion**

In our study we used tuning fork test and questionnaires for hearing loss, Snellen’s chart, Jagger’s chart and ischiara chart and questionnaires for Vitamin A consumption and usage electronic devices for vision abnormalities. Advance techniques can be used to screen even minute hearing loss, to assess the minute thresholds of the hearing capacity, with sound proof assessment set-up like pure tone audiometry, tympanometry etc, developing a new questionnaire which is easy and suitable for this hearing screening in school children."Vision screening", is an efficient as well as cost-effective method to recognize the children who are dealing with visual impairments which can lead to blindness, and loss of vision in children influences their academic opportunities, career choices, and social life, those children can be referred to ophthalmologist for further treatment.

In our study we got lesser prevalence of vision abnormalities and hearing loss which could be due to smaller sample size and as this study was conducted in government school children, it can be studied in larger size and compared with private school children.

Abstract

Tooth carving on wax/plaster/plastic to reproduce reference models of teeth is used to teach dental students anatomy of the tooth. There is a ongoing debate on value of tooth carving exercise in undergraduate dental curriculum. Perception of students on utility of tooth carving is important in planning dental curriculum.

Objective: The present study seeks to analyze the perception of undergraduate dental students about tooth carving, its relevance and utility in future clinical practice. The various aids preferred by them to learn dental carving.

Method: Student’s perception was assessed using a self administered questionnaire.

Results: Total 58 students participated in the study (36 girls and 22 boys). Both male and female students perceived that video demonstration of tooth carving, a improved carver design and having a collection of 32 natural teeth in the department and attending workshops will help in more accurate and better understanding of tooth carving. More male students perceived that dental carving will be helpful in their clinical practice compared to females. Majority of students believed that the course content on carving was adequate. 90% of ³rd year students perceived that attending workshops would improve their knowledge on carving compared to 66% ²nd year students and the difference was found to be statistically significant. A higher proportion of ²nd year students compared to ³rd year students perceived that improved carver design would help them carve more accurately. More ³rd year students felt that the course content on carving was adequate. Majority of students perceived that multimedia presentations were the most effective educational aid for teaching tooth carving. Majority of students perceived that having handouts of presentations and POP models will be beneficial to them in learning tooth carving.

Conclusion: There is a need to revise the curriculum emphasizing on the utility of tooth carving in clinical practice. Also there is a need to adopt new innovative method at teaching dental carving, improving on carver design and enriching the course content with emphasis on competency and skills since many students even after having exposure to carving felt the need for further workshops.

Keywords: Dental Carving, Perception, Survey.

Introduction

Dental anatomy, taught in the preclinical years forms the foundation of sound routine dental practice in later years. Students learn the external and internal morphology of each individual tooth and the relationship between teeth within the arch and between arches of both
primary and permanent dentition. Tooth carving on wax/plaster/plastic to reproduce reference models of teeth is used to teach dental students anatomy of the tooth. Carving has been advocated for developing cognitive and motor skills.1-2 By carving teeth anatomy, the dental student begins to develop psychomotor skills for restoring the teeth to proper form and function.2 Students acquire the knowledge to identify teeth, recognize and diagnose tooth anomalies and treat or manage dental pathology.

There is an on-going discussion about the value of tooth carving exercise in the undergraduate dental curriculum. Opinions vary on the effectiveness of the tooth carving exercise and its relevance to students’ later dental practice. Perception of students on utility of tooth carving is important in planning dental curriculum.

The aim of this study was to analyze the perceived importance of tooth carving among undergraduate dental students during their training.

Methodology

The present study was a cross sectional survey carried out among 2nd and 3rd year dental undergraduate students exposed to tooth carving at a tertiary level dental care facility in central Uttar Pradesh. The 2nd and 3rd year students attending lectures of Oral Pathology and Microbiology, King George Medical University, were informed about the purpose of the study and were given a self administered questionnaire to assess their perception on 6 different parameters concerned with Tooth Carving. Students willing to participate in the study, after obtaining the informed consent from all the participant explaining the procedure, were then asked to fill the questionnaire and those not interested were asked to return the questionnaire blank at the end of the lecture. Questionnaire was kept anonymous. Students were asked to only mention but to mention their gender, age and year of BDS. Data was tabulated in Ms Excel and was analyzed using WHO Epi Info software. Statistical difference in perception of students was tested for gender and year of BDS using Chi Square test for proportion.

Results

A total of 58 dental students participated in the survey. Of the students surveyed 40 were 3rd year dental students and the rest were 2nd year students. All students had exposure to carving tooth. 38 students had carved complete set of teeth. Amongst students who had carved complete set of teeth 15 were from 2nd year and 23 were from 3rd year BDS.

Table 1: Age and gender wise distribution of study participants

Table-1 shows the age and gender wise distribution of study participants. Total 58 students participated in the study of which 36 were girls and 22 were boys. Mean age of male and female study participants was 20.5 and 21.5 years, respectively. Majority of study participants, about three fourth i.e. 17 (77%) boys and 28 (77%) girls were aged between 20 to 25 years. About 19% of female study participants were less than 20 years of age compared to fewer boys about 13%.

Table 2 shows the comparison of perception of male and female dental students on tooth carving. No significant difference was observed between male and female students with regard to their perception about tooth carving on 6 parameters studied. Both male and female students perceived that video demonstration of tooth carving would be more useful. Male students compared to females had a higher preference for video demonstration of tooth carving. About 77% i.e. three fourth of both male and female students believed that a improved carver design would help them carve tooth more accurately. While 82% male students perceived that dental carving will be helpful in their clinical practice, about 39% (i.e. more than one third) of female students had no idea, whether dental carving will be helpful in their clinical practice. Majority of male and female students about 90% perceived that having a collection of 32 natural teeth in the department will help more in better understanding of tooth carving. About 82% of both male and female students perceived that course content on carving was adequate. However, 10% students did not agree to the same and reasons for the same needs to be looked in. Majority of both male and female students were of the opinion that attending workshops would improve their knowledge of carving. More female students compared to males were interested in attending workshop on tooth carving.

Table 3 shows the comparison of perception of 2nd year and 3rd year dental students on tooth carving. No, significant difference was observed between 2nd year and 3rd year students with regard to their perception about tooth carving on the parameters studied (5 out of 6), except for their perception on attending workshops would improve their knowledge of carving. 90% of 3rd year students perceived that attending workshops would improve their knowledge on carving compared to 66% 2nd year students. A higher proportion of 2nd year students compared to 3rd year students perceived that improved carver design would help them carve more accurately. More 3rd year students felt that the course content on carving was adequate.

![Fig. 1: Receptivity of dental students to tooth carving lectures early morning](image)

Figure 1 shows the perception of dental students regarding tooth carving lectures in morning. Majority of students (i.e. 62%) were more receptive to having tooth carving lectures early morning. However, about one third of students didn’t agree with the same and reasons for the same needs to be explored.
Figure 2 shows the perception of dental students regarding part of tooth anatomy crucial for clinical subject. While about 26% students were of the opinion that understanding the anatomy of Crown of tooth was crucial for clinical practice in later years, majority of students perceived that knowing the anatomy of both crown and root was crucial.

Figure 3 shows the perception of dental students with regards to the different available education aids for better understanding and learning of tooth carving. Majority of students perceived multimedia presentations were the most effective educational aid for teaching tooth carving. Chalk and board didn’t find much preference. Majority of students perceived that having handouts of presentations and POP models will be beneficial to them in learning tooth carving.
Discussion

In the present study a total of 58 dental students participated of which 40 were 3rd year dental students and the rest were 2nd year students. All students had exposure to carving tooth.

In our study both male and female students perceived that video demonstration of tooth carving would be more useful. Male students compared to females had a higher preference for video demonstration of tooth carving. Similar results were reported in a previous study by Yara Oweis et al where many students found video demonstration of tooth carving to be very valuable if used in addition to live demonstrations. Many students asked for the videos to be made available for them at home to be used while practicing outside lab hours. Another study by JP Ennes et al found that most students agreed that the wax models and technique demonstration videos aid in understanding the stages of the technique.

In our study 82% male students perceived that dental carving will be helpful in their clinical practice, about 39% (i.e. more than one third) of female students had no idea, whether dental carving will be helpful in their clinical practice. Similar findings were reported in a previous study by Mayank T et al, where majority 62.3% of survey respondents agreed that carving influenced their knowledge of tooth anatomy. They believed that carving was helpful in restorative dentistry (62.6%), understanding dental occlusion (53.8%) and overall improved their clinical skills (65%).

The findings of our study reveal that majority of male and female students perceived that having a collection of 32 natural teeth in the department will help more in better understanding of tooth carving. Previously published literature has reported that some educators believe that the tooth anatomy can be learned by collecting and studying of intact extracted teeth.

About 82% of both male and female students perceived that course content on carving was adequate. However, 10% students did not agree to the same and reasons for the same needs to be looked in. Majority of both male and female students were of the opinion that attending workshops would improve their knowledge of carving. More female students compared to males were interested in attending workshop on tooth carving. This is in accordance with study conducted by Abu et al. In doing this their horizon will broaden about the subject and the students might find the monotonous carving interesting this further lays their foundation for being better clinicians in future.

In our study majority of students perceived multimedia presentations were the most effective educational aid for teaching tooth carving. Chalk and board didn’t find much preference. Majority of students perceived that having handouts of presentations and Plaster of paris models will be beneficial to them in learning tooth carving. A previous study by Maggio MP et al reported that interactive media module was just as effective as the traditional classroom method for successful dissemination of foundational knowledge in dental morphology. The online module was found to positively engage the students and was preferred by students, however it was not regarded as a total replacement for the traditional course.

Conclusion

There is a need to revise the curriculum emphasizing on the utility of tooth carving in clinical practice. Also there is a need to adopt new innovative method at teaching dental carving, improving on carver design and enriching the course content with emphasis on competency and skills since many students even after having exposure to carving felt the need for further workshops. The training of skills of dental anatomy/tooth morphology can be enhanced using various current technologies like computer animated graphics, implementation of CAL programs, 3D images, digital atlases, photorealistic 3D models of human teeth and NEVO scanner with E4D compare software.

Abstract

Introduction: Oligohydramnios is an extremely rare condition where there is a deficiency of liquor amnii in the amount of less than 200ML at the time of delivery. Sonographically, it is a maximum vertical pocket of liquor is < 2 cm or the amniotic fluid index is < 5 cm (less than 5 percentiles) is specified.

Patient History: A 23 years old ANC & 8 months mother was admitted on 11.9.2019 with the complaints of reduced fetal movements and abdominal discomfort.

Past History: Patient has history of blood transfusion 3months back and has history of cervical cerclage at 7months of pregnancy.

Clinical Findings: Reduced fetal movements, abdominal discomfort, leaking of the amniotic fluid, low amniotic fluid on ultrasound, low maternal weight gain, pre labor rupture of membranes.

Investigations: Ultrasonography (AFI=5cm), Hb%-9.1gm%, MCV-74, MCH-23.5pico/gm, HCT-28.5%, Total WBC Count–8000/cu.mm, Lymphocytes-20%.

Surgical Management: Patient does not have any past surgical history.

Medical Management: Tab. AFI plus BD, L- Arginitrate sachet 5gm/BD/orally, Tab. iron OD, Tab. Calcium OD.

Nursing Management: Assess both maternal and fetal conditions carefully, fetal heart rate and vital signs should be assessed properly. During labor, an amnio-infusion should be given via intrauterine catheter. Fluid should be administered via amniocentesis before giving birth. The level of amniotic fluid may help by increasing the amount of oral fluid intake.

Conclusion: Patient was admitted to AVBRH and was diagnosed as oligohydramnios and got appropriate treatment and her condition has improved.

Keywords: Oligohydramnios, amniotic fluid, cervical cerclage, amniocentesis.
in abdomen, pain in the lower back and reduced fetal movement.

**Past History:** Patient has history of mild anemia 3 months back where she has undergone the blood transfusion and she has history of cervical cerclage in 7 months of pregnancy for which the patient was hospitalized, she complaints pain in lower back and reduced fetal movement since 1 month back and came to AVBRH for further management.

**Past Interventions and Outcome:** My patient was diagnosed as oligohydramnios at 7 months of pregnancy where cervical cerclage has done at that time, from that time onward patient was admitted to hospital time to time for treatment. The treatment was found effective as the patient does not develop complications till then.

**Obstetric History:**

**Menstrual history:**
Age of menarche- 14 years
Duration of menstrual period- 3-4 days
Duration of cycle in days- 28 days
Regularity- regular
LMP – 28/6/19
EDD – 4/3/2020
POG – 32.2 wks

**Antenatal assessment:**
Weight – 45 kgs
Height – 15 cm
Edema – absent
Previous no. of antenatal visits – 2 visits
Treatment – patient has taken 2 doses of TT injection, and she’s taking iron and calcium tablets.

**Clinical Findings:** Reduced fetal movements, abdominal discomfort, leaking of the amniotic fluid, low amniotic fluid on ultrasound, low maternal weight gain, pre labor rupture of membranes.

**Etiology:**
1. **Fetal conditions**- fetal chromosomal or structural anomalies, renal agencies, obstructed uropathy, spontaneous rupture of the membrane, intrauterine infection, post maturity, intrauterine growth retardation.
2. **Maternal conditions** - hypertensive disorders, uteroplacental insufficiency, dehydration, idiopathic.

**Investigations:**

1. **CBC**
   - HB% - 9.1 gm%
   - Total RBC Count – 3.87 mil/cu.mm
   - Total WBC Count – 8000/cu.mm
   - Total platelets count – 1.83 lacs/cu.mm
2. **LFT**
   - Total bilirubin – 0.6 mg/dL
   - SGPT – 20 U/L
   - SGOT – 40 U/L
3. **USG**
   - Single cell uterine fetus with 32.2 wks with oligohydramnios
   - AFI = 5CM

**Therapeutic Intervention:**
1. First trimester – counselling, serial USG
2. Second trimester – counselling, consider amnioinfusion, serial USG, termination of pregnancy SOS
3. Third trimester – deliver post term cases, serial USG & Doppler in IUGR, conservative management for protein pre-labor rupture of membranes till 34 weeks.

**Medical Management:**
- Tab. AFI plus BD
- L- Argininate sachet 5gm/BD/orally
- Tab. iron OD
- Tab. Calcium OD

**Nursing Management:**
- Assess both maternal and fetal conditions carefully, fetal heart rate and vital signs should be assessed properly. During labor, an amnio-infusion should be given via intrauterine catheter.
- Fluid should be administered via amniocentesis before giving birth.
- The level of amniotic fluid may help by increasing the amount of oral fluid intake.
Discussion

The patient 23 years old was apparently admitted in AVBRH on date 11/09/2019. Patient complaints of pain in the lower abdomen, lower back and decreased fetal movement, as she has complaints all this things patient was underwent several investigations like blood investigation, ultrasonography. After all this investigation patient was diagnosed as oligohydramnios where her amniotic fluid index(AFI) was 5cm. The condition of patient was improved after getting care by various multidisciplinary health care team. She was admitted in the ANC ward for further management.2,3

A clinical trial on oligohydramnios during the third trimester of pregnancy was done in 2012 at Moradabad city, U. P. The results shows that 24. 583. 99 SD was the patient mean age and out of these 46. 15% were the age between 21-25 years. 36% were primigravida and 64% patients were multigravida. Among 78 pregnant women 74% was mild oligohydramnios and 25% was severe. Around 68% were preterm delivered which means who delivered before completing 37 weeks of gestational age. 72% cases were delivered by caesarean section, out of all these 51% were due to fetal distress, 33% were normal Cardiotocography (CTG) and 66% were abnormal at the time of admission. The normal colour of the amniotic fluid was found in 69% cases at the time of membrane rupture whereas 31% cases meconium stained was found. Mostly, in severe oligohydramnios the chances of caesarean section was high than the mild and moderate oligohydramnios group. Perinatal outcome like Apgar score, weight of the baby, meconium aspiration syndrome, respiratory distress syndrome and neonatal ward admission. 65% cases were found to be low birth weight baby among 78 newborn babies. Among 78 babies, 21 babies APGAR score was less than 7 at 5 minutes. Respiratory distress syndrome was suffered by 15% babies and 10% were suffered meconium aspiration syndrome. Due to all these complications 15 babies were admitted to NICU.4,5

Oligohydramnios is well known to be associated with high adverse risk during the perinatal period. However, it is a poor indicator for the adverse effects during this period. But it is also used as a predictor for delivery.6,7 So, closely monitoring of the volume of amniotic fluid during antenatal period is very helpful to find out the risk of the adverse effects during perinatal period.8,9

Conclusion

Oligohydramnios is one of the most common complications during the pregnancy which can cause maternal mortality and morbidity. But if it is diagnose in early stage and if it is treated properly we can reduce the maternal and fetal complications. My patient has received proper care and her conditions also improved as evidenced by the patient conditions and the treatment is still going on till my last date of care.

Ethical Clearance: Taken from institutional ethics committee.

Case Report on Full Term Normal Delivery

Pradnya Gavhale¹, Shalini Moon², Manoj Patil³

¹M.Sc. Nursing, ²Asst. Professor, Dept. OBGY Nursing, Smt. Radhikabai Meghe Memorial College of Nursing Sawangi (Meghe), Wardha, Datta Meghe Institute of Medical Sciences (Deemed to be University) Maharashtra, India, ³Research Consultant, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences (DU) Sawangi (M), Wardha India

Abstract

**Background:** Labor has been defined as that of the initiation of periodic painful contractions of progressive deletion as well as dilation of a cervix, followed by a decent part going to lead to the expulsion of its fetus & placenta from the uterus of mother. Post-natal treatment was its individualized treatment provided that meet the needs of the baby and mother after delivery/childbirth.

**Case Report:** Mrs. Nikita Matram 25-year-old female was admitted in AVBR Hospital with the complaint of pain in abdomen and increased fetal movement on date 4/01/2020 and she delivered female baby on date 6/01/2020 and the baby weight was 2.8 kg at 1:40 am now her complaint was pain on suture side and weakness. but the patient has a previous history of abortion after marriage of four month two and half month of baby was abort. That time dilatation and curettage was done.

Patient delivered female baby throughout the vaginal delivery and baby and mother was normal after delivery baby was kept with mother on same bed and initiate breastfeeding within one hour after delivery.

**Conclusion:** Case report conclude that after normal delivery and post-natal care mother and baby was normal.

**Keywords:** Full term normal delivery, post-natal care, newborn, delivery.

Introduction

Giving birth, commonly defined of labor and birth, seems to be the conclusion of pregnancy once an or maybe more kids exit the mother via going through the womb or even the caesarean delivery and, throughout delivery, a baby is released through the womb. There are different forms of vaginal delivery. Supported vaginal and instrumental vaginal birth, accidental vaginal delivery, triggered vaginal birth, natural vaginal delivery.

Treatments that are consistent to protection. Given medical and scientific innovations through managing complex health problems, this same current setting with maternity services had also increased rates for healthy mothers and infants. There have been fears all around the community that evidence-based strategies and procedures across labour and childbirth are standard occurrence.¹ There is significant mis-use of advantageous techniques, over-use of detrimental or inefficient method, or lack of desire and over consequences of insufficiently measured method.² Enhance the efficiency with maternity services for both developed and emerging nations is an essential part with efforts to reduce maternal and infant mortality and morbidity.

**Case Presentation:** Mrs. Nikita Matram 25-year-old female diagnosed with G2,A1, with 38 .2 wks. of gestational age with full term normal delivery was admitted in AVBR Hospital with the complaint of pain in abdomen and increased the fetal movement on date 4/01/2020 and she delivered female baby on date 6/01/2020 and the baby weight was 2.8 kg at 1:40 am now her complaint was pain on suture side and weakness. Before pregnancy the patient menstrual cycle was regular 28 days of cycle and duration was 3-4 days.
and Last menstrual period was 11/04/2019 and Expected date of delivery was 16/01/2020.

Mrs. Nikita Matram has a previous history of abortion after marriage of four month & two and half month of baby was aborted. That time dilatation and curettage was done. She has not used any contraception method & no any medical history like DM, Hypertension, TB, Asthma. She lives in joint family in their family five member are living together including newborn and she was belonging from middle class family and in their houses all facilities are available like electricity, water supply from municipality etc. her monthly income was 25000/- per month. Mrs. Nikita and her family members were psychological stable. She maintains good interpersonal relationship with others. She is taking only vegetarian diet. She doesn’t have any allergic reaction from any food and no any history of any bad habits like chewing tobacco, smoking etc.

Patient general examination was state of health was unhealthy, conscious, Body built thin, Posture erect, hygiene was good. General parameter height was 154 cm, weight 45 kg. Vital sign is Temperature 98˚c, Pulse 84 b/m, Respiration – 20 b/m, BP – 120/80 mmHg. In breast some changes occur because of pregnancy enlargement of breast, nipple was large erectile and discharge was present of milk secretion. In abdomen linea nigra, striae gravidarum present. Lochia rubra was present.

**Investigations:**
- **CBC**
  - Hb 12.7 gm %
  - Total RBC 3.92 million/cu mm
  - Total WBC 13900 cu.mm
  - Total platelet counts 2.69 lacs/cu.mm
- **LFT**
  - SGPT 17
  - SGOT 31
  - Albumin 3.6 g/dl
- **USG**
  - Fetal no. – single
  - Lie – variable
  - Placenta – anterior, grade –II

Presentation – variable
Fetal movement – present
Liquor – adequate

Impression of USG – single intrauterine live fetus of average gestational age of 27 weeks 1 day and corresponding to weight of 999GMS.

The drugs are used Inj. Metrogyl 100cc, I.V., TDS.Action – Metronidazole injection is also to prevent infection when used before, during, and after colorectal surgery. Metronidazole injection is in a class of medications called antibacterial. It works by killing bacteria and protozoa that cause infection, Inj. C-Tax 1 gm, I.V., BD., Action - C Tax 1gm Injection is an antibiotic medicine used to treat bacterial infections in your body. It is effective in infections of the brain, lungs, ear, urinary tract, skin and soft tissues, bones and joints, blood and heart. It is also used to prevent infections during surgery, Inj. Oxytocin 10 IU.Oxytocin is a uterine stimulant, prescribed for the initiation of uterine contractions and induction of labor in women as well as stimulation of contractions in cases where the uterus does not contract enough during labor.

If any complication occurs during normal delivery than patient refer for lower segment Cesarian section. Mother should take care of self and self-care may include Rest and ambulance -early ambulation after delivery, hospital stay, diet, perineal care, care of bladder, care of bowel, sleep, care of breast, rooming in, aseptic and antiseptics, immunization post-partum exercise, follow up, daily observation and care of newborn. After normal delivery mother and baby should come for check up and follow up after discharge of six weeks, and explained the client about if any sign of infection and side effect of medication immediately informed to the doctors. Immunization of baby follow up is necessary.

**Discussion**

Present case reveals that the antenatal patient come in hospital with the complaint of pain in abdomen and increased the fetal movement on date 4/01/2020 and she delivered female baby on date 6/01/2020 and the baby weight was 2.8 kg at 1:40 am now her complaint was pain on suture side and weakness. After delivery mother and baby was normal Apgar score was ten and baby was kept with mother in same bed it will help to initiate breast feeding, thermoregulation, create bonding between mother and child, mother learn how to provide
the care to baby etc. after that pain was managed by painkiller. Condition of baby and mother was good.

Most broadly, the phrase ‘natural life’ in scientific research and healthcare policy refers to conception without and with minimal surgical intervention. The 2007 systematic review by both the prenatal care Planning Group, Making Natural Childbirth a Fact, provided for such a uniform approach of hospital birth to improve trust for auditors or tracking practice patterns. A subsequent description defined natural delivery or non-assisted vaginal delivery without intervention of labour; epidural, spinal and general anaesthesia or episiotomy. Unlike many other meanings, an interpretation with Werkmeister has been restricted to a pregnancy and birth and it does not apply to birth outcomes like vertical presentation as well as intact perineum.

This same delivering of a full-term baby originally referred with service only at gestational age of 37-42 weeks, even though defined by last menstruation cycle or through ultrasound dating as well as assessment. A Naegel rule is indeed a frequently used formula besides predicting a due date mostly on date from the last menstruation cycle. Its legislation states a 28-day menstruation periods as well as a mid-stage ovulation. Ultrasound dating will be much more accurate, especially because once implemented early in the pregnancy and used to substantiate or adjust a due date focused on last menstruation cycle. About 11 per cent of singleton birth is pre-term and 10 per cent of all births are post-term. As a result, nearly 80 per cent of babies are born on even a full-term basis, but only 3-5 per cent of births arise mostly on expected delivery date.

Healthcare offers patient care, encourages convenience, listens to emotional needs through a comprehensive wellbeing paradigm, and teaches nutrition or self-care. Even so, in today’s popular health care setting, postnatal nurses are very often responsible to devices or for mothers and babies. It is critical that organizations develop trust and expertise in order to make a transition towards a humanizing birth feasible. This topic problem in such a major nursing review offers important resources to help caregivers encourage, endorse and defend regular births. Nursing staff have a special and significant role to play in deciding the treatment procedures encountered by women. Unfortunately, nursing staff may well be functionally removed from important method of data interchange as well as from making a contribution to a treatment plan. This can influence the ability of nursing to successfully encourage, help or secure regular births. Since medicalized conception presents a threat of iatrogenic damage to the both mothers and infants, nurses have a duty obligation to encourage natural delivery in order to improve patient health. Studies on Prenatal diagnostic and treatment modalities were reviewed.

**Conclusion**

After delivery, mother and baby was normal. Apgar score was ten at birth. Condition of baby and mother was good after pain management pain was reduced.

**Ethical Clearance:** Taken from institutional ethics committee.

Case Report on Obsessive-Compulsive Disorder

Samuel Vanlalpeka¹, Jaya Gawai², Manoj Patil³

¹M.Sc. Nursing, ²Associate Professor, Dept. of Mental Health Nursing, Smt. Radhikabai Meghe Memorial College of Nursing Sawangi (Meghe), Wardha Datta Meghe Institute of Medical Sciences (Deemed to be University) Maharashtra, India, ³Research Consultant, Jawaharlal Nehru Medical College, Datta Meghe Institute of Medical Sciences (DU) Sawangi (M), Wardha India

Abstract

Introduction: Obsessive-compulsive disorder is an anxiety disorder in which people have recurrent, undesirable thoughts, ideas or sensations (obsessions) that make them feel compelled to go and do something (compulsion) repeatedly. Repetitive habits, such as washing hands, inspecting items or bathing, can substantially interfere with the everyday routines and social experiences of an individual.

Symptoms: Behavioral changes like hyperactivity, impulsivity, repetitive movement, perfectionism and social isolation. Mood changes like anxiety, anger and apprehension. Psychological changes like sleep disturbance, fear, repeatedly going over thoughts and narcissism.

Investigation: Hb% - 13 mg/dl; Glucose plasma random – 86 mg%; Serum Globulin– 3.2gm %; serum-Protein- 7gm %; HIV, HCV, HBsAg, VDRL, all of these tests were negative.

Surgical Management: Patient have no past surgical history.

Medical Management: Patient was treated with Ativan (Lorazepam) 3mg q6hr per oral and Therapies like Aversion therapy and Group Psychotherapy was also used.

Nursing Management: Assess for physical, psychological and social data. Aware for Impact of obsessions and compulsions on physical health, mood, self-esteem and natural capacity to cope. Remember that the defense mechanisms used, the nature or structure of the feeling, the suicidal risk, the capacity to work and the space accessible for social support services.

Conclusion: Patient was admitted to AVBRH and was diagnosed to have Obsessive-compulsive disorder. The got appropriate treatment and therapy and his condition has improved well.

Keywords: Obsessive-compulsive disorder, anxiety, compulsion, obsession, lorazepam, narcissism.

Introduction

Individuals with obsessive-compulsive personality disorder are very serious and Obsessive-compulsive personality disorder is very severe and formal, and has emotional difficulty. They are highly rigid, perfectionist, and keen on law. They are resistant to change about how tasks will be handled, and dedicate themselves to success to the exclusion of personal satisfaction. An extreme fear of making mistakes leads to a challenging decision-making process. The disease is relatively widespread and appears more often in men than in women. It appears to be most common in the oldest children within the family group.¹

The obsessive-compulsive disorder is, according to ICD9, a state in which “the outstanding symptom is a feeling of subjective compulsion which must be resisted - to carry out some action, to dwell on an idea, to recall an experience, or ruminate on an abstract topic. Unwanted thoughts, which include the insistency of words or ideas are perceived by the patient to be inappropriate or nonsensical. The obsessional urge or idea is recognized as alien to the personality, but as coming from within the
self. Obsessional rituals are designed to relieve anxiety, e.g. washing the hands to deal with contamination. Attempts to dispel the unwelcome thoughts or urges may lead to a severe inner struggle, with intense anxiety.

**Patient information:** A male patient 47 years from Halwadi, Wardha was admitted to Psychiatric Ward, AVBRH on 10th January 2020 with a case of Obsessive-compulsive disorder.

**Present Medical History:** My patient was apparently asymptomatic 2 years back when he was working in a private company while he was firing from his job due to his lack of responsibility according to his employer. Since then, he started maintaining self-disciplined and directing himself to his work with fear of losing the new job again. His behavior getting very excessive that leads to difficulty in coping with family and the society. He was brought to AVBRH by his wife on 10/01/2020, when he was diagnosed with Obsessive-compulsive disorder.

**Past Medical History:** My patient was apparently asymptomatic 2 years back when he was fired from his job due to lack of responsibility. He started devoting himself to his new job, maintaining new job self-disciplined that eventually leads to excessive behavior disorder like sleep disturbance, lack of interaction, perfectionist, difficulty in completing task due to perfectionism and strict standards, maintaining extreme hygiene of self and surroundings.

**Family History:** My patient belongs to a nuclear family, middle class living with his wife and two sons in their own house in Halwadi, Wardha. He is working as a clerk in a private school and is a breadwinner of the family. His two sons, one is 11th standard and the other is 9th grade. His wife has a small grocery store in their house.

**Clinical Findings:** Behavioral changes like hyperactivity, impulsivity, repetitive movement, perfectionism and social isolation. Mood changes like anxiety, anger and apprehension. Psychological changes like sleep disturbance, fear, repeatedly going over thoughts and narcissism.

**Predisposing Factors:** From a psychoanalytical point of view, one of overcontrol is the parental style in which the adult with obsessive-compulsive personality disorder was reared. Such parents want their children to live up to and reject their set standards of behaviour if they do not. Praise is bestowed on the child with far less frequency than punishment for unwanted behaviors. Individuals are specialists in this setting of knowing what they can not do to escape retribution and criticism, rather than what they should do to gain respect and praise. They learn to follow strict rules and regulations. Significant accomplishment are expected, taken for granted and acknowledged only occasionally by their parents, whose responses and decisions are restricted to pointing out transgressions and infringement of the rules.

**Pathophysiology:** Anxiety, obsessive-compulsive, most likely and associated disorder are caused by multiple factors. A graphic description of this multiple association hypothesis is provided in the Stress/Adaptation Transactional Model.

**Mental Status Examination:** A mental status examination was performed on my patient and it was found out that there was an impaired in the stream of thought and in the insight, the score was 2 i.e. the client denies of him having mental illness.

**Diagnostic Assessment:** Hb% - 13 mg/dl; Glucose plasma random – 86 mg%; Serum Globulin– 3.2gm %; serum-Protein - 7gm %; HIV, HCV, HBsAg, VDRL, all of these tests were negative.

**Therapeutic Intervention:** Tab Ativan (Lorazepam) 3mg PO x q6h. Therapies like Aversion therapy and Group Psychotherapy was also used.

**Discussion**

A male client of 47 years old from Halwadi was admitted to Psychiatric ward, AVBRH on 10th January 2020 with a complaint of strict personality and disciplined, which cause him to interact or cope with his family or society (according to the patient). According to the patient’s wife, the patient was an extreme self-disciplined, perfectionist, and he also wanted to change the bedsheet, clothes, shoes and blankets every day and he was very violent when they disobey him and this behavior had started in the past 2 years ago. He was diagnosed as Obsessive-compulsive disorder. As soon as he was admitted to hospital investigations were done and appropriate treatment were started. After getting treatment, he shows great improvement and the treatment was still going on till my last date of care.

A study was done on, “An epidemiological study and...”
severity assessment of obsessive-compulsive disorder in Warangal region, India”. The study aimed at to clinically assess the prevalence and assess the severity of obsessive-compulsive disorder (OCD) in Warangal region, India. A prospective observational study was done for a duration of 6 months i.e. from July-December 2013 at various Neuropsychiatric Centres in Warangal region. A total of 113 patients (male: 65, female: 48) were screened using specially designed data collection form to collect and record demographic data. Structured interviews were conducted to obtain Yale Brown Obsessive-Compulsive Scale (YBOCS) scores. All the data were analysed by ANOVA and Chi Square test using Statistical Package for Social Sciences (SPSS) software version by dividing the patients into age groups of decades from 11 to 60. It was found out This obsessive-compulsive disorder was more common in subjects between the ages of 21 and 30 (46%) and literate in patients (98.2%). More patients were married (61.6%) than single patients (38%). The most prevalent obsession was fear of harming (81.25%) while of the most prevalent compulsions was repeating (76.1%). Based on YBOCS scale, OCD severity was categorized into subclinical (2.7%), mild (23.9%), moderate (41.6%), severe (23%) and extreme (8.9%). The study concluded that the prevalence of OCD condition was more among the age group of 21 to 30 years and among literates. Sociodemographic factors like age, socioeconomic status and urban were risk factors in assessing the severity of OCD. Fewarticles related to various aspects of prevalent psychological problems and associated factors were reviewed 4-11. Ethical clearance-Taken from institutional ethics committee.

Yash Scoring System in the Diagnosis of Acute Appendicitis

Yeshwant Lamture¹, Rahul Y. Netragaonkar², Varsha Gajbhiye³, Ranjeet Ambad⁴

¹Professor, Dept. of General Surgery, J.N.M.C. Sawangi (Meghe) Wardha, ²Associate Professor, Dept. of Community Medicine, DVVPF’S Medical College, Ahmednagar, ³Asso. Professor in Pharmacology, Datta Meghe Medical College. Nagpur, ⁴Associate Professor in Biochemistry, Datta Meghe Medical College. Nagpur

Abstract

Background: Acute appendicitis is amongst the most encountered emergencies seen in casualties requiring intervention. The incidence of negative laparotomy is 15% to 25% and is associated with notable morbidity. Scoring systems are useful and logical for distinguishing acute appendicitis from non-specific abdominal pain. Presently many scoring systems exist that aids in the diagnosis of acute appendicitis but still fail to decrease the rates of wrong diagnosis and the negative appendicectomy rate. This study has been undertaken to evaluate the efficacy of the newer Yash scoring system which has been found more effective for the Indian population in diagnosing acute appendicitis.

Method and Material: A prospective study of the Yash scoring system was done on 50 patients. The decision of an appendicectomy was taken by the consultant surgeon. The outcomes of the Yash scoring system in terms of sensitivity, specificity, positive predictive value, negative predictive value, and diagnostic accuracy were calculated.

Results: The Yash scoring system had sensitivity, specificity, PPV, NPV, and DA of 94.28%, 93.33%, 97.05%, 87.50%, and 94% respectively.

Conclusion: The Yash scoring system was a good tool to diagnose acute appendicitis.

Keywords: Negative appendicectomy, C-reative protein, Hyperaesthesia in sherrens triangle, Blumberg sign.

Introduction

Acute appendicitis is amongst the many encountered emergencies seen in casualties requiring intervention. There is a 6% chance of appendicitis in the general population[¹]. Though the mortality has declined from 26% to 1% with the dawn of broad-spectrum antibiotics and timely surgery, it remains 5 to 15% in the elderly[²]. The incidence of negative laparotomy is 15% to 25% and is associated with notable morbidity, the frequency being more in women of reproductive age group (till 45%) due to the commonness of inflammatory tubo-ovarian diseases, ectopic pregnancy, and other gynecological pathology[³]. The delay in diagnosis may lead to rupture of the appendix in 17% to 40% of cases mostly in extremes of age. In the adolescents and elderly, it is linked with dramatic complications like an intra-abdominal abscess, wound infection, and ultimately death[⁴]. Thus, confirmation of acute appendicitis is very crucial to achieve lower morbidity and mortality rates.

The regular laboratory investigations of blood and urine are necessary. Leukocytosis is a convenient finding but is non-specific and may be missing in the elderly[⁵] C – Reactive protein is elevated in almost all acute inflammatory conditions, hence is considered as a non-specific marker but its estimation guides a surgeon in reducing negative appendicectomies[⁶,⁷].

Corresponding Author:
Dr. Rahul Y. Netragaonkar
Associate Professor, Dept. of Community Medicine, DVVPF’S Medical College, Ahmednagar
e-mail: dryrlamture@yahoo.co.in
Magnetic resonance imaging (MRI) as an investigation is only taken typically in the pregnant population where radiation exposure is not warranted. It provides outstanding resolution and is highly efficient in diagnosing acute appendicitis. MRI has high sensitivity and specificity of 100% and 98% respectively. The PPV and NPV of MRI are 98% and 100% respectively. It is also operator-independent. The only issue is its higher cost, motion artifact, and complexity in reading MRI by non-radiologists with limited experience [6].

Despite the use of all these imaging techniques, the incidence of negative appendicectomy is not decreasing. These unmerited operations have a complication rate of approximately 13%, which is nearly to that of an inflamed appendix. Removal of a healthy appendix has a mortality of 0.65%. Protracted clinical observations aiming to reduce undesired operations may mean a delay in operations in 28% of cases and considerable danger of perforation[7,8,9].

Scoring systems are useful and logical for distinguishing pain of acutely inflamed appendix from vague abdominal pain. Presently numerous scoring systems exist that aid in diagnosing acute appendicitis. However, these systems do not replace clinical acumen thereby just helping in the determination of acute appendicitis and aids in approaching a conclusion, whether a particular case should be operated or not, thus lowering the negative appendicectomy rate (NAR)[10,11].

The study done by Lamture YR et al[12] in India on the Yash scoring system reveals a sensitivity of 99.48%, a specificity of 92.86%, PPV of 99.48%, and NPV of 92.86%. Though the validity of the Yash scoring system is promising for the Indian population, its only disadvantage was in the mode of a single study.

Despite various scoring systems and developments in the diagnostic and imaging modalities, the diagnosis of appendicitis is in dilemma which fails to decrease the rates of wrong diagnosis and the negative appendicectomy rate. This sequentially increases the cost for diagnosis by the use of expensive radiological modalities like Computed Tomography and MRI thus causing a delay in the treatment leading to an increase in morbidity and mortality of the patients[13].

This non-randomized prospective study has been undertaken to evaluate the effectiveness of the newer Yash score which has been found more effective for the Indian population in diagnosing acute appendicitis.

Method

The present study was undertaken in the department of surgery, Jawaharlal Nehru Medical College, Wardha in collaboration with Datta Meghe Medical College Hingana, Nagpur, Datta Meghe Institute of medical science (DMIMS), Sawangi, Meghe, Wardha, Maharashtra India.

Study Design: Prospective non-randomized study.

Study Population: All patients of acute appendicitis with age >15 years and <60 years.

Study Duration: July 2018-July 2020.

Sample Size: 50 Patients

Inclusion Criteria: All patients with right lower quadrant pain and clinically diagnosed as acute appendicitis of age >15 years and <60 years.

Exclusion Criteria:
1. Patients with appendicular mass.
2. Patients of appendicitis with a known case of connective tissue disorder.
3. Patients with a past history of renal or ureteric stones and pelvic inflammatory disease.
4. Pregnant women.

Ethical clearance was obtained from the Ethics committee of Datta Meghe Institute of Medical Sciences (Deemed to be University) [Ref. No. DMIMS(DU)/IEC/2018-19/7426]. This prospective non-randomized study was conducted in Acharya Vinoba Bhave Rural Hospital, Sawangi. All the patients who fulfilled the eligibility criteria were subjected to routine hematological investigations, C-reactive protein, USG, and were scored based on the Yash scoring system.

The components of the Yash scoring system are as follows:
• Migration of pain to the right iliac fossa = 1 point
• Nausea and vomiting = 1 point
• Anorexia = 1 point
• Right iliac fossa tenderness = 2 points
• Rebound tenderness = 1 point
• Hyperesthesia in Sherren’s triangle = 1 point
• Fever = 1 point
- White blood cell count > 10,000 mg/dl = 2 points
- C-reactive protein (> 15mg/dl) = 3 points
- Ultrasonography = 4 points

A score of 7 or more is suggestive of acute appendicitis requiring surgery\(^{[12]}\).

The decision to operate was taken by a consultant surgeon by clinical diagnosis with help of other appropriate investigations in special circumstances. All patients underwent appendicectomy with prior consent and the specimen was subjected to histopathological examination for confirmation of diagnosis. The minimum criteria for acute appendicitis were the appearance of neutrophils in mucosa, submucosa, and lamina propria\(^{[1]}\).

The result of the Tzanakis score and Yash score was reported independently. The result was correlated with the findings obtained on histopathological examination and the data was analyzed using the necessary statistical calculations using SPSS 24.0 version, the results were then presented.

**Observations and Results**

Graph No. 01: Gender distribution

Graph 02: Characteristics of Yash score
Graph 03: Outcome of YASH scoring system

Graph 04: Negative Appendectomy rate of Yash scoring system:
Acute appendicitis continues to exist as the most widespread emergency in the world. A delay in making a diagnosis is associated with various complications which increases the morbidity and mortality in patients therefore a prompt and reliable diagnosis of acute appendicitis is mandatory. Further more, negative appendicectomy also accounts for the loss of financial resources and is associated with morbidity in 10 to 15% of cases.

Despite big breakthroughs in the imaging field, there remains uncertainty in diagnosing acute appendicitis due to atypical presentations of the disease. It has been repeatedly shown that investigations like USG lack specificity due to its operator dependency whereas investigations like CT scan and MRI are highly-priced demanding more advanced equipment and competency. This makes a detailed clinical examination with primary investigations such as leucocyte count as the backbone in diagnosing acute appendicitis. This has compelled many surgeons to use diverse scoring systems for diagnosing acute appendicitis. The clinical evaluation is reliable in 50% to 80% of cases. The evaluation is more complex in the extremes of age and women of reproductive age group due to atypical presentations.

The current study will deal with the evaluation of the Yash scoring system to diagnose acute appendicitis in a simple, reliable, and cost-effective way thereby reducing the negative appendectomy rate and thus morbidity associated with it.

In this study, the sample population consisted of 50 patients out of which 58% were males and 42% were females (see graph 01).

All the patients who accomplished the eligibility criteria were subjected to detailed clinical examination, routine hematological investigations, C-reactive protein, USG and were scored based on the Yash scoring system. The decision to operate the patient including patients with scores less than the cut-off value was based on the clinical assessment and judgment taken by the consultant surgeon. All the patients underwent appendectomy with prior consent and the specimen was subjected to histopathological examination to confirm the diagnosis.

In our study, 82% of the patients were operated by open method whereas 18% of patients were operated by laparoscopy. The study done by Malla BR et al[14] consisted of 200 patients in which 128 patients (64%) underwent appendectomy by an open method and 72 patients (36%) underwent appendectomy by laparoscopy.
The most common incision used in open appendectomy was Mc Burney’s in about 83% of cases followed by the right Para median which was used in 17% of cases. Similarly, in the study done by Lamture YR et al[12] the most common incision used was Mc Burney’s in 94.74% of patients followed by right Para median in 5.26% of cases. In our present study, 35 out of 50 patients (70%) had inflamed appendix intra-operatively. Out of the remaining 15 patients, five patients had enterocolitis, three patients had Meckel’s diverticulitis, three patients had the pelvic inflammatory disease (salpingitis), two patients had a ruptured ovarian cyst and two patients had inflamed mesenteric lymph node (with or without pus) as the intra-operative findings. Shashikala V et al[9] in her study had five out of 50 patients with the alternative diagnosis; out of which one patient had enterocolitis and four patients had the pelvic inflammatory disease.

Another study was done by Kumar SLA et al[13] his study also reported six patients with alternative diagnoses in which three patients had salpingitis, two patients had an ovarian cyst and one patient had Meckel’s diverticulitis.

The new Yash score described by Lamture YR et al[12] in 2017 has a significant role in identifying acute appendicitis. It differs from earlier scoring systems by including various parameters such as C-reactive protein, leukocyte counts, USG, and clinical data. A score of seven or more in patients was considered as acute appendicitis and such patients were subjected to operative intervention.

In our study, out of ten parameters, tenderness in the right iliac fossa was the commonest sign seen in 100% of patients. The other two signs i.e. rebound tenderness and hyperesthesia in Sherren’s triangle was seen in 82% and 26% of patients respectively. The most common symptom was fever which was present in 88% of cases followed by nausea or vomiting which was found in 86% of the cases. Anorexia was seen in 72% of patients, whereas 68% of patients gave a history of migratory right iliac fossa pain. Out of the three investigations included in the scoring system, leucocytosis defined as WBC count more than 10000/mm$^3$ was present in 80% of cases. C-reactive protein with a value of more than 15mg/dl was present in 28% of cases with USG showing features of appendicitis in only 46% of cases (see graph 02).

In the present study, 34 patients had a score of seven or more, and 16 patients who had a score of less than seven according to the Yash score. Out of the 34 patients who scored seven or more, there were 33 patients with features of appendicitis on histopathological examination whereas only one patient had a histologically normal appendix with no features of inflammation. Similarly, out of 16 patients who scored less than seven, there were 14 patients with a histologically normal appendix with no features of inflammation and only two patients with features of appendicitis on histopathology.

The sensitivity and specificity of the Yash scoring system in the present study were found to be 94.28% and 93.33% respectively. It had PPV and NPV of 97.05% and 88.50% respectively. The overall diagnostic accuracy of the Yash scoring system in our study was found to be 94% (see graph 03). The following results are comparable to the single original study done by Lamture YR et al in which the sensitivity, specificity, PPV, and NPV was 99.48%, 92.86%, 99.48%, and 92.85% respectively. The diagnostic accuracy of the Yash score reported by Lamture YR et al was 98.56%.

The negative appendicectomy rate (NAR) of the Yash scoring system in the present study was found to be zero percent in males and 4.76% in females. This discrepancy in NAR was due to the high probability of another possible diagnosis in females of reproductive age group such as pelvic inflammatory diseases and ovarian cyst. The overall NAR observed for the Yash scoring system was 2% (see graph 04) which is way lower than the accepted rate of 15 to 25%. In the study done by Lamture YR et al[12], the NAR was found to be 6.69% which is comparable to our study[14].

The negative appendicectomy rate of the Yash scoring system was dramatically lower than other studies and the diagnostic accuracy of this scoring system is better when compared with other studies (see graph no 5).

**Conclusion**

The study also shows that the Yash scoring system is a better tool to avoid unnecessary operations due to its exceptionally low negative appendicectomy rate thus lowering morbidity in patients of acute appendicitis and thereby lowering the cost of treatment and prevention of misuse of valuable resources and manpower.

Abstract

Background: Acute appendicitis is amongst the most encountered emergencies seen in casualties requiring intervention. The incidence of negative laparotomy is 15% to 25% and is associated with notable morbidity. Scoring systems are useful and logical for distinguishing acute appendicitis from non-specific abdominal pain. Presently many scoring systems exist that aids in the diagnosis of acute appendicitis but still fail to decrease the rates of wrong diagnosis and the negative appendicectomy rate. This study has been undertaken to evaluate the efficacy of the Tzanakis scoring system for the Indian population in diagnosing acute appendicitis.

Method and Material: A prospective study to evaluate Tzanakis scoring system on 50 patients. The decision of an appendicectomy was taken by the consultant surgeon. The outcomes of the Tzanakis scoring system in terms of sensitivity, specificity, positive predictive value, negative predictive value, and diagnostic accuracy were calculated.

Results: The Tzanakis scoring system had sensitivity, specificity, PPV, NPV, and DA of 71.42%, 66.67%, 83.33%, 50%, and 70% respectively.

Conclusion: Tzanakis scoring system in diagnosing acute appendicitis has a lower value in Indian populations.

Keywords: Inflammation of the appendix, gangrene of appendix, perforation peritonitis.

Introduction

Acute appendicitis is amongst the many encountered emergencies seen in casualties requiring intervention. There is a 6% chance of appendicitis in the general population[¹]. Though the mortality has declined from 26% to 1% with the dawn of broad-spectrum antibiotics and timely surgery, it remains 5 to 15% in the elderly[²].

The incidence of negative laparotomy is 15% to 25% and is associated with notable morbidity, the frequency being more in women of reproductive age group (till 45%) due to the commonness of inflammatory tubo-ovarian diseases, ectopic pregnancy, and other gynecological pathology[³]. The delay in diagnosis may lead to rupture of the appendix in 17% to 40% of cases mostly in extremes of age. In the adolescents and elderly, it is linked with dramatic complications like an intra-abdominal abscess, wound infection, and ultimately death [⁴]. Thus, confirmation of acute appendicitis is very crucial to achieve lower morbidity and mortality rates.

Ultrasonography (USG) with graded compressions has immense capacity in diagnosing appendicitis in its acute stage[⁵]. Various studies have been conducted on
the utilization of these imaging systems. These studies reported a sensitivity of 75% to 94%, a specificity of 86% to 100%, and gross precision up to 96%\cite{6}. Its superiority over computed tomography is the absence of exposure to ionizing radiation thus helpful in pregnant and pediatric patients. The major disadvantage is that it is operator dependent leading to inter-observer bias and failure to see the appendix during the scan does not rule out the possibility of having an inflamed appendix\cite{5}.

Despite the use of all these imaging techniques, the incidence of negative appendicectomy is not decreasing. These unmerited operations have a complication rate of approximately 13%, which is nearby to that of an inflamed appendix. Removal of a healthy appendix has a mortality of 0.65%. Protracted clinical observations aiming to reduce undesired operations may mean a delay in operations in 28% of cases and considerable danger of perforation\cite{7}.

Scoring systems are useful and logical for distinguishing pain of acutely inflamed appendix from vague abdominal pain. Presently numerous scoring systems exist that aid in diagnosing acute appendicitis. However, these systems do not replace clinical acumen thereby just helping in the determination of acute appendicitis and aids in approaching a conclusion, whether a particular case should be operated or not, thus lowering the negative appendicectomy rate (NAR).

The original study done by Tzanakis et al\cite{8} in Greece reported sensitivity and specificity of 95.4% and 97.4% respectively. The diagnostic effectiveness of the score was 96.5% in his study. But in India, this scoring system was found inferior. For example, a comparative study between Tzanakis score and Alvarado score done by Shashikala V\cite{9} in India revealed that Tzanakis scoring system had a sensitivity of 79.62%, a specificity of 83.3%, PPV of 97.72%, and NPV of 31.25% which was found better than Alvarado scoring system but still posing difficulties in diagnosis with a NAR of 12%. Another study was done by Iqbal MM et al\cite{10} in Postgraduate medical center, Karachi, Pakistan revealed that the Tzanakis score had a sensitivity of 99%, the specificity of 91%, PPV of 99%, and NPV of 91% with a diagnostic accuracy of 95%. Similarly, A study done in Kathmandu Model Hospital, Nepal did by Sigdel GS et al\cite{11} reveals that Tzanakis has a sensitivity of 91.48%, a specificity of 66.66%, and diagnostic accuracy of 90%.

Despite various scoring systems and developments in the diagnostic and imaging modalities, the diagnosis of appendicitis is in dilemma which fails to decrease the rates of wrong diagnosis and the negative appendicectomy rate. This sequentially increases the cost for diagnosis by the use of expensive radiological modalities like Computed Tomography and MRI thus causing a delay in the treatment leading to an increase in morbidity and mortality of the patients.

This non-randomized prospective study has been undertaken to evaluate the effectiveness of the Tzanakis score in diagnosing acute appendicitis.

**Method**

The present study was undertaken in the department of surgery, Jawaharlal Nehru Medical College, Wardha in collaboration with Datta Meghe Medical College Hingana, Nagpur, Datta Meghe Institute of Medical science (DMIMS), Sawangi, Meghe, Wardha, Maharashtra India.

**Study Design:** Prospective non-randomized study.

**Study Population:** All patients of acute appendicitis with age >15 years and <60 years.

**Study Duration:** July 2019-July 2020.

**Sample Size:** 50 patients

**Inclusion Criteria:**

1. Patients with appendicular mass.
2. Patients of appendicitis with a known case of connective tissue disorder.
3. Patients with a past history of renal or ureteric stones and pelvic inflammatory disease.
4. Pregnant women.

**Exclusion Criteria:**

1. Patients with appendicular mass.
2. Patients of appendicitis with a known case of connective tissue disorder.
3. Patients with a past history of renal or ureteric stones and pelvic inflammatory disease.
4. Pregnant women.

Ethical clearance was obtained from the Ethics committee of DattaMeghe Institute of Medical Sciences (Deemed to be University).This prospective non-randomized study was conducted in Acharya VinobaBhave Rural Hospital, Sawangi. All the patients who fulfilled the eligibility criteria were subjected to routine hematological investigations, USG, and were scored based on Tzanakis scoring system.
Tzanakis scoring system combines 4 variables as follows:

- Presence of right lower abdominal tenderness = 4 points
- Rebound tenderness (Bloomberg sign) = 3 points
- Laboratory findings: the presence of white blood cells greater than 12,000 in the blood = 2 points
- Ultrasound findings: the presence of positive ultrasound scan findings = 6 points

A score of 8 or more is suggestive of acute appendicitis requiring surgery[8].

The decision to operate was taken by a consultant surgeon by clinical diagnosis with help of other appropriate investigations in special circumstances. All patients underwent appendicectomy with prior consent and the specimen was subjected to histopathological examination for confirmation of diagnosis. The minimum criteria for acute appendicitis were the appearance of neutrophils in mucosa, submucosa, and lamina propria[1]. The result of the Tzanakis score was calculated. The result was correlated with the findings obtained on histopathological examination and the data was analyzed using the necessary statistical calculations using SPSS 24.0 version, the results were then presented.

**Observations and Results:**

Graph No. 01: Gender

Graph 02: Individual characteristics of Tzanakis score:
Graph 03: outcome of Tzanakis Scoring system

Graph 04: Negative appendicectomy rate of Tzanakis scoring system:
Acute appendicitis continues to exist as the most widespread emergency in the world. A delay in making a diagnosis is associated with various complications which increases the morbidity and mortality in patients therefore a prompt and reliable diagnosis of acute appendicitis is mandatory. Furthermore, negative appendicectomy also accounts for the loss of financial resources and is associated with morbidity in 10 to 15% of cases.

Despite big breakthroughs in the imaging field, there remains uncertainty in diagnosing acute appendicitis due to atypical presentations of the disease. It has been repeatedly shown that investigations like USG lack specificity due to its operator dependency whereas investigations like CT scan and MRI are highly-priced demand more advanced equipment and competency. This makes a detailed clinical examination with primary investigations such as leucocyte count as the backbone in diagnosing acute appendicitis. This has compelled many surgeons to use diverse scoring systems for diagnosing acute appendicitis. The clinical evaluation is reliable in 50% to 80% of cases. The evaluation is more complex in the extremes of age and women of reproductive age group due to atypical presentations[12,13].

The current study will deal with the evaluation of the Tzanakis scoring system to diagnose acute appendicitis in a simple, reliable, and cost-effective way thereby reducing the negative appendectomy rate and thus morbidity associated with it.

In this study, the sample population consisted of 50 patients out of which 58% were males and 42% were females (see graph 01). The male to female ratio in our study was found to be 1.4:1 which is comparable to the study done by Kumar SLA et al[14] in which the male to female ratio was 1.6:1.

All the patients who accomplished the eligibility criteria were subjected to detailed clinical examination, routine hematological investigations, USG, and were scored based on the Tzanakis scoring system. The decision to operate the patient including patients with a score less than the cut-off value was based on the clinical assessment and judgment taken by the consultant surgeon. All the patients underwent appendectomy with prior consent and the specimen was subjected to histopathological examination to confirm the diagnosis.

In our present study, 35 out of 50 patients (70%) had inflamed appendix intra-operatively. Out of the remaining 15 patients, five patients had enterocolitis,
three patients had Meckel’s diverticulitis, three patients had the pelvic inflammatory disease (salpingitis), two patients had a ruptured ovarian cyst and two patients had inflamed mesenteric lymph node (with or without pus) as the intra-operative findings. Shashikala V et al[9] in her study had five out of 50 patients with an alternative diagnoses; out of which one patient had enterocolitis and four patients had a pelvic inflammatory disease. Another study was done by Kumar SLA et al[14] his study also reported six patients with alternative diagnoses in which three patients had salpingitis, two patients had an ovarian cyst and one patient had Meckel’s diverticulitis.

Tzanakis et al[8], in 2005 revealed a more comprehensible system to help in making the diagnosis of appendicitis. It includes four parameters comprising of specific signs, laboratory and radiological investigations such as right iliac fossa tenderness, rebound tenderness over the right iliac fossa, leucocytosis (WBC count>12,000/mm$^3$), and USG. A score of 8 or more is considered as acute appendicitis.

In our study, out of the four parameters present in the scoring system, tenderness in the right iliac fossa was the commonest sign seen in 100% of patients whereas rebound tenderness and leucocytosis was found in 82% and 68% of the patients respectively. USG showed features of appendicitis in only 46% of cases (see graph 02).

In the present study, 30 patients had a score of eight or more, and 20 patients who had a score of less than eight according to the Tzanakis score.

The 30 patients who scored eight or more had 25 patients with features of appendicitis on histopathology whereas 5 patients had a histologically normal appendix with no features of inflammation.

Similarly, 20 patients scored less than eight out of which there were 10 patients with a histologically normal appendix with no features of inflammation and 10 patients with features of appendicitis on histopathology.

The sensitivity, specificity, PPV, NPV, and diagnostic accuracy of the Tzanakis scoring system in our study was found to be 71.42%, 66.67%, 83.33%, 50.00%, and 70% respectively (see graph 03). The low sensitivity and specificity rate was due to the presence of high false-negative and false-positive results.

The study done by Tzanakis et al[8] in 2005 had a sensitivity of 95.4%, the specificity of 97.4%, PPV of 96.5%, NPV of 96.5%, and diagnostic accuracy of 96.5% which is much higher as compared to our present study. This difference may occur due to low sample size, ethnic variation, and other demographic factors such as diet (see graph 5).

The study done by Shashikala V et al[9] in 2016 reported a sensitivity of 79.62%, a specificity of 83.3%, PPV of 97.72%, and NPV of 31.25% which were comparable to our present study. The study done by Iqbal MM et al[10] in 2018 had results similar to that of Tzanakis et al[8] with a sensitivity of 99%, a specificity of 91%, PPV of 99%, NPV of 91%, and diagnostic accuracy of 95% (see graph 5).

The study was done by Sigdel GS et al[11] and Kumar SLA et al[14] in 2017 had a specificity of 66.66% and 71.43% respectively which was comparable to our study whereas the NPV of both the studies was lower than our present study. Both studies had a sensitivity and PPV higher than our present study but the difference is not significant (see graph 5).

Similarly, the study done by BR Malla et al[15] in 2014 had sensitivity, specificity, PPV, and NPV of 86.9%, 75%, 97.5%, and 33.3% respectively. The outcome of the Tzanakis scoring system in the study conducted by Malla BR et al was comparable to our present study (see graph 5).

The negative appendicectomy rate (NAR) of the Tzanakis scoring system in the present study was found to be 10.34% percent in the males and 9.52% in females. The overall NAR observed for the Tzanakis scoring system was 10% (see graph no 04).

The negative appendicectomy rate in our present study for the Tzanakis Scoring system was comparable to NAR obtained in the studies done by Shashikala V et al[9](12%) and Iqbal MM et al[10] (10.30%).

The disadvantage of the Tzanakis scoring system is that it does not include more clinical symptoms such as fever, nausea and vomiting, anorexia, migratory right iliac fossa pain, and supportive investigations such as CRP which augments the accuracy of the scoring system. Another factor for the low specificity of the Tzanakis score is that it gives the highest weightage to ultrasonography in its scoring system which has variable sensitivity and specificity due to inter-observer bias.
Conclusion

• Similarly, the Tzanakis scoring system had sensitivity, specificity, PPV, NPV, and DA 71.42%, 66.67%, 83.33%, 50.00%, and 70% respectively.

• The overall negative appendicectomy rate of the Tzanakis scoring system was 10%.

Ethical Clearance: Taken from institutional ethics committee.

Abstract

Background: Acute appendicitis is amongst the most encountered emergencies seen in casualties requiring intervention. The incidence of negative laparotomy is 15% to 25% and is associated with notable morbidity. Scoring systems are useful and logical for distinguishing acute appendicitis from non-specific abdominal pain. Presently many scoring systems exist that aids in the diagnosis of acute appendicitis but still fail to decrease the rates of wrong diagnosis and the negative appendicectomy rate. This comparative study has been undertaken to evaluate and compare the efficacy of the Tzanakis scoring system with the relatively newer Yash scoring system which has been found more effective for the Indian population in diagnosing acute appendicitis.

Aim: To compare the efficacy of the Yash scoring system with the Tzanakis scoring system in diagnosing acute appendicitis.

Method and Material: A prospective comparison of the Tzanakis scoring system and Yash scoring system was done on 50 patients. The decision of an appendicectomy was taken by the consultant surgeon. The outcomes of the Tzanakis scoring system and Yash scoring system in terms of sensitivity, specificity, positive predictive value, negative predictive value, and diagnostic accuracy were calculated and compared.

Results: The Yash scoring system had sensitivity, specificity, PPV, NPV, and DA of 94.28%, 93.33%, 97.05%, 87.50%, and 94% respectively. The Tzanakis scoring system had sensitivity, specificity, PPV, NPV, and DA of 71.42%, 66.67%, 83.33%, 50%, and 70% respectively.

Conclusion: The Yash scoring system was significantly better than the Tzanakis scoring system in diagnosing acute appendicitis.

Keywords: Appendix, laparotomy, score, diagnosis, inflammation.

Introduction

Acute appendicitis is amongst the many encountered emergencies seen in casualties requiring intervention. There is a 6% chance of appendicitis in the general population[1]. Though the mortality has declined from 26% to 1% with the dawn of broad-spectrum antibiotics and timely surgery, it remains 5 to 15% in the elderly [2]. The incidence of negative laparotomy is 15% to 25% and is associated with notable morbidity, the frequency being more in women of reproductive age group (till 45%) due to the commonness of inflammatorytubo-ovarian diseases, ectopic pregnancy, and other gynecological pathology[3]. The delay in diagnosis may lead to rupture of the appendix in 17% to 40% of cases mostly in extremes of age. In the adolescents and elderly,
it is linked with dramatic complications like an intra-abdominal abscess, wound infection, and ultimately death [4]. Thus, confirmation of acute appendicitis is very crucial to achieve lower morbidity and mortality rates.

Conventional history and clinical examination continue to exist as the potent and actual diagnostic modalities in pinpointing acute appendicitis[5]. The chronology is the commencement of periumbilical pain shifting to the right iliac fossa with subsequent development of anorexia and nausea or vomiting. The clinical examination may disclose signs resembling peritonitis such as local rebound tenderness (Blumberg’s sign), guarding, rigidity, cutaneous hyperesthesia, and tenderness on rectal examination. Thirty-three percent of all cases with inflamed appendix present with unusual symptoms such as blunting of pain by the presence of overlying bowel in cases of retrocecal or retro iliac position of the appendix, increased urinary frequency, and tenesmus. Several conditions mimic appendicitis such as enterocolitis, terminal ileitis, pelvic inflammatory diseases, ureteric colic, peptic ulcer, diverticulitis, etc, and hence should be considered in the list of differential diagnosis[6].

The regular laboratory investigations of blood and urine are necessary. Leukocytosis is a convenient finding but is non-specific and may be missing in the elderly [2]. C–Reactive protein is elevated in almost all acute inflammatory conditions, hence is considered as a non-specific marker but its estimation guides a surgeon in reducing negative appendicectomies[7].

Plain x rays have validity in diagnosing appendicitis in only 8% of cases showing non-specific findings with low sensitivity and specificity [8]. The reliability of barium enema examination is 50% to 84%, but it has a major complication of caecal perforation when done in acute inflammatory conditions [9]. Computed tomography (CT) is another imaging modality used to confirm appendicitis and is exceedingly efficacious and precise. It is operator independent and has shown a sensitivity of 90% to 100% and specificity of 91% to 99%. CT has a positive predictive value (PPV) of 92% to 98% and a negative predictive value (NPV) of 95% to 100%[10].

Ultrasonography (USG) with graded compressions has immense capacity in diagnosing appendicitis in its acute stage[10]. Various studies have been conducted on the utilization of these imaging systems. These studies reported sensitivity of 75% to 94%, a specificity of 86% to 100% and gross precision up to 96%[10,11]. Its superiority over computed tomography is the absence of exposure to ionizing radiation thus helpful in pregnant and paediatric patients. The major disadvantage is that it is operator dependent leading to inter-observer bias and failure to see the appendix during the scan does not rule out the possibility of having an inflamed appendix[10].

Magnetic resonance imaging (MRI) as an investigation is only taken typically in the pregnant population where radiation exposure is not warranted. It provides outstanding resolution and is highly efficient in diagnosing acute appendicitis. MRI has high sensitivity and specificity of 100% and 98% respectively. The PPV and NPV of MRI are 98% and 100% respectively. It is also operator-independent. The only issue is its higher cost, motion artifact, and complexity in reading MRI by non-radiologists with limited experience [11].

Despite the use of all these imaging techniques, the incidence of negative appendicectomy is not decreasing. These unmerited operations have a complication rate of approximately 13%, which is nearby to that of an inflamed appendix. Removal of a healthy appendix has a mortality of 0.65%. Protracted clinical observations aiming to reduce undesired operations may mean a delay in operations in 28% of cases and considerable danger of perforation [12].

Scoring systems are useful and logical for distinguishing pain of acutely inflamed appendix from vague abdominal pain. Presently numerous scoring systems exist that aid in diagnosing acute appendicitis. However, these systems do not replace clinical acumen thereby just helping in the determination of acute appendicitis and aids in approaching a conclusion, whether a particular case should be operated or not, thus lowering the negative appendicectomy rate (NAR).

The original study done by Tzanakis et al [13] in Greece reported sensitivity and specificity of 95.4% and 97.4% respectively. The diagnostic effectiveness of the score was 96.5% in his study. But in India, this scoring system was found inferior. For example, a comparative study between Tzanakis score and Alvarado score done by Shashikala V[14] in India revealed that Tzanakis scoring system had a sensitivity of 79.62%, a specificity of 83.3%, PPV of 97.72%, and NPV of 31.25% which was found better than Alvarado scoring system but still posing difficulties in diagnosis with a NAR of 12%. Another study was done by Iqbal MM et al[15] in
Postgraduate medical center, Karachi, Pakistan revealed that the Tzanakis score had a sensitivity of 99%, a specificity of 91%, PPV of 99%, and NPV of 91% with a diagnostic accuracy of 95%. Similarly, a study done in Kathmandu Model Hospital, Nepal did by Sigdel GS et al. [16] reveals that Tzanakis has a sensitivity of 91.48%, a specificity of 66.66%, and diagnostic accuracy of 90%.

The study done by Lamture YR et al. [17] in India on the Yash scoring system reveals a sensitivity of 99.48%, a specificity of 92.86%, PPV of 99.48%, and NPV of 92.86%. Though the validity of the Yash scoring system is promising for the Indian population, its only disadvantage was in the mode of a single study.

Despite various scoring systems and developments in the diagnostic and imaging modalities, the diagnosis of appendicitis is in dilemma which fails to decrease the rates of wrong diagnosis and the negative appendicectomy rate. This sequentially increases the cost for diagnosis by the use of expensive radiological modalities like Computed Tomography and MRI thus causing a delay in the treatment leading to an increase in morbidity and mortality of the patients.

This comparative non-randomized prospective study has been undertaken to evaluate and compare the effectiveness of the Tzanakis score with the relatively newer Yash score which has been found more effective for the Indian population in diagnosing acute appendicitis.

**Method**

The present study was undertaken in the department of surgery, Jawaharlal Nehru Medical College, Wardha in collaboration with Datta Meghe Medical College Hingana, Nagpur, Datta Meghe Institute of medical science (DMIMS), Sawangi, Meghe, Wardha, Maharashtra India.

**Aim:** To compare the efficacy of the Yash scoring system with the Tzanakis scoring system in the diagnosis of acute appendicitis.

**Objectives:**

1. To study the outcome of the Yash scoring system regarding its sensitivity, specificity, positive predictive value, negative predictive value, and diagnostic accuracy.
2. To study the outcome of the Tzanakis scoring system about its sensitivity, specificity, positive predictive value, negative predictive value, and diagnostic accuracy.
3. To compare the outcome of Yash and Tzanakis scoring system.

**Study Design:** Prospective non-randomized study.

**Study Population:** All patients of acute appendicitis with age >15 years and <60 years.

**Study Duration:** July 2018-July 2020.

**Sample size:** 50 patients

- The sample size was calculated by the modified Fischer’s formula. The prevalence rate of appendicitis was taken as 6% from the study done by Yogesh Pralhad Chaudhari, Prasanna Gambhir Jawale [18] in 2015.

- Where \(N \geq \frac{Z_{1-\alpha/2}^2 \times P \times (1-P)}{d^2}\)

- \(Z_{1-\alpha/2} = \) is standard normal variate (at 5% type 1 error \((P<0.05)\) it is 1.96 and at 1% type 1 error \((P<0.01)\) it is 2.58). In most of the studies, \(P\) values below 0.05 are considered significant. Therefore, value of 1.96 is employed in formula.

- \(p = \) prevalence of appendicitis in community anticipated on the basis of past studies.

- \(d = \) Absolute error or precision – decided by researcher.

- \(p = 6\%

- \(d = 0.07 (7\% \text{ error of margin})\).

The minimum sample size would be 44.12 patients, thus 50 patients included in the study.

**Inclusion Criteria:** All patients with right lower quadrant pain and clinically diagnosed as acute appendicitis of age >15 years and <60 years.

**Exclusion Criteria:**

1. Patients with appendicular mass.
2. Patients of appendicitis with a known case of connective tissue disorder.
3. Patients with a past history of renal or ureteric stones and pelvic inflammatory disease.
4. Pregnant women.

Ethical clearance was obtained from the Ethics committee of Datta Meghe Institute of Medical Sciences.
This prospective non-randomized study was conducted in Acharya Vinoba Bhave Rural Hospital, Sawangi. All the patients who fulfilled the eligibility criteria were subjected to routine hematological investigations, C-reactive protein, USG, and were scored based on Yash and Tzanakis scoring system.

Tzanakis scoring system combines 4 variables as follows:

- Presence of right lower abdominal tenderness = 4 points
- Rebound tenderness (Bloomberg sign) = 3 points
- Laboratory findings: the presence of white blood cells greater than 12,000 in the blood = 2 points
- Ultrasound findings: the presence of positive ultrasound scan findings = 6 points

A score of 8 or more is suggestive of acute appendicitis requiring surgery.[13] Similarly, the components of the Yash scoring system are as follows:

- Migration of pain to the right iliac fossa = 1 point
- Nausea and vomiting = 1 point
- Right iliac fossa tenderness = 2 points
- Rebound tenderness = 1 point
- Hyperesthesia in Sherren’s triangle = 1 point
- Fever = 1 point
- White blood cell count > 10,000 mg/dl = 2 points
- C-reactive protein (> 15 mg/dl) = 3 points
- Ultrasonography = 4 points

A score of 7 or more is suggestive of acute appendicitis requiring surgery.[17]

The decision to operate was taken by a consultant surgeon by clinical diagnosis with help of other appropriate investigations in special circumstances. All patients underwent appendicectomy with prior consent and the specimen was subjected to histopathological examination for confirmation of diagnosis. The minimum criteria for acute appendicitis were the appearance of neutrophils in mucosa, submucosa, and lamina propria[1]. The result of the Tzanakis score and Yash score was reported independently. The result was correlated with the findings obtained on histopathological examination and the data was analyzed using the necessary statistical calculations using SPSS 24.0 version, the results were then presented.

Discussion

Acute appendicitis continues to exist as the most widespread emergency in the world. A delay in making a diagnosis is associated with various complications which increases the morbidity and mortality in patients therefore a prompt and reliable diagnosis of acute appendicitis is mandatory. Furthermore, negative appendicectomy also accounts for a loss of financial resources and is associated with morbidity in 10 to 15% of cases.

Despite big breakthroughs in the imaging field, there remains uncertainty in diagnosing acute appendicitis due to atypical presentations of the disease. It has been repeatedly shown that investigations like USG lack specificity due to its operator dependency whereas investigations like CT scan and MRI are highly-priced demand more advanced equipment and competency. This makes a detailed clinical examination with primary investigations such as leucocyte count as the backbone in diagnosing acute appendicitis. This has compelled many surgeons to use diverse scoring systems for diagnosing acute appendicitis. The clinical evaluation is reliable in 50% to 80% of cases. The evaluation is more complex in the extremes of age and women of reproductive age group due to atypical presentations.

The current study will deal with the evaluation of the Yash scoring system with the Tzanakis scoring system to diagnose acute appendicitis in a simple, reliable, and cost-effective way thereby reducing the negative appendectomy rate and thus morbidity associated with it.

In this study, the sample population consisted of 50 patients out of which 58% were males and 42% were females. The male to female ratio in our study was found to be 1.4:1 which is comparable to the study done by Kumar SLA et al[19] in which the male to female ratio was 1.6:1. A larger part of the study population (50%) was present in the age group of 15 to 29 years. The age group of 30 to 44 years had 26% of patients followed by 24% in the age group of 45 to 60 years. This is comparable to the study done by Kumar SLA et al[19] in which 40% of patients were in the 2nd to 3rd decade of life, 27% of patients in 3rd to 4th decade of life, and only 3% of patients in 5th to 6th decade of life.

All the patients who accomplished the eligibility criteria were subjected to detailed clinical examination, routine hematological investigations, C-reactive protein, USG and were scored based on Yash and Tzanakis scoring system. The decision to operate the patient including patients with scores less than the cut-off value.
was based on the clinical assessment and judgment taken by the consultant surgeon. All the patients underwent appendectomy with prior consent and the specimen was subjected to histopathological examination to confirm the diagnosis.

In our study, 82% of the patients were operated by open method whereas 18% of patients were operated by laparoscopy. The study done by Malla BR et al [20] consisted of 200 patients in which 128 patients (64%) underwent appendectomy by an open method and 72 patients (36%) underwent appendectomy by laparoscopy. The most common incision used in open appendectomy was Mc Burney’s in about 83% of cases followed by the right Para median which was used in 17% of cases. Similarly, in the study done by Lamture YR et al [17] the most common incision used was Mc Burney’s in 94.74% of patients followed by right Para median in 5.26% of cases. In our present study, 35 out of 50 patients (70%) had inflamed appendix intra-operatively. Out of the remaining 15 patients, five patients had enterocolitis, three patients had Meckel’s diverticulitis, three patients had the pelvic inflammatory disease (salpingitis), two patients had a ruptured ovarian cyst and two patients had inflamed mesenteric lymph node (with or without pus) as the intra-operative findings. Shashikala V et al [14] in her study had five out of 50 patients with an alternative diagnosis; out of which one patient had enterocolitis and four patients had a pelvic inflammatory disease. Another study was done by Kumar SLA et al [19] his study also reported six patients with alternative diagnoses in which three patients had salpingitis, two patients had an ovarian cyst and one patient had Meckel’s diverticulitis.

The new Yash score described by Lamture YR et al [17] in 2017 has a significant role in identifying acute appendicitis. It differs from earlier scoring systems by including various parameters such as C-reactive protein, leukocyte counts, USG, and clinical data. A score of seven or more in patients was considered as acute appendicitis and such patients were subjected to operative intervention.

In our study, out of ten parameters, tenderness in the right iliac fossa was the commonest sign seen in 100% of patients. The other two signs i.e. rebound tenderness and hyperesthesia in Sherren’s triangle was seen in 82% and 26% of patients respectively. The most common symptom was fever which was present in 88% of cases followed by nausea or vomiting which was found in 86% of the cases. Anorexia was seen in 72% of patients, whereas 68% of patients gave a history of migratory right iliac fossa pain. Out of the three investigations included in the scoring system, leucocytosis defined as WBC count more than 10000/mm$^3$ was present in 80% of cases. C-reactive protein with a value of more than 15mg/dl was present in 28% of cases with USG showing features of appendicitis in only 46% of cases.

In the present study, 34 patients had a score of seven or more, and 16 patients who had a score of less than seven according to the Yash score.

Out of the 34 patients who scored seven or more, there were 33 patients with features of appendicitis on histopathological examination whereas only one patient had histologically normal appendix with no features of inflammation.

Similarly, out of 16 patients who scored less than seven, there were 14 patients with a histologically normal appendix with no features of inflammation and only two patients with features of appendicitis on histopathology.

The sensitivity and specificity of the Yash scoring system in the present study were found to be 94.28% and 93.33% respectively. It had PPV and NPV of 97.05% and 88.50% respectively. The overall diagnostic accuracy of the Yash scoring system in our study was found to be 94%. The following results are comparable to the single original study done by Lamture YR et al [17] in which the sensitivity, specificity, PPV, and NPV was 99.48%, 92.86%, 99.48%, and 92.85% respectively. The diagnostic accuracy of the Yash score reported by Lamture YR et al was 98.56%.

The negative appendicectomy rate (NAR) of the Yash scoring system in the present study was found to be zero percent in males and 4.76% in females. This discrepancy in NAR was due to the high probability of other possible diagnoses in females of reproductive age group such as pelvic inflammatory diseases and ovarian cyst. The overall NAR observed for the Yash scoring system was 2% which is way lower than the accepted rate of 15 to 25%. In the study done by Lamture YR et al [17], the NAR was found to be 6.69% which is comparable to our study.

Tzanakis et al [13], in 2005 revealed a more comprehensible system to help in making the diagnosis of appendicitis. It includes four parameters comprising of specific signs, laboratory and radiological investigations such as right iliac fossa tenderness, rebound tenderness...
over the right iliac fossa, leucocytosis (WBC count>12,000/mm³), and USG. A score of 8 or more is considered as acute appendicitis.

In our study, out of the four parameters present in the scoring system, tenderness in the right iliac fossa was the commonest sign seen in 100% of patients whereas rebound tenderness and leucocytosis was found in 82% and 68% of the patients respectively. USG showed features of appendicitis in only 46% of cases.

In the present study, 30 patients had a score of eight or more, and 20 patients who had a score of less than eight according to the Tzanakis score.

The 30 patients who scored eight or more had 25 patients with features of appendicitis on histopathology whereas 5 patients had a histologically normal appendix with no features of inflammation.

Similarly, 20 patients scored less than eight out of which there were 10 patients with a histologically normal appendix with no features of inflammation and 10 patients with features of appendicitis on histopathology.

The sensitivity, specificity, PPV, NPV, and diagnostic accuracy of the Tzanakis scoring system in our study was found to be 71.42%, 66.67%, 83.33%, 50.00%, and 70% respectively. The low sensitivity and specificity rate was due to the presence of high false-negative and false-positive results.

The study done by Tzanakis et al [13] in 2005 had a sensitivity of 95.4%, a specificity of 97.4%, PPV of 96.5%, NPV of 96.5%, and diagnostic accuracy of 96.5% which is much higher as compared to our present study. This difference may occur due to low sample size, ethnic variation, and other demographic factors such as diet.

The study done by Shashikala V et al [14] in 2016 reported a sensitivity of 79.62%, a specificity of 83.3%, PPV of 97.72%, and NPV of 31.25% which were comparable to our present study. The study done by Iqbal MM et al [15] in 2018 had results similar to that of Tzanakis et al [13] with the sensitivity of 99%, a specificity of 91%, PPV of 99%, NPV of 91%, and diagnostic accuracy of 95%.

The study was done by Sigdel GS et al [16] and Kumar SLA et al [19] in 2017 had a specificity of 66.66% and 71.43% respectively which was comparable to our study whereas the NPV of both the studies was lower than our present study. Both studies had a sensitivity and PPV higher than our present study but the difference is not significant.

Similarly, the study done by BR Malla et al [20] in 2014 had sensitivity, specificity, PPV, and NPV of 86.9%, 75%, 97.5%, and 33.3% respectively. The outcome of the Tzanakis scoring system in the study conducted by Malla BR et al was comparable to our present study.

The negative appendicectomy rate (NAR) of the Tzanakis scoring system in the present study was found to be 10.34% percent in the males and 9.52% in females. The overall NAR observed for the Tzanakis scoring system was 10%.

The negative appendicectomy rate in our present study for the Tzanakis Scoring system was comparable to NAR obtained in the studies done by Shashikala V et al [14](12%) and Iqbal MM et al [15](10.30%).

The result of the Yash scoring system as compared to the result of the Tzanakis scoring system in our present study reveals that the Yash scoring system had a better outcome than the Tzanakis scoring system and was more efficacious than Tzanakis scoring system in diagnosing acute appendicitis. The disadvantage of the Tzanakis scoring system is that it does not include clinical symptoms such as fever, nausea and vomiting, anorexia, migratory right iliac fossa pain, and supportive investigations such as CRP which augments the accuracy of the scoring system. Another factor for the low specificity of the Tzanakis score is that it gives the highest weightage to ultrasonography in its scoring system which has variable sensitivity and specificity due to inter-observer bias.

The negative appendectomy rate of the Yash scoring system was dramatically lower than that of the Tzanakis scoring system.

**Conclusion**

- The Yash scoring system had sensitivity, specificity, PPV, NPV, and DA of 94.28%, 93.33%, 97.05%, 88.50%, and 94% respectively.
- The overall negative appendicectomy rate of the Yash scoring system was 2%.
- Similarly, the Tzanakis scoring system had sensitivity, specificity, PPV, NPV, and DA 71.42%, 66.67%, 83.33%, 50.00%, and 70% respectively.
• The overall negative appendicectomy rate of the Tzanakis scoring system was 10%.

• Thus, our study reveals that the Yash scoring system is a valuable and plausible modality in detecting acute appendicitis and reducing NAR due to its outstanding outcome regarding its sensitivity, specificity, PPV, NPV, and diagnostic accuracy when compared to Tzanakis scoring system.

• The study also shows that the Yash scoring system is a better tool to avoid unnecessary operations due to its exceptionally low negative appendectomy rate thus lowering morbidity in patients of acute appendicitis and thereby lowering the cost of treatment and prevention of misuse of valuable resources and manpower.

Abstract

‘Euthanasia’ is a compound of two Greek words ‘eu’ and ‘Thanatos’ meaning, a good death. It is a practice of intentionally ending life to relieve from suffering and pain which are immeasurable within human limits. Basically it’s ending of life for the impaired, which is unable to achieve ‘moksha’ even after persistently or willingly trying to. In medical language, ‘termination of life by doctors at request by the patient’s close relatives or attendants for patient bedridden for years struggling and unable to revive. Euthanasia is a complex matter of concern. It poses both, positive and negative implications which should be worked on and implemented under guidelines by administrations at different settings. As certain developed nations have legalized Euthanasia, their proposals and recommendations for considerations can be considered as a base for projecting Euthanasia in developing countries like India.

Keywords: Euthanasia, legalized, implication, India.

Introduction

“Death is Not the Greatest Loss; The Greatest Loss is Dying within While One Lives”.

‘Euthanasia’ is a compound of two Greek words ‘eu’ and ‘Thanatos’ meaning, ‘a good death. Its a practice of intentionally ending life to relieve from suffering and pain which are immeasurable within human limits. Basically it’s ending of life for the impaired, which is unable to achieve ‘moksha’ even after persistently or willingly trying to. In medical language, ‘termination of life by doctors at request by the patient’s close relatives or attendants for patient bedridden for years struggling and unable to revive. Everyone who wishes well for the concerned want him/her to be free from the vicious cycle of sufferings and merciless they face on daily basis. Like the other terms filched from history, euthanasia had different meanings depending on usage. The first apparent credit goes to historian Suetonius, who described how Emperor Augustus, dying quickly and without suffering in the arms of his wife, Livia, experienced euthanasia he wished for. Francis Baconin the 17th century used euthanasia in medical context to refer it as an easy, painless, and happy death(1). He referred to an ‘outward euthanasia’, the term ‘outward’ he used to distinguish from a spiritual concept the euthanasia which regards the preparation of the soul. The author would like to highlight case of Aruna R. Shaunbagh(2) case which brought the entire nations vision towards passive euthanasia. Yes! It is the case which brought about the point of Euthanasia in India. This case attained limelight after the remorseless death of a nurse named, Aruna. Aruna was an Indian nurse who spent 42 extensive years in a vegetative state as a result of the sexual assault in 1973. While working as a junior nurse at King Edward Memorial Hospital, Parel, Mumbai, and Shaunbag was sexually assaulted by a ward boy. The boy strangulated
her with a dog chain around her neck which cut off oxygen supply to her brain leaving her deaf, blind, and deaf, paralyzed. From the day of her assault till the day she died on May 18, 2015 she survived on mashed food, she couldn’t move her hands or legs couldn’t talk or perform basic function expected from a human being.

To a surprise, the accused was charged with attempted murder, and was sentenced for seven years imprisonment which was reduced to six years and was finally set free in 1980. While, Aruna remained in a vegetative state for rest of her life it was 2009, a petition was accepted by the honorable Supreme Court on insistence of a journalist and activist, Pinki Vikrani. A 1994, constitutional validity of Indian Penal Code Section (IPC Sec) 309 was challenged in the Supreme Court(5). The Supreme Court declared that IPC Sec 309 is unconstitutional, under Article 21 (Right to life) of the constitution in a landmark judgment. But later, Vikrani questioned the court that if in the Article 21 of the Constitution of India can give Right to Life then why not Right to Death(5).

The Supreme Court of India later felt that Aruna wasn’t brain dead and could respond to certain stimulus. So, the petition was rejected. But, this case brought a revolution in the history of medical profession within India. Later, the panel of judges finally accepted the petition and granted legalized passive euthanasia making it a sensible judiciary act. Passive euthanasia is grossly different from active euthanasia, as the latter induces death or end the life of patient by administration of lethal agents. The apex court hereby, laid stringent guidelines under which passive euthanasia would be legally allowed only via a high-court monitored mechanism. An author has a question, was Aruna living a life or strangulated everyday for 42 years on the hospital couch? Did she deserve to be on the couch for 42 long years?

Another victim of circumstances, who laid on the death-bed hoping to donate all organs of his body for a noble cause, Kolavennu Venkatesh, a young chess player from Hyderabad who fought a bitter legal battle to compete in life is only fit to live in this world. But if an individual is incompatible to perform these acts and dependent for years to come isn’t it unfair to keep them in agony forever. To the honest, the author thinks, if Euthanasia is wrong the same should be applicable for the world. The debate has been increasingly significant because of the recent development in Netherlands and England wherein euthanasia is allowed. As a result, many nations across are now hotly debating whether to follow or not the Dutch example(4). In India, many health professionals, philosophers, psychologists have expressed their views for the same. Some are in favor while others are against. According to the author, Euthanasia is a way by which a doctor can free a patient from trap of misery. An individual who once wanted to live, be happy is now on the verge of daily suffering, whose dreams have been crushed and along with them their family is struggling, who want to wish to bring him out of it and wish for an end for him with a heavy heart.

Once a cheerful person lying on the hospital bed for all eternity, whose goals have now become a grave, whose identity is just a ‘ward patient ‘helpless’. Think of him/her ‘who once wanted to fill life with colors, wanted to nurture himself, grow and achieve something great in life, is lying pale and lifeless. Think for the mother who gave birth to a child, wishing success and fortune, blessed him to achieve something great in future, but seeing him lifeless, struggling, pale may give agony to her Darwin’s theory of ‘Survival of the fittest’ says that all species of organisms arise and develop through natural selection, inherited variations that increases the individual’s ability to compete, survive and reproduce. In simple language the specie that is fit to reproduce and compete in life is only fit to live in this world. But if an individual is incompatible to perform these acts and dependent for years to come isn’t it unfair to keep them in agony forever. To the honest, the author thinks, if Euthanasia is wrong the same should be applicable for Medical Termination of Pregnancy (MTP)(5). One may be thinking why? So, it would be wise to say that the person lying in a vegetative state couldn’t melt one’s heart enough to end his sufferings then what about ending a life that is not yet born. A distinction may be made between Euthanasia and abortion. Death intervenes before life in earnest has even begun. In Euthanasia people make decision about death at the other end of life, after in earnest has(2). But the Constitution doesn’t give right to end a suffering. How unfair is that? If mercy killing is unethical then MTP should also be considered the same. If the Supreme Court can approve MTP, then why not euthanasia?

The authors of the article analyzed both aspects against and favor of the concerned topic. As we recognize that it’s not only for competent patients, but also incompetent ones who can suffer from conditions that make their lives not worth living (5). We cannot
effect legal change in one go; we shall appreciate for liberalization of law. Once even if any modest change is made, people might realize that the next step and consecutive are also acceptable, even if we cannot see it now(4). The argument invoked by legal Right to die opponents is that the Right will be abused and that no legal safeguards can prevent its abuse. Example for voluntary euthanasia always a written consent is a legal requirement but this is not always obtained(6). In long run, the euthanasia may definitely be misused to end up the lives of the care needy or people suffering from terminal illness, or people who are to undergo transplantations(7). In earlier times, majority of people died before they reached the hospital but now due to gradual medical advancement life can be prolonged but not to the extent of bringing back the dead ones. Malafide Intention(7), in the era of declining mortality and justice, there is a possibility of misusing euthanasia for inheriting the property of the patient. ‘Mercy killing’ should not lead to ‘killing mercy’ in the hands of the noble medical profession(7). Previously disease outcomes was discussed in CURE but in contemporary world of disease and debated in terms of CARE(7).

CONCLUSION:Euthanasia is a complex matter of concern. It poses both, positive and negative implications which should be worked on and implemented under guidelines by administrations at different settings. As certain developed nations have legalized Euthanasia, their proposals and recommendations for considerations can be considered as a base for projecting Euthanasia in developing countries like India.

Survey as Research Design for Medical and Allied Health Care Professionals

Pooja Chaudhuri¹, Aksh Chahal², Nitesh Malhotra³

¹Associate Professor, Department of Physiotherapy University of Science and Technology, Meghalaya, India, ²Professor, MM Institute of Physiotherapy and Rehabilitation, Maharishi Markandeshwar (Deemed to be University), Ambala, Haryana, India, ³Assistant Professor, Amity Institute of Physiotherapy, Amity University, Uttar Pradesh, India

Abstract

Formally speaking, survey means encapsulating information from respondents by direct or indirect means (person to person, telephonic, post and electronic communication). Survey as method of extracting information form population (small or large) to study various health issues and its associated factors play an important mode in healthcare clinical practice and research domain. Nearly, all fields under the umbrella of healthcare are making use of surveys as their study design to extract the desired information via optimum method of performing a survey to their best for analyzing, devising and implementing associated health care policies. Surveys are being used in increasing number as they provide benefits to researchers, in contrast, it also posses certain setbacks which are greatly impactful if a less potential method of survey is chosen for a specific arena if its associated pit falls are ignored. Surveys when used in medical fraternity are generally classified as Epidemiological, Health delivery service and Questionnaire surveys.

Keywords: Healthcare, Professionals, Survey, Research, Questionnaire.

Introduction

Formally speaking, survey means encapsulating information from respondents by direct or indirect means (person to person¹, telephonic², post³ and electronic communication)⁴. Survey as method of extracting information form population (small or large) to study various health issues and its associated factors play an important mode in healthcare clinical practice and research domain⁶. Nearly, all fields under the umbrella of healthcare are making use of surveys as their study design to extract the desired information via optimum method of performing a survey to their best for analyzing, devising and implementing associated health care policies⁸. Surveys are being used in increasing number as they provide benefits to researchers, in contrast, it also posses certain setbacks which are greatly impactful if a less potential method of survey is chosen for a specific arena if its associated pit falls are ignored. Surveys when used in medical fraternity are generally classified as Epidemiological, Health delivery service and Questionnaire surveys⁹.

In the current article, the authors aim to throw light on issues in contest to:

1. Fabricating a survey.
2. Formulation of a questionnaire with basic guidelines.
3. Role of Pilot study in facilitating efficiency of a survey.
4. Benefit and shortfalls of different modes of survey.

1. Fabricating a survey: The most vital aspect to be kept in mind while planning a survey is “What is the researcher looking for”⁷? “What information does the researcher want to procure from his respondents”.

Corresponding Author:
Nitesh Malhotra
Assistant Professor, Amity Institute of Physiotherapy, Amity University, Uttar Pradesh, India
e-mail: malhotra.nitesh@gmail.com
When this aspect is clearly defined in the researcher’s mind, it enables the emergence of questions focused in the concerned area which the researcher commences to document in the form of a ‘Questionnaire’. Any confusion regarding the proximities of the topic to be studied will lead to unnecessary installation of either irrelevant or excessive number of questions in the questionnaire leading to unwanted deviation from the topic finally complicating the research process and producing unfruitful results.

2. **Formulation of a questionnaire:** In research when planning a questionnaire for survey as a study design, a researcher has two options:

A. **To use a reliable and validated questionnaire:** Using a validated questionnaire brings ease to the researcher in many ways. Firstly, the validated questionnaire exhibits favorable question, minimal exfoliates negligible topographical errors etc. Secondly, as the questionnaire has been used already in one population, the same questionnaire when used in different population provides with significant comparison or disguised in conclusion. Finally, if the researcher seeks hurry to perform a survey in a short span of time, it is greatly advised to use a ready validated questionnaire as validating questionnaire usually is a time consuming process.

B. **Designing a new questionnaire:** If a researcher plans to design a new questionnaire, many aspects have to be kept in mind right from the beginning process to the final implementation in the population. When documenting questions to be asked in a survey, researcher should prioritize and imply basic requirements for the optimum gathering of information from their respondents. After all these considerations are fulfilled, the final step should be validation of the questionnaire.

**Basic guidelines while designing a questionnaire for survey:**

- All questions should be framed in focused direction to procure exact information.
- Educational background of the population to be studied should be given prior most importance. Individuals with high to medium degrees can diversify in terms of mental engagements while responding to the questionnaire, whereas when studying people with low educational background, set of question in the questionnaire should be put to their simplest form.
- Any possible question, even with a slight predicting attitude to confuse the respondent, should not be inducted in the questionnaire.
- Vital questions should be documented in the beginning followed by questions of descending importance.
- Questions related to demographic information should be asked in last.
- Locally adhered terminologies should be used so as to prevent respondents from getting confused and preventing them from not responding to the questionnaire. Even if one question is left unanswered due to any reasons, shall lead to dropout and that particular questionnaire cannot be used for analysis.
- Short sentences, pictorials and diagrams (if possible) etc should be used.
- Use of long sentences should be kept at minimal as these produce high risk of creating confusion among respondents.
- Use of multiple and bright colors should be instituted in the form of pictures, diagrams or statements to make the questionnaire vibrant, hence catching eyes of respondents, hence getting visually attracted to questionnaire may make them feel happy and promotes active participation towards the survey.
- Questions in relation to privacy, affection, habits etc should be discussed in later phase of the questionnaire as in the beginning it’s important for a researcher to gain respondent’s trust rather than directly jumping on sensitive questions making the respondent feel uneasy and reluctant to answer for the same and leaving the questionnaire incomplete. This systematic procedure greatly accelerates the quality and quantity of information procured. Any incomplete questionnaire shall not be considered for statistical analysis leading to misinterpretation of results.
- Researcher should incorporate only optimum number of questions with concentration on quality and quantity of information.
- All questions with the aim to abstract associated information should be numbered in close proximity as it helps respondents to answer the nearly associated questions in a flow as respondents respond with deeper aspect and concentration, rather haphazardly arranged
Role of Pilot study in facilitating efficiency of survey: A pilot study should be considered as an important aspect before commencing a survey on a large sized population. Pilot study enables professionals with various benefits:

- Making necessarily corrections in the questionnaire.
- Checking spelling mistakes.
- Disarrangement of sequence for questions.
- Analyzing attitude of respondents towards questions.
- Attitude towards sensitive questions (if any).
- Need of modification in question language and series.

These alterations when executed in the early stage and on a small population help researcher when the same study is performed on a larger population with clarity in mind from absence of pitfalls from the questionnaire point of view and thus the researcher main focuses on data analysis for concluding with results.

Benefits and shortfall of different modes of survey:

Analysis: Data received on completion of survey should be analyzed using respective statistical test for which s is always advised to have an experienced statistician right from day 1, as he/she is involved in steps from formulation, implementation and analysis of data. The mode of data analysis should be planned right from the beginning of designing of the survey. Data to be arranged in the form of tables with rows and columns should be well posturized before the final formatting of questions in the questionnaire. Data from telephonic and electronic communication can be easily compiled and put to analysis while data from person to person and telephonic survey needs time to input and arranged for data analysis. Test for significance relevant to the survey are expressed by the statistician to represent results in the best projective and expressive direction.

Conclusion

Survey in research is a method of excellence to gather information directly or indirectly from respondents if performed in a systematic manner. While planning
a survey, benefits and pitfalls of the selected method should be prioritized to move in the right direction to deliver accurate results after analysis of data.

Impact of Quarantine on Psychological and Psychosocial Aspects in Individual and Health Care Staff

Nitesh Malhotra¹, Pooja Chaudhuri², Aksh Chahal³

¹Assistant Professor, Amity Institute of Physiotherapy, Amity University, Uttar Pradesh, India, ²Associate Professor, Department of Physiotherapy University of Science and Technology, Meghalaya, India, ³Professor, MM Institute of Physiotherapy and Rehabilitation, Maharishi Markandeswar (Deemed to be University), Ambala, Haryana, India

Abstract

Even a thought for an outbreak of an infectious disease provokes unwarranted panic and emotional distress in population causing development of negative impacts on psychological and psychosocial parameters of an individual. So, in case of any real epidemic/pandemic outbreak the normal psychological and psychosocial parameters start getting affected gradually which rise in amplitude as time pass while the disease is in air. Immediately, starts the phase of stress and fear of either being a carrier or a healthy individual who will have to live a compromised life for a particular duration. Previous studies have shown quarantine period to grimly affect individuals along with their health care providers which can even go along for the coming years. These impacts if controlled by early execution of strategies through governmental, administrative and social bodies working resourcefully and effectively can reduce the distress before being amplified. The present paper outlines the negative impacts of quarantine on psychological and psychosocial domain in individuals put in quarantine along with health staff engaged in their treatment. In addition, the article also narrates and suggests recommendations after reviewing articles from reputed database published following the outbreak of Severe Acute Respiratory Syndrome Syndrome (SARS), Ebola Virus Disease (EVD) and Middle East Respiratory Syndrome Corona Virus (MERS CoV) with added suggestions in reducing the effects during and after quarantine.

Keywords: Quarantine, Isolation, Negative, Psychological, Psychosocial, Health, COVID-19.

Introduction

‘Quarantine’ is a public health measure characterized by separation and restriction in movement of individuals’ who are assumed to be exposed to a contagious disease, to confirm if they become unwell so as to reduce the risk of spreading the same to the healthy population¹,². Quarantine is similar to Isolation but not the same. ‘Isolation’ is defined as separation of patients diagnosed with a contagious disease from population who are not sick³,⁴. The well-known example of isolation is of Human Immunodeficiency Virus (HIV) positive patients in Cuba during the 80’s and 90’s⁴,⁵. Generally, both these terminologies are used as synonyms to each other but in fact, they differ in the categorization of patients from normal healthy population. Looking back in history, the term quarantine was used for the first time in 1127 AD in Venice, Italy following the outbreak of Leprosy which nearly wiped their major population². The same term was used after 300 years with an outbreak of Plague in United Kingdom, killing large number of people and health care workers⁶. Since then, the term has been used couple of times following outbreak of Ebola Virus Disease (EVD) during 2005 originating in Congo, West Africa⁷, Severe Acute Respiratory Syndrome (SARS) during 2003 originating in Toronto

(Canada)\(^8\), Middle East Respiratory Syndrome Corona Virus (MERS-CoV) in Korea during 2015\(^9\) and now, its Corona Virus named ‘COVID-19’ starting from Wuhan, a city in China in 2019 which rapidly spread to other nations\(^2\). As an immediate response, the city of Wuhan was lockdown and the suspected individuals put to quarantine irrespective of their gender and age. In a short span, even nearby cities and major cities of China were put to lockdown with strategies following as exhibited in Wuhan for months to come while the remaining population was either asked to be contained at home or embossed at their present site till further communications\(^2\). This sudden outbreak left both, the people in quarantine and lockdown in a nowhere to go situation, firstly due to lack in awareness of the virus being spread and whether they themselves are affected by the virus and if they are affected, concern regarding their self, families, future, issues in association with social stigma \(^4, 10\), fulfillment of daily, personal and financial needs \(^11, 12, 13\). These thoughts start dominating an individual’s psychology creating negative engravings towards short and long term goals and propositions of life. The affected individual are put in quarantine while the unaffected to a lockdown wherein people still share and exhibit advantage than people in quarantine as they spend time with their family and loved ones, peruse studies if students, control financial balance by working from home, eat food of their choice etc. In the present article, the author would concentrate specifically on the negative impacts of quarantine. To achieve this goal, the impacts shall be documented as; negative impacts of quarantine. To achieve this goal, the impacts shall be documented as; negative impacts of quarantine.

The impacts shall be documented as: negative impacts of quarantine.

Strategies to mitigate consequences of quarantine:

1. Swift action to shrink emotional, psychological and social negative picture in a person promoting a normal psychological approach towards the existing temporary situation from professional Psychiatrist. Role of Psychiatrist have been proved to be vital in researches during quarantine following previous outbreaks \(^9\).

2. Availability of reliable, rational and uncomplicated information from governmental and public health departments involved directly in action or working in combination with the main agencies for recent intervention being implemented, along with future projections to be implied if required should be broadcasted on regular basis for betterment of even the underprivileged section of population \(^32\).

3. Dietary and sleep schedule, similar as that of prior to outbreak of Quarantine, should be followed as these unswervingly have an effect on mental Health.

4. Individuals can be kept occupied by endorsing them in their respective hobbies, choice thus preventing growth of even tiny negative impact on mental wellbeing.

5. A positive approach of helping others to conquer similar situation amongst family associates and populace in contact through social media promote ability to be occupied and accepting the condition and possibly looking for ways to eradicate the same \(^11, 15, 34\).
6. Assurance of a regular supply of daily needs for subjects in quarantine to individuals from underprivileged sections reduces risk for development of negative impact\(^3\).

7. In today’s world, mobile is a necessity than luxury. It has proved its metal to be efficient in slowing the creation of negative impacts even during long stays during quarantine as the individual are occupied by exploring their interest, exchanging views via social networking websites and coming across developments across the world\(^3,33\).

8. Government should initiate free online, broadcasting counseling programs via television and radio to minimize the figure of people being engraven amid negativeimpacts\(^34\).

9. Special focus to be paid on health staff working during quarantine by administrative and agencies delivering and monitoring services\(^35,36\).

10. Prioritization of steps taken to balance professional, psychological, personal and social attributes for staff engaged with quarantine subjects\(^35\) by benefitting from comfortable working hours in shifts, remuneration and perks apart from regular salaries should be constituted.

**Conclusion**

The phase of quarantine produces negative impacts on one’s psychological and psychosocial aspects of life. Some individuals present with few, while mostly demonstrate multiple negative impacts making the situation concernable bringing in interventions even from other domains of health care, example Psychiatry. Majority of individual kept in quarantine facilities present with sadness due to detachment from family, relatives and fear and concerns regarding upcoming future rejections from neighbors’, social setups. Anger towards inability to balance personal, daily and financial needs summite addition of other effects bulging the balloon of negative impacts. Even the health care providers experience the same issue of neglect from family, relatives and neighbors as they are thought to bring in infection from the quarantine facilities. Health worker friendly policies should be instituted from governmental agencies to minimize the exposure time for health workers, providence of duty off on regular intervals, extra remuneration. All health workers work in quarantine facilities with dedication without stepping back to impart best available treatments serving mankind. It should be brought to think that these health care workers too are humans and experience similar views as they are the one exposed to the pandemic or epidemic disease as the first shield of prevention of spread of the disease.

Development and Assessment of Fluorinated Graphene Nanoparticles Modified Dental Adhesives

Rafal M. Maryoosh¹, Abdulla M. Al-Shamaa²

¹B.D.S., M.Sc. (Conservative Dentistry), Ministry of Health/Al-Rusafa Health Department, Baghdad, Iraq
²Assist. Professor, B.D.S., M.Sc., Ph.D. (Conservative Dentistry), Department of Conservative, College of Dentistry, University of Baghdad, Baghdad, Iraq

Abstract

Background: The success of adhesion to the tooth structure plays an important role in the dental restoration, which can effectively avoid the terrible clinical problems during the bonding process, including the secondary caries and the loading of adhesive compositions with fillers and nanoparticles with antibacterial properties has led to a significant reinforcement effect of the adhesive.

Objective: The current study is designed to investigate the effects of addition of 2% of fluorinated graphene on the adhesive-dentin hybrid layer for two types of commercially available universal adhesive, guided using the etch and rinse technique as a bonding procedure.

Method: Forty extracted premolar teeth will be divided into four groups of ten teeth. Group I: the non-incorporated (Prime & Bond Universal) bonding agent (Control group). Group II: using the 2% FG nanoparticles incorporated (Prime & Bond Universal) bonding agent. Group III: non-incorporated (All Bond Universal) bonding agent (Control group). Group IV: using the incorporated (All Bond Universal) bonding agent. The degree of conversion was also measured using Fourier transform infrared spectroscopy (FTIR). The antibacterial activity of the adhesives was evaluated using agar diffusion test against the following bacteria: Streptococcus mutans and Lactobacillus salivarius obtained from saliva.

Results: A significantly greater antibacterial activity was obtained with adhesives containing a 2% fluorinated graphene nanoparticles than other groups (P<.01). Degree of conversion of tested adhesives was not change significantly after addition of 2% of fluorinated graphene nanoparticles.

Conclusion: The antibacterial effect of adhesives that incorporated with 2% of fluorinated graphene nanoparticles was higher than the non-incorporated etch- and rinse adhesive systems. The degree of conversion of adhesives was not significantly different.

Keywords: Adhesive systems; Antibacterial activity; Degree of conversion; Etch & Rinse adhesive technique.

Introduction

Success in adhesive dentistry means long-lasting restorations. Notwithstanding, the loss of adhesion or retention of a resin composite restoration is a frequent problem observed by dental practitioners, especially due to bond strength degradation¹ ². The loading of adhesive compositions with fillers and nanoparticles has led to a significant reinforcement effect of the adhesive ³ ⁴ ⁵. Fluorinated graphene (FG), an up-rising member in the family of graphene derivatives, is a kind of one-molecule-thick material ⁶. Graphene has been reported to be highly cytotoxic for bacteria and can thus serve as an antibacterial material, so we could speculate that as a...
member of graphene family, FG may also have similar effect (7). In previous studies, the antibacterial function of graphene is believed to be caused by both physical and chemical effects (8).

**Materials and Method**

**Preparation of modified universal adhesives:**

Two commercial universal adhesive agents; Prime & Bond Universal adhesive (Dentsply, Tulsa dental specialties, USA) and All-Bond Universal adhesive (Bisco Inc, USA) were selected in this study. The fluorinated graphene nanoparticles (FGN) (Hyper Chem Co., chaina, Let. No. Q19011701) was used as filler particles and it was submitted to the silanization process to improve the adhesion interface between the filler nanoparticles and the adhesive matrix so that the FGN was treated with 3-metacryloxypropyltrimethoxy (MPS) silane coupling agent using a procedure described by Deb et al. in 1996 (9,10).

A percentage of 2 w% of FGN was chosen from a pilot study out of 4 different percentages (1, 2, 3, 4 w. %) because this concentration didn’t adversely affect the viscosity, color stability and flowability of the adhesives (11). Then the FGN was dispersed in 6 ml of each adhesive by ultrasonication for 1 h to obtaining a homogenous mixture.

**Degree of conversion test:** For FTIR spectroscopic analysis, equal droplet amount of each adhesive resin was placed on a transparent poly-ethylene film. With a gentle steam of air, the solvents were evaporated for 30 seconds and then covered with a second film and pressed softly to form a thin layer of the adhesive. The “sandwich” was placed into the sample holder of FTIR spectrometer (Equinox 55, Bruker, Germany) (Fig. 3), and the absorbance peaks of the unpolymerized adhesives were recorded by transmission mode at a resolution of 4 cm⁻¹, with scans in the range of 400-4000 cm⁻¹. The adhesives were then light-cured with an LED Bluephase (IvoclarVivadent, Lichtenstein) light-curing unit with a light intensity of 600 mW/cm² for 40 seconds and the absorptions were recorded for the cured adhesive specimens. The DC% was calculated from the ratio of absorbance intensities for aliphatic C=C (peak at 1638 cm⁻¹) and the internal reference of aromatic carbon-carbon double bonds (peak at 1608 cm⁻¹) were recorded before and after curing the specimens, according to the following equation (12): 

$$DC = \frac{1 - \frac{(1635 \text{ cm}^{-1} \times 1608 \text{ cm}^{-1})_{\text{uncured}}}{(1635 \text{ cm}^{-1} \times 1608 \text{ cm}^{-1})_{\text{cured}}}} \times 100\%$$

![Fig. 3. Set-up for measuring degree of conversion of adhesive resins by Fourier transforms infrared (IR) spectroscopy (13)].
**Microbiological Study:** The microbiological study was conducted in the Department of Microbiology in the Medical Center in Baghdad, to evaluate and test the antibacterial activity of incorporated adhesives and was compared to the control non-incorporated adhesives against selected microorganisms which was *Streptococcus mutans* and *Lactobacilli*, since these are the main microorganisms associated with the development and progression of carious lesion (Primary and secondary caries).

Adhesive specimenwells with an inner diameter of 8 mm and a depth of 1.0 mm was prepared. Total forty wells were prepared, ten wells for each group, 5 wells of each group were used for each microorganism. The medium that used for antibacterial activity test will be Mueller-Hinton agar for *Streptococcus mutans* and MRS broth for *Lactobacilli* (19).

The selective medium for the cultivation of *Streptococcus mutans* was Mitis Salivarius Bacitracin Agar and for *Lactobacilli* was MRS Agar.

**A. Culture Medias:**

1. **Mitis Salivarius Bacitracin Agar (MSB):**
   Mitis salivarius bacitracin (MSB) agar is the selective medium for the cultivation of MutansStreptococci.

2. **MRS Agar (Lactobacillus Selection Agar):** MRS Agar was a semi-defined, partially selective medium for the isolation and enumeration of lactobacilli from foods and from intestinal, vaginal, and dental flora.

**B. Isolation of microorganisms:**

The microorganisms were cultured directly from swabs that were taken directly from mouth of volunteer patients. The swab will be rolled over a small area of the surface at the edge on MSB agar and MRS Agar; then was streaked for isolation from this inoculated area.

For MSB agar, the plates was incubated anaerobically utilizing a gas pack for 48 hours at 37 °C then aerobically for 24 hours at room temperature, while for MRS Agar, the plates was incubated anaerobically for three days at 37 °C (15).

**C. Measurement of the inhibition zone:** After 24 hours of incubation, the MRS agar plates was removed from the incubator and was examined for the inhibition zone around each well in (mm) after 48 hours of incubation using a ruler around each disc. The measurement of the inhibition zone was done by two microbiologists separately to get the best and reliable standardized results for this test.

**Statistical Analysis:** Statistical analysis was done by Statistical Package for Social Sciences (SPSS) version 24. Results were calculated as mean ± standard error of means (SEM). Comparison among groups was done by using a one-way Analysis of variance (ANOVA). The statistically significant differences were considered when P<0.05.

**Results**

**Degree of conversion (DC%):** Table 2 and figure 2 showed that there were non-significant differences (P>0.05) in degree of conversion of incorporated All Bond Universal adhesive agent with 2% fluorinated graphene (Group II) compared to the corresponding degree of conversion of the non- incorporated All Bond Universal adhesive agent (Group I). Mean±SEM of degree of conversion of (Group I) & (Group II) were respectively, 85.9200±.27479 and 86.2600±.27536. Similarly, table 2 and figure 2 there were non-significant differences (P>0.05) in degree of conversion of the incorporated Prim & Bond Universal adhesive agent with 2% of fluorinated graphene (Group IV) compared to the non-incorporated Prim & Bond Universal adhesive agent (Group III). Mean±SEM of degree of conversion of (Group III) & (Group IV) were respectively, 74.8800±.21124 and 75.9200±.18547.

Discussion

Durable and high bond strength to dentin is the goal of all the restorative materials and procedures. Clinical failure of adhesive restorations happens more often due to insufficient sealing of cavity margins, with subsequent discoloration, rather than complete loss of retention. Results from the present study showed that the degree of coversion of tested adhesive agents that incorporated with FG nanoparticles and the pure adhesives are not change significantly. Secondary caries is one of the most common reasons which are responsible for the limited longevity of indirect restoration. In previous studies, the antibacterial function of graphene is believed to be caused by both physical and chemical effects. The most important mechanism is the bacteria cell membrane destruction by the sharp edges of graphene nanosheets in suspensions. The chemical effect is primarily oxidative stress created by reactive oxygen species (ROS) and extraction of phospholipids from the cell membrane. A study found that graphene layer reduces the attachment of microbes. Recently, researchers found that graphene oxide nanosheets would be an effective antibacterial material against dental pathogens. Our research showed that the antibacterial behavior of the conventional adhesives could be enhanced by FG and the effect is more obvious for specimens with higher FG. Similar to graphene, the physical damage toward bacteria by sharp edges and chemical effect may also be responsible for its antibacterial property.

Conclusion

In addition, adhesive/FG composites showed superior performance of killing S. mutans and Lactobacilli bacteria. The presented work shows FG has potential to improve antibacterial properties and degree of conversion of adhesive agents.

Duodenal Obstruction in the First Month of Life

Omar Abdulqader Ajaj1, Mohaned Shaker Mahmood2, Arkan Hadi Ahmad2

1Pediatric Surgeon, Al-Anbar College of Medicine, Anbar, Iraq,
2Pediatric Surgeon, Al-Ramadi Children and Maternity Teaching Hospital, Anbar, Iraq

Abstract

Introduction: Duodenal obstruction in the 1st month of life is the most common etiology of bowel obstruction. We aim to analyze the causes, clinical and diagnostic spectrum, management and surgical outcome of duodenal obstruction in the first month of life. The method that we used were 26 newborns of duodenal obstruction reviewed by a cross-sectional study for 30 months (January 2017 - Jun 2019). All of the newborns were investigated to the demographic details, causes, clinical presentation, associated anomalies, radiological findings, surgery performed and their outcome. Our results show that of 26 neonates (16 males, 10 females). 17 newborns were presented within the first 3 days of life. The mean gestational age was 36.88 weeks (10 preterms, 16 terms). The birth weight was normal in 16 newborns. Duodenal atresia was the most frequent cause in 9 (35%) neonates followed by the annular pancreas in 8(31%), malrotation in 6(23%), congenital duodenal web in 2 (8%) and congenital peritoneal band in 1 (4%). Greenish vomiting was the most common presentation in 38%. Double bubble gas by abdominal x-ray in 65%. Associated anomalies were noted in 58%, cardiac defects being the most frequent 53%. Duodenoduodenostomy was performed in 73%. Feeding intolerance is the most frequent complication in 48%. 4 (15%) neonates died, mostly in malrotation 50%. The commonest cause of death was midgut gangrene in 50%. We concluded that the Duodenal obstruction is a common problem in newborns. Greenish vomiting was the most common warning finding. Associated anomalies were noted in more than half, cardiac defects being the most frequent. Early diagnosis and treatment is key to reduce post-surgical complications and improving outcome.

Keywords: Duodenal obstruction, annular pancreas, duodenal atresia.

Introduction

Duodenal obstruction in the 1st month of life is the most common etiology of bowel obstruction. Its incidence about once/2500 to 10,000 live newborns[1,2]. It can lead to complete or partial obstruction of the duodenum due to various intrinsic and extrinsic reasons for obstruction[3,4]. Various developmental defects (recanalization or rotation) of foregut lead to duodenal obstruction in the newborns[5,6]. The common causes of NDO are DA, CDW, MR of the gut and AP[2].

The clinical presentation of NDO varies depending on anatomical defect type[1,5]. Bilious emesis is a common clinical spectrum[1]. The helpful diagnostic modalities are plain x-ray of abdomen and upper gastrointestinal contrast x-ray[5]. There are many anomalies (cardiac, down syndrome, renal and others) have associated with NDO[6]. Timely diagnosis and aggressive resuscitation strategy of NDO is important to maximize the outcome[7]. Published studies on duodenal obstruction in the 1st month of life are very limited in Iraq. It is therefore important to report our experience in NDO. The main objective was to analyze the causes, clinical and diagnostic spectrum, management and surgical outcome of duodenal obstruction in the first month of life.

Patients and Method

Study Design: Twenty-six newborns of duodenal obstruction were reviewed with across-sectional study.
at the unit of pediatric surgery at Al-Ramadi Children and Maternity Teaching Hospital, Anbar-Iraq for 30 months from January 2017 till Jun 2019. We excluded newborns with the duodenal obstruction which died preoperatively. All of the newborns were investigated to the demographic details, causes, clinical presentation, associated anomalies, radiological diagnostic findings, surgery performed and their outcome. A complete examination of all newborns was done, the abdominal x-ray was done on all newborns which showed double bubble appearance in 17 neonates, water-soluble (upper gastrointestinal) contrast studies were done when indicated (2 newborns showed partial duodenal obstruction), abdominal ultrasound and ECHO were done when indicated to rule out associated anomalies. Preoperative resuscitations and surgical exploration have been done in all neonates, different surgical procedures undertaken according to the etiology. We defined birth weight as low if there was less than 2.5kg, as normal if it was more than or equal 2.5kg. The term neonate was considered if the gestational age of more than or equal 37 weeks and the preterm neonate was considered if the gestational age is less than 37 weeks. Postoperative care and follow up was provided for all neonates. Written informed consent from the patient’s parents has been taken. Ethical approval was obtained from the ethical approval committee at the University of Anbar.

**Statistical Analysis:** IBM’s SPSS Statistics (Statistical Package for the Social Sciences) for Windows (version 25, 2017) and Microsoft Excel for Windows (2019) was used for statistical analysis of the collected data. Categorical variables were expressed as frequency and percentage. One sample Chi-square test was used to compare the actual frequency of each subcategory against its expected frequency assuming all subcategories have an equal incidence at presentation. All tests were conducted with a 95% confidence interval. The P-value is generated by the chi-square goodness-of-fit test. The P-value is significant when < 0.05.

**Results**

26 neonates presented with NDO during the study period. Out of 26 neonates, 16 (62%) were males and 10 (38%) were females. The overall male to female ratio was 1.6:1. The age at the time of presentation (1-29) days, 17 (65%) newborns were presented within the first 3 days of life and the rest, 9 (35%) presented after 3 days of life. The mean gestational age was (36.88 weeks) ranged between 31-41 weeks (10, 38% were preterm and 16, 62% were term). The birth weight of these newborns was normal in 16 (62%) neonates and it was low in 10 (38%) neonates. The mean of hospital stay was 13 days ranged (5-25) days.

The causes of NDO are shown in table (1). Duodenal atresia was the most frequent cause which occurred in 9 (35%) neonates followed by the annular pancreas, which occurred in 8 (31%) neonates. Other causes of NDO were 6 (23%) neonates were malrotation, 2 (8%) neonates were congenital duodenal web and 1 (4%) neonate was a congenital peritoneal band.

More than half of newborns (15, 58%) had one or multiple associated anomalies. The majority of these anomalies are cardiac, observed in 8 (53%) newborns and appear to be statistically significant (p value= < 0.001). Anomalies of multiple, renal, skeletal, umbilical hernia and imperforate anus were also detected. (Table 3).

Radiological findings of NDO, only one newborn had polyhydramnios by prenatal ultrasound, two newborns had PDO (CDW) by water-soluble (upper gastrointestinal) contrast studies and 17, 65% (9=DA, 8=AP) newborns had double bubble gases by abdominal x-ray. While the operative findings of NDO are DA in 9 neonates, AP, in 8 neonates, 6 neonates were MR, 2 neonates were CDW and 1 neonate was CPB.

The surgical repair was performed for 26 neonates (according to type of anomalies), duodenoduodenostomy was performed to 19 (73%) neonates (DA=9, AP=8 and CDW=2). Ladd procedure was performed to 7 (27%) neonates.

During the postoperative period, feeding intolerance is the most frequent complication 10 (48%) newborns with statistically significant (p value= < 0.001), death in 4 (19%), wound infection in 3 (14%), sepsis in 2 (10%), dehiscence and aspiration pneumonia each in one newborn. (Table 4).

Discussion

NDO is the most frequent etiology of bowel obstruction in the 1st month of life[8,9]. Among 26 study populations, 16 (62%) were males and 10 (38%) were females. The overall male to female ratio was 1.6: 1. There is a male predominance in this study, which agrees with reports of other studies [6,7,10] that found (m=16,f=14),(m=193,f=94), (m=56,f=25) respectively. The age at the time of presentation (1-29)days, 17(65%) newborns were presented within the first 3 days of life and the rest, 9(35%), presented after 3days of life, which was similar to the results conducted by other studies[11] that found day one of life is the most frequent age of presentation (12 newborns).

In this study, the mean gestational age was (36.88 weeks) ranged between (31-41) weeks, 16 (62%) were term and 10 (38%) were preterm, which agrees with reports of other series [10,11] that found (term=79%, preterm=21%), (term=61%, preterm=39%) respectively. The birth weight of these newborns was normal in 16 (62%) neonates and it was low in 10(38%)neonates, these findings confirmatory to the other studies[11] were found that 2.15kg was the mean birth weight. The mean of hospital stay was 13 days ranged (5-25)days.

In this study, more than half of newborns (15, 58%) had one or multiple associated anomalies, which seems to be higher than the results of other studies [6,7,10,12] that found the associated anomalies are [57%, 50%, 27%, 50%] respectively. The majority of these anomalies are cardiac, observed in 8 (53%) newborns and appear to be statistically significant (p value= ˂ 0.001). This result is consistent with other studies[7,10,13] who found cardiac anomalies were the most common defect (32%, 7%, 48%) respectively. While in the other studies Kumar P. et al[11], Avci V. et al [12] found that trisomy 21 it was higher associated anomalies(32%,69%) respectively, this might be due to difference in sample size and newborn characteristics.

Greenish vomitus was the typical presentation of NDO reported in 24 (38%) neonates followed by dehydration in 18(28%)neonates. This result is consistent with Qiang Shu et al[7] who found that vomiting was the most common symptom (86%) followed by dehydration (30%), while Rattan K. N. et al[10], Avci V. et al [12] found that vomiting was the most common symptom (100%, 75%)respectively, followed by upper abdominal fullness (69%, 38%)respectively, this might be due to recurrent vomiting led to dehydration.

In this study, more than half of newborns (15, 58%) had one or multiple associated anomalies, which seems to be higher than the results of other studies [6,7,10,12] that found the associated anomalies are [57%, 50%, 27%, 50%] respectively. The majority of these anomalies are cardiac, observed in 8 (53%) newborns and appear to be statistically significant (p value= ˂ 0.001). This result is consistent with other studies[7,10,11] who found cardiac anomalies were the most common defect (32%, 7%, 48%) respectively. While in the other studies Kumar P. et al[11], Avci V. et al [12] found that trisomy 21 it was higher associated anomalies(32%,69%) respectively, this might be due to difference in sample size and newborn characteristics.

Radiological findings of NDO, by prenatal ultrasound only one newborn had polyhydramnios, by water-soluble (upper gastrointestinal) contrast studies...
two newborns had PDO (CDW) and by abdominal x-ray 17.65% (9=DA, 8=AP) newborns had double bubble gases. Kumar P, et al\[11\] in their study found that among 31 newborns, the polyhydramnios was observed in one neonate. On the other hand, Qiang Shu et al\[7\], Kumar P, et al\[11\], Avci V. et al\[12\]found that among(287, 31, 32) newborns respectively, double bubble appearance was observed in(143, 31, 24) newborns respectively, this might be due to difference in sample size and causes of obstruction.

The surgical repair was performed on all newborns, according to a type of defects, diamond duodenoduodenostomy was the preferred procedure in DA, CDW and AP \[14,15\], It was performed to19, 73% neonates(DA=9, AP=8 and CDW=2), Ladd procedure was performed in 7,27% neonates. Few studies evaluate NDO postoperative complication, in this study feeding intolerance is the most frequent complication(10, 48%) newborns with statistical significant (p value= < 0.001) followed by death(4, 19%newborns) and wound infection (3, 14%newborns), while other studies\[7,13\] found that the most frequent complication is wound infection (7,3) newborns respectively followed by dehiscence (3,1) newborns respectively, this might be due to reasons related to NDO and chronic intrauterine duodenal obstruction led to dilatation of duodenum and stomach that lead to dysmotility\[13\].

Out of 26 neonates in this study, 22 (85%) neonates were survived. Overall mortality was 4 (15%), which was in between reported international publication Kaddah SN, et al \[4\], Rattan K. N. et al\[10\], Kumar P. et al\[11\], Avci V. et al\[12\] and Erickson J et al\[16\] were observed a mortality of (21%, 13.5%, 22.5%, 9%, and 22.5%) respectively. Prematurity, sepsis, post-surgical complications, associated anomalies, and pneumonia are contributing factors to high mortality in newborns with duodenal obstruction \[17,18\]. In this study the highest mortality was observed in malrotation 2(50%) deaths, our opinion, there was a significant association between mortality and malrotation(Odds Ratio = 1), while Kaddah SN et al\[4\] found that the highest mortality was observed in newborns of duodenal atresia(27%) this might be due to a different distribution of associated anomalies. In this study the commonest cause of death was midgut gangrene 2(50%) deaths followed by sepsis and aspiration pneumonia each in 1(25%) death, while in the other studies Qiang Shu et al\[7\] were observed 50% of death result of bowel necrosis and sepsis, Avci V. et al\[12\] were observed that sepsis and cardiac defects are the most frequent cause of mortality, Rattan K. N. et al\[10\], Kumar P. et al\[11\] were observed that sepsis was the most frequent cause of mortality (50%, 39%) respectively, this might be due to different presentation time and distribution of associated anomalies. Our opinion that early diagnosis and treatment of NDO is key to reduce post-surgical complications and to improving outcome.

**Conclusion**

DO is a common problem in newborns. NDO presentation can be varied, but greenish vomiting was the most common warning finding. Associated anomalies were noted in more than half of newborns, cardiac defects being the most frequent. The important investigation work-up of NDO was a plain abdominal x-ray. Early diagnosis and treatment of NDO is key to reduce post-surgical complications and improving outcome.

Levels of Some Cytokines in Iraqi Patients with Multiple Myeloma

Ali Sabah Salman¹, Eman Saadi Saleh², Mohammed Saleem Abbas³

¹Lecturer Assistance, ²Professor Assistance, College of Pharmacy, University of Baghdad/Iraq, ³Consultant Hematologist, Baghdad Hospital in Medical City/Iraq

Abstract

Introduction: Multiple myeloma is hematological disease characterize by abnormal functioning plasma cell result in deterioration in different organs include bone and kidneys in addition to other complications. The study aimed to measure some cytokines in the serum and determined if there is possibility to use this cytokines as predictor for the multiple myeloma.

Materials and Method: Blood samples was drown from 58 patients and 24 sex and age match control, serum then isolated and proper ELISA kit then used to determined level of β2 microglobulin, interleukins-13, 19, and 38.

Result: The result demonstrated significant increase in β2 microglobulin in patients compare to control (1.347+0.714 vs. 0.913+0.253), p = 0.00, interleukin-13 significant increase in patients group compare to control group (204.56+189.84 vs. 106.17+52.07), p=0.001, interleukin-19 non-significant increase in patients group compare to control group (22.46+42.09 vs. 11.252+8.574), p= 0.211, interleukin-38 significant increase in patients group compare to controls (60.087+54.131 vs. 26.791+21.382), p= 0.00.

Discussion: The results of this study indicate that IL-13 and 38 possible to use as predictor for the disease.

Keywords: Health, Iraqi patients; myeloma; cytokines.

Introduction

Multiple myeloma (MM)is malignant disease effect plasma cell, this accompany with a number of changes include elevation in calcium levels, renal insufficiency, bone lesion and metabolic disorder in addition to the abnormal protein in the urine contributed to renal disorder (1).

The bone disorder is the most common complication in the MM, the damage that occur in the bone result from stimulation of osteoclast formation. In addition, there is decrease in the bone formation have been reported and this attributed to the suppression effect of myeloma cell on osteoblast cell (2).

Other MM complications is renal disorder that occur due to light chain immunoglobulin (LCI) accumulation (3). Anemia is common hematological complication and account (60% to 80%) untreated active MM patients and its usually normochromic and normocytic type (4).

Interleukin 13 is a Cytokine involve in allergy and inflammation, they produce pathological effect when produce in high dose, however, in considerable dose useful against intestinal helminthic parasite (5).

Interleukin 19 (IL-19) is one of interleukin 10 (IL-10) family that produce from activated monocyte, T and B cell to lesser extent, non-immune cell like keratinocytes and foetal membranes (6, 7).
Interleukin-19 receptors abundant in the skin, lung and reproductive organ tissue, and seen to be important in production T helper 2 (TH 2) cytokine and induce expression of IL-6, IL-8 and IL-10 in monocyte. IL 19 elevated in the asthma and a number of the disease include type1 DM, aging, vascular disease and rheumatoid arthritis[8].

Interleukin 38 one of interleukin family 1 that include 11 type and play important role in the inflammation, it have specific receptor called IL-1 receptor-related protein 2 (IL-1Rrp2, IL-36R) these receptor considered as interleukin36 (IL36) receptor antagonist.

Interleukin 38 considered anti-inflammatory agent through inhibit the effect of IL 36 in that receptor[9].

Beta2 microglobulin is a polypeptide presented in the serum its origin is the cell membrane of all nucleated cell in which found in tight junction with major histocompatibility complex 1(MHC1): elevated its level reflected increase intrinsic kinetic activity of tumor cell including DNA and RNA kinetic, therefore, it's important for staging, determined disease severity, response to chemotherapy and prognosis[10].

This study was aimed to: Determined level of some cytokines in the serum of the patients with multiple myeloma.

Study the possibility of the serum level of these cytokines to be used as predictor of multiple myeloma disease.

Subject, Material and Method

The study was conducted in Baghdad city in (Baghdad hospital/medical city and hematological center) from October 2018 to May 2019 where (58) patients diagnosed to be have multiple myeloma and most of them regularly visit the hospital to receive the chemotherapy. From the total number of the patients, (36) was male and (22) was female.

The control subjects were randomly selected which were apparently healthy, the control were age, sex, body mass index (BMI) matching to patients group.

Disposable syringe and needles used for blood collection, venous blood sample about six ml collected from patients and healthy volunteers in plain tube, blood sample were centrifuge at 2000 rpm for 5 minute to obtain serum.

The serum were divide in Eppendorf tubes and freeze in -20 C° until all serum collected to measure the biomolecules by ELISA.

Serum β2- Microglobulin determined through use commercial kit from Demediect by sandwich ELISA method.[11]. Reference range of β2 microglobulin (1-2 microgram/milliliter) [12].

Serum IL-13 and IL-19 determined using commercial kit obtain from CUSBIO, using sandwich ELISA method.[11].

Serum IL-38 determined using commercial kit obtain from My BioSource, using sandwich ELISA method [11].

The results were express as mean (+/-) standard error of the mean. The statistical analysis was perform using statistical package for social science (SPSS 23), independent student (T) test use to test the degree of significance difference between the patients and control, the p value less than 0.05 considered statistically significant.

Results

Serum levels of biomolecules: Table (1) showed serum level of β2 microglobulin, IL-13, 19 and 38 in controls and patients group.

</table>
The results express in term of (mean ± standard deviation of the mean), n=number of the subject, (*) = significance difference, (p<0.05) compared to control group.

**Discussion**

The study showed level of \( \beta_2 \) microglobulin significance increase in patients group compare to control group despite most of the patients received MM therapy, this indicate the disease is active.

Interleukin 13 significant increase compared to control group, T helper 2 (Th2) cell one of the immune cell that secreted IL-13, so activation of Th2 cell enhance it to secrete the cytokines that include IL-13, Th2 derived from T helper 0 cell (Th0) and required to IL-4 for this development (13), IL-4 secreted from number of cell like natural killer (NKC), Basophil, or even CD4 cell themselves (14).

Many studies showed that total CD4 cell significant reduce in the number among MM patients and CD4/CD8 ratio going to be reduce (15, 16), besides that, T helper 2 in most studies reported to be either decrease or not significance change in MM in contrast to other CD 4 cell like T helper 1 cell and T regulatory cell (16,17), so, from all above it is possible to suggest that Th2 cell have no any role in increase IL-13 in this study.

Eosinophil cell is large factory that secreted many type of biomolecules include the IL-13 (18), so, high level of IL-13 in this study can possibly attributed to activation of eosinophil.

The role of eosinophil in MM have been studied and showed that eosinophil found in association with plasma cell in bone marrow and secrete factors that necessary to plasma cell survival in B.M. (19).

In pathological aspect, Tinaet.al. Showed eosinophil also to enhance myeloma cell proliferation and considered distinct pathway involve in myeloma cell development beside the proliferation development produce by stroma cell pathway (20).

Basophil is another cell that secreted IL-13 (21), however, few studies that determined the relation between basophil and MM, the only information available indicated the basophil stimulate and secrete IL-13 in response to IgE secretion (22), the same relation it’s possible to be found in case IgE myeloma, however IgE myeloma considered as one of unusual myeloma that include also IgD and IgM which is totally represent more than 10% of all MM cases (23).

Mast cell also synthesis and release IL-13 in addition to other mediators (24), many studies noted the role of mast cell in MM pathogenesis especially in the angiogenesis and osteolytic disorder through secretion of its mediators (25, 26).

Mast cell can be activated by IgG which is one of the most anti body secreted by myeloma cell also could be considered one of the biomolecules that stimulate mast cell to secrete IL-13 (27).

Additionally, interaction between Mesenchymal stem cell and MC cell lead to higher secretion of stem cell factor (SCF) (28) which is in turn stimulate mast cell to secrete IL-13 (29), all of these factor strongly suggest the mast cell stimulation as one of main cause of increase IL-13 in this study.

Natural Killer cell (NKC) is another immune cell that secrete IL-19, however, involvement of these cell in IL-13 level elevation in MM it’s unlikely, since these cell showed inverse relationship with stage of myeloma, this support by the study that demonstrated normal or arise in the levels of NKC in the early or treatment stage of MM (30), while in advance and active disease going to depleted (31).

The study demonstrated non-significant difference in IL-19 between control and patients group.

T helper 2 cell one of the immune cell secreted IL-19, T cell in all type (CD4 and CD8) have been reported either decrease or not change in MM (15,16), so, T cell unable to increase IL-19 secretion in MM and this agree with this study.

Although IL-19 secrete also from B cell, its effect on IL-19 level is negligible since the studies showed the secretion of this cytokine from B cell is very low and irregular (32,33).

Monocyte is other immune cell that secrete IL-19, number of the studies evaluate the level of monocyte in MM, one of them showed deterioration in monocyte function including chemotactic function in patients with MM (34), other demonstrated deterioration in monocyte that showed improvement in monocyte enhance dendritic cell activity upon immunotherapy (35), so give the possibility to suggest that activation of monocyte to secrete and increase IL-19 is unlikely and this agree with this study.
The study demonstrated significant increase in IL-38 level compare to the control. Interleukin 38 release from apoptotic cell like in lung or breast cancer (36), IL-38 act to decrease IL-6 secretion from macrophage that play significant role in the MC growth and proliferation, so, increase IL-38 secretion can explain as a compensatory mechanism to fight MC development (37).

Myeloma cell also report to increase apoptosis of immune cell, and this considered as way to explain increase in IL-38 level since these IL release from apoptotic cell as mention before (38). Interleukin 38 have been report to be secrete from B cell (39).

**Conclusion**

Multiple myeloma produce change in the number of cytokines, either proinflammatory and anti-inflammatory both can be effected. Elevation of IL-13 is possible in the patients with MM and this possibility attributed to the stimulation of number of immune cell that known to secrete IL-13 in MM like eosinophil, mast cell. Possibility to use IL-13 and IL-38 as predictor for MM disease.

The Incidence of Orofacial Cleft in Wassit

Abdulkhudur A alwan

Lecturer Dr. B.D.S-F.C.A.B.M.S. Maxillofacial Surgeon/Wassit University-Iraq

Abstract

Cleft lip and palate are the second most common congenital deformity after club foot. The aim of this study is to determine the incidence of orofacial cleft in Wassit. This a retrospective study is diagnosed 300 patients with various types of orofacial cleft from 125800 live births. The incidence of clefs in our population higher than other countries. Cleft lip and palate are more common than other types of orofacial cleft and more common in male than female. While isolated cleft palate are more common in female than male.

Keywords: Incidence, orofacial cleft.

Introduction

Cleft lip and palate are the second most common (about 1 in 700 live births) congenital deformity, after club foot deformity, these localized clefs produce multiple local and regional medical challenges: they affect face shape, speech, and swallowing, as well as increase the frequency of middle ear infections.(1)

Isolated cleft palate (CP) occurs with a genetic pattern differ from that of cleft lip (with or without cleft palate). (2) The cleft lip incidence is 0.47% of live births, with a male: female ratio of 0.74 (in Caucasians) (2) while the occurrence of cleft lip with palate varies among genetic groups, 0.4 per 1000 in blacks, 1 per 1000 in Caucasians, 1.5 per 1000 in Chines, 2.2 per 1000 in Japanese, and 3.5 per 1000 in Amerindians (3). The M:F ratio of CL/P is 2:1 and of CL is 1.55:1 (in Caucasians)(2).

Aim of Study: Determine the incidence of orofacial cleft in Wassit and provide database for health care foundation to improve the provided care.

Patients and Method

This a retrospective study is include all the live birth in was sit between May 2013-May 2018. All the variants of orofacial clefs were recorded in this study. All the normal and abnormal perineonatal deaths were excluded from this study. The number of orofacial clefs in this study depends on the documentation of oral and maxillofacial department which the only center in the government deals with such cases, due to poor registration of hospitals regarding the congenital deformities.

Result

For five years, all the hospital in wassit recorded about 125800 live birth. Three hundred patients with orofacial cleft attended to department of oral and maxillofacial surgery which the only department that receive such cases in the wassit government, 2.3 for 1000 birth.

From 125800 live birth, 170 patients were presented with cleft lip and palate (1.3 for 1000 birth), while 25 patients with isolated cleft palate (0.01 for 1000 birth), and 105 with cleft lip only (0.8 for 1000 birth), table 1.

From 300 cases with orofacial cleft, 105 are cleft lip, 170 are cleft lip and palate and 25 cases present with isolated cleft palate, table 2.

From 170 patients were presented with cleft lip and palate 110 patients were male (64%) and 60 were female (35%), from 105 patients with cleft lip, 75 were male and 30 were female, from 25 patients with isolated cleft palate, 20 were female (80%) and 5 were male (20%), table 3.

Discussion

In this study the incidence of orofacial cleft in our government slightly higher than other countries that may be explain by: the relative causes of clefts are the following: genetic, environmental, and developmental factors. The occurrence of orofacial cleft in families containing varied numbers of clefts conclude that the interaction of three to six genes that responsible for this malformation. MSX1 and TGF b3 are among the most responsible genes. There are over 350 known syndromes associated with clefts of which half are of monogenic origin, in our population many of parents are genetically related, especially in the rural area, also that explain why the prevalence higher in rural area (periphery) than the center of city (urban), when the parents belong to one grant family (second or third relative) when the genetic factor play a great role in this situation. Also higher incidence of orofacial cleft in our population may be belong to environmental cause: when high percentage of pregnant ladies suffering from anemia, uterine viral infection and malnutrition (vitamin deficiency), and deficient of regular follow up during pregnancy to avoid the environmental precipitating factor like: folic acid, vitamin B6, B12 and iron deficiencies.

In this study cleft lip and palate higher than cleft lip or cleft palate only, and this is agree with most of studies.

Also in this study the incidence of cleft lip and cleft lip and palate higher in male than female in contrast to isolated cleft palate higher in female than male and it is agree with most of studies.

Conclusion

1. The incidence is higher in our government than other developed countries.
2. The incidence is higher in low socioeconomic people.
3. Cleft lip and palate higher than other types of clefts.
4. Isolated cleft palate higher in female than male.

Suggestions:

1. The health care providers in the government should be improved their efforts to get expansion in number of orofacial cleft and establish large qualified center.
2. Regular gynecological follow-up to the pregnant ladies to avoid environmental causes anemia, vitamin deficiencies, viral infection etc.
3. Regular visits to rural area to avoid late diagnosis, as the surgical intervention should be in fixed schedule.
4. Provide good and continuous training for health provider and work as multidisciplinary team.

Reference Range of Chest Expansion in Healthy Adult Living in al-Muthanna Governorate

Ahmed Hasan Reheem¹, Hussam Riyadh Dakhil², Muslim Talib Jabbar²

¹Ass. Prof. Dr. Hammurabi Medical College, University of Babylon/Iraq,
²Specialist M.B.Ch.B. Al-Muthanna Health Director/Iraq

Abstract
Measurement of chest expansion is one of the important steps in clinical examination of respiratory system and this can be done by chest palpation with hands or more accurately by using of tape measure. Assessment of chest expansion can give an important idea about different disorders in the thoracic cage or in the lung itself by detection of any limitation of chest expansion. Also it used for evaluation of progression and treatment response of many pulmonary, neurological and rheumatological diseases. In number of famous clinical text books the lower normal limit of chest expansion is 5 cm but we suggest that the reference range of chest expansion is varied in different races. In this study 130 healthy non smoker volunteers living in al-Muthanna governorate, 65 females(50%) and 65 males(50%), were involved by measuring of their chest expansion with tape measure at level of the fourth intercostal space for two times and best reading was taken for each participant. The body weight of the participants in this study range from 52 kg to 86 kg in females and from 50 kg to 90 kg in males. According to this study normal range of chest expansion was(2-5 cm) (mean=3.35cm,SD=0.685) for females and (2 - 5.5cm)(mean=3.38 cm, SD=0.734) for males where the best result was in athletics. There is age wise reduction of chest expansion for both male and female where the mean chest expansion in 18-34 years age group is 3.74 cm for female and 3.72 for male, in 35-64 years age group is 3.57 cm for female and 3.66 cm for male and in those of 65 years and more is 2.63 cm for female and 2.66 for male. So the chest expansion lower normal limit of participants in this study (as sample of Iraqi people) is vary from other reference ranges. This can be explained by the difference of life style and genetic factors between societies and we should not depend on same reference range for chest expansion in deferent races.

Keywords: Chest expansion, Reference range, Tape measure.

Introduction
Normal chest expansion is vital for respiratory system function and tissues oxygenation and this depend on presence of effective normal thoracic cage mobility and healthy lung where any disorder interfere with chest expansion will affect the oxygen supply of the vital organs of the body. Evaluation of chest expansion is important step in physical examination of respiratory system that include inspection, palpation, percussion and auscultation. Clinically thoracic mobility and expansion can be checked by inspection and manual palpation or use of tape measure which is more accurate, simple and inexpensive method [1,2]. The tape measure do not detect any asymmetry in chest expansion, which is useful clue for many underlying respiratory diseases. There are many method for detection of chest expansion by tape measure with little difference. Some of them use level of 4th intercostal space and repeat the test two times and take the best result while other depend on 6th rib level for measurement of chest expansion [3,4]. Frequent measurements of chest expansion is reliable method for
severity assessment and treatment response of many primary pulmonary, neurological and musculoskeletal diseases such as such as: chronic obstructive pulmonary diseases, Ankylosing spondylitis, muscular dystrophy and spinal cord injuries \cite{5,6,7}. These disorders affect normal movement and expansion of chest and interfere with normal pulmonary function. With good surgical and/or medical treatment including physiotherapy, there will be good chance for chest expansion improvement and regular chest expansion assessment and better to do that with tape measure, as the manual method for chest expansion test is subjective and less accurate can effectively monitor this. Many clinical references consider a difference of more than 5cm between full expiration and full inspiration is normal \cite{8}. The dependence on same normal range of chest expansion for deferent races is scientifically unaccepted as there is significant genetic and environmental factors determine the body characters of different populations. In male chest expansion is more than that in female because of difference in surface area between the two and respiratory muscle of the male is relatively stronger than female \cite{9}. Thoracic cage compliance is reduced with age after third decade of life, according to that the chest expansion will reduced \cite{9,10}. Few studies deal with placement of normal range of chest expansion for Iraqi population. This study was done to detect normal chest expansion in healthy adult of al-Mthanna city, Iraq.

**Method**

This observational study was achieved at center and periphery of al-Muthenna governorate in Iraq. This study was completed between July 2018 and February 2019. 130 healthy wealthy Persons without history of respiratory disease or smoking or trauma or concurrent disease. The age of participants is 18 years and above of both genders.

**Study Protocol:** Chest expansion was measured circumferentially with a centimeter tape measure and diametrically transversely by means of tape measure. Readings were carried out in one plane at 4th intercostal space, the difference between deep expiration and deep inspiration has been measured for two times and the best reading was taken, the patient in sitting position.

**Statistical Analysis:** Data was analyzed by using Primer of Biostatistics. For descriptive statistics mean, standard deviation, proportions and percentages were used. For Analysis of Variance (ANOVA) were used. Statistical significance was taken as $< 0.05$.

**Results**

Table 1: Gender wise mean and range of chest expansion of the study subjects .

<table>
<thead>
<tr>
<th>Gender (n=65)</th>
<th>Mean (cm)</th>

<td>2.66</td>
<td>0.51</td>
</tr>
<tr>
<td>P value</td>
<td>&lt;0.00001*</td>
<td></td>
</tr>
</tbody>
</table>

Mean chest expansion of males was 3.72 cm (SD=0.56) in (18 – 34) years, 3.66 cm (SD=0.59) in (35 - 64) years, 2.66 cm (SD=0.51) in (65 and above) years.

Mean chest expansion of females was 3.74 cm (SD=0.46) in (18 – 34) years, 3.57 cm (SD=0.56) in (35 - 64) years, 2.63 cm (SD=0.43) in (65 and above) years.

In Table no. 2 and 3, it was observed that there was statistically significant age-wise difference in chest expansion values of measurement in both male and female subjects.
Discussion

One of the important steps in physical examination is assessment of chest expansion and this can be done by inspection and palpation with examiner hands (manual) or by tape measure. Several respiratory, neurological and rheumatological disorders can affect normal chest expansion and pulmonary function. Careful regular measurement of chest expansion is important for effective management of these disorders. The reference range of chest expansion in different populations is not the same and special range for each community should be present. In this study we try to determine the reference value of chest expansion for healthy fit adult Iraqi population. Mean chest expansion of female in this study was 3.35 cm at 4th intercostal space and mean chest expansion of males was 3.38 cm at the same intercostal space. So the value in female is slightly lesser than that in male and this related to difference in body built of different genders. In our study chest expansion results was higher for younger age group (table 2 and 3) and this can be explained by aging effect on musculoskeletal compliance by calcification of the cost chondral cartilage and reduction of elasticity of the thoracic cage connective tissue [11]. In comparison with the western population, Iraqis have lesser chest expansion and this may be related to difference in genetic and environmental factors including life style and social activities. Other study showed some sort of relation between body mass index and chest expansion [10] but in our study there is no such relation.

Conclusion

According to this study, the normal chest expansion range at 4th intercostal space for healthy adults of al-Muthanna city in Iraq is 2-5.5 cm. Male has slightly greater value of chest expansion than female and there is decline in chest expansion in older age group for both males and females. There is no significant relation between chest expansion value from one side and height and weight from other side. We focus on vital need for special reference range of chest expansion in each country to reach more accurate diagnosis and assessment of many neurological, pulmonary and rheumatological diseases as there is significant variation in normal chest expansion in different populations. We suggest making larger studies in different areas in Iraq with higher number of participants.

A Correlative Study to Assess the Knowledge and Practice of Housewives Regarding Householdwaste Management in Selected Rural Community at Mangalore with a View to Provide an Information Pamphlet

Abin Baby¹, Shycil Mathew²

¹Nursing, Lecturer Dept. of Community Health Nursing, City College of Nursing, ²Lecturer Department of Community Health Nursing, Yenepoya Nursing College, Yenepoya (Deemed to be University), Deralakatte, Mangaluru, Karnataka, India

Abstract

Background: Improper waste management deteriorates public health, degrades quality of life, and pollutes local air, water and land resources. It also causes global warming and climate change and impacts the entire planet. Environmental problem faced by communities living near garbage dumps and marshy lands include air pollution, fires, smoke, flooding etc. Long term health problems like asthma, bronchitis, hepatitis, jaundice, malaria, elephantiasis and typhoid too have been faced by communities. So waste which are considered to be hazardous need to be disposed off safely and adequately.

Materials and Method: A descriptive correlative research design was used for this study. The sample comprised of 60 housewives between 18-55 years of age. The sample was drawn through purposive sampling technique. The study was carried out in rural community at Mangalore. A structured knowledge questionnaire was used to determine the knowledge of the subjects and practice rating scale was administered to assess the practice scores of housewives regarding household waste management.

Results: Majority of the subjects (65%) were having only average knowledge with knowledge score ranging between 0-20 with median 18 and SD 3.01 and majority of the subjects were have moderate practice score on waste management with median 20 and SD 3.52. There was a significant relationship between knowledge score and practice score of the subjects on waste management (r=0.346, df=59.000, p<0.05).Conclusion: The findings of this study suggest that there is a need for educating the mothers regarding the proper household waste management. Women take a key role in housekeeping and disposing domestic waste. So the Government and frontline health workers need to take special initiatives to curb this public issue.

Keywords: Knowledge; practice; waste management; housewives; information pamphlet.

Introduction

Waste is a material that no longer serves a purpose and so is thrown away(1) . In some cases, what one person discards may be re-used by someone else(2). All wastes are particularly hazardous (3). Improper disposal of wastes causes negative impact on the environment, whether it is unsightly litter in urban streets or contaminated air, soil or water (4). This improper waste disposal can affect the life negatively by creating an
environment that is potent for developing diseases in man as well as other living things. Toxic waste can seep into the ground and contaminate our water supplies, and sometimes cause widespread diseases. Due to uncollected waste and improper disposal techniques drains also get clogged which lead to mosquitoes by which various diseases like malaria, chikungunya, viral fever, dengue etc. arise and affect the health of people adversely\(^\text{\textsuperscript{4,5}}\). The output of daily waste depends upon the dietary habits, lifestyles, living standards, and the degree of urbanization and industrialization\(^\text{\textsuperscript{6}}\). In India we produce 300 to 400 Gms of solid waste per person per day in town of Normal size but exceptionally about 500 to 800gms of solid waste is generated per capita per day in metro cities like Delhi and Bombay\(^\text{\textsuperscript{7}}\). The total population of Karnataka as per 2011 census is 5.273 core (52.73), Urban 33.98\% and rural 66.01\%. In Karnataka the waste quantities are estimated to increase from 46 million tons in 2001 to 65 million tons in 2015\(^\text{\textsuperscript{7,6}}\). In a day-to-day life many people are unaware of the proper domestic waste disposal and its harmful effects on the health and environment\(^\text{\textsuperscript{8}}\). Community based education, especially in women, on household waste management and hygiene is essential in order to improve the health of the community\(^\text{\textsuperscript{9}}\).  

**Aim:** The aim of this study is to assess the knowledge and practice of housewives regarding household waste management in a selected rural community at Mangalore with the view to provide an information pamphlet.

**Objectives of the Study:**

1. To determine the level of knowledge regarding household waste management among housewives as measured by a structured knowledge questionnaire.
2. To identify the practice of housewives on household waste management as measured by a practice rating scale.
3. To find the relationship of knowledge and practice scores of housewives on household waste management.
4. To find the association of knowledge scores of housewife on household waste management with the selected demographic variables.
5. To find the association of practice scores of housewife on household waste management with the selected demographic variables.

**Materials and Method**

**Study setting and sample size:** A descriptive correlative research design was used for this study. The sample comprised of 60 housewives between 18-55 years of age. The samples were selected by purposive sampling technique. The study was carried out in rural community at Mangalore, India. A structured knowledge questionnaire was used to determine the knowledge of the subjects with 34 knowledge items with the maximum score of 34 to assess the knowledge of housewives regarding household waste management, and practice rating scale was administered to assess the practice scores of housewives regarding household waste management with 17 statements with three point scale i.e. always, sometimes and never. The statements were scored 2, 1, 0 respectively. The maximum possible score is 34. In order to educate the housewives on this regard the investigator has developed and distributed an information pamphlet to all subjects after collecting the data.

**Data Analysis:** The data was collected after obtaining prior permission from the concerned authority to conduct the study. The participants were assured about the confidentiality of their responses. The data was analyzed in terms of objectives of the study using both descriptive and inferential statistics. The data obtained was plotted in the master sheet.

**Findings:**

**Results**

**Section I. Description of baseline Proforma**

- Maximum number of subjects (38.3\%) were in the age group of 30-39 yrs.
- Maximum number of subjects (48.3\%) were Muslims
- Most of the subjects (40\%) have primary education
- Most of the subjects (45\%) belong to nuclear family
- Majority of the subjects (40\%) had monthly income of 4001-6000
- Most of the subjects (41.7\%) received information from Magazines/Newspapers.
Section II: Knowledge score obtained by the subjects regarding household waste management.

- Majority of the subjects (65%) have average knowledge, 33.3% of subjects have good knowledge and only 1.7% of them have excellent knowledge regarding house hold waste management. This shows that majority of the subjects (65%) have only average knowledge regarding house hold waste management. (figure-1)

Section III: Practice score of subjects regarding household waste management

- Out of 60 housewives, 80% housewives had average disposal practices, 20% had good practices on disposal of house hold waste management. (Table-1).

Section IV: Correlation relationship between knowledge and practice scores of subjects regarding household waste management

- There is a moderate positive correlation between the knowledge and practice score \( (r = -0.346, \text{df}=58, \text{table value}=0.236) \). (Table-2)

Section V: Association between knowledge score and selected demographic variables.

- There is no significant association between knowledge score with demographic variables except in religion and educational qualification.

Section VI: Association between practice score and selected demographic variables

- There is no association between practice score of subjects with demographic variables

Discussion

- The present study revealed that, majority of the subjects (65%) have average knowledge, 33.3% of subjects have good knowledge and only 1.7% of them have excellent knowledge regarding house hold waste management.

- Results obtained from this study consistent to the results reported in another study conducted by Arora L et al it was found that 162(54%) of the respondents could be classified as possessing low knowledge, whilst 138(46%) respondents were having medium level of knowledge regarding waste management (2).

- In present study results revealed that out of 60 housewives, 80% housewives had average disposal practices, 20% had good practices on proper disposal of house hold waste management. The findings of the study was similar the study conducted by John Jince V el al(2014) 75.1% had average practice, 24.9% had poor practice and none of them had good practice regarding domestc waste management (13).

There is moderate positive correlation between the knowledge and practice score \( (r = -0.346, \text{df}=58, \text{table value}=0.236) \).

The findings of the study was similar the study conducted by John Jince V el al(2014) The study shows a positive correlation between knowledge and practice of housewives on management of domestic plastic waste \( (r=0.071) \)(13)

Section II: Knowledge score obtained by the subjects regarding household waste management.
Section III: Practice score of subjects regarding household waste management.

Table 1: Distribution of practice score of subjects on household waste management in terms of frequency and percentage N-60

Figure 2: Scatter diagram showing the correlation between knowledge and practice scores of housewives regarding household waste management

Conclusion

The findings of this study revealed that, majority of the subjects had only average knowledge regarding household waste management and the study suggest that there is a need for educating the mothers regarding the proper waste disposal, since the women take a key role in housekeeping and disposing domestics waste. So the Government and frontline health workers need to take special initiatives to curb this public issue.

Effectiveness of an Animation Video on Behavioral Response to Pain among Toddlers During Immunization in a Selected PHC at Mangalore India

Bijimol N.J.¹, Shycil Mathew²

¹M.Sc. Nursing, Lecturer Dept. of Community Health Nursing, St. John’s college of Nursing Koramangala, Bangalore, ²Lecturer Department of Community Health Nursing, Yenepoya Nursing College, Yenepoya (Deemed to be University), Deralakatte, Mangaluru, Karnataka, India

Abstract

Background: Immunization is regarded as one of the most significant medical achievements of all times. Recently, increasing attention has been paid to the pain resulting from routine childhood immunizations. In addition, lack of adequate pain management during immunization exposes children to unnecessary suffering and the potential for long-term consequences, such as fear of needles. Hence this study is intended to assess the Effectiveness of an Animation Video On behavioral Response to Pain among Toddlers during Immunization.

Materials and Method: A quasi-experimental research (non-equivalent post-test-only control group) design was used for this study. The sample was drawn through purposive sampling technique and comprised of 60 toddlers undergoing for immunization (30 in experimental and 30 in control group) in a selected PHC at Mangalore, India. Data was collected using Behavioral response assessment scale to pain. (Modified FLACC behavioral assessment scale).

Results: Majority of the toddlers in Group I (83.33%) were having moderate behavioural response to pain, only 16.7% were having severe behavioural response to pain whereas in Group II (100%) all the toddlers experienced severe behavioural response to pain during immunisation. The mean score of behavioural response to pain of Group II (10.97±1.69) was greater than that of Group I (7.17±1.206).

Conclusion: An animation video during immunization can be an effective, simple, non-invasive, and cost effective diversional technique had a positive effect on children’s distress behaviour and pain and having no side effects on the toddlers.

Keywords: Animation video, immunization, behavioral response, pain, toddlers.

Introduction

Prevention of disease is one of the most important goals in child care. During infancy and childhood, preventive measures against certain infectious diseases are available. Immunization is an important and cost effective public health tool for disease control(1). Routine immunization injections are the most common painful procedures in childhood. Most of the immunizations are administered early in a child’s life. Most toddlers and many school-age children experience high distress during immunization injections(2).

Untreated immunization pain might also lead to distorted negative memories of that experience.

Correspondence Author:
Ms. Shycil Mathew
M.Sc. Nursing, Department of Community Health Nursing, Yenepoya Nursing College, Yenepoya (Deemed to be University), Deralakatte, Mangaluru, Karnataka-575018

Ultimately, early pain is linked to poorer healthcare attitudes and elevated fear and avoidance of medical procedures in adulthood\(^3\). The child’s distress is upsetting not only for the child but also for the adults involved—both parents and professionals—and it often makes it more difficult to complete the needed procedure\(^4\).

Non-pharmacological method of pain control are widely accepted and can be used with or without analgesics\(^5\). A cardinal responsibility of a community health nurse taking part in giving immunisation is to alleviate pain, promote growth, and development of child\(^6\).

**Aim:** To assess the Effectiveness of an Animation Video On behavioral Response to Pain among Toddlers during Immunization.

**Objectives of the Study:**
1. To determine the behaviour response to pain among toddlers receiving immunisation with animation video (Group I) as measured by structured behavioural response assessment scale to pain (modified FLACC behavioural assessment scale).
2. To identify the behaviour response to pain among toddlers receiving immunisation without animation video (Group II) as measured by structured behavioural response assessment scale to pain.
3. To compare the effectiveness of animation video on behavioural response to pain among toddlers in Group I and in Group II during immunisation.
4. To find the association between behavioural response to pain among toddlers receiving immunisation in Group I and in Group II with their selected demographic variables.

**Materials and Method**

**Study setting and sample size:** A quasi-experimental research (non-equivalent post-test-only control group) design was used for this study. The sample was drawn through purposive sampling technique and comprised of 60 toddlers undergoing for immunization (30 in experimental and 30 in control group) in a selected PHC at Mangalore India. The parents were interviewed on the basis of baseline proforma. The child along with the caregiver was taken to the treatment room. In experimental group (Group I) the investigator made the parent sit on the chair comfortably with the child on the lap and showed the animation video. In control group (Group II) the children were placed in position and restrained by the nurse or parent as routine practice of the clinic.

The behaviours of the subjects were observed by the investigator in three phases during the procedure, i.e., placing the child in position, pre immunisation, and actual procedure until the child is out of the immunisation room. The investigator observed and scored the child’s behavioural response to pain during immunisation injection using the behavioural response assessment scale to pain. Data was collected using behavioral response assessment scale to pain. (Modified FLACC behavioural assessment scale).

**Data Analysis:** The data was collected after obtaining prior permission from the concerned authority to conduct the study. The participants were assured about the confidentiality of their responses. The data was analyzed in terms of objectives of the study using both descriptive and inferential statistics. The data obtained was plotted in the master sheet.

**Findings:**

**Results**

**Section I: Description of baseline proforma**

- Majority (83.3%) of the samples were between 12-18 months of age.
- Majority (63.3%) of the samples were male.
- All (100%) of the children were undergoing DPT immunisation.
- Highest percentage (46.7%) of the children showed minimal resistance to previous immunisation.
- Majority (56.7%) of children had more than 10 kg of weight at the time of immunisation.

**Section II: Description of level of behavioural response to pain among toddlers during immunisation procedure in Group I:** The area-wise mean percentage shows that the behavioural response to pain was more in the areas arms (mean percentage=66.67%) legs (mean percentage=65.00%), and restlessness (mean percentage=65.00%). There was less behavioural response to pain in the areas like muscle tone (mean percentage=33.33) cry and vocalisation (mean percentage=58.33%) and facial expression (mean percentage=41.67), in the Group I. [Table-1].
Section III. Description of level of behavioural response to pain among toddlers during immunisation procedure in Group II.

The area wise behavioural response to pain in Group II was more in the areas of arms, muscle tone, and restlessness (mean percentage=96.67%) cry and vocalisation (mean percentage=95%) leg (mean percentage=88.33%), and facial expression (mean percent=71.67%). [Table-II]

Section IV. Comparison between level of behavioural response to pain scores in Group I and Group II

The majority of the toddlers in Group I (83.33%) are having moderate behavioural response to pain, only 16.7% are having severe Behavioural response to pain whereas in Group II all toddlers (100%) experienced severe behavioural response to pain during immunisation. [Figure-1].

Section V: Significant difference between level of behavioural response to pain among toddlers during immunisation injection in Group and Group II

Significant difference between level of behavioural response of pain in Group I and Group II showed that Group II has severe behavioural response than Group I (10.97±.928 V/S 7.17±1.206). The calculated value (t=13.680, p<0.001) indicates the significant difference between the behavioural response scores between the two groups. [Table-III].

Section VI: Association of level of behavioural response to pain among toddlers in Group I and Group II with their selected demographic variables

The behavioral response to pain among toddlers in Group I and Group II with their selected demographic variables shows no significant association at 0.05 level of significance. [Table-IV].

Discussion

The present study revealed that the behavioral response to pain among toddlers during immunization procedure in Group I and Group II showed that, the Group I had moderate behavioral response to pain (83.3%) and 16.7% had severe behavioral response to pain while undergoing immunization, whereas Group II had severe pain (100%) during the immunization.

The above findings are consistent with a quasi experimental study conducted at pediatric surgery ward (6th floor, C block) of Advanced Pediatric Centre (APC), PGIMER, Chandigarh by James Jet et al (2012) The mean pain score was significantly less i.e. almost half with animated cartoon (2.26 ± 2.18) as compared to routine care (4.76 ± 2.08) at pre venipuncture. Similarly the mean pain score during venipuncture was significantly less with animated cartoon (6.24 ± 2.09) as compared to routine care (8.06 ± 1.70)(19).

The present study findings showed that there is no association between level of pain among toddlers in Group I and Group II and selected demographic variables (Fisher exact test, p>0.05).

The above findings are consistent with a quasi-experimental study was conducted on children of 3 to 6 years of age who were undergoing venipuncture in selected hospitals of Mangalore by MM Lobo and Umarani j (2012).The findings also revealed that there was no significant association between the level of pain and demographic variables(20).

Conclusion

Present study findings showed that, Distraction techniques like showing the animation video during immunizations are effective means for reduction of behavioural response to pain. It can also be used as a routine with immunisation so that children’s behavioural distress can be managed in an effective way. The study concluded that animation video is effective on behavioural response to pain in children receiving immunisation. It is important for the nurses, who administer immunisation, to alter the painful responses as much as possible. Nurses must meet the challenges in relieving response by distracting the children.

Acknowledgement: The investigator sincerely acknowledges the support given by Mrs. Shycil Mathew and Shanti Lobo for their timely support and smart guidance to complete the project. Sincere gratitude towards the study participants for their cooperation.

Financial support and sponsorship: Nil.

Conflicts of Interest: There are no conflicts of interest.

Ethical Clearance: Written informed consent was obtained from the parents of the children who brought their children for immunization at PHC. Ethical clearance was obtained from institutional ethics committee of CHCT, Mangalore.

Abstract

Stunting is one of worrying nutritional problems in Indonesia as its prevalence grows every year. The general objective of this study is to determine factors related to stunting. This study used cross-sectional approach conducted in Kendari City and Semarang City from April to December 2019. The population was children under two years old in Kendari City and Semarang City. Data were analyzed quantitatively, consisting of univariate and bivariate analysis with the help of SPSS. Data analyzed were presented in the form of table and description to discuss the results. The results showed that variables that were significantly correlated with stunting in this study were birth weight (p = 0.014), feeding (p = 0.014), mother’s height (p = 0.004), ANC (p = 0.008), mother’s education (p = 0.007), drinking water use (p = 0.0001), toilet use (0.047). To prevent stunting, it is suggested based on this study to focus on variables like feeding suitability, mother’s weight, ANC examination, drinking water use and toilet use.

Keywords: Stunting, toddler, birth weight, feeding.

Introduction

Stunting arises as one of prevalent nutritional problems in the world recently, especially in poor and developing countries. It becomes a problem because it elevates the risks of diseases and death ¹⁻³ and leads to suboptimal brain development, causing delayed and impaired mental and motor development. Children whose parents have short stature, whether both or one of them, are more likely to have similarly short stature compared to those whose parents have normal height ⁴. Parents with short stature, because of the genes in chromosomes that carry the short stature traits, will most likely pass those traits onto their children. However, in case the short stature is caused by nutritional or pathological problems, the traits will not be passed onto their offspring ⁵.

The determinants of stunting are complex. Stunting may be influenced by a number of factors such as Low Birth Weight⁶, education and economic level⁷, mother’s nutritional knowledge, and exclusive breastfeeding⁸. Stunting may also be attributable to sanitation, water, hygiene and environmental aspects ⁹. According to Palutturi, Syam, and Asnawi (2020), stunting can even be linked to political contexts. Health problems, stunting is one of them, are closely related to political, cultural and leadership problems ¹⁰⁻¹⁵.

Based on provincial and national data of 2013 Riskesdas, national prevalence of stunting is 37.2%, showing an increase compared to in 2010 (35.6%) and 2007 (36.8%). This rate consists of 18.0% very short stature and 19.2% short stature. In 2013, the very short stature rate saw a decrease from 18.8% in 2007 and 18.5% from 2010 while the short stature rate saw an increase from 18.0% in 2007¹⁶. In 2018 Riskesdas, a decrease of 6.4% was observed for 5-year period, bringing the number to 30.8% in 2018 from 37.2% in 2013. However, this decrease still fell short of 2019 RPJMN’s target of 28% for toddlers under two years old. The prevalence of stunting in Southeast Sulawesi is 34.5%.

Materials and Method

In design, this was a cross-sectional study. It was conducted in Kendari City and Semarang City from April to November 2019. The population was children under two years old in both cities, with a sample size of 245 children (125 in Kendari City and 125 in Semarang City). The samples were collected using purposive sampling technique. Bivariate analysis was performed to determine the relationship between dependent variables and independent variables with Chi-square statistical test.

Results

Based on the nutritional status determination according to TB/U index, 42.9% of the children were stunted, 53.5% of them were male and 46.5% were female. In age group, 51.0% of them were aged 6-12 months. Only 2% of them were <20 years old, while 84.9% of them were 20-35 years old and 13.1% of them were >35 years old. 66.2% of the fathers had medium education, 11.4% had low education and 22.4% had high education. The majority of the family head were father with 85.7%.

In Table 2, out of 218 samples, 88 (40.2%) of them had normal birth weight but stunted and 131 (59.8%) of them had normal birth weight but not stunted. Out of 20 samples, 4 (20.0%) of them were given solid foods and stunted and 16 (80.0%) of them were given solid foods but not stunted.

Out of 221 mother’s height samples, 88 (39.8%) of them had normal height with stunting status, and 133 (60.2%) of them had normal height without stunting status. Meanwhile, out of 24 short stature mother samples, 7 (29.3%) of them were normal while 17 (70.8%) of them were stunted. Out of 159 ANC samples, 78 (49.1%) of them received inadequate ANC and were stunted and 81 (50.9%) of them received inadequate ANC but not stunted. Out of 54 high mother’s education samples, 13 (24.1%) of them were stunted and 41 (75.9%) of them were normal. Out of 145 protected water samples, 51 (35.2%) of them were stunted and 94 (64.8%) were normal. Out of 236 samples, 104 (44.1%) of them used gooseneck toilet or similar and suffer from stunting and 132 (55.9%) of them used gooseneck toilet or similar and were free from stunting.

### Discussion

**Relationship between Birth Weight and Stunting Status:** The statistic test using Chi square obtained a p-value of 0.014, smaller than the alpha (p<0.05), indicating a relationship between birth weight and stunting status. This was in line the study by 17, expressing that toddlers with low birth were at increased risk for stunting.

The study by Nasution et al. on low birth weight (LBW) with stunting in children aged 6-24 monthsfound that there was a significant relationship between LBW and stunting incidents in children aged 6-24 months (OR=5.60; 95% CI:2.27-15.70).

LBW infants also experienced digestive tract disorders because the digestive tract had not functioned properly, as in less able to absorb fat and digest protein and cause a lack of reserves of nutrients in the body. Consequently, it would impair the growth of LBW babies and if this continued unchecked, coupled with inadequate feeding, multiple infection episodes, and poor health care, it might lead to stunting.
Relationship between Feeding and Stunting Status: Table 2 shows that out of 20 samples, 4 (20.0%) of them received solid foods and suffered from stunting and 16 (80.0%) of them received solid foods and did not suffer from stunting. Furthermore, out of 218 exclusive formula/breastfeeding samples, 124 (55.1%) of them were normal and 101 (44.9%) of them were stunted.

Based on the chi-square test, there was no relationship between energy sufficiency level and stunting incidents in children under five both in rural or urban areas, while zinc and iron sufficiency levels were observed to have a significant relationship. In rural areas there was a significant relationship between protein and calcium sufficiency and stunting incidents in children under five, evidenced by a p-value of $<\alpha$ (0.05). However, for urban areas the p-value was $>\alpha$ (0.05), meaning that protein and calcium sufficiency levels were not correlated with stunting incidents in children under five.

This was in line with the study by Salsa (2016) stating consumption of foods containing vitamin C affected stunting incident. Vitamin C is important for forming collagen and protein structure. Collagen is needed for the formation of bones and teeth and scar tissue. Vitamin C is also instrumental in boosting immunity against infections. Vitamin C is needed in the growth process through its role in the synthesis of collagen, proline hydroxylation and lysine conversion to hydroxyproline.

Relationship between ANC and Stunting Status: Table 2 shows that out of 159 inadequate ANC samples, 78 (49.1%) of them suffered from stunting and 81 (50.9%) did not suffer from it. Furthermore, out of 86 adequate ANC samples, 59 (68.6%) of them were normal and 27 (31.4) of them were stunted. The statistic test using Chi-square obtained a p-value of 0.007, smaller than the alpha (p<0.05), indicating there was a relationship between ANC and stunting status.

This was also in line with the other study on risk factors of child stunting, one of which was ANC visits. ANC visits made regularly can detect pregnancy risks early in 18 mothers, especially ones related to nutritional status (Ni’amah, 2014). In this study it was found that mothers who made only one ANC visit (fewer than the minimum standard of four times) had a risk of having a stunted toddler 2.4 times greater than mothers who made ANC visit according to the standard.

Relationship between Mother’s Height and Stunting Status: Parents’ height is closely related to the child’s physical growth. Mothers with short stature are one of factors correlated significantly with stunting incidents. This finding was in line with the study by Rahayu (2011) revealing that a child born from a mother and father with short stature was at risk for stunting. One or both parents with short stature due to pathological condition (such as growth hormone deficiency) possess genes in chromosomes that carry short height traits, effectively increasing the probability of the child inheriting said genes and suffering from stunting.

Another study concluded that parents with short stature, low education levels and low income are risk factors associated with stunting incidents in children under five. Other study also stated that genetic factors in the mother, namely height, have a strong correlation with stunting incidents in children.

Relationship between Mother’s Education Level and Stunting Status: The education level is associated with the level of difficulty for mothers to access and receive information about nutrition and health from external sources. A mother with higher education level receives information from external sources with more ease, compared to a mother with lower education level. The level of education of the majority of families of stunted toddlers fell into the low category, which was mainly due to economic condition, holding them back from continuing to higher education levels. In fact, higher education levels were nearly out of question when they struggled to provide foods with complete nutrition.

The statistic test using Chi-square obtained a p-value of 0.007, smaller than the alpha (p<0.05), indicating there was a relationship between mother’s height and stunting status. It showed that mother’s education level was not a determinant factor in stunting incidents. This was in line with the study by Ni’mah and Muniroh (2015) stating that mother’s education level was not correlated with stunting incidents in children under five.

This was also in line with the study by Astuti (2013) revealing that there was no correlation between mother’s education and stunting incidents. Similar results were also obtained by Ni’mah and Muniroh (2016) in their study.

Relationship between Drinking Water Use and Stunting Status: Clean drinking water source is an important element for health and helps decrease the risk
of various diseases such as diarrhea, cholera, and typhus. Children are a vulnerable subject for infectious diseases since their immune system is naturally weak. Mortality and morbidity in children are generally associated with contaminated drinking water sources and poor sanitation. Several studies in many countries showed that drinking water quality is positively correlated with the reduction in diarrhea incidents and mortality in children (Adeware, et. al. 2011).

Protected drinking water sources which are the manifestation of healthy environmental sanitation indirectly influences toddler’s health which ultimately affects their nutritional status or stunting incidents. Nutritional problems, in addition to being caused by a lack of nutrient intake, are also caused by poor environmental sanitation, in this case drinking water sources and personal hygiene, which facilitate the emergence of infectious diseases. This was in line with the study by Zairinayanti and Purnama Rio (2019), revealing that there was a relationship between hygiene and environmental sanitation and stunting incidents.

Relationship between Toilet Use and Stunting Status

Community-led total sanitation program (STBM) is a national policy based on the Decree of the Minister of Health No. 852/Menkes/IX/2008, which was then extended with Permenkes No. 3 of 2014. The objective of this program is to realize hygienic and sanitary community behavior independently in order to improve public health to the highest level possible. The implementation of STBM relies on 5 principles; Stop Open Defecation; Use Soap to Wash Hands; Household Drinking Water and Food Management; Household Waste Management; and House Wastewater Management.

Conclusions

Based on the results and discussion, the conclusion drawn is that in this study, factors that are significantly related to stunting incidents are birth weight, feeding, mother’s height, ANC, drinking water consumption and toilet use. The researchers suggest that in order to prevent stunting, factors such as feeding, mother’s height, ANC, drinking water consumption and toilet use need closer attention.

Frequency of Occurrence of Different Kennedy Classified Cases in College of Dentistry (Iraq)

Zainab Mahmood Al-Jammali¹, Anas Al-Yasiry M.Sc Dentistry², Mohamed Falih³, Montather Dawood³, Marwa Yosif³

¹M.Sc. Lecturer, Department of Prosthodontics, ²B.D.S., Department of Basic Science, ³B.D.S., Department of Prosthodontics, College of Dentistry, University of Babylon.

Abstract

The Aim: To assess the incidence of Kennedy’s classification among partially edentulous individuals along with its correlation with age and gender.

The Method: The subject in this study was consisted of 191 patients. All patients seeking for replacement of missing teeth were included in the study. The data related to partial edentulism was recorded in a self-designed proforma. The clinical data were summarized, frequencies and percentages as appropriate in association with age, gender. Kennedy’s classification was used to determine the pattern of partially edentulous arches.

The Result: The occurrence of Kennedy Cl. III partial edentulism was 17.8% in the maxillary arch and 9.42% in the mandibular arch. Followed by Cl. II in both the maxillary and mandibular arch, while cl. IV was the least among the other classes. The cl.III has the highest prevalence in group III patients. Cl. I and II have the highest incidence among group IV patients. The number of female was more than male and the highest frequency of cl. II was for females, followed by cl. III, while the lowest cases was cl. IV, for males, the most frequent was cl.II followed by cl. IV.

The Conclusion: There is an increase in Cl.I and II and a decrease in Cl. III and IV with an increase in age. The prevalence of Cl. III was predominant among younger population, whereas in group IV Cl.I was predominant.

Keyword: Frequency, occurrence, different, kennedy, dentistry.

Introduction

Psychological, social, and biologic levels of the oral health-related quality of life are affected by tooth loss, the people can be early seeking for treatment significantly if received good education which help them giving more attention to signs of tooth loss associated diseases thus reduced the degree of tooth loss in different countries in last periods¹-³. The tooth loss across all ages have been observed by Bruce⁴ who found that the major cause of losing tooth was the caries (83%) then the periodontal disease (17%). The improvement in the oral health of the population can be reflected by the reduction in edentulous people number⁵-⁶, and also it was mean that preventive measures by the health care system was successful¹,⁷ Recently, there were a decrease in edentulous patient’s number is predicted by trends in dental health care that support natural dentition preservation.⁸ In maxillary and mandibular arches, more than 65000 potential mixtures of partial edentulism pattern were found, therefore, the classification of partially edentulous arches that have common characteristics was reasonable to enable the communication between the various dental professionals⁹-¹² The partially edentulous arches can be classify according different classifications to distinguish probable combinations of tooth to ridges, and also loss of teeth patterns is a good pointer for the oral hygiene levels, the management and the magnitude of dental health problems, dental health awareness, and the edentulous space was used to identify tooth loss, which is a space in the dental arch naturally full by one tooth or more, for different reasons it may be
Presently, the best mostly accepted classification for partially edentulous arches was the Kennedy’s classification because it allow the recognition of prosthesis support, direct visualization, also the valuation of the design of removable partial denture characters. Presently, the best mostly accepted classification for partially edentulous arches was the Kennedy’s classification because it allows the recognition of prosthesis support, direct visualization, also the valuation of the design of removable partial denture characters.13-15 In different countries the tooth loss pattern has been assessed in various populations.14-19

In males a greater incidence of edentulism has been found by Hoover and McDermount 20 than females, on the other hands, Marcus et al. 21 found that there was no relation between the gender and the edentulism prevalence. The health care epidemiological information and its associated concerns are important for designing health care in the future.22 As epidemiologic findings on the loss of tooth and the edentulism were differ significantly in prevalence between countries and between geographic areas within countries.23-25

The aim of the study: The present study aimed to evaluate the incidence of Kennedy’s classification between partially edentulous individuals along with its correlation with age and gender, and because there are no available studies (to our knowledge) that have investigated the prevalence of partial edentulism among subjects in Babylon region, this would be of valuable information to oral health planners for proposing strategies helping in the development of dental health care management in Iraq.

Patients and Method

This cross-sectional study was approved by the Research Committee at the Faculty of Dentistry in Babylon University. The survey was conducted in Prosthodontics Department at the College of Dentistry/Babylon University/Hilla/Iraq. The study was conducted in patient reported to outpatient section of the college. The data collections were carried out during the period of October 2016 – May 2017 for patients requiring removable partial dentures. The subject in this study was consisted of 191 patients ( 90 male and 101 females). All patients seeking for replacement of missing teeth were included in this study. All the patients attended to the college clinics were surveyed and the cases for this study are selected according to the certain criteria’s. The inclusion criteria consisted of patients from both genders, above the age of 20 years, having partially edentulous areas in either or both arches. The Kennedys modification areas were not included to avoid the complexity. Patients with an only missing third molar, unerupted or congenitally missing teeth, root tips, and loose teeth that were indicated for extraction were not included in the study. All relevant data related to partial edentulism was recorded in a self-designed proforma. The clinical data were summarized, frequencies and percentages as appropriate in association with age, gender. Kennedy’s classification was used to determine the pattern of partially edentulous arches. Modification areas were not included in the assessment to avoid complexity.

Result

Prevalence and pattern of partial edentulism among dental patients attending College of Dentistry, Babylon University were studied. The mean age of the selected patients was 33.3 years. The table (1) show the age-group distribution. The results in table (2) and fig. (1) showed that the occurrence of Kennedy Class III partial edentulism was 17.8 % in the maxillary arch and 9.42 % in the mandibular arch. Followed by Class II in both the maxillary and mandibular arch with an average of 11.51% in the maxillary arch and 14.65% in the mandibular arch, while class IV was the least among the other classes in both the maxillary and mandibular arch with an average 10.99%. Based on these results, Kennedy’s Class III was the most prevalent partially edentulous pattern 27.22% among the maxillary and the mandibular arch.

Distribution of different classes in the age groups is shown in table 3 and figure 2. The results reveal that class III has the highest prevalence in group III (40–49 years) patients. With increasing age, a transition of bounded saddles into free end saddles was found. Classes I and II have the highest incidence among group IV patients (40–49 years), as shown in Figure 3. It is obvious from table (3) that the highest number of patients was in group III (40–49) years in both arches.

In this study the number of female was more than male and the highest frequency of Kennedy cl. II was for females, followed by cl. III, while the lowest cases was cl. IV, for males, the most frequent was cl.II followed by cl. IV (table 4 and fig. 3).
Table 2: Incidence of different Kennedy’s classes among the maxillary arch and the mandibular arch.

Fig. 1: Incidence of different Kennedy’s classes among the maxillary and mandibular arches.
Discussion

It is increasingly recognized that the impact of disease on quality of life should be taken into account when assessing health status. It is likely that tooth loss in most cases being a consequence of oral diseases which affects the oral health related quality of life. The main aim in using a classification for RPDs is to facilitate the description of partially edentulous cases. In the current study, Kennedy classification was selected because it simplifies the description of partially edentulous cases, permits immediate visualization of the partially edentulous arch, provides a logical way to display the problems of design, and to simplify the application of basic principles of partial denture design. The present study was initiated to assess the prevalence and pattern of partial edentulism among dental patients attending the College of Dentistry, Babylon University, Iraq. The findings of the present study showed that the frequency of partial edentulism in the maxillary arch was higher than the partial mandibular at almost equality in the prevalence of Kennedy’s classification in both arches edentulism among the study population, and this result was disagree with the study of Curtis et al. who reported that mandibular removable partial dentures are more common than maxillary removable partial dentures, and that the class I mandibular RPD is the most prevalent type of RPD for either dental arch.

In this study Kennedy’s Class III was found to be the most prevalent pattern of partial edentulism and this result was agree with the study of Hatim et al. which state that the Kennedy Cl.III was the most common pattern (57.14%) in a sample of the Iraqi population, and with the study of Benin, Ehikhamenor, et al. which state that the most commonly restored edentulous area was Kennedy’s class III (57.3%). The data of present study suggesting predominance on class III pattern of partial edentulism may be due to the fact that a higher frequency of younger age groups was encountered, whereas a higher frequency of older population was seen in other studies, and the study reported the increased awareness of among the younger populations with large number of younger groups reporting to the prosthodontic department for replacing missing teeth which that tooth loss may be due to the fact that the first molar is the first permanent tooth to erupt into the oral cavity, having a higher caries percentage and a higher chance of the tooth being extracted prior to the anterior teeth and/or they have greater surface area for caries attack because
at this early age the children cannot perform adequate oral hygiene maintenance and their low socioeconomic status leading to early tooth loss.

**Conclusion**

The present study showed that, among dental patients attending outpatient clinics, College of Dentistry, Babylon University, there is an increase in Cl.I and II Kennedy classification and a decrease in Cl. III and IV with an increase in age. The prevalence of Class III was predominant among younger population of 40–49 years, whereas in group IV (50-59) years Cl.I was predominant. It can be stated that the need for prosthodontics care is expected to increase with age, and hence, more efforts should be made for improving dental education and motivation among patients in Hilla region.

**Financial Disclosure:** There is no financial disclosure.

**Conflict of Interest:** None to declare.

**Ethical Clearance:** All experimental protocols were approved under the College of Dentistry and all experiments were carried out in accordance with approved guidelines.

Nurses’ Knowledge toward Traumatic Head Injury During Golden Hour

Sabah Abdullah Jaafar2, Raja Ibrahim Abed2

1Ph.D., Student, Adult of Nursing Department, College of Nursing, University of Baghdad, 2Assistant Professor, Fundamental of Nursing Department, College of Nursing, University of Baghdad

Abstract

Background: Nurses have a central role in management critical ill patients, not only to save their life but to improve their outcomes. Also, there is no safe practice unless the nurses had enough knowledge.

Objectives: The objective of this study was to assess nurses’ knowledge toward traumatic head injury during golden hour neurosurgical hospital, and to find out relationships between their demographics and total knowledge.

Method: A descriptive study using a purposive sample (non-probability) was used to survey 25 nurses who met the sampling criteria in one main neurosurgical hospital in Baghdad city to assess their knowledge toward traumatic head injury during golden hour. The official permission begin before study starting. The study starting from June 15th July 14th 2019. Based on comprehensive literature, the tool of study constructed by the researcher and tested for validity and reliability.

Results: The majority of the study sample 64% were (20-24) years old. Most of them were female (80%), and (52%) was married. Also, most study samples had high school nursing graduation (80%). Regarding the workplace, most of the study sample (64%) works in Neurosurgical ICU. Regarding years of experience, half of the study sample (52%) had less than three years of experience in the current workplace and more than one-third (36%) had total years of employment in nursing between 9 to 12 years. The majority of the study sample (52%) has participated in training courses about traumatic head injury and (64%) was the day shift of work. The total mean of the score of nurses’ knowledge was fair (0.42).

Conclusion: Despite the total nurse’s knowledge was fair 0.34-0.67, the majority of them were junior, graduation from secondary school nursing, and had poor knowledge toward traumatic head injury during golden hour. On the other hand, 48% of nurses not participated in continuous education lectures about traumatic head injury. Regarding these results, researchers recommend encouraging nurses who had a diploma and bachelor in nursing to work in critical care units at neurosurgical hospital and update continuous education program lectures to cover all nurses to improve their knowledge about traumatic head injury.

Keywords: Traumatic head injury, Nurse, Knowledge, Golden Hour.

Introduction

In a critical care unit, where the patient takes the closely monitoring and advance health care by a multi-disciplinary team, nurse have a central role, in the identification of patient problems, the ability to solve problems, anticipating and preventing possible complications. Therefore, the development and enhancement of nurses knowledge are necessary to promote clinical judgment[1]. The enhancement of the nurses’ knowledge and skill in the care of the patients with a traumatic head injury, is the most important way to promote their patients’ outcomes. So, the enhancement includes, well-structured of evidence-
based information and continuous practice in the hospital area\cite{2}. Kinds of literature mentions, knowledge base and learning in nursing are long-life aspects and essential to maintaining not only their competencies also encouraged to improve their clinical practice. Indeed, the importance of safe nurses’ knowledge level and the significance of educational components programs in the improvement of their knowledge \cite{3,4}. Works of literature discussed the factors that can effects patients outcomes after traumatic brain injury, one of these factors is how the patients managed at injury moment and the definite care does not include only in the field of injury, may continue at a hospital\cite{4,5}. In Iraq, the country that fought terrorism on behalf of the world, in the last two decades, the incidence of traumatic head injury increase to peak since the first gulf war. Traumatic head injury increase, related to many factors including, terrorism attacks, uses of not programmed weapon, and lack of road safety \cite{6}. According to the Iraqi Medico-Legal study report, fatal head injuries have high percents among medico-legal deaths and 24\% of cases death is delayed after different periods from the admission to the hospital \cite{7}. Basrah, one of the largest cities in the south of Iraq, the mortality rate was significant in-hospital, even head injury was mild \cite{6}. Despite much literature, well-known nurses’ knowledge in a critical care setting in Iraq, the little study focused on the management of traumatic head injury and there is no study to assess nurses’s knowledge toward traumatic head injury during the golden hour \cite{8}.

**Material and Method**

**Design:** This is a descriptive study that was conducted to describe nurses’ knowledge toward traumatic head injury during golden hour using a questionnaire that contains questions based on the best available information.

**Ethical Approval:** This study was approved by the Institutional Ethics Committee, and The IRB was obtained from the University of Baghdad and the Ministry of Health, Directorate of Al Rusafa Health Administration in Baghdad city. The purpose of the study was explained to the nurses who work in the ICU and emergency unit in the neurosurgical hospital. The informed consent was reviewed and permitted by the Center of Staff Development and Scientific Research. Every participant had the right to withdraw and refuse participation from the study at any time without any penalties.

**Study sample:** A non-probability (purposive) sample technique was used to collect the data. The populations are nurses who work in ICU and emergency in Neurosurgical hospital. The target population that provided the sample data was a group of nurses who met the sampling criteria. The official permission begin before study starting. The study starting from June 15th July 14th 2019. All male and female nurses with different educational levels who work in ICU and emergency were included in this study. Also, nurses who work in a day and night shifts were included in this study. The total sample size was 25 who agreed to participate in this study, the completed survey was included in the statistical analysis.

**Instrument:** Tools constructed by the researcher based on deep literature and standard textbooks in nursing. The validity of instruments obtained via 13 experts. The reliability of this tool shows was used test-retest, Cronbach’s alpha was 0.81. This tool consists of 54 questions regarding traumatic head injury during golden hour in Neurosurgical critical care units. The total score for the tool measured based on the mean of the answers(poor knowledge, fair knowledge, and good knowledge). The code of correct answer was (1) for true and (0) for a false answer.

Also, the first part of questionnaire included nurses’ demographics: age, gender, level of education, years of experience in the ICU, total years of employment in nursing, a shift of work, and participation in continuous education lectures and seminars about traumatic head injury.

The second part of questionnaire contain five domains of knowledge include questions (anatomy and physiology of head and brain=9 questions, physiology of intracranial pressure, cerebral perfusion pressure and blood pressure=16 questions; primary and secondary survey domain=10 questions; Fluid supply= 7 questions; and information about golden hour=12 questions).

**Data Analysis:** The statistics done by the Statistical Package for the Social Sciences (SPSS) version 24 software was used to perform the statistical analysis that included descriptive statistics (frequency, percentage, and mean of score) and inferential statistics (standard deviation and independent t-test and ANOVA).

**Findings:** In the Current study, twenty-five nurses have been studied in critical care units, were data analysis for the demographic characteristics’ and association for
all participants. Regarding descriptive data analysis were showed in table 1, the mean of nurses’ age was 25.1 and the standard deviation was 6.77 with a range of 20 to 39 years old. More than three-quarters of study samples were female gender accounts 80% and 20% were males. Concerning marital status, the majority of participants were married 52% and single accounts 48%. Regarding educational status, 84% of study samples belonged to high school nursing graduation, 12% were medical institute graduation, and 4% college of nursing graduation. According to Neurosurgical hospital distribution, the majority of study participants 64% was work in the intensive care unit and 36% work in the emergency unit. More than two-third 88% of the study sample was day shift, night shift accounts 12%. In regard to years of experience in the current place, 52% of the study sample was spent less than three years, 24% spent three to six years and 24% spent more than six-year. Also, total years of employment in nursing accounts 36% of study samples spent nine to twelve years as total years in nursing. Regarding participation in the training course, more than half the study subject 52% participated in training courses, and 48% have no participation in training courses.

Table 2 showed the level of assessment for study sample knowledge, 52% of study sample mean of the score was between 0.00 to 0.33, accounts poor knowledge, 36% was between 0.34-0.67 accounts fair knowledge and 12% was between 0.68-1.00 accounts good knowledge.

Table 3 showed nurses’ age has significance association (F =6.850, p=0.003)their knowledge. Regarding marital status, there is a significant association (F=6.600, p=0.004) between nurses’ educational status and their knowledge. The Nurses who reported for years’ experience in the current place have no significance (F=0.827, p=(0.642 with their knowledge. Also, total years of employment in nursing have no significance association (F=0.561, p=0.845) with their knowledge.

Finally, the result in table 4, tested by independent t-test shows, study sample gender have significance association (t=5.593, p=0.000) with their knowledge. However, there is no significant association (t=-0.482, p=0.634) between nurses’ marital status and their knowledge toward traumatic head injury during the golden hour. Also, The result indicated there is no significant association (t=0.703,p=0.439) between nurses working in emergency or intensive care unit and their level of knowledge. According to the work shift, there are no significant correlation (t=-2.016, p=0.56) nurses who work in the day or night shift and their knowledge. Whatever, the analysis shows nosignificant differences(t=0.181, p=0.858) between nurses who attended the training course and their level of knowledge.

Discussion

In the current study, the average of nurses’ knowledge between 0.34 to 0.67 respectively. Despite the nurses underline fair knowledge and more than half participate in training courses, secondary school nursing graduation, but 52% of having poor knowledge regarding level of assessment. The rationale underlines just how important educational status in nurse’s knowledge about head injury in critical care units. Also, the result shows a significant association between age groups and gender with their level of knowledge assessment. These results disagree with Kiewiet, where she studied professional nurses’ knowledge and clinical practice regarding traumatic head injury, she found there is no significant correlation between age groups and gender and level of nurses knowledge [9]. Regarding nurses years of experience in nursing and in the current workplace, there is no significance with their knowledge. These Results share a number of similarities with Ahmed et al. findings[10], they found the years of experience had no effect on nurses’ knowledge toward trauma patients during the golden hour. In regard to the workplace, the analysis did not confirm any significant differences between nurses who work in emergency or works in the intensive care unit and their knowledge. The reason for these results, there are no specific nursing guidelines to manage patients with a traumatic head injury during golden hour in neurosurgical critical care units.

Conclusion

Despite the total nurse’s knowledge was fair 0.34-0.67, the majority of them were junior, graduation from secondary school nursing, and had poor knowledge toward traumatic head injury during golden hour. On the other hand, 48% of nurses not participated in continuous education lectures about traumatic head injury. Regarding these results, researchers recommend encouraging nurses who had a diploma and bachelor in nursing to work in critical care units at neurosurgical hospital and update continuous education program lectures to cover all nurses to improve their knowledge about traumatic head injury during golden hour.

Abstract

The study was conducted in the city of Kirkuk in the period from October 2019 to March 2020, which included 100 pregnant women with type 2 diabetes who attended obstetric, gynaecology and paediatric hospital in Kirkuk city and 100 people intact and without any chronic disease. The study included the laboratory examination of the reactions samples, where close quantities of midstream urine were collected for both groups. After collecting the calories, the calories were examined microscopically, and then the reactions were transplanted into the available culture media to isolate the aetiology of urinary tract infections such as blood agar and MacConkey agar, and the CLED agar to isolate and diagnose bacteria of all kinds. In addition, the sensitivity test for antibiotics was applied by the feeding medium where the method were relied upon Global standard bacteriological culture procedure, isolation and diagnosis by biochemical tests. Among diabetes mellitus patients included in this study, 80% were positive for UTI patients, while 20% were negative for UTI. According to the distribution of the isolated bacteria among the study groups, the common isolated bacteria among DM was E. coli which constituted 26.36% followed by K. pneumoniae which constituted 17.27%, S. aureus and P. mirabilis which constituted 8.18% and the lowest percentage was Enterobacter cloacae for 1.81%. In this study S. aureus showed high rate of sensitivity to ciprofloxacin and oxacillin (88.23%) while it was resistant to ampicillin and lincomycin with rate of 100%. Staphylococcus epidermidis showed high rate of sensitivity to tobramycin and oxacillin (92.85%) while it was resistant to ampicillin, lincomycin and oxacillin (100%) Escherichia coli showed high rate of sensitivity (93.02%) to ceftazidim and it was 100% resistant to oxacillin and lincomycin. Klebsiella pneumoniae showed high rate of sensitivity (81.48 %) to amoxiclave and it was resistant to ampicillin, tetracycline, erythromycin, oxacillin and lincomycin (100%).

Keywords: UTI; Type 2 Diabetes; Pregnancy.

Introduction

Urinary tract infections (UTIs) are frequently encountered in pregnant women. Pyelonephritis is the most common serious medical condition seen in pregnancy. Thus, it is crucial for providers of obstetric care to be knowledgeable about normal findings of the urinary tract, evaluation of abnormalities, and treatment of disease (1). During pregnancy, urinary tract changes predispose women to infection. Ureteral dilation is seen due to compression of the ureters from the gravid uterus. Hormonal effects of progesterone also may cause smooth muscle relaxation leading to dilation and urinary stasis, and vesicoureteral reflux increases (2). Bacterial contamination of the urine within the urinary tract (bacteriuria) is common and can at times result in microbial invasion of tissue responsible for the formation, transport and storage of urine. Pathogen-related conditions (such as the presence of invasion or virulence factors) affect the severity of the infection and its resistance to antibiotic therapy, but also different host related characteristics have been individuated, that play a role in particular in the possibility of infection recurrence (3). Urinary tract infection may involve only the lower urinary tract or both the upper and the lower tracts (1). The term cystitis has been used to describe the syndrome involving dysuria, frequency,
and occasionally suprapubic tenderness\(^4\). More than 95% of urinary tract infections are caused by a single bacterial species. *Escherichia coli* is the most frequent infecting organism in acute infection\(^4\). Other organisms that can be responsible for UTIs include Gram positive cocci, such as *Enterococcus faecalis*, *Staphylococcus aureus* and coagulase negative staphylococci (CoNS). Other Gram negative organisms responsible for causing UTIs include *Klebsiella* species, *Proteus* species, *Pseudomonas aeroginosa* and *Enterobacter* species\(^5\). The aim of the study was to evaluate the relation of UTI with type 2 diabetes

**Material and Method**

The study was conducted in the city of Kirkuk in the period from October 2019 to March 2020, which included 100 pregnant women with type 2 diabetes who attended obstetric, gynaecology and paediatric hospital in Kirkuk city and without any chronic disease. The study included the laboratory examination of the reactions samples, where close quantities of median reactions were collected for both groups. After collecting the calories, the calories were examined microscopically, and then the reactions were transplanted into the available culture media to isolate the etiology of urinary tract infections such as blood agar and MacConkey agar, and the CLED agar to isolate and diagnose bacteria of all kinds. In addition, the sensitivity test for antibiotics was applied by the feeding medium where the method were relied upon Global standard bacteriological culture procedure, isolation and diagnosis by biochemical tests. Type 2 diabetes has been defined as any person with diabetes who is over 15 years old and who uses oral treatment, not insulin.

**Finding:** Among diabetes mellitus patients included in this study, 80% were positive for UTI patients, while 20% were negative for UTI. Patients without DM showed no positivity for UTI … Table 1.

In the present study the ages of the patients ranged between 16 and 65 years old. As shown in Table 3, the highest percentage of the patients among DM women were within the age group 26-35 years old constituted 44%. The lowest percentage was within the age group of 16-25 years old which constituted 31.03%.

P. value 0.048

According to the distribution of the isolated bacteria among the study groups, as shown in Table 4, the common isolated bacteria among DM was *E. coli* which constituted 26.36% followed by *K. pneumoniae* which constituted 17.27%, *S. aureus* and *P. mirabilis* which constituted 8.18% and the lowest percentage was *Enterobacter cloacae* for 1.81%.

In this study *S. aureus* showed high rate of sensitivity to ciprofloxacin and oxacillin (88.23%) while it was resistant to ampicillin and lincomycin with rate of 100%. *Staphylococcus epidermidis* showed high rate of sensitivity to tobramycin and oxacillin (92.85%) while it was resistant to ampicillin, lincomycin and amoxicillin (100%). *Staphylococcus saprophyticus* showed high rate of sensitivity to cephalothin, ciprofloxacin, oxacillin and lincomycin while it was 100% resistant to ampicillin, erythromycin and amikacin. *Escherichia coli* showed high rate of sensitivity (93.02%) to ceftazidim and it was 100% resistant to oxacillin and lincomycin. *Klebsiella pneumoniae* showed high rate of sensitivity (81.48%) to amoxiclav and it was resistant to ampicillin, tetracycline, erythromycin, oxacillin and lincomycin. *Proteus mirabilis* showed high sensitivity rate to cefotaxim (94.44%) and it was resistant to erythromycin, ampicillin, oxacillin and lincomycin (100%). *Proteus vulgaris* showed high sensitivity rate to nitrofurontoin, cefotaxim (92.85%) and low rate of sensitivity to erythromycin. *Pseudomonas aeruginosa* showed high sensitivity rate to cefotaxim (86.66%) and low rate of sensitivity (20%) to ampicillin. *Enterobacter cloacae* showed high sensitivity rate to cefotaxim (100%) and it was resistant to erythromycin, tobramycin, oxacillin, streptomycin, cephalothin and amikacin (100%). All these results were summarized in Table 5.

Discussion

Urinary tract infection (UTI) in pregnant women with DM have special importance due to complication that results from its which can be dangerous to both mother and baby. Diabetes mellitus has long been considered to be a predisposing factor for urinary tract infection. Among DM patients included in this study, 82.14% were positive for UTI among married women. This clarifying the significance of the relation between DM and the occurrence of UTI among married women in this study which supported by other study, which showed that urinary tract infection is more prevalent among married women with DM. Nasir in his study found that there is an increase in the prevalence of asymptomatic pyuria among diabetic females with complications of retinopathy and nephropathy. The choice of antibiotic depends on the spectrum and susceptibility patterns of the uropathogens, its effectiveness for this indication, its collateral effects and coast. In current study Staphylococcus aureus showed high sensitivity to ciprofloxacin and oxacillin 88.23% and it was resistant to ampicillin and lincomycin with rate of 100%. Staphylococcus epidermidis showed high sensitivity to tobramycin and oxacillin with rate of 92.85%, while it was 100% resistant to each of ampicillin, lincomycin and amoxicillin. Staphylococcus saprophyticus was 100% resistant to each of ampicillin, erythromycin and amikacin. A study done by Amin et al showed that the most effective antibiotics against Gram –positive cocci was kanamycin, tobramycin and ciprofloxacin. A study by Mahdi who reported that gentamicin is the most effective antibiotic against Staphylococcus aureus. The current study was in agreement with Kandela who reported that multi resistance to antibiotics ranging between (7-19) antibiotics, and all isolates of K. pneumoniae were resistant 100% to ampicillin, cephalaxin, amoxicillin, penicillin, tetracycline, gentamycin and amikacin, in addition the isolates showed high resistance to third generation of cephalosporin included 60% resistant to ceftazidim and 80% resistant to cefotaxim and ceftriaxone. Imipenem and azteronem was found to be the most effective agents against the isolates. Amin in his study found that Gram negative bacilli were responsible for UTI infections, the most common isolated bacteria from urinary infections were E. coli and the most effective antimicrobial agents were amikacin, tobramycin and ciprofloxacin against Gram negative bacilli. A study by Fakhriddeen reported that the result of sensitivity appeared that most of used antibiotics were ineffective on E. coli isolates with exception of amikacin meropenem and ciprofloxacin respectively. A study done by Wu et al reported that most bacterial isolates exhibited sensitivity to antibiotics norfloxacin, cefotaxim, were the more effective antibiotics on bacterial isolates, while gentamicin, streptomycin and ultracloxam showed low effect. The highly sensitivity of all bacterial isolates to norfloxacin lead to consider that this drug is the best for treatment of UTI.
Conclusion

It was concluded that there was a significant relation of UTI with T2D and E. coli plus S. aureus were the predominate causes.

Nutritional Condition among Children Less than 5 Years Old in AL-Najaf City

Yasser Hatef Hedawi¹, Sarah HatimAjeel²

¹R.N. Community Health Nursing, ²Assist. Lecturer, Nursing Department, Altoosi University College, Iraq

Abstract

Background: A good nutrition is an essential component of good health. Malnutrition is known contributing factors to diseases and death. In the developing world, malnutrition affects approximately 800 million people, greater than 340 million whom are children under the age of five years. Over six million of those children die every year from malnutrition²).

Objectives: The study aims at assess the domains of nutritional status in term of (weight and height for age) through anthropometric measurements.

Methodology: A descriptive/Cross-sectional study is conducted throughout the period of October 1st 2019 to June 17th 2020 in order to nutritional status for children less than 5 years old in AL-najaf city in terms of (weight and height for age) through anthropometric measurements. And also, to find out the relationships between child’s and mother’s demographic characteristics and nutritional status.

A non-probability convenience sample of (1000) children with their mothers visiting the primary health care centers. This sample is distributed throughout two primary health care sectors according to Najaf Health Directorate. A total of (10) primary health care centers is selected for the purpose of the study. A pilot study was conducted and the questionnaire validity was achieved through a panel of (17) experts.

Results: The majority of children were normal with assessed regard the nutritional status by weight for age indicators, as well as, nutritional status assessed through height for age and weight for height nutritional indicators. Some socio-demographic characteristics influenced children nutritional status, especially the mother educational, level economic status of the family and breast feeding.

Conclusions: The majority of study sample recorded normal nutritional status according to all three nutritional indicators; weight for age (WAZ), weight for height (WHZ), and height for age (HAZ).

Recommendations: Nutrition counseling and education to the mothers is an important component on health services which would help to decrease the effect of ignorance and faulty cooking or dietary practices. As well as proper feeding, home health care, food preparation, hygiene.

Keywords: Assessment, Nutritional condition, Children less than 5 years.

Introduction

In Iraq there are several studies that are conducted in regarding the assessment of nutritional status in different children groups and different geographical areas, results reveals that nutritional status may affected the children health(¹). Malnutrition conceded single of the chief problems in community wellbeing challenges in developed countries. Regularly refer on the way to a silence urgent situation cases, it has devastation special effects resting on offspring especially under five years, society and future human-kind. It is several of the factor that strength give explanation the reason of such widely spread mal-nutrition in children low down delivery weight, inadequate provisions of nutrients, commonness of communicable disease, not have of breastfeeding, in addition to inappropriate child care(²).
Assessment of nutritional status for under five years’ children are monitored by the use of anthropometric measurements, specifically height and weight (BMI), which in combination with the age of the child forms the anthropometric indices. These are further classified as weight-age, measurement lengthwise or tallness-age, weight-measurement lengthwise or tallness in addition to body gathering guide-age\(^3\). The causes of under nutrition are diverse but in most cases include some degree of quality or else quantity of foodstuff, suboptimal feed practice, in addition to elevated tariff of communicable diseases \(^4\). The consideration of dietary condition of children be a necessary element of monitor physical condition in increasing countries. Early identification of whichever relating to diet problem is fundamental for the reason that, family unit, teacher, community psychotherapy as well as treatment interference are additional to be expected previous to undernourishment be converted into not as good as. The World Health Organization (WHO) estimate that a number of 3 billion populaces be ill with undernourishment of one type or other\(^5\). The better nutrition means immune systems stronger, due to fight infectious diseases and a lesser amount of ill health, enhanced wellbeing status as well as a community fruitful. Self-determination commencing lack of food in addition to undernourishment is a essential individual rights as well as their improvement is a basic precondition used for individual in addition to nationwide progress\(^6\).

**Objectives:** The study aims to assess the domains of nutritional status in term of (weight and height for age) through anthropometric measurements.

**Methodology**

A descriptive/Cross-sectional study is conducted throughout the period of October 1st 2019 to June 17th 2020 in order to nutritional status for children less than 5 years old in AL-najaf city in terms of (weight and height for age) through anthropometric measurements. And also, to find out the relationships between child’s and mother’s demographic characteristics and nutritional status.

A non-probability convenience sample of (1000) children with their mothers visiting the primary health care centers. This sample is distributed throughout two primary health care sectors according to Najaf Health Directorate. A total of (10) primary health care centers is selected for the purpose of the study. A pilot study was conducted and the questionnaire validity was achieved through a panel of (17) experts. Data were analyzed through the application of descriptive statistical data analysis approach that includes, frequencies and percentages; and inferential statistical data analysis approach that include Chi-squared test.

In assessing nutritional status by (WAZ): weight for age z scores, (HAZ): height for age z scores, and (WHZ): weight for height z scores. F= Frequency, %= Percentage

The findings revealed the distributions of the study sample according to the nutritional status indicators in term of WHZ, HAZ, and WAZ. Nutritional status is classified into three levels (underweight, normal, overweight and obesity) that concerning weight for age, (normal, tall and stunting) that concerning height for age. In concerning weight for height, the level includes (normal, overweight, obesity and wasting). In general, the proportion of normal weight recorded a higher percentage in first nutritional indicator (77%) through assessing the weight for age. In assessing nutritional status by height for age the normal account (65.8%). Regarding assessing nutritional status by weight for height indicators the table reveals that the results account (80%) of children were normal.

**Discussion**

The preschool period is the period between 3 and 6 years of age, this is a time of continued growth and development. Physical growth continues much more slowly compared to earlier years. The average preschool age child will grow (6.5-7.8cm) per year. The average 3 years old is (96.2cm tall), the average 4 years old is (103.7cm tall), and the average 5 years old is (118.5cm tall). Average weight gain during this time period is about (2.3kg) per year. The average weight of a 3 years old is (14.5kg), increasing to an average weight of (18.6kg) by age 5(7). The results in this work agree with the results obtained by other reposts such as (8) who have studied nutritional status of under five children in Baghdad-Iraq. Their findings indicate that the (52.7%) of the study sample are male. Also this agree with the (rapid nutritional assessment survey carried out by UNICEF 2010-2011) which shows that (53%)of children under 5 years are males. The present of underweight stunting and wasting in this study are similar in the finding of study conducted in Turkey the researchers found the prevalence’s were 4.8%, 8.2% and 10.9 respectively (9) these figures are lower than ours. But our findings are much lower than the findings gained by other researchers in different districts in many developing countries. In Nagpur who found that underweight, stunting and wasting (46%, 52%, and 20.7%) (10).these variations between the findings of this study and other studies may be due to the variation in socioeconomic wellbeing status or the variations in the study designs and sample sizes. Our results are lower than that reported by a hospital based local study conducted by (11).Regarding children age in the present study ranged from (0-47) months and above. The higher percentage of the sample is among age group (23- 34) which constitutes (53%) table (1). The World Health Organization estimates that malnutrition accounts for 54 percent of child mortality worldwide, in this age group was 1 million children every year. Another estimate also done by WHO states that childhood underweight is the cause for about 35% of all deaths of children under the age of five years worldwide(12). These results are concurrent with the study which has been assessed relating to diet condition of kindergarten children: a socio-economic learning of
rural area of Kasaragod District in Kerala. Their findings indicate that most children are in the age group (39-43) month (13).

Study results depicted that the (39.6%) of mothers had primary school levels of education table (2). A study has been tested relating to diet status of underneath five years’ age children in Akure South Local Government, Ondo State, Nigeria. Their findings indicate that the most of mothers (66%) are primary school educated and most of them are household. Results concludes that the mothers’ education affected the health status of the children (14). Concerning monthly income, most of families have been insufficient monthly income that account (53.4%) which affects their socio-economic status table (2).

These results concurrent with the results reported by a study conducted on determinants of nutritional status in children under 5 years in India: A multilevel approach study. Their results indicate that the most of families making low socio-economic status and low income (15). Socio-economic status particularly monthly income is an important factor that affects nutritional status in positive and negative terms, in an example regard the socio-economic status, a study has been tested factors affected HB and anemia among children. Their findings indicate that the families with low income may have a difficulty to buy food or medicines rich in iron or others need as recommended by the health care providers. Otherwise, families with high monthly income they will able to provides all the necessary food or others needs to treat the anemia, so the economic status is an important factor that will affects the HB level and others needs related to balance diet that protect the health of rapidly growing children under five (16). As personal point of view, mothers as being employed to improved economic status of the family directly and higher economic status provide and facilitate all children’s needs regarding nutrition, health care needs, education, family type, live in crowded or big families and all aspect of life. But mother employment some time affect child nutritional status negatively, because employed mothers spend many hours outside the house which reduce time for child care(17).

**Conclusion**

The majority of study sample recorded normal nutritional status according to all three nutritional indicators; weight for age (WAZ), weight for height (WHZ), and height for age (HAZ). Most of the mothers were primary school educated and more than half of them were housewife. Most of the fathers were highly educated and they were employed or have their own free work. Most demographic characteristics of parents and children have influenced their children nutritional condition.

Relationship of ABO Blood Groups with Body Mass Index

Sarah Abdulateef Kadhum¹, Wafaa Abd Ali Hattab², Musaab Majid Abdulwahhab²

¹M.Sc. (Al-Bayan University-College of Nursing-Adult Nursing Department),
²Ph.D. (University of Baghdad-College of Nursing-Adult Nursing Department)

Abstract

Background: Obesity predisposing factors have been raised as a major concern of researchers due to the consequences of obesity on health such as diabetes, hypertension, and depression, ABO blood groups linked to many diseases, so may affect directly or indirectly on the incidence of obesity.

Objectives: The study aims to find out the association of ABO blood groups with body mass index.

Method: A cross-sectional study was conducted with a non-probability purposive sample of 2604 young adulthood age (18-25 years) that does not have previous surgery or chronic diseases through an electronic questionnaire in Iraq. A statistical package for social science (SPSS) program, version 24 was used for descriptive and inferential statistics.

Results: Blood group O was a common frequency in people with increased body mass index, so high statistically significant association recorded (p ≤ 0.001). In addition, most of the subject (86.6%) have positive rhesus (RH +).

Conclusions: People with blood group O and positive RH were most vulnerable to increase their body mass index.

Keywords: Relationship, ABO blood groups, Body Mass Index.

Introduction

It is really important to identify the obesity predisposing factors; Obesity has major consequences on the physical and psychosocial aspects. Hypertension², diabetes mellitus³, cardiovascular diseases⁴, depression, and anxiety⁵ may develop as a result of obesity; this study tries to find out if the ABO blood groups are a factor to develop obesity. Many studies demonstrate that the blood groups correlate to several diseases such as osteoporosis, thyroid disorder, and hyper-cholesterolemia.⁶,⁷ These studies help to identify the diseases vulnerability and take preventive measures to decrease the incidence and that what are going to do in this study. If we recognize the blood group that has the highest vulnerability to develop obesity so we can take more attention to help prevent people with this blood group to develop obesity.

Objectives of the Study: The study aims to find out the association between blood groups with body mass index.

Materials and Method

Design of the Study: A cross-sectional study was conducted with a non-probability purposive sample of 2604 young adulthood age (18-25 years) that does not have previous surgery or chronic diseases through an electronic questionnaire in Iraq.

Study Instrument: BMI was calculated by division body weight in Kilogram on the height in Metric Square

**Results**

Study results demonstrate that the blood group O records the highest percentage (40.8%) of the study sample followed by (34.8%), (22.6%), (12.8%) of A, B, and AB blood groups respectively (Figure 1). While the majority (86.6%) of Rhesus was positive with (13.4%) negative (Figure 2).

Concerning the classification of BMI, most of the subject (54%) was obesity 3 followed by Obesity 2 that record (20%) and the lowest percentage (4%) was recorded in an underweight group. In addition, the males were (54.7%) and female (45.3%). (Figure 4)

The BMI record high statistically significant association with ABO blood group (Table 2) added to that, the Rhesus was being found a statistical difference with BMI (Table 3).

Discussion

The study aims to find out the impact of ABO blood groups on the incidence of obesity so we can provide preventive measures to that group with the highest vulnerability to obesity such as a healthy lifestyle and dietary habits.

The study result showed that the majority (40.8%) of our sample was the blood group O, followed by A, B, and AB. In addition, the positive rhesus records the highest distribution (86.6%) in comparison to negative rhesus. These results come along with many studies about the distribution of ABO blood groups in Iraq.[7-10]

The blood group O takes the highest frequency of increase body weight, the main cause of that result need to be more studied. However many articles demonstrate that the blood group O preferred the high protein diet with lean meat and fish[11] added to that the type O blood group tend to Yoga and limited exercise in comparison to other blood groups that may prefer lifting weights and heavy exercise, eventually blood hormones level (such as catecholamines and cortisol) will be changed according to that exercise.[12]

The individuals with positive Rh record significant difference and obvious increase in their body weight when compared with peoples that have negative rhesus. Much more studies needed to explain that’s fact and that may affected by race or specific geographical area.[13, 14]

Acknowledgements: The authors thank to the University of Baghdad - College of Nursing for their cooperation to complete the official request for conducting the research.

Conflict of Interest: There are no conflict of interest concerning this research and the manuscript has not been submitted to another journal or publishing venue.
Financial Resources: The authors have no affiliation with any organization with a direct or indirect financial interest in the subject matter discussed in the manuscript.

Informed Consent: Before filling the questionnaire, all participants were asked if they agree or disagree to participate in the research.

Conclusions: There are differences concerning physical and economic status between Americans and Iraqis. Americans record better physical activity and economic status. The psychological domain demonstrates that both communities had negative emotions, anxiety and depression as a result of COVID 19, curfew and social distancing.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the Al-Bayan university-College of Nursing-Adult Nursing Department and all experiments were carried out in accordance with approved guidelines.

Clinical Profile and Outcome of Children of Aged 6 -59 Months Admitted with Severe Acute Malnutrition at Medical College, Silchar, Assam

Pathak Nripendra Nath¹, Debnath Sanjib Kumar², Ray Prajnan Sankar³

¹Associate Professor; ²Assistant Professor; ³Junior Resident, Department of Pediatrics, Silchar Medical College, Assam, India

Abstract

Background: Inspite of significant economic improvement of India, prevalence of malnutrition specifically severe acute malnutrition is significantly high. According to NFHS-4(2015 -2016) report, 7.4% of malnourished children are severely wasted in India and in Assam it is 6.2%. Clinical profile of acute severe malnutrition (SAM) is different from place to place. Understanding of child health profile in different geographical area will help to prioritize intervention and resource allocation.

Material and Method: Hospital based prospective observational study carried out in the department of Pediatrics, Silchar Medical College, Assam, India from July 2018 to June 2019. 50 SAM children of aged 6 months to 59 months were included into the study after meeting the inclusion criteria. Historical, clinical and laboratory data were recorded in a predesigned proforma. Data were analysed using appropriate statistical method.

Results: The prevalence of severe acute malnutrition is 2.7%. The mean age of study population is 21.86 ± 14.85 months. 68% were male and 32% were female out of the 50 SAM children. Nondematous SAM were more (56%) than the edematous SAM (44%). Highest incidence of SAM were in the age group of 6-24 months (68%). Almost all the cases (96%) belonged to low SES. 78% mothers were either illiterate or primary school educated. EBF up to 6 months of age were only in 16% of cases. Major clinical presentation were diarrhea (70%), fever (68%), anorexia (66%), ARI (56%), vomiting (38%), eye problems (38%). Co-morbid conditions associated with SAM were anemia (86%), pneumonia (42%), worm infestation (40%) followed by UTI (38%) & tuberculosis (16%). Recovery rate is 54%. Mean hospital stay is 10.28± 5.84 days. 2 children (4%) died during hospital stay.

Conclusion: Severe acute malnutrition is the most severe life threatening form of malnutrition which requires urgent attention. Timely identification and intervention of various risk factors, clinical and co-morbid condition is likely to break the viscous cycle of undernutrition, infection and SAM and thereby improve outcome.

Keywords: Severe acute malnutrition, female literacy, socio-economic status, wasting.

Introduction

Malnutrition in children is the most serious health problem affecting globally till twenty first century with much more prevalent in the developing countries including India. Many children die everyday directly or indirectly from malnutrition. With proper attention and nutritional therapy most of these deaths can be prevented.¹ Severe acute malnutrition (SAM) is an unique type of severe
malnutrition. It is the most severe and life threatening form of malnutrition in children and is responsible for high morbidity and mortality among malnourished children. Globally approximately 19 million children under five years of age suffered from SAM in 2015. The World Health Organization (WHO) has recommended this special classification for identifying and managing children with life threatening malnutrition. Severe acute malnutrition is defined as presence of any of the following: weight for height/length below -3 standard deviation (SD or Z score) of the median WHO growth reference ii) presence of bipedal nutritional edema or iii) mid upper arm circumference below 115 mm in the age group of 6 months to 59 months. A vast majority (over 90%) of children with SAM is located in south and south east Asia and Sub Saharan Africa. India has the greatest population of severely malnourished children in the world and accounts for over 20% of under five childhood death every year and around 2.1 million children in this country do not survive to celebrate their first birthday. According to National Family Health Survey 4 (NFHS-4, 2015-2016) report, in India, 7.4% of malnourished children are severely wasted (weight for height < -3 SD) and in Assam, 6.2% of under five children are severely wasted. Since wasting denotes acute malnutrition, these children are said to have severe acute malnutrition.

Better clinical characterization, triage and appropriate treatment of complications on admission along with nutritional therapy and targeted supportive treatment as outlined in the WHO protocol is associated with improved outcome.

Clinical profile of severe acute malnutrition is different from place to place or region to region. As the underlying clinical factors, co morbidities and health system infrastructure differ in places and countries, understanding of the childhood profile in different places will help to enable proper targeting and prioritizing of intervention and resource allocation.

There is wide a variation of spectrum of nutritional disorders in this southern Assam, India, a geographically landlocked region with population of diverse ethnicity, multilinguality, religion and cultural practices with the rest of the country.

Objective: on the background of the above introduction, the present study was conducted with the objective of determining 1. The prevalence of SAM in this region 2. The clinical profile associated with SAM like risk factors, co-morbid conditions and type of SAM 3. Outcome of SAM after hospitalization and treatment.

Material and Method

This hospital based prospective study was done in the department of Pediatrics, Silchar Medical College, Assam, India for a period of one year (July 2018 to June 2019). A total of 50 children of age 6 months to 59 months admitted in the department for severe acute malnutrition related complaints were included for study. The geographical locations of the study population were Barak Valley, Assam and neighbouring states. The children were enrolled for the study after satisfying the following inclusion and exclusion criteria.

Inclusion Criteria:

(i) Wt for ht/length < -3 SD or Z score of median WHO growth reference.
(ii) MUAC < 11.5 cm
(iii) Nutritional edema of feet.

Exclusion Criteria:

(i) Children with non nutritional causes of SAM.
(ii) Children with congenital anomalies, mental retardation, cerebral palsy, chronic renal diseases, congenital chronic hemolytic anemia.

Informed consent of parents was taken before inclusion to the study. Details clinical and laboratory parameters were recorded in a pre designed proforma. Anthropometry was done with electronic weighing machine with sensitivity of ±10 gm, infantometer and stadiometer, narrow flexible nonstretchable measuring tape. Z score was calculated using WHO MGRS standard deviation chart. Laboratory tests like blood sugar(R), hemoglobin level, serum electrolytes, TC, DLC, X-Ray chest, mantoux test, stool and urine for routine and culture were routinely done. Other specific tests were done whenever necessary. Therapeutic management of all the cases was done according to the protocol of WHO and Indian Academy of Pediatrics (IAP).

Discharge criteria. SAM cases were discharged when they met the following criteria.

1. Satisfactory weight gain i.e >15% of admission weight.
2. Edema resolved.
3. Return of good appetite.
4. Medical complications treated.

Statistical analysis of data was done using Statistical Package for Social Sciences (SPSS 16.0 version).

**Results**

1. Prevalence of SAM. The overall prevalence of severe acute malnutrition in our study population is 2.7%.

2. Socio demographic profile (Table 1).

**Discussion**

The prevalence of SAM in our study is 2.7% which is lower than the national prevalence (7.9%, NFHS-3). Similar prevalence were reported by A S Bhadoria from northern India and H D Shewade from Puducherry as 2.2% and 3.6% respectively. Prevalence of SAM varies widely across the Indian states.

We observed that male children with SAM were almost twice as that of female (68% vs 32%). Similar findings were observed by few workers. However, studies by M B Sing and S Rao found higher prevalence of SAM among girls. Higher prevalence in males in our study may be due to more importance given to male child for medical care because of societal attitude.
Though our study population is from the Hindu majority area, more number of SAM (56%) is seen amongst Muslim children. We could not correlate any association of prevalence of SAM with religion. This may be because of small sample size and needs further socio-demographic studies.

The mean age of the study population is 21.86 ± 14.85 months. Two third (68%) of the total cases belong to the age group of 6-24 months. Similar results also reported by Aguaya et al in studies in Jharkhand where 77.7% of SAM patients were below 2 years of age. More number of cases in our study is seen between 6-12 months. This may be due to late introduction of complementary feeds, inadequate (thin) food, less birth spacing.

Almost all the SAM cases in our study (96%) belong to lower socio-economic class (Kuppuswamy scale IV and V). No cases belong to upper SE class. This indicates the unavailability of food, poor purchasing power, lack of nutrition knowledge in a deprived community. Similar observation was made in other study also.

78% of mothers and 40% fathers of SAM children were either illiterate or had only primary school education. Only 28% mothers were high school educated. Parental education specially women literacy is the most important determinants of malnutrition. Educated mother will have a greater awareness of nutrition, balanced diet and health of their children. Several studies from Bangladesh and India observed such correlation between low parental education and malnutrition in children.

84% of the SAM children did not receive exclusive breast feeding up to 6 months of age. Similarly 35(70%) children had delayed start of complementary feeding with thin or watery food. These two-non EBF and improper complementary feeding caused SAM in majority of cases below 2 years of age. Similar observations were made by K Mishra et al in their study. Other risk factors observed likelow maternal education, incomplete immunization were 78 and 70% respectively. Out of 50 SAM cases, non edematous SAM was more (62%) than edematous SAM in our study.

Diarrhoea (70%) and fever (68%) were the most common clinical presentation followed by anorexia (66%), ARI (56%), vomiting (38%), eye problems (38%) and hypoglycemia 14% of SAM cases. Similar findings were reported by R Kumar et al in their study.

Among the co-morbid conditions, 43 children (86%) had anemia of varying grades. Prevalence of other co-morbid conditions were pneumonia (42%), worm infestations (40%), UTI (38%) & tuberculosis (16%). These findings are consistent with previous reports.

On analysis of outcome of SAM cases in this study, it is found that 54% recovered (wt gain >15% of admission wt) and 30% did not respond (wt gain < 10 gm/kg/day) to treatment. Average weight gain and mean duration of hospital stay were 7.5 gm/kg/day and 10.28 ± 5.84 days. Six children (12%) defaulted & 2(4%) died during hospital stay. In a similar study by K Sing, N Badgaiyan and K P Kushwaha in Uttar Pradesh in 2010, they reported average weight gain as 7.3 gm/kg/day, average hospital stay of 13.2 days, recovery rate of 46.8% and discharge without recovery as 53.2% in their study.

Conclusion

Severe acute malnutrition is the most severe and life threatening form of malnutrition which requires urgent attention. Timely identification and intervention of various risk factors, clinical and co-morbid conditions is likely to break the vicious cycle of undernutrition, infection and SAM and thereby improve outcome.

New Media from Plant Extracts for Isolation of Some Pathogenic Bacteria that Produce Protease on Linum Usitatissium Seed Powder Agar and to Identify Serratia Marcescens

Manal Khalid Mohammad1, Suhad Y. Abed1, Afrah Abdulridha Ajeel1

1Researcher, M.Sc. of Microbiology, Collage of Science, Department of Biology, Mustansiriya University, Iraq

Abstract

Prepared two concentration of four new enriched media for isolation of some pathogenic bacteria including Acinetobacter baumannii, Klebsiella pneumoniae, Escherichia coli, and Serratia marcescens and identification of Serratiamarcescens that produce red pigment (prodigiosin). The first concentration 12.5 g/l of plant extracte showed heavy growth of pathogenic bacteria on the four media. The second concentration 25 g/l showed also growth of the pathogenic bacteria incubation in 37°C for 24h except on the Elettaria cardemomum agar and, Fenugreek (Trigonella foenum-graecum) seeds agar. Serratia marcescens produce red pigment on all the new media in both concentration. All isolates produce protease enzyme on Linum usitatissium seed agar. The result is a synthesis enrichment and inexpensive medium for different species of bacteria like Linumusitatissium enriched with a different materials and salt as a mineral that suitable for growth organism without any morphological change of metabolisms feature, also identification Serratia marcescens by produce red pigment that important in medical with a wide range of biological activities.

Keywords: Prodigiosin, Trigonella foenum-graecum, Serratia marcescens, pigment.

Introduction

Pathogenic bacteria causes different disease including pneumonia, tuberculosis, and food borne illnesses in immunocompromised patients and healthy individuals that have antibiotics resistance with wide range.(1)

Serratia marcescens is agram negative bacteria that secreted serratiopeptidase enzyme used for treatment sinusitis, surgery, arthritis and different disease(2,3,4). Prodigiosin is the red pigment secreted from Serratia marcescens with biological activities in wide range as anti fungal, immunosuppressant, antimalarial and antibiotic agent which produce the pigment needs optimum condition(5,6) including the presence of NaCl, soy bean meal, PH, temperature, salts, and others(7).

Protease enzyme is one of an important industriual enzyme that produce from different type of pathogenic bacteria and use in medical, food, and industrial field. The Protease enzyme is an extracellular enzyme which responsible for virulence of pathogenic bacteria(8).

The parts of plant consist of many different components that including proteins and oil some of which are carbohydrates, vitamins, sugar, aminoacids and minerals(9). The plants can be found in many places and used for various diseases as therapeutic agent because the presence of phenol like tannins that have ability to form hydrogen bonds with carbohydrates and proteins by inhibition of some enzymes in the living cell leading to inhibit growth pathogenic bacteria(10,11).

Elettaria cardamomum is one of spices old very in the world and commonly known as green or true cardamom, Heilin Arabic(12,13,14).
This grain be smell and taste that contains fixed and evolution in seeds and contains metal and material natural. *Elettaria cardamomum* have activity compounds are Glycosides, Saponins, Alkaloids, Volatile, and Tannins\(^{15}\).

Flax (*Linum usitatissimum*), also known as linseed or common flax\(^{16}\).

Activity compounds of flaxseed (*Linum usitatissimum*) are saponins, flavonoids, Resins, glycosides, alkaloids, Vitamin, carbohydrates, Protein oil and oil components from fatty acids are fatty acids\(^{17,18}\).

Flaxseeds protecting from cancers, which contain high levels of fatty acids, and omega-3 which inhibit the growth of cancerous tumors\(^{19}\).

Fenugreek (*Trigonella foenum-graecum*) is one of the medicinal plants

Common name is Fenugreek (Hilba), Scientific name: *Trigonella foenum-graecum L*\(^{20,21}\).

The composition of Fenugreek seeinclude, alkaloids, coumarins, flavonoids, saponins and vitamins\(^{22}\).

Fenugreek seeds used in the treatment of stomach ulcer, and Urinary tract infection\(^{23}\).

*Laurus nobilis L.* from the family Lauraceae, that comprises numerous aromatic and medicinal plants\(^{24}\).

The plant content of the compounds was identified effective by preliminary chemical tests of plant powder, plant leaves where the containment of tannins, saponins, flavonoids, alkaloids, glycosides, Resins, and Phenols. Antibacterial and antimicrobial properties are essential oil of leaves\(^{25,26}\).

**Materials and Method**

**Sample of plant:** The plant used in this study consisted of *Laurus nobilis L.* (bay laurel) leaf and, Flax (*Linum usitatissimum*) seeds, *Elettaria cardamomum*, Fenugreek (*Trigonella foenum-graecum*) seeds were purchased from a local market in Baghdad, Iraq and grounded to powder for further use.

**Plant Extract Preparation:** Aqueous hot extract: Weight 50 g of air-dried powder of plant was added to 500 ml of distilled water, boiled for 15 minutes leave to cool then it was filtered through 6 layers of muslin cloth into a sterile flask later the filtered plant extracts into sterile glass plate which dried in an oven for 24h. At 50 Celsius then crushed drying the plants extract into powder then preservation the drying particle into a sterile container for each plants extracts\(^{27,28}\).

Preparation plant powder agar: The (20g/l)agar-agar was Prepared (Difco) and autoclave at 121°C\(^0\) for 15 min and cool to(45-55)°C then added plants powder (25g/l) the pH was adjusted to 7.0 mixed well and dispensed into sterile Petri dishes for each type of plants\(^{29}\). Another concentration 12.5 g/l will prepared at the same method. The media (*Linum usitatissimum seeds agar, Laurus nobilis L. leaves agar, Trigonella foenum-graecum seeds agar and Elettaria cardamomum agar*) were inoculated with isolates of (*Acinetobacter baumannii, Klebsiella pneumoniae, Escherichia coli*, and *Serratiamarcescens*) and incubated at 37°C for 24 hours.

Microbial isolates: Four isolates *Acinetobacter baumannii, Klebsiella pneumonia*, *Serratia marcescens*, and *Escherichia coli* were isolated from clinical specimens that had been submitted to the bacteriology laboratory in Al-Kindy Educational Hospital, Baghdad, Iraq. The Vitek 2 system (Biomerieux) using to identified all isolates.

**Results and Discussion**

All isolates showed a growth on *Linum usitatissimum* agar, *Laurus nobilis L.* agar and *Trigonella foenum-graecum* agar and *Elettaria cardamomum* agar that prepared in the first concentration 12.5g/l all isolate incubated in 37°C\(^0\) for 24 hours as shown in (fig.1, 2) (Table1), while the second concentration 25g/l shown also growth of pathogenic bacteria on *Linum usitatissimum* agarand *Laurus nobilis L.* agar except *Elettaria cardamomum* agar and *Trigonella foenum-graecum* agar no pathogenic bacteria growth (Fig.3)(Table2). These four new media contain many compounds like proteins, carbon, vitamins, minerals, salts, fatty acids, oils, and other nutrition factors \(^{48}\). While *Elettaria cardamomum* contain the some nutrition factor, is useful as good media for growth in low concentration but in high concentration cause kill of bacteria because contain antimicrobial agent for various disease moreover due to the presence of phenolic compounds, alkaloid, glycosides, saponins, tannins and other compound\(^{4}\). *Serattia marcescens* produce red pigment in all new four media but on *Laurus nobilis L.* agar cannot mentioned this pigment in the first
concentration 12.5g/l (fig.1, 2, 3, 4) (Table 1, 2). That a useful media for to rapid identified and enumerated *Serratia marcescens* because this medium contain the main compound and condition to produce the red pigment, PH, temperature, source of carbon, nitrogen and salt\(^{29, 30, 26, 27}\). All pathogenic bacteria Hydrolysis a protein is very clear in Linum usitatissimum agar that by produce protease enzyme because the media contain 18g protein/100g linum (fig.4)\(^{30}\).

### Table 1: Growth of pathogenic bacteria on plant extracts in 12.5 g/l of concentration incubated in 37C for 24 hours.

The Role of Child Sexual Abuse Victims and Pornography as the Etiology of Rape by Male Adolescents in Bengkulu Province, Indonesia

Emi Kosvianti1,2, Emy Susanti3, Windhu Purnomo4, Agung Suhadi5

1Doctor Candidate, Faculty of Public Health, Universitas Airlangga, 2Lecturer, Department of Public Health, Muhammadiyah University of Bengkulu, 3Professor, Department of Sociology, Universitas Airlangga, Indonesia, 4Associate Professor, Faculty of Public Health, Universitas Airlangga, Indonesia, 5Lecturer in English Department, Muhammadiyah University of Bengkulu, Indonesia.

Abstract

Introduction: Rape against adolescent girls, a big crime and unacceptable whatever its forms because it is a part of human rights violation and a serious problem in reproductive health. For victims, it definitely has profound impact on their long-term life; socially and psychologically as well. Yet, these cases throughout the world increase rapidly and massively, especially in developing countries. This study attempts to investigate the etiology of rape offenders by male adolescents in Bengkulu province, Sumatra, Indonesia.

Method: In this study, the researchers used qualitative method with 29 rape offenders as research informants (they were male adolescents less than 18 years). All informants are being sentenced at the 3 Correctional Institutions and 1 Institute for Special Child Development (LPKA). The data were collected through semi-structured interview—a technique for in-depth interview under a guidance of interview guidelines. Thus, the manuscripts of interview will be interpreted and analyzed by interrelated or intercross of sexual violence theory.

Results: The results obtained the etiology of rape offenders by male adolescents less than 18 years are caused by two factors: First, pornography exposure. Informants have been exposed by pornography exposure at various ages, between elementary and high school age. Second, victim of sexual assault. Informants have ever victimized of sexual violence where found that the perpetrators are adult people around their life. Some forms of sexual violence, such as seduction urge to visit prostitution location, having free-sex, and watch pornographic contents through internet, gadget, and computer.

Conclusion: In short, this study has set out two important findings; the rape by male adolescents less 18 years are caused by past experience of sexual assault and the role pornography exposure. Meanwhile, other behaviors allegedly relate to the factors of alcohol consumption and drugs abuse are not discussed in this study.

Keywords: Pornography, child sexual abuse, victim, adolescent, rape.

Introduction

Regarding to the rape against adolescents, its impacts and characteristic of perpetrators have been observed throughout the world. This crime, according to some research findings, sexual violence is a part of serious problem that demands massive cost consequences due to the incidence of depression, unwanted pregnancy and the resulting HIV/AIDS[1]. Many health problems
caused by causing sexual violence are not only a concern for criminal law throughout the world but also the field of public health[2]. Several studies on sexual violence showed various results regarding the incidence of child sexual violence throughout the world. As reported by a meta-analysis of child sexual violence, from 217 publications as published between 1980 and 2008 which involved 331 independent samples with a total of 9,911,748 participants. Overall, the self-report study an estimated prevalence of child sexual violence was 127/1000, whereas toward participants study a prevalence rate of 4/1000 3 was obtained [3]. The perpetrators of sexual violence, a group of adolescents age are estimated almost 20-30 percent of the total sexual crime rate [4]. Some previous studies, 1/3 of adolescents who are convicted due to the sexual crimes have repeated their actions. This recidivism violence is a significant problem in the population of perpetrators, especially adolescents who commit various sexual offenses [5].

Related to the sexual aggression, most offenders are often found by adults perpetrators (Mampuru, 2007; Zorn and Noga, 2004). While, it is very rarely found of rape offenders among adults adolescents. Many previous studies link pornography and sexual experiences, with the behavior of rape that has been carried out. Research on informant groups; sexual violations at a young age indicate that exposure to child pornography is described as having an impact on criminal behavior[4]. Meanwhile, Burton (2003) described the mechanism of the plausibility relationship between sexual violence behavior and experiences as victims of past sexual crimes, including in terms of modeling the perpetrators by victim. Sexual experience is also thought to be triggered by various factors including experience as a victim varying between 30-50%. This is conditioned as a result of combining several causes of sexual stimulation through sexual violence with signs such as the type of action that appears, and adopting permissive attitudes and beliefs about sex between adults and children [6].

According to our observation, there are many previous studies in term of rape offenders, but there have no study more specific on rape offenders by male adolescents less than 18 years. This study attempts to investigate the child sexual abuse materials as etiology of rape offenders by male adolescents. Therefore, this study investigated the etiology rape offenders by male adolescents at three Bengkulu Correctional Institutions and one Institute for Special Child Development of Bengkulu province, Indonesia.

**Method**

**Design and Participants:** In this research, the researchers were qualitative method that conducted toward male adolescents less than 18 years, they are all the perpetrators of sexual crime cases, such as rape, copulations with minor, and attempted rape. The informants consisted of 29 adolescents, and are being undergone a sentence at Correctional Institutions. The prospective informants are taken from four institutions of Bengkulu province; 12 informants of Special Child Development Institute (LPKA); 2 informants at Bengkulu Correctional Institution; 13 informants at Correctional Institution of North Bengkulu, and 2 from South Bengkulu.

**Data Collection:** Data obtained through semi-structured interviews with each participant, which is conducted within six months, from May to October 2019. The interview activity is divided into two sessions; firstly, the interview explores the general information in term of informants’ demographic data, such as age, and history of sexual crime cases. Secondly, the session interview to investigate the past history of sexual violence and pornography exposure. Each interview session took between 60 to 90 minutes. With this approach, the informant and interviewer are expected to be able to explore the experience and place it in a context. Moreover, this allows the rape perpetrators to reconstruct in-details of their past experiences. The above, the interview guide is based on the following topics; (1) history of sexual assault cases, (2) experience as a victim of sexual violence, and (3) history of pornography exposure.

**Analysis and Interpretation:** Data analysis and theoretical interpretation refer to the research problem formulation, namely: (1) how did the informant ever experience sexual violence in the past? (2) what is the history of exposure to research informant pornography? The researcher conducted a thematic analysis of the in-depth interview transcript. Furthermore, the researcher interprets the production of the meaning of rape behavior text and compares it with the findings of data from various studies and previous studies.

**Ethical Approval and Informed consent:** In this research, before and within data collection, have obtained Ethical Clearance, which issued by Health Research Ethics Committee, Nursing Faculty, Airlangga
Findings: According to our analysis on interview manuscripts, the child victims of sexual violence group are caused by two factors; first, their sexual violence history and pornography exposure experience. All above these upon in-detail are revealed in the following explanation, as follows;

Childhood and Sexual Violence: In term of child victim of sexual assaults, the results of this study revealed that unconsciously informants have ever victimized of sexual violence by adults people around them. Informants, as a prepubescent group who were less than 18 years, are mentally influenced by fantasy or sexual desire activities where they actually did not understand at all its hazard impacts on their future life, such as an influential drive to visit prostitution location, having sex with commercial sex workers, sexual engagement with older couples, and there was persuasion and influence to watch pornographic images or movies; both are free and being asked to pay some money. Thus, this study further explored informants’ history as a victim of sexual harassments, the perpetrators of sexual violence were closest people around their life; they were older people, such as cousins, adopted brothers, friends, adult partners, and commercial sex workers at prostitution location.

The case above as has elaborated from sexual violence lenses, the World Health Organization (WHO) states that sexual violence on child relates to the sexual activity where they do not fully understand and consent [7], developmentally, it is not prepared, violate the law or considered taboo in the social community outlook [8]. In the child group, sexual abuse can be in several forms or activities between children and adults or other children based on age or development in term of responsibility, trust and strength as well. The activities carried out are aimed at satisfying or fulfilling the needs of others, including activities that violate the law, but are not limited to inducement or coercion to a child to have sexual relations, the exploitative use of children in prostitution or other sexual harassment practices, and the exploitative use of children in pornographic performance and material [9].

Some findings of previous researches pointed out the childhood victim experience of sexual violence significantly played a role as deviant predictor of sexual behavior in adult sexual offenders [10]. One negative symptom of past traumatic experiences is an increased risk of criminal behavior, including sexual crimes such as rape [11]. Significantly, the effect of traumatic experience is more found in men than women [12]. Other researches identified the influence of previous trauma exposure, especially strong feelings of fear as triggers of sex offenses namely 85% of perpetrators [13].

Pornography Exposure Experience: Based on the interview results obtained some information in term of child pornography exposure experience. All informants found that they have accustomed with the exposure of pornography in various ages; between elementary and high school. They admitted to be interested to watch pornography movies and images as well due to some influences of their peers or adults people. The youtube channel is the same as gadget and computer, are often used as media to access pornographic images and movies. Importantly, for schools and home environment, especially private room as a convenient place for child to access pornography movies. Their habits in watching the content of pornography have triggered their curiosity drive, and want to know about sexual intercourse, so it further encourages them to do rape behavior.

Under article of Law number 44/2008, pornography is a picture, sketch, illustration, photo, text, sound, sound, moving picture, animation, cartoon, conversation, gestures, or other forms of messages through various forms of communication and/or media shows in public, which all contains sexual obscenity or exploitation that violates the norms of decency in society [14]. Pornography consumption can give a direct impact, such as addiction, demanding more, ignorance or being insensitive to pornographic content and coveting impingement. While for long term, it can have an impact on the creation of ‘Sexually Active Society’, which is characterized by a sexually active society (sex desacration or sex is no longer considered a sacred thing), there are no norms that regulate sexual relations and many people live as husband and wife without wedlock, or extramarital relations become unlawful, free-sex have become commonplace [15].

Some tenets of feminists, pornography causes men to rape women [13]. This theory is based on three interrelated assumptions, as follows; Sexism and male domination are depicted and celebrated in pornography, which sequentially display images of women as objects of sexual exploitation. Pornography tends to promote and legitimate sexual violence by men. It
sexually underestimates on women, which requires the fragmentation of a woman’s body and eroticization of parts of their body. They argue that pornography demeans and denigrates women, glorifies violence, and legitimizes sexism. MacKinnon argues that sexual objectification is the main root of women’s oppression[14].

According to the Cultural Spillover theory (Baron and Straus, 1987), a support for rape may not be limited to the beliefs and attitudes that directly condone sexual violence, for example the myth of rape. There may be other aspects of culture that indirectly function to legitimize rape. This can happen if physical force pattern in one area of life—for example, physical punishment at schools, mass media violence, and the use of government violence must be generalized within relations between the sexes [13], if these cases still happen, violence for non-sexual and socially agreed with the purposes will be associated with the behavior, such as rape.

**Conclusion**

This study has set out the findings, some of child rape offending have experienced at childhood violence committed by adults around them. These forms including strong drive to visit and engage sexual activity at prostitution location, and asked to make out and watch pornography as well. The habits of consuming pornography through gadget, internet cafe were found in all informants of rape less than 18 years, which began at various ages; from elementary to senior high age. It is very interesting to be concerned seriously that some places that are often used by children to access pornography content, such as school environment, private room.

**Implication for Practice and Policy:** This finding reinforces our understanding that sexual crime behavior such as rape can be triggered by past traumatic experiences; experiences as victims of sexual violence. Sexual violence can be carried out by close people around child environment such as family and adults people. Therefore, efforts are needed to improve children’s acquaintance and skills in term of the sexual violence risks, both as victims and perpetrators.

Pornography is often a latent danger whose existence which is not realized by parents. The school and home environment should be a safe place for children, it often turned out to be widely used to access pornography, through gadget and computer. Therefore, good cooperation between parents and schools is needed for preventing and controlling the consumption of pornography among children.

**Acknowledgment:** The authors would like to say high appreciation to all components, which have supported and participated in conducting this research, especially all informants in Bengkulu Correctional Institutions and Special Child Development Institute. Moreover, a big appreciation to LPDP Scholarship (Indonesian Endowment Fund for Education), Doctorate Program of Public Health Department, Universitas Airlangga, Minister of Law and Human Rights of Indonesia Republic.

FOXP3 and HER-2/ErbB2 in Breast Cancer: Finding Regulatory Links

Abdulrazzaq N. Zghair¹, Nihad Khalawe Tektook², Ahmed A. Mohsin¹

Abstract

The transmembrane tyrosine kinase receptor, HER2/ErbB2, has been a subject of many studies owing to its predictive and prognostic values and its being a target of antibody-mediated treatment. Retrospective evidence strongly proposes that the over expression of HER2 is related to reduced disease free and overall survival in node positive and perhaps also node negative breast cancers. Prospective attempts showed that antibodies to HER2 can form tumor responses in advanced breast cancer women which overexpress this molecule. The existence of forkhead box protein 3 (FOXP3) in cells of breast cancer is a subject of debate. We have systematically analyzed the FOXP3 expression in 20 breast carcinoma samples at transcript levels. Recent progresses in understanding breast cancer crosstalk, homing processes, tumor cell dormancy, premetastatic niche formation and finally recognition of their micromilieu cytokines, growth factors and chemokines might provide the foundation of developing targeted treatment plans potentially rendering primary carcinomas and their metastases more responsive to chemotherapies. The current review has focused on the deep connections between HER-2 and FoxP3 in context of considering the determination of both of these molecules together to rationalize or more personalize the future research directions leading to better treatment for women with breast carcinoma.

Keywords: Her-2, Breast cancer, Foxp3, Inhibit, Therapy, Trastuzamab.

Introduction

Breast cancer is a major cause of concern in women worldwide. It is responsible for an appreciable amount of morbidity and mortality in women, with every 8th women showing symptoms which sooner or later progresses into disease. Human epidermal growth factor receptor 2-overexpressing (Her-2⁺) breast Ca represents about 20–25% of breast cancer and has been shown to be more aggressive as compared to the Her2⁻. Her2 is a reliable biomarker whose overexpression is frequently correlated to poor prognosis and clinical outcomes. Trastuzumabor (Herceptin), the monoclonal antibody which targets the extracellular domain of HER2, has been long used in treating patients with Her2⁺ breast carcinoma. Nevertheless, many patients suffering from Her2⁺ tumors possess de novo resistance without response to Trastuzumab, while others developed resistance after a period of Trastuzumab therapy. Her2⁺ signaling mechanism has been extensively studied to identify additional targets to design effective treatments to Her2⁺ breast cancer patients with Trastuzumab resistance. One of such potential targets can be Foxp3 which is an important factor overexpressed in all cancers including breast cancer. Its relation to Her2⁺ signaling shows that it plays an important role in suppressing Her2 oncogene. On the contrary, Foxp3 is also a fundamental partner of Treg cells which suppresses the immune response against tumor in tumor milieu. Studies have also shown that Foxp3 inhibition in Her2⁺ over expressing breast carcinomas could be correlated with better prognosis and relapse free with general survival. Thus, Foxp3 can be envisaged as a pivotal target whose down regulation in tandem with other breast cancer targeted therapies can have astounding effects in women with breast carcinoma. FOXP3 and related mechanism have an essential role in breast cancer metastasis inhibition and such finding might introduce a new target to clinically control the metastasis of breast cancer in the
future. There is an inverse relation between expression of FOXP3 nuclei of breast tumor cells and breast cancer metastasis. Thus, targeting Foxp3+ Treg cells in the microenvironment of cancer combined with anti-Her2 treatment can be a novel strategy against breast cancer particularly chemotherapy-resistant breast cancers. In this review, we have discussed the relation between Her2 and Foxp3 and their role in breast cancer with some recent therapies targeted against them.

**HER2 in Breast Cancer:** Her2 is an oncogene which is a member in the family of human epidermal growth factor. Other members of this family are HER-1, HER-3, HER-4 and HER-2 which are involved in more than ¼ of breast cancer cells. It is present on the long arm of the chromosome No. 17 and it encodes a transmembrane tyrosine kinase receptor. The Her 2 and the other member receptors have an extracellular ligand binding site that is rich in cysteine residues, a transmembrane domain and an intracellular domain having tyrosine kinase activity. HER2 has no direct ligand.

HER2 is normally present as a monomeric receptor on the surface of epithelial cells of mammary glands at a very low level. In tumor cells, HER2 expression increases manifolds. Studies have shown that gene amplification is the reason behind HER2 overexpression. HER2 receptor is activated by ligand binding followed by dimerisation of receptor through homomeric or heteromeric binding with other EFGR receptors. Extracellular domain rich in tyrosine residues is involved in this binding. HER. Neuregulin-1, a cell adhesion molecule, is a direct ligand for HER3 and HER4 and binds with either HER3 or HER4. After ligand binding, HER2 forms heterodimer with HER4 or HER3. This dimerisation of receptor is followed by the autophosphorylation of the tyr residues of intracellular domain through the activation of tyrosine kinase activity of HER2, which turns up cascades of events that are involved in the activation of intracellular signaling pathway. Several signal transducers bind to the activated heterodimer through their src homology domain and initiate signal transducing pathways thereby, stimulating PI3/Akt or MAPK signaling pathways and various transcription factors and overproduction of VEGF. Various protooncogenes e.g c-fos, c-jun, c-myc are also activated. HER-2 over-expression thus activates multiple pathways involved in the process of metastasis. The heterodimer also degrades cell cycle inhibitor P27. Loss of P27 causes proliferation of cancer cell.

**FoxP3 and Immunosuppressive mechanisms in tumor milieu:** Forkhead (FKH) box proteins is a big transcription factor family utilized in different cellular processes. The gene encoding (FOXP3) is present on the chromosome X which contains eleven coding exons and three non coding exons. The characteristic feature of these transcription factors is the existence of a highly preserved (100) amino acids C-terminal FKH binding domains. The FKH with crystal structure domains showed that it has the DNA binding ability and described as a “wing-helix” owing to its similarity to the butterfly morphology. This highly conserved carboxy terminal FKH domain (aa 338 to 421) is responsible for DNA binding ability. The N-terminal domain of FOXP3 comprising of 2 proline-rich regions implicated to mediate transcriptional repressions. The central region of Fox3 protein comprises a zinc finger (A.A. 200-223) & a leucine zipper (LZ)-like motif (A.A. 240-261), that promotes FOXP3 homo-dimer or tetramer formation (Fig. 1).

![Figure 1](image-url)

**Figure 1:** Foxp3 domains (a) N-terminal repressor domain having tumor suppressor activity inhibiting the suppression of ErbB2 (erb-b2 receptor tyrosine kinase-2), SKP2 (S-phase kinase associated protein-2), STAT3 (Signal transducer and activator of transcription 3), c-Jun (transcription factor c-Jun), HDAC7 (histone deacetylase)
The scurfy mutant mouse strain having frame shift mutation of (FKH) box transcription factor (Foxp3) sustaining a lethal lymphoproliferative disorders causing death within an age of 3 to 4 weeks. Mutations in FOXP3 resulted in various autoimmune diseases such as hepatomegaly, splenomegaly, insulitis and massive lymphatic infiltration in liver and skin. Humans (FOXP3) mutation leads to an autoimmune disorder causing death within an age of 3 to 4 weeks. Mutations in FOXP3 resulted in various autoimmune diseases such as hepatomegaly, splenomegaly, insulitis and massive lymphatic infiltration in liver and skin. Humans (FOXP3) mutation leads to an autoimmune syndrome called IPEX (immune dysregulation, polyendocrinopathy, enteropathy and X-linked disease), syndrome termed as IPEX (Foxp-3+ Treg) cell depletion by gene mutation that encode Treg specific transcription factor (foxp3) leading to a lethal multiple organ insufficiency in its production, they absorb IL-2 from the surrounding. This limits IL-2 amount which is available for Tconv cells and as a result, leading to the activation insufficiency in its production, they absorb IL-2 from the surrounding. This limits IL-2 amount which is available for Tconv cells and as a result, leading to the activation.

**Treg-mediated suppression mechanisms:** Foxp3+ CD25+CD4+ Treg (Foxp3+ Treg cells) cells mediated Treg cell development is impaired by gene mutation that encode Treg specific transcription factor (foxp3) leading to a lethal multiple organ autoimmune syndrome termed as IPEX (Tconv) cell and lethal autoimmune disorders and affect several body tissues and organs. Treg cell depletion anti CD25 antibodies, by the in vivo antibody administrations histocompatible T-cell-deficient mice can efficiently eliminate different inoculated syngeneic cancers. Treg cell development is impaired by gene mutation that encode Treg specific transcription factor (foxp3) leading to a lethal multiple organ autoimmune syndrome termed as IPEX (Tconv) cell and lethal autoimmune disorders and affect several body tissues and organs. Treg cell depletion anti CD25 antibodies, by the in vivo antibody administrations histocompatible T-cell-deficient mice can efficiently eliminate different inoculated syngeneic cancers.

**C.T.L.A.-4 is a high effective co-inhibition molecules that is expressed by (Treg) cell and (Tconv) cell following their activations.** The C.T.L.A.-4 Treg-specific deletion in mice causes systemic high multiplication of (Tconv) cell and lethal autoimmune disorders and affect several body tissues and organs. A heterozygous C.T.L.A.-4 mutation in humans is characterized by many autoimmune symptom accompanied with Treg cells suppressive function’s impairment. C.T.L.A-4 exhibit a high affinity for (CD28) their (CD80) and (CD86) ligands. The C.T.L.A-4 which is expressed by the Treg cell will physically outcompete the (CD28) expressing (Tconv) cell to bind the (CD80/CD86) on the antigen presenting cell, therefore inhibiting the stimulation of Tconv cell. The C.T.L.A-4 on Treg cells also down modulate the (CD80/CD86) expression on the DC, hence, inhibiting the Tconv cells activation. The C.T.L.A-4 and other accessory molecules are further upregulated by the TCR stimulation of Treg cells, specially the adhesion molecules like LFA-1, whose...
deficiency compromise suppressive activity. The high L.F.A-1 and other accesssorymoleculeexpression pribefore T.C.R stimulations can lead to establish a less threshold to T.C.R-induced activations of the Treg cell[40]. The attenuated T.C.R signal may save the Treg cell from activations induced cell deaths upon their exposure to antigen, assisting them for better survival than (Tconv) cell, since such Treg cells override Tconvattumor sites. This combined effect of collective highly CD25 & C.T.L.A-4 expressions, reliance upon the exogenous Interleukine-2 and T.C.R stimulations have decisive role in the Treg mediated suppressions.

**Foxp3 and cancer:** A large number of Treg cells often infiltrate different mice & human tumors. In humans, the lung[41], liver[42], head & neck[43], breast[44], gastrointestinal tract[45] and ovary[46] tumors were shown to bear a highly numbers of tumor infiltrated Treg cell[47]. The decreased ratio of tumor infiltrating (CD8+) T cells to FOXP3+ Treg cells were correlated with bad prognosis, mainly in breast cancer patients[48], gastric[49] and ovarian cancer[50]. A previous met a-analysis published data specified that in most breast, kidneys, cervix tumors and melanoma, the highly frequent tumor-infiltrated FOXP3+ cell was associated with patient’s survival negatively[51].

**Interplay between HER2 and FoxP3 in breast cancer:** A study by Parej et al on the correlation between circulating Treg cells in Her2+ and Her2 Bc cells showed that Her2+ tumors were characterized by increased levels of FoxpTreg cells in the blood of BC patients[52]. The high levels of Treg cells have been frequently correlated with MAB or LABC. Her2+ and Her2- tumors when subjected to chemotherapy with trastuzumab alone or in combination with other drugs caused overall reduction in the Treg cells frequencies to normal levels. Some of the Her2+ patients initially responding to trastuzumab therapy exhibited disease recurrences after sometime which was correlated with increase in Treg cell frequency. A correlation between changes in circulating Treg frequency and plasma HER-ECD (extracellular domain) implied that at least some of those cells can respond to and recognize the systemically circulating (HER) proteins. Patients who respond to trastuzumab treatment by decreasing plasma HER-ECD also demonstrated flow frequency of Treg. It was noticed that HER was eliminated from blood circulation by antigen-trastuzumab complex production and uptake by phagocytic cells via combining with Fgr[53-54]. HER-trastuzumab complex formation also led to maturation, activation and reinforced antigen cross presentation by the Antigen Presenting Cell[55] and along with low Treg frequency, may possibly induce an enhanced antitumor responses.

**Foxp3 is recognized during Scurfin position cloning, which is the gene responsible for X linked autoimmunedisorders in humans and mice (Immune dysregulation, enteropathy, polyendopathy, X-linked & IPEX)[56-59].** Mice heterozygous for Foxp3sf spontaneously developed malignant tumors among which more than half were mammary carcinomas. To establish a link between mammary carcinomas and Foxp3 mutation mice, heterozygous for Foxp3sf were treated with a carcinogen, 7,12-dimethylbenz[a] anthracene (DMBA). It was observed that mutation for Foxp3sf but not for Otc sf gene leads tomainelevation in susceptibility to the mammary carcinomas. A comparison of Foxp3 expression normal and mammary epithelium from both wild-type and Foxp3sf+ mice showed that Foxp3 mRNA was identified in normal epithelium of both WT and Foxp3sf mice, but not in mammary carcinomas. This decrease in Foxp3 MRNA was concurrent with significant increase in HER2 mRNA in mammary epithelium. There was also increased HER2 mRNA expression in FOXp3sf/sf epithelium than in wild type female mice indicating a potential gene dosage impact of in vivo Foxp3 of HER2 regulation. Repression of HER2 by Foxp3 is mediated by a direct binding between Forkhead domain of foxp3 onto the promoter region of HER2. The Foxp3 binding site deletion increased the Her2 promoter activities and relieved Fox3 mediated Her2 repression. In most breast cancers, LOH alone was enough for the locus inactivation, probably owing to Xchromosome inactivation. Silencing of Foxp3 gene by Foxp3 siRNA decreased Foxp3 expression by more than (100)fold, while increasing Her2 mRNA by 7 folds. A comparison of Foxp3+ and Foxp3− cancer samples revealed that Foxp3+ samples have reduced HER2 scores compared with Foxp3− specimens suggesting a decisive role for Foxp3 in repressing HER2 expression. Further results revealed that mice heterozygous to Foxp3 mutations spontaneously developed high rates of mammary cancer. Cells where WT allele was silenced by X inactivations had inactive Foxp3 and overexpression of Her2. Most of these mutations concentrated on zing finger & FKH domains which inactivated tumor growth inhibition & repressor activity of Foxp3 (Fig. 2). It could be concluded that the FKH and Zinc finger domains of intracellular transcription factor foxp3 is directly
bound with the promoter’s region of Her2 and acts as a restraint on the transcription of her 2. Any deletion or mutation in foxp3 relieves Her2 of this restraint resulting in its overexpression ultimately causing tumorigenesis [60].

Figure (2): Schematic representation of HER2 signalling mechanism. Receptor tyrosine kinases cause dimerization of HER2 by phosphorylating at tyrosine residues which further activate various downstreaming pathways resulting in cancer. This heterodimerisation activate PI3/AKT, MAPK, PTEN and PKC pathways which further activate downstream signalling molecules P70 and AP-1 that in turn activates proto-oncogenes c-fos, c-myc and c-jun involved in cell proliferation. However PTEN has antagonistic effects on the PI3/AKT pathway.

FOXP3 prevents metastasis and inhibits angiogenesis in breast carcinoma cells: The nuclear expression levels of the protein (Foxp3) were evaluated in the cell line of breast carcinoma. Among these cell lines, S.K.B.R-3 & M.D.A-M.B-231, expressed relatively lower Foxp3 level, while T47D and M.D.A-M.B-361, expressed relatively higher Foxp3 levels. Upregulation of Foxp3 in S.K.B.R-3 and M.D.A-M.B-231 cells decreased the breast Ca cell invasion capacity, whereas, Foxp3-siRNA mediated silencing in T47D and M.D.A-M.B-361 cell had about two fold elevation in the rate of tumor invasion in comparison with the control group cells. The results suggested that Foxp3 overexpression has an inhibition impact on breast Ca cell invasions & adhesions, while Foxp3 silencings possesses an opposite impact. This could be due to the gene expression change viz. C.D.44 R.O.C.K2, E.C.M.1, D.L.G.A.P.5 and Serpine1 associated with cellular movement. Downregulation of these genes, particularly CD44, was most significant in reducing BC invasion and metastasis. C.D.44, the hyaluronic acid cell surface receptor is an adhesion molecule which has a long standing correlation with breast Ca cell invasions & metastasis [61-62]. Foxp3 mediated its inhibitory effect on breast Ca metastasis via linkage with the promoters of gene encoding C.D.44 thereby inhibiting expression of breast Ca cells [63]. An inverselyrelation between CD44 expression and foxp3 reveals that FOXP3 inhibits metastasis via downregulation of CD44 expression [64]. Chemokine CXCL12 and its receptor CXCR4 (CXCL12/CXCR4) play a main role in regulating malignant cell growth, invasion, metastasis and secretion. Foxp3 regulates CXCL12/CXCR4 expression demonstrating an inverse correlation between Foxp3 and CXCL12/CXCR4. Foxp3 showed low mRNA and protein levels in MCF-7 and MDA-MB-231 BC cell lines compared to normal breast epithelial cells. However, stable Foxp3 overexpression in MDA-MB-231 cells led to reduced CXCR4, ErbB2/HER2, SKP20 and c-MYC expression.
Thus, Foxp3 regulates breast Ca metastasis by downregulating the expression of some metastasis-related molecule including C.D.44 and C.X.C.R.4\cite{65}. In addition to its inhibitory role in metastasis, fox p3 has also been implicated to inhibit VEGF-mediated angiogenesis. It was observed that ectopic expressions of Foxp3 in M.C.F-7, T47D and M.D.A-M.B- 231 cell lines downregulates VEGF expression and that silencing endogenous FOXP3 by shRNA upregulated VEGF expression at both the mRNA and protein levels. High Foxp3 expression was a protective factor for breast cancer survival, while high VEGF expression enhances breast cancer survival (Fig. 3). Foxp3-positive samples also showed a lower blood vessel density when compared with nuclear Foxp3-negative samples. These data hypothesize that Foxp3 is negatively related to angiogenesis in breast Ca. Foxp3 inhibits breast Ca angiogenesis invitro and in vivo. This foxp3 mediated downregulation of VEGF took place by a direct interaction of forkhead-binding motifs of Foxp3 with the VEGF promoter 1.2 kb upstream of transcription start site, thus inhibiting VEGF promoter transcription and activity\cite{66}.

![Figure 3](image)

**Figure 3**: Schematic representation of role of Foxp3 as a inhibitor of oncogenes ERBB2 and SKP2 which cause breast cancer. Foxp3 also inhibits VEGF which is an important factor responsible for angiogenesis and metastasis to distant organs. Contrary to these Foxp3 maintains the expression of p27 a cell cycle inhibitor gene, thus exerting tumor suppressive function. Both ERBB2 and SKP2 inhibit expression of p27.

**Therapies targeting FOXP3**: In immunotherapy, the major hurdle is the T cell expressing Foxp3. Foxp3 is an intracellular transcriptional factor. It has been observed that the regulatory T cells elevate the breast cancer by suppressing the antitumor immunity. According to the research work carried out by Takeuchi, the tumors which are not recognized earlier by regulatory T cells triggers a strong antitumor response resulting in the blockage of several immune checkpoints. Thus, in order to elevate the efficacy of vaccines, Foxp3 expressing T regulatory cells are needed to be suppressed\cite{67}.

**Antigen, antibody, peptide or protein**: In their study, Devi and Nath prepared novel vaccines containing synthetic mRNA encoding Foxp3 antigen and delivered them into dendritic cells. Upon transfection or pulsation the peptides of tumor antigens, total protein or total mRNA isolated from tumor cell, DNA encoding specific tumor antigens or synthetic tumor-antigen-encoding mRNA entered into dendritic cells. These tumor antigen-associated dendritic cells resulted in
subsequent generation of mature dendritic cells, which could efficiently elicit tumor antigen specific cytotoxic T lymphocytes fundamental in destruction of cancer cells[68].

A synthetic peptide P60 and antitumor DC vaccines were used to treat mice bearing LM3 and 4T1 tumors. P60 monotherapy was shown to inhibit tumor growth in immunocompetent in addition to the immuno-compromised animals, primarily by inhibiting the secretion of immune-suppressive cytokine IL-10 secretion in FOxp3 expressing breast carcinoma cells. Furthermore, combined treatment with antitumor dendritic cell vaccines and P60 increased the therapeutic efficacy of these vaccine in experimental models[69].

**Conclusion**

The important role of FOXP3 as a tumor suppressor is evident by the fact that it not only represses HER2 and SKP2 breast cancer oncogenes, but also inhibits VEGF a pivotal player causing in angiogenesis and metastasis. However, it has totally contrary role in tumor milieu where its presence on the tumor infiltrating Treg cells results in suppression of anti-tumor response. As such patients initially respond to chemotherapeutic drugs develop resistance over a period of time. Patients who have Her-2$^+$ over expressing breast cancer with primarily response to gradual trastuzumab acquired resistance. Foxp3 mediated inhibition of Her2 signaling mechanism has been extensively studied to identify additional targets to design effective treatment to those patients with drug-resistant Her2$^+$ breast Ca patients. Studies have also shown that Foxp3 inhibition in Her2$^+$ overexpressing BC could be correlated with better prognosis and overall and relapse free survival. Thus, Foxp3 can be envisaged as a pivotal target whose down regulation in tandem with other breast cancer targeted therapies can have astounding effects in BC patients. A synergistic inhibition of Foxp3 in tumor milieu and anti-HER2 therapy on similar lines with anti-HER-2 and anti-VEGF therapy in HER2-positive breast carcinoma can be developed. Foxp3 can be envisaged as an important future candidate in designing an effective therapy against HER2- overexpression particularly drug resistant HER2- overexpressing breast cancer.

Molecular Identification of the Dermatophytes Causing Tinea Diseases Using ITS Sequencing Analysis

Tiba Salim Naseif¹, Abdulameer Jasim Mohammed², Haael Subhi Abbas³

¹Microbiologist, Master, Directorate Wasit of Health, Ministry of Health, Iraq, ²Asst. Prof., PhD, ³Asst. Lec., Master, Collage of Health and Medical Technology, Middle Technical University, Iraq

Abstract

Background: Tinea is a group of keratinophilic fungal infections caused by dermatophytes that invade the skin, hair, and nails. As the conventional methods for dermatophytes detection are time-consuming or lack enough specificity, accurate diagnostic methods such as molecular techniques are required for precise identification and differentiate between two closely related species of dermatophytes.

Objective: To disclose the useful role of DNA sequencing in the recognition of dermatophytes using the ITS region and comparing the current local isolates with those provided by the NCBI.

Method: Thirty clinical tinea specimens were collected from the patients between December 2016 and June 2017. All specimens were examined microscopically then cultured on DTM. Positive dermatophytes’ cultures were confirmed by PCR using ITS1 and ITS4 primers. The PCR products were sequenced for species-specific dermatophyte identification.

Result: Culture results of 30 specimens revealed predominant positive dermatophytes (23, 77%) comparing the rest of no growth. The PCR amplification of the 23 dermatophytes for species identification showed distinct fragment lengths for different species; 550bp for T. tonsurans and T. equinum, 650bp for T. verrucosum, T. bullosum and M. appendiculatum, 690bp for T. rubrum and T. mentagrophytes, 700bp for T. interdigitale, and 740bp for M. canis and E. floccosum. Sequencing analysis exhibited a novel local T. rubrum strain that recorded in the NCBI with accession number (MG786552.1). The genetic compatibility between the reference strain of T. rubrum in India and the local strain was 99%.

Conclusion: Dermatophytes identification by sequencing analysis of the ITS region is a faster, precise, and more dependable diagnosis at species and subspecies levels than the conventional laboratory methods.

Keywords: Dermatophyte, PCR, ITS, Sequencing.

Introduction

Tinea (dermatophytosis) is a mycotic infection brought about by dermatophytes; filamentous fungi invading the keratinized tissues of the skin, hairs, and nails. Dermatophytes are restricted to keratinized layers as they have keratinase enzymes and require keratin for growth[1]. Dermatophytes affiliated to the genera “Trichophyton, Epidermophyton, and Microsporum”, with two possible infections pathways, directly (person to person contact) and/or indirectly (animal to human contact)[2]. Tinea, dependent on the affected site, has been clinically classified into “Tinea capitis (head), Tinea barbae (beard), Tinea corporis (body), Tinea manuum (hand), Tinea cruris (groin), Tinea pedis (foot), and Tinea unguium (nail)”[3]. Direct microscopy of clinical tinea specimens is a speedy method for fungal structures recognition, but it is non-specific and less precise[4].
Cultivated dermatophytes can be pinpointed dependent upon various morphological hallmarks like colony pigmentation, texture, outgrowth rate, and presence of conidia, hence culture is important for both therapeutic and epidemiological studies [5]. Besides, the conventional laboratory methods for dermatophytes detection is either slow or lack enough specificity, and in sometimes the cultural features were unpredictable, thus the perfect diagnostic methods for dermatophytosis should be simple, specific, rapid, and cost-effective [6]. Molecular methods for discrimination between the genotyping characteristics of the dermatophytes species are more specific, precise, rapid, and differentiate between two closely related species as well as are less likely to be affected by external influences such as temperature and chemotherapy [7]. Molecular techniques also provide a better understanding of classification, epidemiology, and ecology. Recently, the diagnosis of dermatophytes dependent on DNA amplification and sequencing analysis of the internal transcribed spacer (ITS) regions [8].

The ITS regions of the ribosomal DNA (rDNA) gene in the dermatophytes were used as a reliable marker for species identification. Also, the ITS region is a chunk of unusable RNA existing amidst formational ribosomal RNA (rRNA) on the universal predecessor transcript [9]. The ITS region is highly changeable even between closely related species of dermatophytes and the sequence consistency of its region is vastly utilized in taxonomy and molecular phylogeny as it can be amplified effortlessly even from little amounts of DNA (as a result of many rRNA genes copies) [10]. As mentioned earlier, the current study aimed to discover the beneficial role of DNA sequencing in the recognition of dermatophytes causing tinea diseases utilizing the ITS region and matching the current local isolates with those provided by National Center Biotechnology Information (NCBI) data.

**Materials and Method**

Subjects: Twenty-three clinical tinea specimens (skin scrapings, nails and hair clippings) were collected from patients, irrespective of age and gender, attending the Dermatology Department of Kadhimiya Teaching Hospital/Baghdad between December 2016 and June 2017. The clinical identification of tinea was performed by a specialized dermatologist, and the patient’s medical history was recorded using a self-administered questionnaire. However, a proper explanation of the study was addressed to the patients and the consent was taken from them before the collection of the sample.

The specimens were examined microscopically after treating with 20% potassium hydroxide. The specimens were also cultured on Dermatophyte Test Medium (DTM) (HiMedia Laboratories, India) and incubated at 28°C for 2-4 weeks. Dermatophytes were disclosed based on a color change in the DTM due to their ability to produce alkali substances that promote the pH and change the medium’s phenol red from yellow to red [11]. DNA extraction performed for positive dermatophytes’ cultures using Fungal/Bacterial DNA MiniPrepTM kit (Zymo Research, USA), DNA extraction of an appropriate amount of fungal cells by bead bashing method, which depends on disruption of the cell wall by beads according to the manufacturer instructions. Extracted DNAs were electrophoretically on 1% agarose gel to determine DNA bands through which observed by UV transilluminator. Thereafter, DNAs were amplified by polymerase chain reaction (PCR) using universal primers; a forward primer (ITS1 F: 5′- TCCGTAGGTAACCTGCGG-3′) and a reverse primer (ITS4 R: 5′-TCCTCCGCTTATTGATATGC-3′). Primers set supplied by Integrated DNA Technologies (IDT Company, Canada). The PCR amplification was done using a Thermal Cycler (Gene Amp, PCR system 9700, Applied Biosystems, USA) in a total volume of 25µl consisting of 1.5µl DNA, 5 µl Taq PCR PreMix (Intron, Korea), 1µl of each primer and 16.5µl of nuclease-free distilled water. Thermal cycling conditions were applied as: Denaturation at 94 °C for 3 min, followed by 35 cycles of 94 °C for 45s, 52°C for 1 min and 72 °C for 1min with final incubation at 72 °C for 7 min. The PCR products were analyzed after RedSafe™ staining by 2% agarose gel electrophoresis alongside DNA Ladder (100 bp). Sanger sequencing of gene performed by National Instrumentation Center for Environmental Management (NICEM) [12] (biotechnology lab, DNA sequencer 3730XL, Applied Biosystems, USA). A homology search was conducted using the Basic Local Alignment Search Tool (BLAST) program that is available at NCBI (online at https://www.ncbi.nlm.nih.gov) and BioEdit/MEGA6 program for multiple sequence alignment, and the sequences result compared with NCBI control strains.

**Results**

The clinical distribution of the types of tinea was illustrated in Figure (1), with higher prevalence of Tinea
corporis (8, 26.7%), Tinea pedis (7, 23.3%) and Tinea capitis (6, 20.0%) compared to other types of Tinea among the 30 cases included in this study.

Figure (1): Clinical distribution of Tinea types among thirty cases in this study.

Figure (2) showed the cultivation results of Tinea cases on DTM. Among 30 clinical cases in this study, 23 (77%) predominant positive dermatophytes cultures contrasting 7 (23%) of no growth.

Figure (2): The cultivation results of thirty clinical tinea cases on DTM.
DNA sequencing analysis of highly variable ITS regions (ITS1 and ITS2 and the 5.8S gene) was applied for 23 PCR products of dermatophytes isolates. This study revealed a predominant T. Mentegrophytes (22%) and E. floccosum (17%) followed by T. tunsurans, T. bullosom, and T. rubrum (13%, 13%, and 9% respectively), comparing M. appendiculatum, M. canis, T. equinium, T. interdigitalie, and T. verrcossum with lower prevalence (4% for each one). The current study exhibited a novel T. rubrum strain that recorded in the NCBI with accession number (MG786552.1) as illustrated in Figure (4). The genetic compatibility between the reference strain of T. rubrum in India and the novel strain in the current study was manifested in Figure (5), through which the compatibility percentage between these two strains was 99%.

Discussion

Identification of dermatophytes at the species level is very important not for diagnosis only but for therapeutic strategies since the conventional diagnostic procedures for dermatophytes detection are slow, lower specificity, and further testing was required to confirm their identity. Misidentification also was one of the main reasons that make the dermatophytes among the first fungal groups studied using molecular techniques.

In this study, thirty clinically diagnosed specimens of patients with different types of tinea infections were collected and cultivated on DTM as differential and selective medium for dermatophytes. The current findings demonstrated that 23 among 30 clinical specimens were positive (red color change) for dermatophytes. These results were in harmony with a study by Singh et al. in India [13], which revealed that DTM is a well reliable media for eczicent incipient isolation, and early discernment, of dermatophytes. The failure of the growth of 7 specimens on DTM might be due to the utilization of antifungal or corticosteroid drugs before specimen collection, clinical misdiagnosis, or inadequate specimen [14]. Besides, the vying between the dermatophytes and the escorted saprophytes at the lesion sites may disserve and forbid the growth of the dermatophytes on agar media [15].

Molecular techniques are more advantageous for dermatophyte identification as they are rapid, highly sensitive and specific. Moreover, these methods depend on genetic character, which is more persistent than phenotypic features, and they can identify atypical dermatophytes that could not be recognized by culture-based techniques [16]. The PCR technique has rapidly become one of the most widely used techniques in molecular biology for its high discriminatory power and reproducibility, because it is rapid, simple and requires very little specimen materials [17]. Twenty-three dermatophyte isolates were confirmed using PCR for species identification. In the PCR, the ITS region was amplified using the primers ITS1 and ITS4. As expected, the fragment size of PCR products from different species showed different lengths. The size of the amplified product was approximately 690 bp for *T. rubrum* and *T. mentagrophytes*, 740 bp for *M. canis* and *E. floccosum*, 650 bp for *T. verrucosum*, *T. bullosum* and *M. appendiculatum*, 550 bp for *T. tonsurans* and *T. equinum*, 700 bp for *T. interdigitale*, whereas 770 bp for *Microsporum sp.*. These study results were consistent with several studies using PCR as a reliable technique for species-specific identification of dermatophytes, which mentioned that molecular methods utilize ITS regions are more accurate, specific, and effective in the rapid recognition of dermatophyte species in clinical and epidemiological approaches based on the fragment size length ranging from 550 to 740bp [18,19].

DNA sequencing, in this study, was applied for the PCR products, via the maximization of the ITS region in the rDNA gene. The ITS is a powerful significant marker through which it can manage with phylogenetically congenerical extra far fungal species. The PCR products were sequenced in South Korea (Macrogen lab) as a standard sequencing service. Sequence analysis of the more variable ITS region is the beneficial discernment assay for dermatophytes’ species recognition displaying highly pleomorphism of ITS region inside the same genus as well as it’s a potential tool to resolve the phylogenetic relationships within the family Arthrodermataceae [20].

The ITS region of the “nuclear ribosomal DNA repeat unit” is frequently sequenced for enquiries of systematics and taxonomy within the genus/species levels. The region 650bp can be gained via a single run of DNA sequencing and of its sub-regions (ITS1 and ITS2 and 5.8S gene) which manifested a supremely developmental degree of species specificity [21]. In current study, the ITS1F and ITS4R primers were used to amplify the spacers ITS1 and ITS2 to characterize fungal abundance and diversity. Among the 23 sequenced dermatophytes, a novel *T. rubrum* strain was identified and recorded in the NCBI with accession number MG786552.1, which was isolated from the groin of an adult male with Tinea cruris that lived in a rural area. As mentioned, the nucleotide sequencing revealed that the genetic variations happened in a single region, with one transition only at the position (491) that convert it from Guanine (G) to Adenine (A).

This study also demonstrated a highly similar percentage (99%) of genetic affinity between the recorded isolate and the NCBI, and the phylogenetic analysis figured out the high compatibility percentage (about 99%) between the local novel strain of *T. rubrum* in Iraq and *T. rubrum* strain in India. Interpretation of this result, in our opinion, might be due to Indian arrivals to Iraq who had tinea and their admixture with Iraqis resulting in the transmission of tinea infection. Thus, the coinfection of the two distinct strains of *T. rubrum* leads to genetic mutations with the emergence of a new strains.
 Conclusion

Dermatophytes identification by sequencing analysis of the ITS region is a faster, precise, and more dependable diagnosis that can replace, with facilities supported, the conventional methods. Also, this technique becomes essential for correct recognition of dermatophyte species for proper therapies, realize the source of infection, and the epidemiology of uncommon dermatophyte species.

The Welfare State: Construction of the Caliphate System and the Indonesia Constitutional Citizen Health and Social Rights

Abdul Wahid¹, Sunardi², Dwi Ari Kurniati³

¹Associate Professor, Universitas Islam Malang, ²Lecturer, Universitas Islam Malang, ³Lecturer, Universitas Islam Malang

Abstract
The caliphate system is a system which is known to only acknowledge a government or a state leadership as legal if its governance uses the Islamic law as the absolute law, meanwhile other laws such as the positive law (the law which is applied in Indonesia) is deemed as a form of governance which is against Islam. Such understanding is clearly contradictory to the Indonesian Constitution (the 1945 Constitution). In the Indonesian Constitution, it has stated that the implementation of the government or the authority is based on the constitution supremacy. All forms of governance or application of authority (in the state) refer to the norms created by the state through the mandated organizations.

Keywords: Constitution, caliphate, system, state, law.

Introduction
The pro and contra on the caliphate system have often filled the field of public discourse. The group who claim to be pro to this system believe that the caliphate system is suitable to be applied in Indonesia, and should be used as the ideology. This group does not want Pancasila (the five principles which make the ideology of Indonesia) to be the ideology of the state, and they believe that the caliphate system is deemed to be more suitable.

Meanwhile, in Indonesia, there is another group who disagrees if the caliphate system becomes the ideology. The group of people sternly rejects the belief of Pancasila, which has already become the vision and the ideology of the nation, which is to become the welfare state. We can see the difference between the caliphate system and the Pancasila system regarding the welfare state, especially when discussing about health assurance.

There is a common concern which happens everywhere due to some active promotions on the caliphate system. They believe that the governmental system which is applied in Indonesia is against Islam and that the government has failed in creating a social life which is peaceful, fair, and prosper. In this paper, the formulated problems are, in reality, how is the urgency of the welfare state and the fulfilment of the people’s health rights in constitution? Then, in reality, how is the caliphate system and why is the constitution (the 1945 Constitution) more suitable than the caliphate system to be applied in Indonesia?

Research Method
This study used a juridical normative method with a qualitative descriptive approach. Descriptive method is used to describe and explain the factual conditions of the research to find out the solution.

Discussion
The Urgency of the Welfare State in Constitution as the Life of a Nation: In a political community which is organized correctly, the existence of a state is for the people; and this is known as the welfare state. The people who formulated the state cannot establish their own affairs without the highest arbitrary power¹. From this stately construction, many forms of roles are run by some institutions or some people to achieve or to reach the goal which is idealized by the state.

Corresponding Author:
Abdul Wahid
Universitas Islam Malang, Malang City, Indonesia
e-mail: visibos@yahoo.com
There were some amendments of the 1945 Constitution in the form of quality and quantity\(^2\). The many rights of the people which were beforehand non-existent in the constitution, are inserted in the amendment, including health rights which are crucial in a welfare state.

In essence, the main function of the Constitutional Court is to guard and to protect the constitution. It is a correction of the governmental experiences in the past which was caused by multiple interpretations of the Constitution\(^3\). Its function is so that the constitution may always become the “holy book” in the nation. The Constitutional Court’s ideal formation cannot be separated from the judicial review\(^4\).

The existence of the judicial review is to avoid the possibility for constitutional products to bring loss to the people’s interests\(^5\) or to destruct the constitutional rights of the people. Thus, constitution’s constitutionality must be tested as follows: first, the Constitution is a political product of two institutions, which are the president and the People’s Representative Assembly, who are chosen by the majority of the people based on the rule by majority principle, where there is no guarantee of its righteousness and justice based on the 1945 Constitution. Second, the people’s wills are reflected in the 1945 Constitution, meanwhile the Constitution reflects the wills of the political elites in the parliament\(^6\). Karman stated that the constitution is the people’s law, thus it must contain stipulations of the welfare state, including health rights\(^7\).

If the constitution is violated, it will surely disturb the position of the state as a welfare state, which is fundamental. It has the potential to threaten the constitution and the people’s welfare\(^8\). This condition has the potential to hurt the ideals that the constitution is “a higher order law (which) will generally be entrenched,”\(^9\). This construction must be protected by all who are subjects of this nation.

**The Construction of the Caliphate Welfare Paradigm:** The Indonesia ideology system is Pancasila and the welfare state. As a governmental system, the caliphate system is created by human beings, where its contents vary from time to time and from one place to another. In Islam, there is no standard in the governmental nor stately systems. The Muslims of Indonesia are allowed to have a governmental system which is according to the needs and the reality of the Indonesians themselves\(^10\).

The Islamic scholars who participated in establishing and in developing Indonesia as welfare state stated that the state of Pancasila is a final choice and that it does not contradict with the Islamic sharia. Thus, it must be accepted as the noble agreement of the state\(^11\). With all costs, Pancasila must be upheld as the ideology of the state. If seen from the philosophical aspect, all legal systems of Indonesia cannot be separated from the belief that Pancasila is the *Philosophische Grundslag (Grundnorm)*\(^12\).

In the aspect of Indonesia’s life as a state, it can be implemented by adapting and harmonizing the values of Pancasila as the *philosophische grundslag (grundnorm)* and the 1945 Constitution as the *staatsfundamentalnorm*. Both of them are the to be applied in the society, the state, and the nation for the people’s welfare. If this harmonization is applied well, the state won’t easily be broken by other strengths, including those who are consistently preaching the caliphate system as the most correct system.

Hasan states that human beings have the mandate of “welfaresjip”. The doctrines of the Quran state that humans are the only creatures who are given the mandate from God to manage and to use the natural resources and the welfare as “God’s caliph on earth”. It gives human beings the rights for exploration, exploitation, and also the usage of those resources in the efforts to fulfill their needs and to increase the quality of their lives. But humans must be responsible in using those rights\(^13\). This is based on God’s order, “It is He who has made you successors on the earth, and raised some of you in rank above others so that He may test you in respect to what He has given to you.” (The Holy Quran, al-An’am, 6: 165). The reference from the Qur’an above gives guidance to the humans to carry out their activities as “God’s caliph on earth” (*khalifah fil ardl*) beneficially, for example by developing a governance which is transparent and accountable, natural resource usage based on ecological protection, and also protecting the rights; including the health rights of all human beings who embrace variative religions. Every person has the right for prosperity and the right for health rights. This is because this country is a welfare state which embraces diversity and multiple cultures. Thus, all citizens constitutionally have the obligation to respect and to protect each other.

Ucok Unpad states that Indonesia is built based on the agreement of all parties. Its land is spread from Aceh to Merauke. Its foundation is made from five principles
which are explored from the history of the nation. Meanwhile, it is formed by bricks which are made of the various ethnicities, tribes, cultures, and religions with all of their pluralities, which are layered by the cement of mutual desire and mutual feelings due to colonialism, to live together as a nation. This means that it is not right to say that Indonesia is only owned by a group of people. Indonesia is one for all and all for one.

As a comparison, Prophet Muhammad (peace be upon him)’s manner in developing the people or the “state” (the government) is based on the people’s welfare. He acknowledges and upholds diversity. He does not state that the caliphate system is to develop the people. In many aspects which regard the society and the state, Prophet Muhammad was very democratic in delegating members of the society who have particular expertise, like what he stated, “You have better knowledge of the affairs of your world.” (Sahih Muslim 2363). His statement shows there are many potentials and specialness in every human being with all of their diversity in culture, religion, politics, health, education, etc.,

Mahfud also suggested a similar opinion. He states that there is no standard system in the primary sources of Islam. Everything is up to the people according to the condition of the society and the development of the era. The proof is that there are different governmental systems in the Islamic world. There are those which use the kingdom system, the emirate system, the sultanate system, the republic system, etc. This shows that there is not one system which is deemed as correct in the construction of Islam’s governmental system, as all nations have the right to apply the systems which are acknowledged based on their ijtihad as the system which is most suitable and most beneficial for the people and the nation.

The Indonesian constitution and its Pancasila may give the best towards the welfare and health rights in the life as a nation compared to the caliphate system. Wahid, Indonesia’s former president, stated that the acknowledgment and the acceptance of Pancasila as the principle of the government is carried out through religious means. This means that it positions religion and Pancasila in their own places, without contradicting one and another.

Pancasila is the ideologic-constitutional basis. Then, the Islamic aqidah (the Islamic articles of faith) according to the Ahlussunnah wal-Jama’ah paradigm is the basis of faith. They cannot be contradicted between one and another. This is because in essence, someone who has the principle of Pancasila, has the belief on the Almighty God (in this case bringing one of the basic principles in Indonesia).

Mahfud explained that these systems are different from the system of a Pancasila state, which already has a standard until its institutionalism. It is a product of ijtihad which is developed based on the reality of the plural Indonesian people. It is identical to when Prophet Mohammed built the State of Madinah. It is dangerous if the supporters of the caliphate system often state that the Pancasila system of governance has failed in developing justice and prosperity.

The supporters of the caliphate system or paradigm do not understand that the Prophet’s successful standard in developing Madinah was not because he applied the caliphate system. Yet, this is because the Prophet was able to protect and to apply justice to all groups or tribes. This is similar to the condition in Indonesia. If this country is not yet in welfare, nor has it established a strong and a clean government, it is not because of the constitutional system or the Pancasila ideology. But it is caused by the factor of leadership and bureaucracy. At this time, it is difficult to form a social condition or a governmental construction like in the Prophet’s era.

In Madinah, the Prophet took strategic steps from the social, political, and cultural aspects. He unified the groups of people and the tribes in Madinah and those surrounding it, even though they had different traditions and embraced different religions. The diverse people and the various tribes were invited to make a type of “political contract” to live together, to respect and to help each other, to guard Madinah from all kinds of external threats, and to work together in a peaceful and a respectful manner. This is proven from the guarantee that they still have the freedom to run specific religions and to worship according to their religions. The political contract was signed by the tribes of Aun, Haris (Khadraj), Sa’idah, Jusyam, Najjar, Amru, Nabit, Aus, Tsa’labah (Jewish), Syathbiyah (Jewish), Jufnah (Jewish), etc. They agreed to develop the state based on the pluralistic people which is not based by the caliphate system. Yet, it is based on a political agreement to emphasize universal interests, not according the interests of a particular person or a particular group.
The construction of the state of Madinah becomes a great lesson in the field of the governance system. It teaches us that a system cannot be separated from the reality of the people’s social life. The people’s condition of plurality or diversity has great influence on the system’s construction. The caliphate system cannot answer the needs of the Indonesian people. Only a little may be fulfilled by the caliphate system. The caliphate system may also bring a disaster to the Republic of Indonesia, as it may divide the state’s construction of unity.11

If these constitutional norms are obeyed by all citizens, thus the construction of Indonesia’s dignity may be parallel to the “state of Madinah”, as formed by Prophet Muhammad. This is because complying with the constitutional norms means running the basic religious, humane, social, and national norms responsibly.14

In a story, Caliph Umar reminded the Priest on the meaning of pluralism and the freedom in religion or the inclusive-humanistic relations with God, when the Caliph rejected the Priest’s offer for the Muslims to pray in the church. His reason was that he was afraid that there will be some people who will act radically and try to destroy the worshipping place of people from other religions in the future, if he was to pray there.

For Caliph Umar, a place of worship is a sacred reflection which is principle for a religious community. Thus, when the Priest offered him to pray in the church, the caliph did not only think about the religion that he embraced. Yet, he also showed a political-religious behavior which is wise, clear, democratic, and prospective-humanistic, that must be enforced by all religion-embracers in the future.

Conclusion

In the construction of the constitution (the 1945 Constitution), it is clear that the constitutional right to embrace a religion or to believe upon certain paradigms which are thought to be correct is guaranteed. Even so, it does not mean that every system which is against Pancasila may be freely spread and developed. The Indonesian constitution also stated clearly on the welfare state and other rights including the health rights for the people.

In Indonesia, the caliphate system is an unconstitutional system. Such caliphate system is clearly not in line with the constitution of the Indonesians. It is true that the majority of the Indonesian people are Muslims. But they have agreed that the governmental or the state leadership is implemented based on the constitutional supremacy, instead of the caliphate paradigm or system. All kinds of power establishment and governance (in the stately life) is based on the constitution as its “holy book”.

The most important aspect of a stately system is how it gives benefits to the people. It is about how the rights of the citizens, including the health rights, justice, and equality rights are formulated and granted to the citizens. In the Indonesian constitution, the welfare state formulation has been stipulated sufficiently for the sake of the Indonesian people.

Abstract

**Objective:** The organization of the regional general election during the Covid-19 pandemic surely creates threats towards the citizens’ right to live, which is guaranteed by the constitution. It is not easy to guarantee the safety of the organizers as well as the voters and to build a discipline in running the health protocol during the regional general election. This paper aims to describe such condition.

**Method:** This research uses the juridical-normative method with the descriptive-qualitative approach.

**Result:** There needs to be a tight and a measured health protocol which is able to prevent the turning of the regional general election into an arena of mass Covid-19 infection. It is important to strengthen the regulation in the form of prohibitions and sanctions in violating the protocol.

**Conclusion:** The General Election Commission and the government must act strictly to every violation of the health protocol, as it endangers many people. There must be clear regulations on the prohibition of the general election campaign and activities which involve many people in the red areas, and campaign limitations in the green areas.

**Keywords:** Election, regional head, pandemic, health protocol.

Introduction

The global spread of the coronavirus disease (Covid-19) has significantly increased from time to time. Indonesia is also one of the countries which has been impacted by this pandemic. Considering the dangers of this disease, through the mandate stipulated in Article 12 of the Republic of Indonesia’s Constitution, the President has issued the Decree of the Republic of Indonesia President No. 11 of 2020 regarding the Determination of a Health Urgency. Referring to the analysis of an urgent law of governance, the determination of this urgent condition is still in the *staatsnoodrecht* scope, where the state is obliged to issue some policies to face the urgent situation. The implementation of that policy is written in the Large-Scale Social Restrictions in the form of restrictions which have started to be implied and suggestions to avoid activities which involve many people. Recently, the government has applied the policy against homecoming during great religious celebrations to cut the chain of the covid-19 pandemic infections.

Even though it brings many critics, the government has decided to organize the Regional General Election on December 9th, 2020¹. It means that this event, which is organized once every five years, will be organized...
during the Covid-19 pandemic. The Regional General Election stages which were beforehand stopped due to the Covid-19 pandemic have now been continued. Article 8B of the Regulation of the General Election Commission No. 5 of 2020 states explicitly states that, “Execution of the simultaneous voting which was before postponed due to the non-natural disaster of the Coronavirus Disease 2019 (Covid-19), will be carried out on December 9th, 2020”. This Regulation of the General Election Commission is an explanation of the order of Article 201A clause (2) of the Governmental Regulation in Change of the Constitution No. 2 of 2020, which states that, “Execution of the simultaneous voting which was before postponed as mentioned in clause (1) will be carried out on December 20202.

Based on the data from International IDEA (Institute for Democracy and Electoral Assistance), during the period from February 21st to July 19th 2020, there were at least 67 countries and territories in the whole world which decided to postpone national and sub-national general elections due to the Covid-19 pandemic. From this number, at least 23 countries decided to postpone national general elections and referendums. On the same period, 49 countries and territories have decided to execute the organization of national or regional general elections as planned beforehand, From the 49 countries which organized those general elections during the pandemic, there are of course stories which may be extracted and turned into valuable lessons.

The countries which still choose to organize the general elections during the Covid-19 pandemic had experienced many challenges. One of the most difficult challenge is “the responses of the citizens” who are voters in those elections. There is the risk of a Covid-19 infection to the citizens, which is a main consideration which must be answered by the government. The state, through the government, must give a guarantee of safety to their citizens, so that the suffrage rights may be carried out safely and comfortable. The government must make sure that the head of the region general elections will not be a place where the coronavirus disease spread to the citizens with the clusters of the heads of the region elections. Because of that, the General Commission of the General Election (KPU) chooses to decrease the target of the voter participation ratein the heads of the region elections3.

Source: International IDEA

In some other states, there is a decrease of the participation rate of the election when organized during the Covid-19 pandemic. These countries are Iran, Dominica Republic, Vanuatu, Guinea, Mali, Serbia, Iceland, and Croatia. In Iran, the voter participation rate was only 42,32% from the total of 57,918,000
registered voters. On the previous general election on 2016, the voter participation rate in Iran reached 60.09%. A similar thing also happened in Serbia, where the level of voter participation only reached 48.93% from the total of 6,584,376 registered voters. On the previous general election on 2016, the voter participation rate reached 56.07%. Even though the majority of countries experienced a decrease in the participation rate, there are also other countries which experience an increase, which are South Korea and Poland.

This data means that the Indonesian government and the KPU must work hard to increase the general election participation even though they are faced with the risks of the pandemic. It is not easy to guarantee the health of the organizers as well as the voters. There needs to be a strict health protocol which may make sure that the head of the region general election does not become an arena of mass Covid-19 infection.

**Materials and Method**

This paper uses the juridical-normative research method. The approach used in this research is the descriptive-qualitative approach. This means that this research describes how the regional general election will be during the pandemic, where the organizers must fulfil a tight health protocol, so that a cluster health disaster during the election may be prevented.

**Results and Discussion**

The local-level participation of the people is a manifestation of desire and application of the people’s sovereignty principle which hopes for a real impact in creating an output, which is to create a new government. The effort to create a new government in the various regions of Indonesia actually manifests a spirit of nationalism and high hope. But the government and the Indonesian society have an awareness in reading the situation which is happening, where the Covid-19 pandemic is a main problem which must be wisely reacted upon. The relation between the society and the government may be said as a synergy to go through these hard times in the 2020 political contest. In this urgent condition due to the Covid-19 pandemic, all political maneuvers and mechanisms become riskier. The political actors must also have their own strategies to keep on directing the mass, because the aim is to win the competition.

Even if the choice of organizing the election of 2020 becomes optional, the consideration of the legal processes and results must be able to be described in a technique which is easily understood by all parties. This is because the loss experienced by the participants and the voters due to an uncommon technique may cause a long-term problem. Moreover, a great legal consequence may haunt the general election organizers.

Because of that, by issuing the Governmental Regulation in Change of the Constitution No. 2 of 2020, the government is thought to have created an amazing policy. It may be said as too brave. This is because this statement of optimistic law will be written in history. This Governmental Regulation in Change of the Constitution on the Regional General Election also places itself as a legal innovation. This Governmental Regulation is created due to the extreme condition which happens; thus, the head of the region general election must still run in the middle of the pandemic.

One on hand, in the political point of view, the execution of the 2020 general election is a water spring in the dry season of the pandemic’s era of uncertainty. The general election organization (KPU) answers all political efforts of the head of the region candidates. Because of that the prospecting election participants may decrease the excessive expenditures during the pandemic. On the other hand, there is the potential of a lawsuit on the organization technique, which may enter the arena of law enforcement. It is complicated and confusing and also the law during the pandemic is extraordinary law if the government want the regional election not became a disaster.

The organizers must be able to execute the election. It is no secret that the funding money becomes the main problem in organizing an election. If the fund is not enough due to economic policies in handling the Covid-19, there is a risk of a cut of funds for the election, which may decrease the performance quality. The choice to still organize the regional general election must be supported by giving a special budget without decreasing it for any reason.

To develop a discipline in running the health protocol during the regional general elections, it is crucial to strengthen the regulations in the forms of prohibitions and sanctions to the violation of those protocols. Unfortunately, this simultaneous regional general election still uses the regulatory design which
is only applicable during normal conditions. It cannot be applied during an abnormal condition due to the pandemic. Because of that, the prohibitions and sanctions to the violation of the health protocols are not regulated in the regional general election regulations. Meanwhile in Indonesia, we have not yet had enough experiences in organizing an electoral process during an urgent situation.

The point is that the regional KPU during the Covid-19 pandemic should not threaten the life of the citizens. Thus, the management of this simultaneous regional general election must be directed to fulfill the standard protocol in saving the human lives. Because principally, the regional general election is for the sake of the human beings, and not the other way around.

Practically, the KPU has noted 243 alleged cases of health protocol violation during the registration process of head of the region prospective pair of candidates which happened for three days. During the registration process, the prospective pairs of candidates were escorted by masses of supporters which causes the occurrence of crowds and has the potential to spread the coronavirus disease. Before that, President Joko Widodo has asked the Minister of Internal Affairs and the KPU to strictly monitor and act upon the parties who violate the health protocol during the regional democratic celebration to prevent the spread of the coronavirus disease and to prevent the occurrence of regional general election clusters.

Based on the data of the Ministry of Internal Affairs, there were 733 prospective pairs of candidates whose registration applications were accepted. Among them, 294 prospective pairs of candidates were incumbent. Based on the data from the Ministry of Coordinator in the Politic, Law, and Human Rights, Mahfud MD, until Wednesday afternoon (September 9th, 2020), there were 59 prospective pairs of candidates from that number who were confirmed to be positive of the Covid-19 disease, which were spread in 21 provinces. The General Election Commission stated that, even though they were tested positive of the Covid-19 disease, those prospective pairs of regional head candidates will not lose their position as candidates.

The KPU is optimistic that the election will be organized well if four main requirements are met. First, the legal certainty framework must be strengthened before starting the stages. As known before, the Governmental Regulation in Change of the Constitution No. 2 of 2020, the General Election Commission Regulation No. 5 of 2020 on the Stages, Schedules, Programs, and the Decree of the KPU the regional general election execution during the Covid-19 pandemic has been officially released.

The problem which arises is the threat towards the people’s safety and health if the 2020 Regional General Election will still be organized. This will risk the people as the constituents, the participants who are the pairs of candidates and the regional general election organizers who are the KPU and its team. Not only that, the quality degradation of the election organization stages which will be carried out during the Covid-19 pandemic may cause malpractices in its establishment process, starting from the voter data update, the independent candidate requirement of support verifications, campaigns, and the voting process.

The current problems which arrive due to the Covid-19 become universal and basic problems. On the other hand, the government and the related institutions persist to start the 2020 Regional General Election contest on December 9th. So far, Indonesia has not experienced a period of regional general election execution with the threat of a pandemic which has the high potential in influencing the health of the people and which may even cause death. The General Election organizers, especially the KPU must maximally apply the health protocols. They must also prepare adequate supporting equipment to be used in the field, such as personal protective equipment, hand sanitizers, disinfectant sprays, masks, soap, sinks to wash hands, sterilized voting booths, etc. The Regional Governments must increase their awareness towards the symptoms and the spread of the Covid-19 disease in their areas by preparing health facilities and health worker to handle unwanted occurrences.

**Conclusion**

Even though it attracts many critics, the Regional General Election has been determined to be established on December 9th, 2020. This means that this event which is held every five years will be organized during the Covid-19 pandemic. The initial stage of the Regional General Election process has produced more than 200 violations of health protocol, which causes a fatal impact, as 59 person of head of the region candidates were diagnosed as Covid-19 positive.
The General Election Commission and the government must act strictly to every violation of the health protocol, as it endangers many people. There must be clear regulations on the prohibition of the general election campaign and activities which involve many people in the red areas, and campaign limitations in the green areas. The government must increase the budget to prepare health protocol facilities such as personal protective equipment, hand sanitizers, disinfectant sprays, masks, soap, sinks to wash hands, sterilized voting booths, and other hygienic equipment to protect the public and the regional general election officials from the Covid-19.

Characterization and Outcome of Patients Presented with Unilateral Nasal Disease to ENT unit at Hillah, Iraq

Safaa Hussain Alturaihy

M.B.Ch.B./F.I.B.M.S. ENT/Assistant Professor/Department of Surgery/College of Medicine/Babylon University/Consultant ENT in Hillah General Teaching Hospital at Department of Surgery

Abstract

Background: A common finding during daily otolaryngological practice is a patient with unilateral nasal symptoms, nasal polyp or mass. The causes behind most cases of unilateral nasal disorder are inflammatory in nature and responds well to medical intervention and rarely there is need for surgical management. The possibility of neoplastic nature is high when there is unilateral nasal complaint or pathology as neoplastic conditions during their early stages may mimic inflammatory pathologies.

Aim of the Study: The aim of the current study was to highlight the causes of unilateral nasal disease, their most frequent mode of presentation, management strategies and outcome in a sample of Iraqi patients.

Patients and Method: The current prospective study included 96 patients, 42 males and 54 females, with signs and symptoms suggestive of unilateral nasal disease. The study was carried out at Hillah General Teaching Hospital, Babel province, mid-Euphrates region of Iraq and the work with this study has extended from January 2014 to August 2019. All enrolled patients were subjected to routine ENT examination and office flexible endoscopy. Patients were managed by functional endoscopic sinus surgery for purpose of excisional or incisional biopsy.

Results: The current study included 96 patients with a mean age of 49.09± 7.43 years and an age range of 39 to 67 years. There were 42 males and 54 females. The results of complete evaluation have shown the following pathologies at the end of the study: nasal polyposis (31, 32.3%), chronic rhinosinusitis without polyp (16, 16.7%), antrochoanal polyp (14, 14.6%), inverted papilloma (11, 11.5%), frontoethmoidal mucocele (7, 7.3%), concha bullosa (4, 4.2%), squamous cell carcinoma (3, 3.1%), rhinolith (2, 2.1%), fibrous dysplasia (2, 2.1%), adenocarcinoma (2, 2.1%), malignant melanoma (1, 1.0%), cavernous hemangioma (1, 1.0%), pyocele in concha bullosa (1, 1.0%) and non Hodgkin’s (1, 1.0%). Therefore, in the current study, nasal polyposis was the commonest cause of unilateral sinonasal disease followed by chronic rhinosinusitis without polyp, antrochoanal polyp and inverted papilloma. The rate of malignant neoplasms was low.

Conclusion: Differentiating the neoplastic nature form non-neoplastic nature of unilateral nasal pathology is the most critical management step and in the current study, nasal polyposis was the commonest cause of unilateral sinonasal disease followed by chronic rhinosinusitis without polyp, antrochoanal polyp and inverted papilloma. The rate of neoplastic malignant conditions was low.

Keywords: Unilateral nasal polyp, Hillah, Iraq.

Introduction

A common finding during daily otolaryngological practice is a patient with unilateral nasal symptoms, nasal polyp or mass. The causes behind most cases of unilateral nasal disorder are inflammatory in nature and responds well to medical intervention and rarely there
The possibility of neoplastic nature is high when there is unilateral nasal complaint or pathology as neoplastic conditions during their early stages may mimic inflammatory pathologies. Actually, the mission of an otolaryngologist is to discover neoplastic conditions in association with unilateral nasal complaint in order to offer the best management options that can assure cure with high rate. Despite the fact that unilateral nasal complaint is a frequent finding in daily clinical practice, literature dealing with the characterization and outcome of these conditions is relatively scanty.

Unilateral nasal discharge, nasal congestion and nose bleeding in addition to dysosmia, migraine, and facial swelling are most common presenting clinical complaints in patients with unilateral nasal disease. Clinical characterization of a patient complaining of single-sided nasal symptoms mass is an essential challenging health issue because they are often accompanied by multifactorial underlying etiology. Evaluation of such health issue should include good history taking, thorough local examination and endoscopic investigation in addition to radiologic evaluation. Findings on imaging play a significant role in the diagnosis and workup of sinonasal pathology. Bilateral versus unilateral involvement is a key feature that can differentiate between different etiologies.

The poverty of national and international publications dealing with clinical presentation and pathologic characterization of unilateral nasal complaint justified the planning and conductance of the current study in Hillah General Teaching Hospital, mid-Euphrates region of Iraq.

Patients and Method

The current prospective study included 96 patients, 42 males and 54 females, with signs and symptoms suggestive of unilateral nasal disease. The study was carried out at Hillah General Teaching Hospital, Babel province, mid-Euphrates region of Iraq and the work with this study has extended from January 2014 to August 2019. All enrolled patients were subjected to routine ENT examination and office flexible endoscopy. Patients were managed by functional endoscopic sinus surgery for purpose of excisional or incisional biopsy.

The ethical approval was issued by the ethical approval committee of the local health institute and a verbal consent was obtained from all participants following full illustration of the aim and the procedure of the study. The principal outcomes were the clinical presenting features and the type of pathology.

Data were transformed into SPSS (statistical package for social sciences) software (IBM, Chicago, USA, version 23) for purpose of statistical description. Categorical variables were expressed as number and percentage, whereas, quantitative data were expressed as range, mean and standard deviation.

Results

The current study included 96 patients with a mean age of 49.09± 7.43 years and an age range of 30 to 67 years. There were 42 males and 54 females. The results of complete evaluation have shown the following pathologies at the end of the study: nasal polyposis (31, 32.3%), chronic rhinosinusitis without polyp (16, 16.7%), antrochoanal polyp (14, 14.6%), inverted papilloma (11, 11.5%), frontoethmoidal mucocele (7, 7.3%), concha bullosa (4, 4.2%), squamous cell carcinoma (3, 3.1%), rhinolith (2, 2.1%), fibrous dysplasia (2, 2.1%), adenocarcinoma (2, 2.1%), malignant melanoma (1, 1.0%), cavernous hemangioma (1, 1.0%), pyocele in concha bullosa (1, 1.0%) and non Hodgkin’s (1, 1.0%). Therefore, in the current study, nasal polyposis was the commonest cause of unilateral sinonasal disease followed by chronic rhinosinusitis without polyp, antrochoanal polyp and inverted papilloma. The rate of malignant neoplasms was low, as demonstrated in figure 1.

The presenting clinical features are shown in figure 2. The most frequent clinical symptom was nasal obstruction which was seen in 81 cases (84.4%), followed by rhinorrhea (69 cases, 71.9%), then postnasal drip (33 cases, 34.4%) and anosmia (23 cases, 24.0%). Other manifestations included: epistaxis, facial pain, otologic symptom, visual problem and toothache in 8 (8.3%), 8 (8.3%), 4(4.2%), 3(3.1%) and 3(3.1%), respectively.

The radiological findings of some patients have been demonstrated in figures 3 through 5.
Figure 1: Bar chart showing the frequency distribution of patients with unilateral nasal disease according to etiology.

Figure 2: Bar chart showing the frequency distribution of patients with unilateral nasal disease according to clinical features.
Figure 3: Computed tomogram findings in a patient with unilateral chronic rhinosinusitis

Figure 4: Computed tomogram findings in a patient with unilateral nasal polyposis
Figure 5: Axial view patient with unilateral nasal disease

Figure 6: Computed tomogram findings in a patient with antrochoanal polyp
Discussion

One of the frequent presenting features of patients visiting ENT units is the complaint of unilateral nasal problems. Indeed, it is a challenging presentation to the ENT specialist because of the high possibility of a neoplastic disorder to be seen in association with unilateral nasal presentation than with bilateral nasal presentation; however, overall, the proportion of neoplastic disorders is low in either presentation 11,12.

In the current study, which has extended for more than 3 years, we were able to categorize 96 patients with unilateral nasal disease. The most frequent pathologies were nasal polyposis, chronic rhinosinusitis without polyp, antrochoanal polyp and inverted papilloma. In order to accomplish this mission, we followed the rule of comprehensive clinical evaluations of patient’s age, presenting clinical features, examination using nasoendoscopy, and radiological investigations, computed tomography (CT) in particular. In accordance with current study findings, it has been stated that the majority of pathologies in the sinonasal region are reactive inflammatory disorders and that the minority of them are neoplastic disorders 12.

The problem with neoplastic malignant sinonasal pathologies is that they mimic inflammatory disorders in their early stages, so that the diagnosis of these disorders is often made late. Delay in the diagnosis of such malignant disorders is usually accompanied by poor prognosis; therefore, meticulous evaluation of unilateral nasal presentations is of prime importance to exclude malignant neoplastic disorders 1.

With respect to age, benign neoplasms are often seen in children and young adults (1). The average age at time of detecting unilateral choanal polyps is around 27 (13). Fifth to 7th decade is the usual time for detecting neoplastic disorders in patients with sinonasal disorder with a male predominance and low socioeconomic status 14. Indeed, one of principal observations in the current study was that males were more often affected by neoplastic disorders than women and that inflammatory conditions were mainly seen in younger patients.

A variety of clinical manifestations are associated with unilateral nasal lesions, such as nasal discharge, nasal obstruction, anosmia, headache and epistaxis. In the current study the major presenting symptoms in order of frequency were nasal obstruction which was seen in 81 cases (84.4%), followed by rhinorrhea (69 cases, 71.9%), then postnasal drip (33 cases, 34.4%) and anosmia (23 cases, 24.0%). These findings are approximately the same as the findings of previous authors 1.

Facial pain, dental complaint and visual and otologic manifestation have also been seen in our study in accordance with previous observations made by several authors 14.

Comprehensive understanding of intranasal structure and characterization of intranasal pathologies have been made easy and amenable following the introduction of nasal endoscope 1. Therefore, in the current study, the use of nasal endoscope provided both diagnostic and therapeutic tool since a number of conditions were treated by total excision of nasal pathology. The nasal mass lesions may be seen as single of multiple masses, sessile or pedunculated polyps.

Inflammatory conditions like acute and chronic CRS, either from bacterial or fungal origin were the commonest histopathological diagnosis in our study. Inflammation was the commonest form of nasal pathology in the current study and this is in accordance with previous reports 1. In our study, the commonest benign neoplasm was inverted papilloma (11.5%) and this finding is supported by previous similar findings 1,15. On the other hand, the most common malignant neoplasm in our study was squamous cell carcinoma which is the same observation as the observation of some previous authors 1,16. In our study, a single case of Non-Hodgkin lymphoma was identified. Previous studies have also documented the rarity of Non-Hodgkin lymphoma in this clinical setting 1,17.

Conclusion

Differentiating the neoplastic nature form non-neoplastic nature of unilateral nasal pathology is the most critical management step and in the current study, nasal polyposis was the commonest cause of unilateral sinonasal disease followed by chronic rhinosinusitis without polyp, antrochoanal polyp and inverted papilloma. The rate of neoplastic malignant conditions was low.

Acknowledgement: We would like to express our deep thanks to all patients who participated in the current study to be a baseline report about the anatomical and the pathological presentation of unilateral sinonasal disease in Iraq.
Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the Department of Surgery and all experiments were carried out in accordance with approved guidelines.

The Effect of Special Exercises to Develop Some Physical and Skill Capabilities Using Basketball Auxiliary Materials (3 vs 3) for Youth Players

Zaid Mohammed Jabbar¹, Mohammed Jabbar Monadi²

¹The General Directorate of DhiQar Education/Al-Islah Department, ²The General Directorate of DhiQar Education/Technical Supervisor/Department of Sports and School Activity

Abstract
For weight lifting exercises, these exercises work to develop (the explosive strength of the arms) and (the force characterized by speed, and the bearing strength of the two legs) as well as developing the skill of shooting by jumping with two point and through the researcher’s follow-up to the matches, he found that many young players lose a lot of physical and skill capabilities with the passage of time, especially in the last minutes of the game. Due to the lack of interest in some requirements of the training process, including (the explosive strength of the arms) and (the force distinguished by the speed and the bearing strength of the two legs) in addition to the skill capabilities chosen in the research as well as the small number of training units, which leads to inconsistency with the requirements and training of physical and skill performance and the type of muscular work to perform. Hence, the research problem crystallized, as the researcher decided to study this topic and prepare special exercises to develop some physical and skill capabilities using auxiliary tools to develop and their impact on the performance of two-point hopping by basketball players for (3 vs 3) for youth.

Keywords: Special Exercises, Physical, Skill Capabilities, Basketball.

Introduction
Sports training based on scientific principles is one of the most important factors that enable us to reach the highest level of sports that can be reached, and special exercises are one of the method of sports training that aims to raise the efficiency of players in terms of physical and skill, and from here comes the role of auxiliary tools that have The biggest impact and the basis in training various sports, including the basketball game for (3 vs 3), as we note that the various sports departments and coaches around the world are looking for everything new in order to contribute to developing the level of performance of players and improve their results, which affects and positively in the development of capabilities Players physically and skillfully. The basketball game for (3 vs 3) is one of the games that were recently developed and started to spread in various countries, including our dear country, Iraq. This game has many characteristics that differ from the usual basketball, as it is practiced in half of a stadium measuring (11 m × 15 m) With a time of (10) minutes for the match, the team that scores (21) points ends the match in its favor even if it is before the specified time, and the attack time will be (12) seconds, and this requires a special physical preparation to help the players to continue with physical and skill performance and at the same level.

Among the most important physical abilities in the basketball game for (3 vs 3) are (the explosive strength of the arms) and (the force characterized by speed, and the bearing of force for the two men) As for the skill that is more important is aiming to jump with two points, that training the physical abilities of the basketball game for (3 vs 3) in ages (under 18 years) for young players is one of the essential things in order to build a training base to supplement the national teams, as it represents a stage of preparation in advance for clubs and teams players, using tools and scientific method to achieve better results for them in the future. Hence the importance lies in preparing special exercises to develop skillful physical abilities by using the auxiliary tools, as
these tools have become used by the world as an integral component of weight training and these exercises work to develop (the explosive strength of the arms) and (the force characterized by speed, and the bearing of force for the two men) as well as the development of Shooting skill by jumping with two points⁴.

**Sample homogeneity and sample equivalence:**

**Sample Homogeneity:** The researcher conducted the homogeneity of the sample members, and the researcher used the coefficient of variation and conducted the homogeneity in each of the length, weight, age, training age, and table (1) shows that.

---

**Method**

1. Arab and foreign sources.
2. World Wide Web (Internet).
3. Observation and experimentation.
4. Personal interviews.
5. The assistant team.

**Devices and auxiliary tools used in the research:**

- A device for measuring weight (country of origin, China), count (1).
- A laptop computer (hp - pavilion g6/elite book) (country of origin, America), count (1).
- Canon type digital camera (country of origin, Japan), count (2).
- Stopwatch type (Omega) and (Han Hart) (country of origin, China) count. (2).
- Legal Basket Balls (Molten) Number (10).
- A medical ball weighing 3 kg, count (1).
- Whistle (molten), count (2).
- Chairs, number (4).
- Leather tape measure length (20 m), count (1)
- 4 colored adhesive tape.
- Signs of (10) height (30) cm
- Cones of different heights, number (10).
- Recording papers and pens.
- Half a legal basketball court.
- Ground stairs (1).
- Lean handles.
- Different tensile elastic cords (country of origin Germany - manufacturer/acreative).
- Jumping ropes (country of origin Germany - manufacturer/acreative) count (4).

**Determining the physical and skill capabilities of basketball for (3 vs 3) and its tests:** After reviewing the available scientific sources that are appropriate to the subject of the study and through conducting personal interviews with trainers with expertise and specialization, as well as the researcher relying on his personal experience, physical and skill capabilities were identified where physical capabilities were chosen and
they are both (the explosive capacity of the arms and the strength marked by speed And bear the strength for the two men) As for the skillful abilities, the skill of shooting was chosen by jumping by two points and peaceful aiming.

Determining the tests for basketball’s physical aptitude for (3 vs 3): The test is (a set of exercises given to the individual with the aim of identifying his abilities and aptitudes or qualifications, by examining the researcher on a set of scientific sources as well as conducting personal interviews with coaches and those with experience and specialization in the field of sports training as well as benefiting from the researcher’s modest experience as a player in the league Excellent Iraqi basketball as well as his participation in (3 vs 3) tournaments held by the Iraqi Central Basketball Federation in previous years, a group of physical and skill tests were chosen that are appropriate to the nature of the research.

Describing physical and skills tests:

Describing physical ability tests:

**First : Arms explosive power test:** Throwing a medical ball weighing (3) kg with two hands from a sitting position on the chair.

**The purpose of the test:** To measure the explosive power of the arms of the arms.

**Instruments used:** A medical ball weighing (3) kg, a tape measure and a chair with a secured torso strap.

**Method of performance:** The laboratory sits on the chair and the medical ball is held in hands with hands so that the ball is higher and behind the head.

**Conditions:** The laboratory is granted three consecutive attempts, and the laboratory must be allowed to perform a number of throws for the purpose of warming up before performance. When the laboratory moves during the performance of one of the attempts on the chair, the result is not counted and another attempt is given instead.

**Recording:** The distance between the front edge of the chair and the nearest point the ball places on the ground is calculated. The result of the best attempt is calculated from the three attempts.

**Second: Strength test for the two legs speed:**

**Name of the test:** The forward jump test for the two legs during (10 seconds).

**The purpose of the test:** To measure the characteristic velocity of the muscles of the legs.

**Tools:** Flat space floor space, tape measure, stopwatch, whistle, chalk or marker

**Method of performance:** The laboratory stands on the starting line and when you hear the start beep and start the operation of the stopwatch, the laboratory launches with the maximum speed forward in front of the two legs from the moment of the first whistle until the timing reaches (10 seconds) and the distance traveled by the player during the test time is calculated.

**Recording:** The distance traveled is measured in meters and its parts during time (10 seconds).

**Third: strength tolerance test:**

**Test name:** Endure the strength of the two legs.

**The purpose of the test:** To measure the strength of the two men.

**Tools:** Flat ground or legal basketball court, person with height (30) cm.

**How to play:** Upon hearing the beep, the player starts jumping from the stake of the two sides (right and left) for a period of (30) seconds.

**Recording method:** Calculates the maximum number of jumps for a player within (30) seconds.

**Exploratory Experience:** The exploratory experience is a practical training for the researcher to determine the negatives and positives that the researcher meets during the test to avoid them, and this is why the researcher conducted his exploratory experience on a sample of (8) players from the young players of Al-Furat Sports Club in basketball and with the help of the team after explaining the tests For them and how to register, the experiment was carried out on (1/8/2019) on (Thursday), at exactly (4/PM) and continued for one day divided between physical and skill tests, so it was:

1. Knowing the difficulties and problems that the researcher faces during taking the tests.
2. Knowing the time taken for each user test.
3. Ensure that the auxiliary team understands the vocabulary and how efficient it is in applying it.
4. Find the scientific conditions and transactions for the tests (validity, reliability, objectivity).
5. The appropriateness of the tools and devices used in the test.
6. Knowing the difficulties and problems facing the researcher during the application of special exercises.
7. Knowing the time taken to perform exercises.

The scientific foundations of the test: The researcher has taken into account the scientific conditions that must be met for the selected tests within the study, and mentions QaisNaji and Bastawisi Ahmed (1987) (The most important characteristics of a good test, as well as measurement, are the test of validity, reliability, and objectivity factors for that test or measurement).

Honesty: There are several methods for measuring the honesty of the tests, including (apparent honesty). The apparent honesty means that “the test appears to be true in its apparent form because its name relates to the function to be measured. The apparent honesty can be relied upon in the validity of the test and its sincerity, which is the method the researcher used to find the truthfulness of the tests.

Stability: “The concept of persistence is the degree of confidence, i.e. the result of the test with a constant value during repetition or repetition, i.e. the meaning of persistence of the results obtained by the researcher if the experiment was repeated on the same group. A week has passed since physical tests were repeated on 7/8/2019 on Wednesday, and the researcher used the Law of Correlation Coefficient (Pearson), to extract the coefficient of persistence, and physical and skill tests had a high degree of stability.

Objectivity: The method for calculating the scores in the tests used in the research was determined by time or number and is objective in itself.

Research Procedures: The researcher has determined all the requirements of the main experiment through identifying physical and skill tests using the auxiliary tools, and after conducting the exploratory experiment and benefiting from them in organizing work and preparing for the main experiment, the researcher has conducted a pre-training unit for the individuals of the main experiment sample in order to familiarize the sample members with the nature of the exercises To be trained on.

Pre-test: After providing all the necessary conditions and requirements for the tests, the researcher conducted the tribal tests on (8/8/2019) on Thursday, where the researcher conducted the tests for physical and skill capabilities.

2-11 Exercises:

First-Goals: The researcher prepared exercises aimed at developing (the explosive ability of the arms) and (the force characterized by speed and endurance of strength) for the two men. The exercises also aimed at developing both skills of two-point jumping and peaceful shooting, using the auxiliary tools, for young players in basketball.

Second- Standards:

Test the content of the proposed training curriculum

A- To contribute to achieving the goals of the special preparation stage (physical and skill) for young players (Al-Nassiriya Sports Club in basketball).

B- The contents of the curriculum should be consistent with the physical and skill characteristics of the players.

C - The curriculum was applied by extracting the average tension of all exercises used in the curriculum.

D - to take into account what means and capabilities affect when implementing.

E - Diversity in the contents of the curriculum and flexibility in implementation, which makes the effect of the curriculum clear on implementation.

F- The auxiliary tools used in the research should fit the capabilities of young players to use and interact with these tools.

Third - Training Method: The researcher used the exercises with the method of high intensity young training.

Dimensional tests: After completing the application of the exercises used in the research to the main research sample, the post-tests were conducted on the experimental and control group, taking into account
"in all the circumstances, the method of implementation and the tools used, since the post-tests were done on (9/10/2019) on (Wednesday) the researcher by conducting physical and skill tests.

Statistical Means: The researcher used the necessary statistical means to treat the results in a way that serves the research goals and relying on the SPSS-24 statistical bag, which is:

1. Arithmetic mean
2. Standard deviation.
3. Percentage.
4. (T) for the specimen samples.
5. Persson coefficient of stability.

Circles and standard deviations and value (T) calculated and the significance level and type of significance of the physical capacities and skill shooting by jumping two points in the tribal and posttests of the experimental group, reaching the arithmetic mean of the ability of the explosive armrests in the pre-test (5.51) and standard deviation (In the post test, the mean was (6.16) and the standard deviation was (1.21). The calculated value of (T) was (2.301) and the significance level was (0.05). As for the type of significance, it was (moral). The tribal (18.28) and the standard deviation (6.37), and in the post-test the mean (31.05) and the standard deviation (2.41), while the calculated value of (T) was (3.421). As for the level of significance it reached (0.05) and the type of significance (moral), and the mean of bearing the strength of the two legsin the test (3.62) and the standard deviation (3.50), and in the post-test the mean (53.25) and the standard deviation (3.425) and the level of significance (0.05). The type of significance is (moral). The standard (1.29), the calculated value of (T) was (2.678), and the significance level was (0.05) and the type of significance (moral).

The researcher attributes the positive results to the control group as a result of the coach’s curriculum and their commitment to applying it during the daily training units and the results of physical and skill tests have shown that they have evolved and this confirms the correlation between physical capabilities and basic offensive skills in basketball. “The physical factor must include the strength of the player who helps him to Shooting with strength, agility and flexibility is the player who can take the right position when shooting. Through the foregoing, the researcher sees that the development of basic offensive skills in basketball comes as a result of the practice of regular and planned training correctly, which affected the physical capabilities of the research sample and consequently affected the basic offensive skills that developed well after the application of exercises and that had an effective impact in increasing The accuracy of performing basic offensive skills in basketball, and this is what (Mohammed Hassan Allawi, 1994) indicated that “physical preparation of strength, endurance and speed is considered the main pillar for raising the tactical level of players. The researcher agrees with (Qasim Hassan Hussein) that the training process is “the continuous organized process that gains the individual knowledge, skill, ability, ideas or opinions necessary to perform a specific work or achieve a specific goal as well as achieving organizational goals and adapting to work and what is offered to the individual from certain information, skills, or mental attitudes are necessary in the organizational viewpoint to achieve the organization’s goals”.

Conclusions

According to the research results, the researcher reached the following conclusions: The exercises prepared by the researcher have a positive and effective impact in developing physical abilities and two-point shooting skill by jumping in basketball for youth. As a result of the development of physical abilities, this was the reason for developing the skill of shooting with two points by jumping in basketball for youth.

1. The researcher recommends the use of exercises prepared by the researcher because of its positive impact on changing and developing some physical variables and the skill of aiming with two points in basketball.

2. The researcher recommends adopting the exercises that he prepared in the research to develop the physical capabilities that were chosen in the research.

3. Encouraging trainers to prepare special exercises to develop physical and skill capabilities.

4. Conducting research and studies on the numbers of special exercises for the category of applicants in the basketball game.

5. Carrying out similar studies and other sports activities.

Comparative Study of Small Dose Bupivacaine-fentanyl vs. Normal Dose of Bupivacaine in Spinal Anaesthesia for Patient Above 60 Years Old Undergoing Surgery

Thaer Ali Hussein Al Akam1, Emad Mohammad Hussein1

1FICMSA, Anaesthesiologist, Fellow of Iraqi Council of Medical Speciality, Aldewaniya Teaching Hospital, Iraq

Abstract

The purpose of the study was to compare small dose bupivacaine - fentanyl and normal dose of bupivacaine in spinal anaesthesia for patient above 60 years old undergoing femoral and tibial surgery. 80 elderly patients of either sex belonging to ASA I, II & III undergoing elective orthopedic lower limb surgeries under spinal anaesthesia were studied in this prospective, randomized double blinded study. First group A (n=40) was given inj. Bupivacaine hyperbaric 3 ml (15mg) & group B (n=40) was given inj. Bupivacaine (2 cc) + 25 mcg fentanyl. Parameters like time for adequate level of analgesia (T9), peak sensory level reached, beginning of motor block to recede to L3-L4 level (modified bromage scale), how long sensory block continue and number of complications are noted in both groups result: The time of adequate level of sensory block to be started (T9) was longer for group B than group A. How long of sensory block to be started was slightly more for group A. The time of motor block continue to work was more in A than group B. It is concluded that subarachnoid block with 2cc bupivacaine 0.5%H and 25mcgfentanyl is a more safer and better option for patient above 60 years of age undergoing femoral and tibial surgeries.

Keywords: Spinal anaesthesia, patient, bupivacaine-fentanyl, bupivacaine.

Introduction

Universally agreed that best type of anaesthesia for fracture fixation of tibia and femur surgery is subarachnoid block producing less post operative loss of memory and hallucination than general anaesthesia. However spinal block has got its own inherent complications, especially related to cardiovascular stability. Perioperative hypotension may affect postoperative recovery and also the large number of coronary disease, put patient at risk of ischemia secondary to hypotension. Vasopressor and IV fluids are used to treat or prevent hypotension. Another technique is by using very low titrated dose of local anaesthetic but it may not provide acceptable time for sufficient anaesthesia and better time for surgery. Studies have established that fentanyl and Marcaine anaesthetics administered together intrathecally have very strong synergistic analgesic effect, enhancing spinal blockade without affect the degree of sympathetic blockade ensuring better hemodynamic stability. The purpose of this study was to COMPARE hemodynamic and sensory effect of small dose bupivacaine - fentanyl in regional anaesthesia versus ordinary dose of bupivacaine in patients undergoing surgical correction of lower limb tibial and femoral.

Materials and Method

After approval of institutional ethical committee and informed consent of ASA I, II & III with age > 50 years of both sexes undergoing elective lower limb orthopedic surgeries were included in this double blind randomized trial. Patients with history of allergy to local anaesthetics, severe cardiac or respiratory diseases and uncontrolled hypertension were excluded. After routine and special investigations (if required) are done, patients were randomly allocated to group A (Bupivacaine-15mg,3ml) & group B (Bupivacaine-10mg, 2ml + 25 mcg [1ml] fentanyl). Demographic data were comparable in age, height and duration of surgery (Table-1). Patients were fasted 8-10 hours and in operation theatre preloading with 8 ml/kg Ringer lactate done and standard monitors applied. From previous studies, low dose of bupivacaine and fentanyl was...
identified. Those studies are as below. Diana Fernander 2., Monterrat Rue et al (1996) 12.5 mg1. Plus saline or 25 mcg fentanyl. Ben David, frankel et al (2000) 4mg bupivaacaine plus 3.20 Mcg fentanyl4. Atallah et al (2006) .Under full sterilized and antiseptic precautions lumbar spinal Block was done in sitting position in L3-L4 space by 22 Quincke needle both group were given respective drugs and sensory level of T6- T8 was achieved . patients were given oxygen by ventimask of 4 L/MINUTES .pulse rate, blood pressure, spo2 were measured every 5 minutes for first 20 minutes and then every 10 minutes for next 1 hour and then every hour for the next 24 hours postoperatively hypotension was defined as SBP ≤ 90 or mean arterial BP30% lower than baseline decline of greater than 30% from normal mean arterial pres sure which must treated with an incremental IV bolus of phenylephrine 50 Mic, Bradycardia defined as Heart Rate below 60 BPM must treated with IV Atropine other parameter like time for adequate level of analgesia peak sensory level reached, Time for Motor block to recede To L3-L4 level, duration of sensory block(Table-2) and incidence of complications likeNausea, vomiting, pruritus, sedation, shivering were assessed and compared .Motor block was assessed using modified Bromage scale 0 no paresis – full movement of lower limb

1-- Partial paresis – flex knees and ankles

2-- Partial paresis – flex ankles .

3-- Full paresis – no movement

Sedation status was assessed using

0 –Awake and alert

1-- Respond to voice

2-- Respond to painful stimuli

3-- No response

Results

The study was done in double blinded, prospective randomized manner in 80 patients in al diwaniya teaching hospital and al furat private hospital scheduled to undergo elective orthopedic lower limb surgeries under spinal anaesthesia . the demographic data (age, weight , sex, and ASA grading) were comparable and statically non significant (table 1) ALL surgeries was lasted from 110 to 180 minutes equal distribution of mens and womens in both groups was done and most of them were ASA II – III students T-test was used f0r statistical Analysis .

- The BEGINNING of adequate level of sensory block (T9) was little late for group B (128 +/- 8 sec) than A (95 +/- 10 sec) and was statically significant (table 2)
- HOW long motor block was continued in group A1 (162 +/- 7 min) comparing to B2 (129 +/- 9) and was statistically significant.
- Lower pulse rate less drop in blood pressure was noted in group B2 than group A1, thus there is better haemodynamic stability in group B2
- Incidence of drop in BP and use of vas0press0rs WAS much larger in group A1 and was found to be statically significant
- Latency of sensory block was slightly more for group A1 but was not found to statically significant
- Boutes of bradycardia 0r pruritus was common in group B2.
- No one of the patients in both groups had regurgitation 0r vomiting 0r respiratory depression .
- Shivering was higher in group A
- RASS score was used to assess sedation intraoperative and postoperative. (rantigon agitated sedative score)

Discussion

Maintenance of body physiology as near normal as possible during anaesthesia is one of the primary goals of anaesthesiologist . Marked hemodynamic derangement are often seen following subarachnoid block especially in trauma and elderly patients. Neuraxial opoids are not associated with sympathetic nervous system denervation, muscle power weakness or loss of speech . they predominantly act at the MU receptor present in substantiagelatinosa of spinal cord to exert its synergistic effect more specifically for visceral pain. The recommended level of regional anaesthesia for lower limb surgery is T9 . standard recommended dose of 0.5% hyperbaric bupivacaine is 3cc (15 mg) In our present study, we have added 25 Mcg fentanyl, ahighly lipophilic opoid to lower doses of 0.5% bupivacaine hyperbaric and COMPARED hemodynamic parameters like blood pressure, heart rate changes, side effects of fentanyl and motor and sensory profiles of block.
In our study 16 patients of group A developed hypotension and needed vaspressors compared 4 patients of group B. These findings are in agreement with findings of Ben David et al (2000), Ben David, Frankel (2000), Matyr (2001). There were high increase in the beginning of adequate block in group B (128+/-/8.3 sec) as compared to group A (95+/-/10.3 sec). Addition of fentanyl reduces the pH of hyperbaric bupivacaine. This may be reason for delay in onset of adequate block (table 2). The total duration of sensory block for group A was 227.6 +/- 9.8 min while group B was 211.5 +/- 14.2 min. The difference between two groups was statically insignificant as per Boucher et al (2001) and Rajesh Mahayan V K Grover et al (2005) addition of fentanyl enhances duration of sensory block in which dose of Bupivacaine –H was same. But in our study dose of Bupivacaine in fentanyl group is much lower which can be the reason for slightly lower duration of sensory block.

MOTOR BLOCKED LAST LONGER in group A than group B and none of the patients required any supplementary anaesthetic interventions during surgery.

There was no incidence of sedation or respiratory depression in 2 groups. Fentanyl abolishes shivering by central mechanism in group B. Pruritus is most common side effect of intrathecal opioid in our study 4 among 40 in group B had pruritus which was treated by ondansetron. Nausea and regurgitation were not seen in any of these groups. Adjuvant drug like fentanyl reduces the pH of hyperbaric bupivacaine. It may be the reason for the delay in onset of adequate block.

Conclusion

From current study it was concluded that subarachnoid block with 2 cc bupivacaine 0.5% H and 25 Mcg fentanyl is more safer study, both in terms of maintaining hemodynamic stability and lower incidence of complications without compromising the surgical condition for patients undergoing femoral and tibial surgeries. B+F can be a safer alternative with conventional dose of bupivacaine, which can be reduced after adding Fentanyl in low dose bupivacaine, after completing this study, we will study for other doses.

Public International Law in the Situation of a Pandemic

Sarmad Amer Abbas
Assist. Prof. Dr., University of Babylon/Faculty of Law/Iraq

Abstract
In recent years, there have been considerable developments in international law with respect to the normative definition of the right to health, which includes both health care and healthy conditions. These norms offer a framework that shifts the analysis of issues such as disparities in treatment from questions of quality of care to matters of social justice. Building on work in social epidemiology, a rights paradigm explicitly links health with laws, policies, and practices that sustain a functional democracy and focuses on accountability.

Keywords: Public international, situation, pandemic.

Introduction
International health law, or what is now also called global health law, is a relatively new academic field. In its broadest definition, it includes all international legal regimes relevant to public health—international environmental law, international humanitarian and human rights law, international trade and labor law, international laws relating to arms control, and so on. Construed more narrowly, it incorporates only those international legal regimes specifically designed to address health threats. The two most notable examples are the International Health Regulations (focused on infectious diseases) and the World Health Organization’s Framework Convention on Tobacco Control (FCTC) (focused on chronic diseases). There is an important distinction between international health law and global health law. International health law connotes a more traditional approach derived from rules governing relations among nation-states. Global health law, on the other hand, is developing an international structure based on the world as a community, not just a collection of nation-states. This structure is inclusive of individuals and nongovernmental organizations, especially where health problems are seen as truly global. Globalization has heightened the need for worldwide public health cooperation. International health law developed originally in the mid-nineteenth century to control infectious diseases and has transformed over time to include multiple norms and standards and to become a significant component of foreign policy. Amidst these changes, however, a lack of normative theory has left the field without a basis for justice or common ground on the ethics and governance of threats to global health. Moreover, research to date has neglected normative problems, as well as the role of global health justice in addressing such problems, especially in establishing moral norms that guide the roles of international and domestic law as tools of public health.

WHO law for international regulation of international epidemics: A central and historic responsibility for the World Health Organization (WHO) has been the management of the global regime for the control of the international spread of disease. Under Articles 21(a) and 22, the Constitution of WHO confers upon the World Health Assembly the authority to adopt regulations “designed to prevent the international spread of disease” which, after adoption by the Health Assembly, enter into force for all WHO Member States that do not affirmatively opt out of them within a specified time period. In consideration of the growth in international travel and trade, and the emergence or re-emergence of international disease threats and other public health risks, the Forty-eighth World Health Assembly in 1995 called for a substantial revision of the Regulations adopted in 1969. In resolution WHA48.7, the Health Assembly requested the Director-General to take steps to prepare their revision, urging broad participation and cooperation in the process. After extensive preliminary work on the revision by WHO’s Secretariat in close consultation with WHO Member States, international organizations and other relevant partners, and the momentum created by the emergence...
of severe acute respiratory syndrome (the first global public health emergency of the 21st century), the Health Assembly established an Intergovernmental Working Group in 2003 open to all Member States to review and recommend a draft revision of the Regulations to the Health Assembly. The IHR (2005) were adopted by the Fifty-eighth World Health Assembly on 23 May 2005. They entered into force on 15 June 2007.

**International Health Regulations (IHR):** The International Health Regulations (IHR 1969), replaced by IHR 2005 had been adopted by the World Health Assembly on 23 May 2005 and came into force on 15 June 2007. IHR 2005 are a legally binding agreement among World Health Organization (WHO) member states and other states that have agreed to be bound by them. New revision was necessitated by concerns about increasing global health threats and the need to respond with more effective surveillance and control practices.

The limitations of IHR 1969, which led to their revision, related to their narrow scope, their dependence on official country notifications, and their lack of a formal internationally coordinated mechanism to contain international disease spread. The IHR 2005, which is firmly based on practical experiences, has broadened the scope of IHR 1969 to cover existing, new and re-emerging diseases, including emergencies caused by non-infectious disease agents.

The purpose and scope of the IHR (2005) are “to prevent, protect against, control and provide a public health response to the international spread of disease in ways that are commensurate with and restricted to public health risks, and which avoid unnecessary interference with international traffic and trade.” The IHR (2005) contain a range of innovations, including: (a) a scope not limited to any specific disease or manner of transmission, but covering “illness or medical condition, irrespective of origin or source, that presents or could present significant harm to humans”; (b) State Party obligations to develop certain minimum core public health capacities; (c) obligations on States Parties to notify WHO of events that may constitute a public health emergency of international concern according to defined criteria; (d) provisions authorizing WHO to take into consideration unofficial reports of public health events and to obtain verification from States Parties concerning such events; (e) procedures for the determination by the Director-General of a “public health emergency of international concern” and issuance of corresponding temporary recommendations, after taking into account the views of an Emergency Committee; (f) protection of the human rights of persons and travellers; and (g) the establishment of National IHR Focal Points and WHO IHR Contact Points for urgent communications between States Parties and WHO.

This approach has roots in Aristotle’s political theory and Amartya Sen’s capability approach, but it moves extensively beyond and considerably extends this work for national and global health purposes. From this perspective, health is intrinsically and instrumentally valuable; all individuals should have equal capability to be healthy. It takes the individual as the central moral unit of justice.

Under this approach, if we value, intrinsically and instrumentally, individuals’ capabilities to be healthy, we regard deprivations of health capabilities as inequalities in individuals’ capabilities to function. Decrements in a person’s health constitute direct threats to his or her well-being and agency. Health capabilities are therefore prerequisites to other capabilities, and their moral importance calls for a sense of urgency. From this perspective, a global society and its constituent nation-states must address global health inequalities and global threats to human health. Primary moral responsibility falls on nation-states, within which health inequalities and the sources of health threats lie.

Achieving global health equity requires global law and policy to strengthen the capacities and wills of domestic institutions, laws, and policies to address health issues within their countries; the future of global health law cannot be examined or understood as separate from domestic health law and policy. Global health law and policy also have key roles in the development and internalization of public moral norms to create and sustain health institutions, policies, and laws in the long term.

**Full compliance with international health regulations:** The International Health Regulations, the principle document governing the response to public health emergencies that pose an international threat, were revised in 2005 and became binding international law on June 15, 2007. These new regulations, unanimously approved by the World Health Assembly, differ in important ways from previous versions and represent a major step forward in protecting global public health security. Despite their importance, countries will face several challenges to implementing the regulations.
Many developing countries lack the capacity to detect and respond to public health emergencies, and developed countries may choose to act unilaterally. Decentralized states such as Canada will also face specific challenges to implementation. In May 2008, the Auditor General of Canada issued a report highlighting areas in which Canada has had difficulty complying with the new regulations.

The goal of the revised International Health Regulations are to protect against the international spread of epidemics and other public health emergencies without unnecessary interference with international travel and trade. To achieve this objective, the regulations provide new guidance to member states on several matters. The fundamental premise of the regulations is that preparation and early detection and response are essential to protect against global health emergencies. The regulations therefore require member states to assess their core capacity for effective public health surveillance and response within 2 years and meet requirements for core capacity within the subsequent 3 years.

The revised International Health Regulations have been criticized for subordinating health concerns to security and economic concerns. They have also been described as overemphasizing surveillance not placing enough emphasis on assistance for developing countries and lacking a legal mechanism to ensure compliance.

Despite these criticisms, the new regulations were unanimously approved by the WHO member states. All member states are bound by their requirements unless they specifically objected to them by the end of 2007. As of February 2008, no member states had rejected the regulations, 188 had designated National Focal Points, 76 had already conducted an assessment of their national core capacities, and 50 had nominated individuals to the International Health Regulations Roster of Experts. A number of countries, including Australia, Syria, Finland, Sweden, Columbia, France, Georgia and Germany, have already recognized the regulations as domestic law or have incorporated elements of the agreement into their national health legislation. A number of other countries, including Argentina, Spain, Brazil, South Africa and the European Community, have passed administrative regulations that cite the new International Health Regulations. Still other countries, including the United Kingdom are considering “all-hazards” approaches to the reform of their public health legislation. In spite of these efforts and the recognition of the importance of the regulations, several factors may prevent full national compliance. This is particularly true when compliance may leave countries, or regions within countries, vulnerable. Nevertheless, Under international law, there is a right not merely to health care but to the much broader concept of health. Because rights must be realized inherently within the social sphere, this formulation immediately suggests that determinants of health and ill health are not purely biological or “natural” but are also factors of societal relations. Thus, a rights perspective is entirely compatible with work in epidemiology that has established social determinants as fundamental causes of disease. The first notion of a right to health under international law is found in the 1948 Universal Declaration of Human Rights (hereafter called Declaration), which was unanimously proclaimed by the UN General Assembly as a common standard for all humanity. The Declaration sets forth the right to a “standard of living adequate for the health and well-being of himself and his family, including . . . medical care and . . . the right to security in the event of . . . sickness, disability . . . or other lack of livelihood in circumstances beyond his control. The Declaration does not define the components of a right to health; however, they both include and transcend medical care.

The language of progressive realization and maximal available resources, which suggests different standards for different countries, does not easily jibe with the absoluteness with which people in the world generally think about rights. Yet in practice, due process and other civil rights may vary just as much. Indeed, the egregious disparities among countries, suggest not the irrelevance of defining a right to health but rather the need to situate state obligations within a global political economy in which international institutions and third-party states often exercise inordinate influence over developing countries’ economies and policies. The right to health demands, as do all human rights, “international assistance and cooperation.

The reference to a “highest attainable standard” of health, taken from the World Health Organization constitution builds in a reasonableness standard. That is, the state has a role to play in leveling the social playing field with respect to health; however, there are factors that are beyond the state’s control. Furthermore, the highest attainable standard will necessarily evolve over time, in response to medical inventions, as well as demographic, epidemiological, and economic shifts.
In addition to the ICESCR, a wide array of international and regional treaties recognizes health as a rights issue, and these reflect a broad consensus on the content of the norms. A review of the international instruments and interpretive documents makes it clear that the right to health as it is enshrined in international law extends well beyond health care to include basic preconditions for health, such as potable water and adequate sanitation and nutrition.

Realization of the right to health further implies providing individuals and communities with an authentic voice in decisions defining, determining, and affecting their well-being. Public health has a long tradition of recognizing that participation is integral to health promotion. Further, analyses of the importance of structural determinants of health and political economic context are increasingly common. Framing health as a right adds to the growing literature in social epidemiology that links health with social justice; it does this by first making explicit the link between health and the construction of a functional democracy. That is, health-related resource distribution, evidence of discrimination and disparities, and the like are analyzed not just in terms of their impact on health status but also their relation to laws, policies, and practices that limit popular participation in decision-making and, in turn, the establishment of a genuinely democratic society.

Failure to respect, protect, or fulfill responsibilities relating to health are construed not only in terms of ensuing social or economic problems, but also explicitly in terms of the accountability of the state and, to a certain extent, other actors, under national and international law. Thus, a human rights framework simultaneously acknowledges health as inherently political—intimately bound up with social context, ideologies, and power structures—and removes health policy decisions from being matters of pure political discretion by placing them squarely into the domain of law.

Conclusions

This Essay has argued that the global community has an ethical and moral responsibility to take positive actions to achieve health equity and should do so through global and domestic tools in law, policy, and institutions. It has presented a set of normative principles—moral foundations—for global health law as guidance on critical health issues. It has argued that, while legal principles have existed over the past several centuries, a coherent set of normative principles, grounded in moral theory, has been lacking. This approach does not argue that the global community has an enforceable (coercible) legal duty. Rather, it envisions global health law embedded in a framework of global health governance, whose purpose is realizing global health equity. It achieves its purpose through the voluntary internalization of the public moral norm of health equity and through subsequent domestic law and policy development and implementation.

Public health officials have recognized the importance of collective action to manage international health emergencies. If countries fail to act, or act independently, it will result in a less than optimal response that will increase the harms to their citizens and disrupt the global economy. Compliance with the revised International Health Regulations is a critical step toward preventing this from happening. Canada, a key advocate for the regulations, should lead the way both by demonstrating its own compliance with the regulations and by championing their implementation in all countries.

Antioxidant Activity of Spirulina Powder in Male Rate with Adenine–Induced Chronic Renal Failure

Waleed Khaled Yonis¹, Ayyed Hameed Hassan²

¹M.Sc. Student, ²Prof. Dr., College of Veterinary Medicine, University of Karbala, Karbala, Iraq

Abstract

The present study aimed to evaluate the role of spirulina in reducing the ability of adenine-induced renal failure and its complications in male rats. Twenty-four adult male rats used in the present study and divided into four groups, first group considered as control group, the second group received adenine (100 mg/kg) intraperitoneal, while the third group received mixed with feed and adenine (100 mg/kg) intraperitoneal combined with spirulina powder (750 mg/kg) and the fourth group received just spirulina powder (750 mg/kg) also with feed. The result showed a decrease in homeostasis for (KIM-1, Urea, and Creatinine), lipid profile function test for (cholesterol, triglyceride, LDL and HDL). Parameter of antioxidant concentration for (SOD, GSH, MAD, and NO). In the present study when treated by adenine group that showed increases in KIM, Urea, and Creatinine. The lipid profile results showed a significant increase (p≤0.05) in Cholesterol, TG, and LDL in the second group which administrated adenine while HDL was decreased in the same group. The results showed a significant decrease (p≤0.05) in the GSH, SOD, and increase in the MAD and NO in the second group. Spirulina powder showed significant enhancement in the most of parameters which studied to return near to the control group.

Keywords: Spirulina, Antioxidant, adenine–induced chronic renal failure.

Introduction

Kidneys are efficient organs that represent the main control system to maintain homeostasis of the body. They are affected by various chemicals and drugs that may affect the functions.

Kidney disease is one of the reasons that lead to the reduction quality of individual life in today's years. The kidneys of human are mainly participatory in liquidation and concentrating various materials and chemical factors that may reach a rise concentration and turn into toxic. Renal failure (RF) is considered pathologically deadly because of serious hormonal and metabolic disturbances. Whereas some models of animal renal failure are used to evaluate the pathogenic damage of organs pathogenesis. Chronic renal failure (CRF) results from irreversible and progressive damage of wide numbers of functioning nephrons. Renal toxicities, glomerulonephritis, and diabetic nephropathy may promote oxidative conditions, increase susceptibility of acute renal failure. The free radicals are one of the causes that lead to kidney failure. Oxidative stress is known as a main pathological process in renal failure which activates various pro-inflammatory cytokines and growth factors, finally leads to glomerulosclerosis, tubule-interstitial fibrosis, tubular cells apoptosis and senescence, as well as deactivated cellular regenerative pathways. Spirulina are indicated to filamentous free-floating microalgae with spiral characteristics of its filaments. It is officially called Arthrosporia sp powderspirulina have anti-oxidant properties and scavenge the free radicals' due to that effect in hepatic and renal failure induced rats.

Material and Method

Experimental Design: Using Healthy adult 24 male rats (11-12 weeks old, weighting initially 150-200 gm, divided equally and randomly in to four groups.
The first group (control negative) animal of this group will receive normal saline orally and the second group (control positive) rats in this group will be treated with spirulina (750 mg/kg) orally for 30 days and the third group animal of this group will gavage with adenine orally (100mg/kg) for 30 days to induce renal failure and the fourth group animal of this group will co-administrated adenine (100mg/kg) intraperitoneal and spirulina powder (750 mg/kg) orally for 30 days. After 30 days of experiment animals will be anesthetized and blood will be collected via cardiac puncture then after animal will be sacrificed to isolate liver and kidney in order to measure.

Parameter of study was:

Kidney function measured of (KIM-1, Urea and creatinine) according to manufacture (south Korea).

Lipid profile measured of (Cholesterol, TG, LDL and HDL) according to Fasce, 1982.

Liver function parameter of (AST and ALT) is determined by using a special kit (SPECTRUM AST – kit, Egypt- IFUFCC22 and SPECTRUM ALT – kit, Egypt- IFUFCC25).

Antioxidant of parameter (MAD, GSH, SOD and NO) the (MAD) was done according to 9, while parameter done by 8, the parameter done according to 10 and the (SOD) parameter. The procedure was done according to the instructions of the manufacture of ELIZA Kit -Elabscience biotechnology/china.

Result and Discussion

The data was statically analyses by using SPSS program by use one way ANOVA and differences between mean were compared with the least significant difference (LSD).

N = 6 significant different between tow groups noted by letters (P≤ 0, 0 5)

A transmembrane protein with 90-kDa molecular weight called Kidney Injury Molecule_1 KIM-1. is over expressed found in proximal tubules of rat and has an important role in repair epithelial layer of renal tubule in rat kidney with ischemic injury. KIM-1 considered a remarkable biomarker for acute renal tubular kidney damage. The existing study accept with other previous studies. Aguiar et al.,(2015) found rise of kimi-1 concentration, in induction chronic renal failure in male rats, also, who reported elevation KIM-1 in patients with CRF in humans by comparison with control groups On the other hand, co-administration of spirulina powder with adenine in the present study causes a significant enhancement of the renal function indicators. Our results in coordinate with that reported by Gargouri et al., (2018) who found that spirulina protects neonate rat from leads-induced nephrotoxicity via its antioxidant properties. This enhancement in KIM, urea and creatinine Might be attributed to ability of phycocyanin (a biliproteins pigment found in spirulina components) to the accelerated regeneration of tubular malfunction that caused by adenine or due to a diuretic activity of the phycocyanin. In addition, Abdel-Daim (2014) reported that the presence potassium in alga which in turn possess a diuretic effect. beside, spirulina alga rich in flavonoids that can demonstrate the increase of diuresis because flavonoids cause polyuria.

N=6 Significant different between two groups noted by letters (P≤ 0.05)

Analysis of variance in the found study revealed significant increase in Cholesterol, TG and LDL level in the group of male rats injected intraperitoneally with adenine in comparison with control and other treated groups and our results in agreement with that reported by Ghelani et al., (2019)25. Elevation of LDL in serum of rat with adenine induced chronic renal failure, may be resulted from the downregulation of LDL receptors in responses to chronic renal failure26.

According total cholesterol increment in the present study could be occur as a result of the acceleration biosynthesis of cholesterol throughout the regulation of enzyme called HMG-CoA reductase 28 other explanation to rise cholesterol levels is due to a relative decrease of elimination of cholesterol via liver due to down-regulation of enzyme called cholesterol 7 α-hydroxylase (CYP7A1) in animals undergoing chronic kidney disease 30.

Elevation triglyceride in the blood of chronic kidney disease patients are most common among lipid abnormalities31-33. In addition, expression and activity of hepatic lipase protein is also reduced in rats with chronic kidney disease34. Treatment with spirulina along that showed decreases significantly in serum of LDL,Cholest and Trigly when comparative with group adenine . The HDL level significantly increase when comparative with group adenine .in this study reported with other study(Bhat et al.,2020). The hypo-lipaemic ability of spirulina was also reported in mice with alloxan-induced diabetes represented by reduce triacylglycerol and LDL as well as increase in HDL levels 37. The enhancement of lipid profile could be occurs secondarily to activation of AMP-activated protein kinase signaling pathway which lead to downregulates the gene expression that involved in synthesis of lipid such as 3-hydroxy-3-methyl glutaryl coenzyme A reductase, Sterol regulatory transcription element binding factor-1c, and acetyl Coa carboxylase 35. Moreover, spirulina has ability to change alter microbiota of gut to lowering effects of lipid via increase count. Studies have revealed an increase in abundance of Prevotella, which in turn increases metabolism of bile leading to reduce lipid levels in the blood. Formicates are another group of bacteria which have ability to reduce serum LDL concentrations, which improved with spirulina supplementation.

Abstract

Psychosocial issues are an understudied yet important concern in the overall health of hemodialysis (HD) patients. Stress is a concomitant of chronic illness and its treatment, and may have meaningful influences on psychological and medical outcomes.

A descriptive study was carried out to determine Psychosocial Disturbance among hemodialysis patients with chronic hepatitis virus infection. A non-probability of (60) hemodialysis patients with chronic hepatitis B and C virus. Reliability of the questionnaire form was determined through a pilot study while the content validity of the questionnaire was determined through a panel of experts. And then the Data were collected through the use of the observational tool (questionnaire), which was analyzed through the use of three statistical approaches. They are descriptive statistical analysis (frequencies, percentage, S.D, range of scores, mean of scores and relative sufficiency; inferential statistical analysis (correlation coefficient and chi-square test); and analysis of variance (ANOVA). The study indicates that the Psychosocial domain has the effect due to hemodialysis with chronic viral hepatitis. The study indicated that the negative correlation between the socio-demographic and Psychosocial, except income, socioeconomic status at the social is relations/support domain. On the basis of the results of the study, the researcher recommends to sharing the health cover given and family members to provide psychological support for hemodialysis patients with chronic viral hepatitis accept their condition that maintain peaceful live.

Keywords: Psychosocial, Hemodialysis Patients, Patients, Chronic Hepatitis.

Introduction

Hemodialysis patients have lower immune responses and are at a higher risk for infections viral hepatitis continues to be a potential serious ailment among hemodialysis patients both chronic hepatitis B and C have been implicated to be the main causes of viral hepatitis among hemodialysis patients¹. Hemodialysis patients experience various problems that may adversely influence their quality of life. Hepatitis infection is also the most important problem in hemodialysis patients is that can affect their quality of life². This long survival with hepatitis leads to Disturbance of psychosocial patient even in the absence of clinically significant renal disease; in particular the impact of hepatitis seems to be most dramatic in social and physical function, general health and vitality, such as the effects of hepatitis on families, work environments, and on society as a whole³. Chronic hepatitis are often thought of as of the most severe types of injuries resulting in dramatic

change in all aspects of the individuals’ life and having significant impact on their family and friends. Also the loss of control over the body functions and altered life style secondary be caused by hepatitis, as evidenced by verbalization of inability to cope, expression of anger or other negative feelings. Chronic diseases are associated with several psychosocial problems including quality of life, depression, anxiety and other psychological disorders. The measurement of psychosocial for patient is concerned with quantifying the judgments people make to describe their experiences of health and illness.

Material and Method

Design of the Study: A descriptive quantitative design was carried out through the present study in order to achieve the early stated objectives during the period from 8th of January, 2019 to the 5th of July, 2019.

Setting of the Study: The study has been conducted on the hemodialysis patients with chronic viral hepatitis B and C at AL-Basra/AL-Basra Health Directorate/AL-Basra Teaching Hospital/Hemodialysis Unit, Thi-Qar/Thi-Qar Health Directorate/AL- Hussein Teaching Hospital/Hemodialysis Unit, Misan/Misan Health Directorate/AL- Sader Teaching Hospital/Hemodialysis Units, Al-Muthanah/Al-Muthanah Health Directorate/AL- Hussein Teaching Hospital/Hemodialysis Unit.

The Sample of the Study: A non-probability (purposive sample) of (60) hemodialysis patients with chronic hepatitis B and C virus.

The Study Instruments: for the purpose of the present study, a questionnaire was constructed by the researcher to study the variable for assessment Psychosocial Disturbance of Hemodialysis Patients with Chronic Hepatitis. The questionnaire was constructed thorough reviewing of previous literature and related studies for Psychosocial Disturbance of Hemodialysis Patients with Chronic Hepatitis. The study instrument comprised of (3) parts these parts related to the following:

Psychological: Domain This domain was measured through (5) sub-domains of negative feelings (7) items; self-esteem (4) items; thinking (5) items; memory and concentration (4) items; and appearance and body image (3) items.

Conducting Pilot Study: A convenient sample of (10) patients were selected from the inpatients in studied hospitals for hemodialysis patients are diagnosed by chronic viral hepatitis B and C this preliminary study was conducted for the period of December 10th, 2018 until the December 20th 2018.

Determine the reliability of the questionnaire .Estimate the time required for the data collection. Obtain the clarity and the content adequacy of the questionnaire and observation Identify the barriers that may be encountered during the data collection process.

Validity: The validity of the instrument was established through a panel of (12) experts. who had more than five years’ experience in their fields in order to achieve study objectives.

Reliability: results of the reliability showed very high level of stability and internal consistency of principle parts concerning item’s responses’ of the questionnaire, all those were calculated by using the major statistical parameter: Alpha Cronbach, revealed that the person correlation coefficient is (0.73).

Statistical Analysis: The data analyzed through the application of statistical procedures and using the package of SPSS version (22).

(*) NS : Non Sig. at P>0.05; S : Sig. at P<0.05

To predicting/or to find out the relationship between quality of life (QoL) domains and socio-demographic characteristics variables, correlation ship through the contingency coefficient of the contingency tables had been constructed in table (3) which were illustrated and testing the effectiveness distribution among different levels of the predicted variables and the two categories of an overall responding of assessment which were reported (under/upper) cutoff point at score value (2) for the Global Mean of Score.

The results has reported that the Socio-demographic characteristics variables (hospital, age groups, gender, education level, occupation, marital status income, residency, crowding index, and socioeconomic status) had no relationship with their overall (QoL) assessments due to main domains according to “Under/Upper” cutoff point for the grand mean of score values at each of the studied main domains, since a non-significant correlation ships were obtained at P>0.05 except with gender factor at the physical status domain, and income, socioeconomic status at the social relations/support domain, and we could conclude that the studied quality of life (QoL) questionnaire can be amend for all individual’s population of “Hemodialysis Patients with Chronic Hepatitis B and C Virus Infection at Southern Provinces in Iraq” whatever a differences with their (Socio-demographic characteristics variables) would be. Relative to the table (1) the majority of the study sample individuals 48(80%) are accounted at Al-Basra Hospital and the remaining are distributed at the others hospitals. This result also comes in agreement with Jawad et, al., 7 who stated of HCV antibody majority of the study sample(41%) among HD patients in the Al-kadymia Teaching Hospital and the remaining are distributed at the others hospitals in hemodialysis unit.

Conclusions

A highest percent of the study sample were females more than males, they were illiterate, read and write, and primary school and married. They were unemployed, with good assessment crowding index, having low monthly income,mostly common occurs among patients in urban residential area more than in rural, with many complications involves all the body systems. The study indicates that the Psychosocial domain has the effect due to hemodialysis with chronic viral hepatitis . The study indicated that the negative correlation between the socio-demographic and Psychosocial, except income, socioeconomic status at the social is relations/support domain.

Abstract

Background: Vaginal infections are considered global health problems for women in child-bearing ages. At the time in which various pathogenic organisms are responsible for those infections, many risk factors may also be attributed for such infections, including sexual activity and partner, contraceptive use, personal hygiene level, female estrogen level and its effect on vaginal mucosa, medical history, and many other factors. However, the disease by itself is not considered an exclusive sexually transmitted infection.

Objective: The goal of the Study is to identify the causes and factors related to the symptoms of vulvovaginal itching and/or vaginal discharge.

Methodology: A cross sectional study conducted on 93 females (16 pregnant & 77 non pregnants females) attending the private clinics in Al-Hindiya district (Karbala governorate) from May 2019 to September 2019. Ethically, patients’ information was treated with confidentiality and privacy throughout data collection and analysis. Tow swabs had been taken from each patient (vaginal and cervical) and sent to a private lab for direct microscopic examination and culturing on appropriate media. Statistically, the quantitative variables were analyzed using non-parametric t-test and the qualitative variables were analyzed using Chi-square test.

Results: Fortunately, the age of all participants was within child-bearing age ranging 15 to 42 with a mean of 28.0 ± 6.9 years. There was no significant association of pregnancy with vaginal infections as noticed in this study, while diabetes mellitus (DM) was found to be significantly related to the presence of infection (P-value=0.003). Similarly, intrauterine contraceptive device (IUCD) usage was also found to be significantly related to the occurrence of infection (P-value = 0.040).On the other, the lab study showed that E. coli is the most common pathogen to be expected in women complaining of vulvovaginal itching and/or vaginal discharge with monilia being the second.

Conclusions: DM and IUCD usage had their burdens on the vaginal cavity causing increasing rate of vaginal symptoms as proven significantly. Simultaneously, the cultivation results revealed that E.coli is the causative agent for of vulvovaginal itching and/or vaginal discharge at the level of our females, a point meriting further evaluation.

Keywords: Vulvovaginal itching, vaginal discharge, vaginal and cervical swabs, E.coli.

Introduction

Vaginal infections are considered some of the most important health problems for women all around the world[1]. Various pathogenic organisms are responsible for those infections, including bacterial vaginosis, candidiasis, and trichomoniasis[2]. Bacterial vaginosis is considered a clinical syndrome of multiple pathogens that results from replacement of Lactobacilli species (which are normally found in vagina) with anaerobic bacterial[3].

Patients are usually presented with symptoms of itching or burning sensation in the vulva or vagina,
abnormal vaginal discharge, or irritation and discomfort. Some of the infections are reported to be present with minimal symptoms[4]. Many risk factors were suggested for bacterial vaginosis, including sexual activity and contraceptive use, although the disease itself is not considered an exclusive sexually transmitted infection[5].

Several complications may occur as a result of vaginal infections, such as pelvic inflammatory disease (PID) that may lead to further consequences such as infertility, ectopic pregnancy, preterm labour, and low birth weight[6, 7].

Diagnosis is usually achieved by clinical examination alone or with the aid of laboratory diagnosis. Classically using direct microscopic exam or cultivation for vaginal swabs[8]. The study aims to identify the causes and factors related to the symptoms of vulvovaginal itching and discharge.

**Patients and Method**

A cross sectional study conducted on a randomly selected 93 females (16 pregnant & 77 non pregnant females fulfilled all inclusion and exclusion criteria) attending the private clinics in Al-Hindiya district (Karbala governorate) from May 2019 to September 2019. Ethically verbal informed consent was obtained from all the patients who were enrolled in data collection after explaining the objectives of the study. Patients’ information was treated with confidentiality and privacy throughout data collection and analysis. Also, patient’s permission had been taken to publish the study.

Data including demography, gravida/para/abortus (GPA), medical history, previous vaginal infections, contraceptive method as well as clinical examination were collected using specially designed format. Tow swabs had been taken from each patient (high vaginal and endocervical) and sent to a private lab where, after processing according to the standard laboratory procedures, a direct microscopic examination done for the vaginal swabs and culturing on appropriate media for the cervical swabs.

The direct microscopic examination done by wet preparation of vaginal swabs, where we looked for epithelial cells, bacteria adherent to epithelial cells, Lactobacilli as their presence in suitable number indicate healthy vagina, and also for polymorphonuclear (PMN) cells. Sometimes, motile bacteria could be seen, giving a correct diagnosis of infecting micro-organism.

Unfortunately, the direct examination of vaginal swabs was inconclusive for most of the patients, which may be due to very superficial swabbing or lab technical errors.

The cervical swabs had processed and each one cultivated on two separated agars, MacConkey, and blood agar, then incubated at 37c for 24 hour in an aerobic environment. The growth of colonies revealed 1-2 days after cultivation. The plates which had demonstrated bacterial colonies, sent for identification of the type of bacteria using the VITEK 2 compact (automated microbiology system of bioMerieux).

**Principles of VITEK2 system:** This system utilizes growth-based technology and accommodates a colorimetric reagent cards that are incubated and interpreted automatically. There are four reagent cards that currently used for the identification of different organisms:

1. GN –Gram negative fermenting and non-fermenting bacilli
2. GP -Gram positive cocci and non-spore forming bacilli
3. YST –yeast and yeast-like organisms
4. BCL –Gram positive spore forming bacilli

The reagent cards have 64 wells that can each contain an individual substrate. Substrates measure the various metabolic activities such as acidification, alkalinization, enzyme hydrolysis, and growth in the presence of inhibitory substances. An optically clear film present on both sides of the card allows for appropriate level of oxygen transmission while maintaining a sealed vessel that prevents contact with organism-substrate admixture. Each card has bar code, lot number, expiration date, and a unique identifier.

Statistical Package for Social Sciences (SPSS®) Software version 23.0 was used to perform statistical analysis. Qualitative data are presented as number and percentage, while continuous numerical data are presented as mean ± standard deviation. Comparisons between study variables were carried out using Chi-square test for categorical data and Student’s t-test for numerical data. P-value of < 0.05 was considered statistically significant.

**Results**

**Demographic characteristics of patients:** This
study enrolled a total of 93 patients complaining of vulvovaginal itching and/or vaginal discharge. The patients’ age ranged from 15 to 42 years, with a mean of 28.0 ± 6.9 years (Figure 1).

In regards to the gravida/para/abortus (GPA) system; the median gravida score of study participants was 3 (G3), median para score was 3 (P3), and median abortus score was 0 (A0). However, these information had not represented by a figure.

![Figure 1: Age group distribution of the study participants](image)

**Association of DM, pregnancy, and IUCD usage with vaginal infections:** To assess the role of DM, pregnancy, and IUCD usage on the occurrence of infection; those variables were compared to the presence of infection using chi-square test.

1. DM was found to have significant relationship with the presence of infection among patients in the study (P-value = 0.003). More than 83% of diabetic patients had infection, while approximately 38% of non-diabetic patients had infection. The odds ratio for diabetic patients to have an infection was calculated to be 3.7.

2. Association of pregnancy with vaginal infections had shown no statistically significant relationship, with chi-square = 0.34, d.f. = 1, P-value = 0.560, as presented in Table 1.

3. Fisher Exacts test was used to assess the association of IUCD use with vaginal infections and there was a statistically significant relationship between IUCD usage and presence of infection, Fisher Exacts P-value = 0.040, as described in the table below. Odds ratio was found to be 2.68. Infection was present in about 77% of women who used IUCD, while it was present in only 40% of women not using IUCD.

**Table 1: Association of DM, pregnancy, and IUCD usage with vaginal infections:**

<table>
<thead>
<tr>
<th>Patient history of DM</th>
<th>Presence of bacterial/fungal growth No. (%)</th>
<th>P-value</th>
</tr>
</thead>

<tr>
<td>Absent (n=52)</td>
<td>28.3± 7.2</td>
<td>28.0</td>
</tr>
<tr>
<td>Total (n=67)</td>
<td>28.0± 6.9</td>
<td>27.0</td>
</tr>
</tbody>
</table>

Pathogenic agents causing vaginal infections: The most common pathogen found among study participants was *E. coli*, with a percentage of more than 32%, as illustrated in Figure (2). The next most common infection was *monilia*, comprising 10% of the study population, half of which was concomitant with *E. coli* infection.
Association of DM, pregnancy, and IUCD usage with pathogenic agents: To further extend the analysis, each pathogenic organism was compared to DM, pregnancy, and IUCD usage.

1. DM was found to have significant relationship to *E. coli* infection, but not to the other types of infection (Table 3).

2. On the other hand, neither pregnancy nor IUCD use were found to have statistically significant relationship with a particular type of infection (pathogenic agent).

### Discussion

Women included within this study were aged between 15-42 years, which roughly represent the reproductive age in women. The highest proportion of patients was within the age group 25-29 years, representing the peak age of sexual activity and the sequel of vaginal symptoms.

Given the increasing rate in vaginal infection among females, many interfering factors to be verified due to their impact in causing vaginal symptoms including, patient’s general health, medical history, sexual activity and sexual partner, pregnancy, type of contraceptive used, PH, change in hormonal balance, poor vaginal hygiene or over use of vaginal douches or perfumed spray, antibiotic and immunosuppressive drugs use, underwear quality, degree of moisture, concomitant infections, frequency of changing pads during period, the way of washing in toilet, and others.

Statistical analysis of patients’ data had demonstrated the following important points:

1. DM has a significant impact in causing infection among young women, with odds ratio of 3.7. This means that diabetic women are approximately 4 times more likely to develop vulvovaginal infection than non-diabetic women. This finding is consistent with the finding by Nowakowska et al. in their case-
control study conducted on 251 women, in which they concluded that risk for vaginal infection is more than 4 times higher in women with DM compared to control group[9].

2. Although all of us agree that pregnancy lowers the immune response of pregnant female making her more susceptible to infection, this study reflects a non-significant effect of pregnancy on the occurrence of vulvovaginal infection. Proportion of pregnant females who had positive result for infection was found to be 37.5%. This percentage was closely similar to the finding by Mengistie et al. in their study conducted on 252 pregnant females from 2011 to 2012, which found that 36.7% of symptomatic pregnant women included in the study had positive microbiological diagnosis[10].

3. At the time in which IUCD has important role in preventing pregnancy, noticeable side effects on the womb had been reported ranging between heavy menses to recurrent vaginal infection, and to be tolerated by the users. Here it was found that more than 77% of women who used IUCD had positive result for infection, compared to 40% of women who did not use IUCD. This finding is consistent with the finding by Jabuk S. in her study conducted in Al-Hilla city from 2012 to 2013, which included 50 women who used IUCD, which concluded that IUCD use significantly increased the risk for bacterial vaginosis compared to other contraceptive method[11].

4. An interesting observation in the study was the significant relationship between diabetes and specific type of microorganisms, namely E. coli., where we always thinks that Candida albicans is the dominant in DM patients. This could reflect the opportunistic nature for this microorganism which is important to note in patients with DM[12]. However, further evaluation is needed to elucidate their opportunity. The second important point is that E. coli. is normal inhabitant of rectum and their transport to vagina may indicate poor hygiene with retrograde (recto-vaginal) washing, where changing PH and effect of female hormones may alter these bacteria into pathogenic type causing infection.

Conclusions

This study has demonstrated that: vaginal infections may occur at any point of reproductive age of patients, where some factors may increase their susceptibility, and the most common infection to be expected in women complaining of vulvovaginal itching and/or discharge is E. coli. A significant relationship between IUCD usage and DM in occurrence of infection, Vaginal infections particularly with E. coli. are closely related to DM.

Assessment of Nurses Efficiency Regarding their Performance in the Operating Rooms at Three Teaching Hospitals in Baghdad

Shatha Saadi Mohammad¹, Wefaqq Mahdi Hadi²

¹Assist. Professor, ²Assist. Lecturer College of Nursing, University of Babylon

Abstract

For the purpose of assessing the performance competency of the operating room nurses in Baghdad’s hospitals, a descriptive study has been conducted from 13th of December 2020 through 13 March 2020. The settings of the performed study were Al-Kindey hospital, Al-Yarmouk Hospital, Baghdad teaching hospital in Baghdad city. For the study of (50) nurses who have been working definitely in the operating room in these hospitals, a purposeful sample has been selected.

For the study purpose, a special tool has been developed which has been used for data collection. There are three part compromising this tool which are dealing with performance of the nurse, demographic data, and affordability of equipment and supplies in the operating room.

A number of highly qualified experts have been asked to assess the validity of the questionnaire, where they confirmed its validity. As for the questionnaire’s legitimacy; it was specified according to the statistically acceptable person correlation coefficient of (r= 92).

Data has been analyzed by using analysis of descriptive data (frequencies, percentages) and inferential data analysis (SPSS, 23).

According to the conclusions that have been revealed by study, graduates from universities and institutes had showed a better practices performance than graduates from primary and secondary level.

The study also indicate that scrub nurse practices in some domains were satisfactory (rehearsal of scrub nurses prior to actually entering OR, wearing operating clothes and gloves, draping and sheeting) and inadequate in some fields (practices concerned with surgical preparation, surgical hand scrub, antiseptic and technique and surgical instruments)).

In the study between sexes, a non-significant variation illustrate years of experience in relation to the nurses’ training sessions in OR.

The investigation suggested that all nurses ought to circulate strategies to the staff concerning this issue; composed arrangements for the OR practice can be shared to the health-care providers for better execution, and supplies to hospitals such as antiseptic hand scrub strategies that inhibit pathogenic microorganism growth.

Keywords: Assessment, nurses’ efficiency, operating rooms.

Introduction

These days’ hospitals are furnished with working theater suites with entrance and rehabilitation units supplying several operating theatres, all with anesthetic, implantation, immediate recovery and scrubbing rooms¹. In surgical services, surgeons, nursing staff, and anesthesia personnel may differ in their conceptions of efficiency, and their motivation to achieve efficient
processes\(^2\). All patients and health-care providers are at a higher risk of infection throughout medical procedures due to microorganism exposure. The right attire of surgery can help in post-procedural infection in patients beside the other elements of aseptic strategies, this can be achieved due to decreasing the opportunity of microorganisms entrance into the patients’ body\(^3\). A few components of surgical apparel are as well configured to lower the risk of exposure of health-care professional to potential blood and tissue infections during surgical treatment, including gloves, caps, masks, gowns, protective eyewear and waterproof aprons\(^4\). Throughout any medical procedure, the most prevalent cause of infection is personals in the operating room. The main focus is thus on keeping the nursing and medical staff aside from the sterilized gowns and caps that were first revealed to be included in the operating room use\(^5\).

Throughout surgeries, infection in the surgical wound can be precipitated by transferring germs and bacteria from the surgical team’s hands for careful surgical scrubbing to lower the amount of bacteria on the skin\(^6\). Among the main reasons of mortality and morbidity is nosocomial or hospital-acquired infection in the hospitalized patients, hospital-acquired infection development can affected by some elements, and cross-infection from patients to patients can take many routes which will lead to a difficulty in making a link between these variable person and nosocomial infection\(^7\). Nosocomial infection is significantly correlated the infection at the surgical site. Most of the risk factors for nosocomial infection have involved the behavior of operating room personnel with relation to the practice of contamination by hand hygiene/antisepsis and universal precaution\(^8\). Nursing staff who work in the theatre can play a great part in the surgical site prevention of infection by undertaking preoperative scrub nurse. In addition, aseptic barriers including sterile gowns and gloves protect sterile areas, isolate clinical sites from pollutants caused by infections and lessen microorganisms number\(^9\).

### Methodology

This descriptive research was carried out to assess the nurse’s efficiency performance at the operating rooms in three surgical hospitals in Baghdad.

The study started from 13th of December 2020 through 13 March 2020. The sample was non-probability (purposive sample) of 50 nurses was selected from three surgical hospitals in Baghdad and they accepted to participate in the study and taken into consideration: age, gender, and level of education.

The data were collected by interviews and constructed with nurses efficiency performance at the operating room questionnaire, after getting the permission of Ministry of Health prior to the initiation of the study.

The agreement of participation was obtained from the nurses who were working in the operating room in these hospitals for this present study and they were responding to the interviewing.

Pilot study have evaluated the questionnaire’s validity and a group of experts to assess the validity. The data were analyzed by applying inferential statistical procedures, percentage, and descriptive statistical frequency. A questionnaire format constructed following enormous review of the available literature and related studies. There are two components of a questionnaire format which include: demographic data for nurses, gender, level of education, and years of experience in hospitals, years of experience in operating room, number of training sessions.

The other part observational questionnaire about the nurses practice in the operating room including scrubbing, equipment and supplies availability, and the nurses usage of the aseptic technique in surgical procedures.

Discussion

Working in a team is essential for successful surgery, even though there are presently no team cohesion indicators to direct training, to analyses the effect of group work on consequences, the researcher will report the first stages in the development of an observational teamwork evaluation and preliminary findings. In this study we found that the majority of the nurses were males, (78%) graduated, (48%) single, (80%) having (1-5) years of experience in hospital and OR (64%), and they had enrolled in (2) time training sessions (84%) (Table 1) These results coincided with (Shabnam 2006), findings in his study of the sample consisted from 50 nurses who worked actually in OR and most of them were males, single but their practices were found to be unsatisfactory in OR. It has been realized that the scrub nurses in the examination of table (2) did not perform their practice of preparation before entering OR in many sub-terms of this preparation although there was a high MS in the domains of (1,3,4,5) related to the performs of practice for preparation before entering OR. Conducted a stated that reported scrub nurses should take bath daily with soap that contains an antibacterial agent, which can reduce shedding. Also, the present study realized that in sub-items in this domain that (20%) of those scrub male nurses did not shave their face. Stated that hair face could be considered a major source of staphylococci. Furthermore, the nurses had put the mask before surgical hand scrub (100%) and they do not touch surgical instruments by hand after the surgical hand scrub (98%). Relative to their practice in the OR, they also observed adequate practice, which was presented through using a sterilizing brush in the hand surgical scrubbing, and they used it between fingers (88%). On the other side, the nurses did not use woods, nail cleaner under nails, and antiseptics solution at the beginning because the supplies were not available in the hospitals. As noted by in his study that the (WHO) The hospital embraced hand hygiene protocols which its research carried out on a team that made comprehensive workflow diagrams for prevalent patient care duties identifying evidence of hand washing. Three months later, health care staff have been equipped to evaluate one another and forwarded relevant information to the Department of Infection Prevention and Control Following the launch of the program, conformance expanded from 60% - 70% to 97% and remains to be maintained at that point. Adequate performance of practice was presented through wearing the gown and gloves and raising the sterilizing hand above hips. In addition, proper surgical attire reduces the danger of clients infection with post-procedures by lowering micro-organisms entering locations of the client’s body throughout the surgery. Revealed that appropriate surgical apparel can diminish the risk of post-procedure infections in clients by decreasing microorganisms that enter the area of the client’s body during the procedure. Throughout data analysis, the study findings had confirmed that all scrub nurses, regardless of their sex has performed adequate practice in the operating room. Conducted a stated that staff nurses had performed adequate practices than practical ones in OR. Concerning the experiences in OR, the study shows that the scrub nurses’ practice was not influenced with years of experience because the correlation between their practices and years of experience was found to be not significant for all domains, but the scrub nurses who had (1-5) years of experience had high –level practice than others. The findings shows that beginner scrub training is influenced externally by its perioperative...
cultural environment and the encourage of senior employees. To sum up, it is extremely important to highlight the role of perioperative cultural surroundings and the support of the senior staff to nurses regarding their novice scrub learning. As senior scrub staff dictated their educating to novices according to their attitudes.

Nurse Midwives Knowledge Regarding Nursing Management of Post-Partum Hemorrhage at in Iraq

Hanan Noor Mohammad

1Assist. Lecturer, College of Nursing, University of Altoosi, Najaf City, Iraq

Abstract

Aims: Today, it is well-known that postpartum hemorrhage (PPH) is the leading cause of maternal postpartum deaths worldwide; so that this study aims to assess nurses and midwives knowledge.

Method: A descriptive cross-sectional study design was conducted from to meet the previously mentioned objectives. All nurse midwives (n=150) were included who works at the hospital of AL-Najaf AL-Ashraf Province. A constructed questionnaire was prepared and adopted by the researcher to meet the objectives of the study.

Results: The result of the study revealed that the mean overall knowledge score of the study participants for all domains was (1.91) which indicated that the overall knowledge of nurse-midwives in Al- Najaf AL-Ashraf city in Iraq hospitals regarding nursing care of PPH was (fair). The overall knowledge score about prevention of PPH was (1.87) which is also considered (fair). The result of the current study also revealed that there is a significant positive correlation had been found between age, duration of experience in delivery room, training courses or workshops

Conclusion: It was concluded that the nurse-midwives have a moderate level of knowledge about the overall concepts, information and skills related to the PPH. They have weak knowledge about definition, types and common causes of postpartum hemorrhage.

Keywords: Nurse-midwives, knowledge, postpartum hemorrhage, management.

Introduction

Postpartum hemorrhage [PPH] is being designated as the most substantial yet inevitable source of death and maternal illness all over the world [1]. Being the utmost prevailing 5th maternal mortality cause, PPH instigate 140,000 demises each year worldwide [2]. Rendering the WHO, the distinct PPH definition is being stated by way of 500ml minimum blood loss after childbirth within 24 hours. However, the severe PPH is termed as 1000ml least blood loss in 24 hours of birth [3]. Another definition is that PPH the sufficient loss of blood causing hypovolemia, a [10%] decrease in the hematocrit or a situation necessitating the transfusion of blood products irrespective of the delivery route [1]. PPH has been categorized into two types: primary and secondary PPH [1]. Primary [immediate] PPH is typified by a blood loss of more than 500ml owning to vaginal delivery and blood loss of 1500 ml owning to caesarean section within first 24 hrs of delivery [2]. Practically uterine atony is considered to be the root of 70% of immediate PPH. Inadequate contraction of the uterus after a child is born referred to as atony of the uterus. The prevalence of immediate PPH is [5%] of all deliveries[4]. An approximated 14 million cases of PPH are registered every year globally with a [1%] case-fatality rate [5]. According to an assessment, about 2% of the women childbirths are associated to PPH. Although, another approximation indicates the ratio of 25% global maternal deaths while marking the PPH as a widely held prime reason of demise in low wages countries. Economically well developed countries has overall less decease risk than the developing nations. In the high-income countries, the total death risk is approximated to be 1:100,000 deliveries as compared to 1:1000 in low-income countries.[3] According to Rath [2011], a recent WHO analysis showed that in high-income countries,
hemorrhage as a result of PPH accounts for [13.4%] of maternal mortality,[ 30.8%] for Asia, and 34% for Africa[5]. With a broad difference globally, the incidence of minor PPH and severe PPH is estimated to be [6%] and [1.86%] of all deliveries[4,5]. Morbidity resulting from severe PPH is approximated at 4.5-6.7/1000 deliveries with nearly 20 million women globally every year suffering from an acute or chronic disability due to PPH [6-8].

Methodology

2.1 Study aims: The purpose of the current study was to investigate the nurse midwives knowledge regarding nursing care of PPH. The current study also aims to find out the relationship between nurse midwives knowledge regarding nursing care of post-partum hemorrhage with their socio demographic and personal characteristics such as (age, marital status, economic status, educational level, etc…….)

2.2 Design of the study: A descriptive cross-sectional study design was conducted from 30/July/2019 to 29/April/2020 to meet the previously mentioned objectives

2.3 Study Sample: All nurse midwives (n=150) were included who works at the hospital of AL-Najaf AL-Ashraf city in Iraq

2.4 Study instrument: A constructed questionnaire was prepared and modified after a thorough review of the relevant literature. This questionnaire covers two parts:

2.4.1 Part 1: Socio- demographic and personal characteristics: This part included the following (age, level of education, duration of experience in delivery room, receiving training courses or workshop about postpartum hemorrhage, accommodation, type of accommodation, marital status, economic status, others) which included (8) items.

2.4.2 Part 2: Knowledge of nurse midwives about prevention of postpartum hemorrhage which included (18)items.

2.5 Validity and Reliability: The content validity of the instrument was established through a panel of (12) experts, the reliability of the items was based on the internal consistency of the checklist was assessed by calculating Cronbach Alpha which was= 0.765

2.6. Data Collection and Data Analysis: A structured questionnaire used to collect data by direct interview. The approximate interview time of 25-30 minutes was provided for the questionnaire completion. To determine whether the objectives of the study were met, the current study data were analyzed by using SPSS, version 25.

Results and Discussion

Table 1., illustrates the demographic characteristics of the 150 nurse-midwives who participated in this study. Age distribution of the participants revealed that the highest percentage is 67 (44.7%) aged 20 – 29 years. Concerning the level of education, highest percentage is 111/150 (74%) nurse-midwives had secondary school of nurse-midwifery level. Regarding accommodation, findings also revealed that 88 nurse-midwives (58.7%) were living close to the health institution, and 62 (41.3%) were living far from the health institution. For, the type of accommodation, owned documented by 79 (52.7%) nurse-midwives and rented by 71 (47.3%). The enough economic status reported by 20 nurse-midwives (13.3%) enough to some limits in 58 (38.7%) and not enough in 72 nurse-midwives (48%). Out of the 150 nurse-midwives, 119 (79.3%) were married, 24 (16%) were single and 7 nurse-midwives (4.7%) were widowed, divorced or separated.

According to the results of the current study, the research outcomes specified age distribution of the respondents while revealing that the highest age group is between (20 – 29) years which made up (44.7%), secondary was age category (30-39) years which constituted (22%). These data may vary from that gotten by (40) who observed that the highest age group is (47-55) years (32.5%), followed by (20-28) years (24.7%). The results of the present study indicate the target sample; it also indicated that young nurses midwives made up the majority among the other groups.

Regarding the educational level, the majority of the study group (74%) are graduated in secondary school of midwifery, this may be due to secondary school of midwifery are the major levels that qualify health care workers in the range of midwifery, principally in Iraq. One previous study achieved in the city of Maraco found that the majority midwives (35.1%) that were included in the current study graduated from secondary schools (9). In relation to residence, results also explained that 88.0 nurse-midwives (58.7%) are living near the health
Concerning the socio-economic status, most of the research respondents (48%) have not sufficient monthly income. This result can be supported by other results about the accommodation which recorded that (47%) of the midwives have rent accommodation (12).

Regarding to marital status, most of the study sample (79.3%) are married, while (16%) are single and (4.7%) are widowed, divorced or separated as shown in (Table 1).

According to the table 2, the distribution of duration of experience in delivery room together with history of training about postpartum hemorrhage was illustrated, where 20 participants (13.3%) had a duration of experience in delivery room for less than one year, 73 (48.7%) had a duration of one to ten years, 31 (20.7%) for 11 – 20 years, 18 (12%) for 21-30 years and 8 nurse-midwives (5.4%) had a duration of experience in delivery room of more than 30 years. Regarding the training about postpartum hemorrhage, 109 nurse-midwives (40%) had received training courses, 90 (33.1%) had participated in workshops and 73 (26.8%) nurse-midwives received other types of training.

Table 3., demonstrated the responses of nurse-midwives about management of PPH; it points that 43.0 respondents (28.7%) had the correct response concerning the assessment of blood loss directly by kidney dish, 72.0 (48%) of respondents have incorrect response and 35.0 (23.3%) they don’t know. The MS was 1.81 and it was a moderate knowledge.

Pads count and weight were correctly identified to be included in the management and assessment of PPH by 65.0 of respondents (43.3%), 44.0 (29.3%) of respondents were incorrect and 41.0 (27.3%) of them did not know. This gave a mean score of 2.14 which is moderate knowledge.
Regarding the responses about recording the vital signs, correct responses reported by 69.0 respondents (46%), incorrect answers by 46.0 (30.7%) and 35.0 (23.3%) did not know with a mean score of 2.15 and it was moderate knowledge. About 36.0 (42%) respondents correctly answered and forty sex (30.7%) incorrectly responded about measurement of pulse and other vital signs every 15 minutes up to stability but 41.0 (27.3%) of respondents do not know. The mean score was 2.11 and it was moderate knowledge. Correct response regarding management of call for help observed by 74.0 respondents (49.3%), incorrect answers were reported by 34.0 (22.7%) and 42.0 (28%) respondents do not know. This gave a mean knowledge score of 2.27 and moderate knowledge. Some other data about this domain are different; Elfaki (2015) observed that nurses-midwives' knowledge about method of assessment of blood loss are (26%), (66.2) and (28.6%) respectively for (pads count and weight), (assess of blood loss directly by kidney dish) and (observe vital signs)(9); while Faiza (2015) found the following correct responses : (77.6%), (53.1%) and (65.5%) respectively for pads count and weight), (assess of blood loss directly by kidney dish) and (observe vital signs)(10).

*Nurse-Midwives Mentioned more than One Choice

Concerning management, good knowledge was gotten by Faiza (2015) for all the questions of the management of PPH. Mohammed et al. (2016) conducted a study in Nigeria showed that about 67.1% of the nurses and midwives have correct answers about using massage as initial step to manage PPH(10); Onasoga et al. (2012) achieved another study in Nigeria observed that 95% of midwives had correctly answered the question about using uterine massage after labor to prevent the development of PPH(11).

Table 4, shows Spearman’s bivariate correlation analysis. A significant direct (positive) correlation had been found between age of participants and their overall knowledge score ($R = 0.412$, p. value $= 0.004$). Other significant direct (positive) correlation was found with duration of experience in delivery room ($R = 0.575$, P. value $= 0.001$). Moreover, a significant direct (positive) correlation was found with receiving training courses or workshops ($R = 0.243$, P. value $= 0.043$). No significant association had been found between overall knowledge scores and other variables including level of education, accommodation, type of accommodation and economic status, (in all of these variables correlation was not significant, P. value $= .05$).

Unexpectedly, this results did not reveal any significant relationship ($p=0.495$) between overall knowledge of nurse-midwives and their level of education, this result agrees with the result obtained by Onasoga et al. [11]. However, disagrees with the study conducted by Jaber and Abbas (2012) who pointed a significant relationship with educational status [14]; another study found that doctors have better scores than midwives [15]. The unexpected result in the present study may be explained by what is mentioned in this chapter that most of the study sample (74%) are graduated from secondary school of midwifery, so that there is no great difference in the level of education of respondents participated in this study.

Concerning training, the current study found a significant correlation ($p=0.043$) between overall knowledge of nurse-midwives and receiving training courses or workshops, this result agrees with the work obtained by Benedict et al. who found that midwives who completed the training courses named “Essential Steps in the Management of Obstetric Emergencies” ESMOE had better knowledge and performance [15]. However, another study conducted in Baghdad did not find a significant correspondence of about $p>0.05$ amongst the training and inclusive understanding of nurse midwives [14].

**Conclusion**

According to the current study, the nurse-midwives have a moderate level of knowledge about the overall information and skills related to the management of PPH. In general, the knowledge of nurse-midwives about PPH increases with age and years of experience.

**Financial Disclosure:** There is no financial disclosure.

**Conflict of Interest:** None to declare.

**Ethical Clearance:** All experimental protocols were approved under the College of Nursing and all experiments were carried out in accordance with approved guidelines.

Comparing Parity, Socio-demographic and Serum Vitamin D among Pregnant Women with and Without GDM

Bushra Jabbar Hamarashid¹, Atiya Kareem Mohammed²

¹Ph.D. Student, Diabetes and Endocrine Center, General Teaching Hospital,  
²Assistant. Prof. Dr. Maternal Neonatr Nursing, College of Nursing, University of Sulaimani

Abstract

Background: Gestational diabetes mellitus can affect pregnancy in short and long term, for both mother and her offspring. Nearly 1% to 28% of all pregnancies are complicated by GDM. Knowing the risk factors can prevent the onset of GDM and early detection of GDM, which is important to prevent or minimize the GDM consequences and optimum treatment.

Objective: To compare the parity, socio-demographic and serum vitamin D state of pregnant women with and without gestational diabetes mellitus.

Method: This is a descriptive analytic study conducted in the Maternity Teaching Hospital in Sulaimani city from December 2018 to January 2019 among 100 pregnant women with GDM and 162 healthy pregnant women. The face-to-face interview was used to collect the information regarding socio-demographic and obstetric history through a specific written questionnaire. At the same time serum vitamin D state was examined using the Roche Elecsys vitamin D₃ assay.

Result: The study found that body mass index, educational state, age at marriage, parity and gravidity significantly higher in the GDM group compare to the non-GDM group. Socioeconomic state does not differ significantly in both group p=0.069.

Keywords: Serum, vitamin D, pregnant, GDM.

Introduction

Gestational diabetes mellitus (GDM) remarkably elevates the risk of later life type two diabetes mellitus¹. GDM is defined as carbohydrate intolerance of varying severity that start or diagnosed during pregnancy. The definition is applicable regardless of whether insulin is used for treatment or the condition persists after pregnancy. GDM is adversely affect the pregnancy outcome not only for the mother, but also it affect fetus, neonate, child adult offspring of diabetic mother². The most frequent complications of pregnancy with diabetes are hyperglycaemia, which increases the risk of pre-eclampsia, premature delivery, and caesarean section. GDM also increases the risk of type two diabetes mellitus in the few years after pregnancy. Women with GDM at higher risk of some chronic diseases such as metabolic syndrome, obesity, cardiovascular morbidities and recurrent GDM in following pregnancy. Also, there are maternal implications secondary to a delivery of a macrosomic or large for gestational age (LGA) fetus, such as an increased rate of cesarean delivery, postpartum hemorrhage (PPH), birth trauma and shoulder dystocia³. The worldwide prevalence of GDM cannot be estimated exactly because of the differences in the diagnostic criteria, race/ethnicity and socio-economic statues of individuals⁴. So, the results of the studies concerning prevalence of the GDM highly variable among countries which ranging from 0.6 to 15%⁵.

The incidence is estimated at 7% worldwide, although the incidence of GDM has increased in the last decades and predicted to increase in future because of the increase in the associated risk factors⁶. The well known risk factors of GDM includes pre-pregnancy body mass index (BMI)³ 30 kg/m², obesity, 35 years and
older at delivery, metabolic syndrome, hypertension, family history of diabetes mellitus or history of GDM, history of unexplained still birth, history of having infant with congenital anomaly, history of macrosomic infant, long term use of steroids, glycosuria, impaired glucose metabolism. A number of the studies found the association between vitamin D deficiency and risk of gestational diabetes mellitus. However, in one large prospective study no association found between vitamin D level and GDM. The huge number of epidemiological studies supports the direct association between serum vitamin D level and insulin responsiveness. Vitamin D deficiency in pregnant women increases risk of gestational diabetes mellitus and pre-eclampsia for mother and increases chance of being small for gestational age for offspring.

The current study tried to compare gravida, para, socio-demographic and serum vitamin D levels of the pregnant women with gestational diabetes mellitus and without gestational diabetes mellitus in Sulaimani City.

Method

Study design and population: This is a descriptive analytic study involving 262 pregnant women, 100 pregnant women with GDM and 162 pregnant women without GDM.

This study was conducted at Gestational Diabetes Center, Maternity Teaching Hospital in Sulaimani city, between December 2018 to January 2019. A non-probability purposive sample was used for selecting study population depending on the inclusion criteria. The inclusion criteria were pregnant women with gestational age more than 24 weeks. The study excludes pregnant women with pre-pregnancy BMI more than 35 and pregnant age more than 40 years old. In the group of GDM, 100 g oral glucose tolerance test (OGTT) was performed to confirm gestational diabetes. Finally, the total of 262 pregnant women recruited in the study. The Ethical Committee of the university of Sulaimani approved this study.

Data Collection: The data collected using questionnaires, by a trained researcher using face-to-face interview. The questions categorized in two parts of socio-demographic history, such as age, blood group, occupation and obstetric history, such as age at marriage, para and gravida. The blood sample was drawn from the participants on the day of the interview and centrifuged at 5000 r/m for 5 minutes, followed by separation of the serum that stored at -80°C in freeze until they defrosted for measurement of serum 25 dehydroxyvitamin D. In this study vitamin D level categorized into three groups of sufficiency (more than 30ng/mL), insufficiency (between 20ng/mL and 30 ng/mL) and deficiency (less than 20ng/mL).

The validity ascertained through a panel; group of 12 experts and reliability calculated by using the correlation coefficient that was \( r = 0.884 \) (statistically adequate). A pilot study applies to groups of 20 pregnant women visiting maternity teaching hospital.

Statistical analysis: the data were analyzed using SPSS version 23.0 software program.

Results

A total of 262 pregnant women recruited in the study. The table 1 shows the demographic characteristics of the pregnant women with and without GDM. In the GDM group majority of samples were at the age between 30 to 39 years old which were 54.0% of the total participants, 41.0% of them were at the age between 20 to 29 years old and the minority of the samples were at the age of 40 and more years which were merely 2.0%. Moreover, the mean and standard deviation of age distribution were 30.10, 4.95 respectively. In non-GDM group majority of samples were in age between 20 to 29 years old which were 54.3% of the total participation; 44.9% of them were aged between 30 to 39 years old and the minority of the total sample was at age of 40 years old and more which were merely 0.61%. Moreover, the mean and standard deviation of age distribution were (28.33, 5.03) respectively.

The table, one shows the obstetric history of the participants with and without GDM. It can be seen in the table that in the GDM group the majority of participants had aged at marriage between 20 to 29 years old which were 65.0% of the total samples. Those who aged at marriage 30 years and over were merely 10.0% of the total samples. However, in non-GDM group majority of samples were in age between 20 to 29 years old which were 54.3% of the total participation; 44.9% of them were aged between 30 to 39 years old and the minority of the total sample was at age of 40 years old and more which were merely 0.61%. Moreover, the mean and standard deviation of age distribution were (28.33, 5.03) respectively.

The table, one shows the obstetric history of the participants with and without GDM. It can be seen in the table that in the GDM group the majority of participants had aged at marriage between 20 to 29 years, which were 65.0% of the total samples. Those who aged at marriage 30 years and over were merely 10.0% of the total samples. However, in non-GDM group majority of participations were getting married between 20 to 29 years, which were 74.7% of the total samples, the minorities of the participants (2.5%) were getting married for 30 years and over.

It is indicated that in GDM group, the majority of the samples (54.0%) of the total participants were in 20 to 29 weeks of gestational age. Moreover, the mean and standard deviation of gestational age equals (29.47, 4.70) respectively. It is indicated in the table that in non-
GDM, 56.2% of the total participation were in 20 to 29 weeks of gestational age and 43.8% of them were in 30 to 39 weeks of gestational age. Moreover, the mean and standard deviation of gestational age equals (29.89, 4.18) respectively.

In the GDM group, 23.0% of the total participations had gravid number one or less and 77.0% of them more than one. Also in non-GDM group, 37.7% of the total participations had gravid number equal to one and 62.3% of them more than one of gravida. The mean and standard deviation were (1.96, 1.06) respectively.

Regarding the number of delivered babied in GDM group, 68.0% of the total participations had a Para one or less and 32.0% of them more than one. In non-GDM group, 85.2% had para number equal to one or less and 14.8% of them had para number more than one.

### Table (1): Obstetric history of pregnant women with and without GDM.

### Discussion

In a study of the association between blood group and disorders it should be taken to account that the distribution of ABO phenotypes varies across the globe and it depends on racial/ethnic origins and geographical regions. In the current study no association found between blood group and risk of GDM. However, association between maternal blood group and risk of GDM reported by several studies. Blood group AB was found to be significantly (p=0.029) higher in GDM women compared to non-GDM women\(^\text{14}\). This finding in contrast with a recent study from the People’s Republic of China, which was a prospective cohort study Chinese women and demonstrated that women with blood group AB were less likely to have a GDM\(^\text{15}\). Relationship between maternal ABO blood group and risk of pregnancy outcome studied among 55320 singleton pregnant women (16). The study demonstrated that there is no any significant association between ABO blood group and GDM. The results of the studies are
not consensus. Different results regarding the magnitude of associations among these studies might lie on various sample sizes, racial/ethnic origins studied, and population characteristics.

The risk of T2DM and low social economic state has been established in previous studies\(^\text{17}\). The definition of socioeconomic state varies in different regional and countries; however, most of the studies agreed that low socioeconomic state increase the risk of GDM development. The current study found no significant differences between Socio-economic state of GDM and non-GDM group. In the study that carried out in china to demonstrate association between lifestyle factor and risk of GDM development, significant association found between income and risk of GDM. They found that women with lower income at higher risk of GDM compare to high income women\(^\text{18}\). A large population based study from Australia reported that low socioeconomic state inversely associated with the risk of GDM\(^\text{19}\) and no association found in the study which carried out by Janghorbani\(^\text{et al.}\). The finding of another study indicated that higher household income was associated with lower risk of GDM\(^\text{20}\).

Obesity that defined as BMI more than 29 kg/m\(^2\), remains an important and increasing risk factor for GDM. Additionally, this relationship appears to vary by race and ethnicity. The risk of GDM between obese Latina and Asian women is twofold higher than African-American and Caucasian women. The current study found significant differences between BMI of women with GDM and without GDM. The large retrospective cohort study that include 24,325 pregnant women, examined the association between BMI and risk of GDM between different ethnicity and race. The study found higher prevalence of the GDM among groups with high BMIs\(^\text{21}\). A prospective cohort study looked at the effect of maternal BMI on GDM and risk of adverse pregnancy outcome. They reported increased prevalence of GDM with increasing BMI\(^\text{22}\).

The previous studies suggest that the educational level of the mother does not affect the risk of gestational diabetes directly, however, it is more likely to act through more proximal risk factors, so it is called mediators. Several factors considered to be potential mediators in the pathway between maternal education and GDM, for instance. Substance use during pregnancy, such as: alcohol consumption and smoking, nutritional information, stress and pre-pregnancy BMI. The large strong population-based prospective study which carried out among large group of pregnant women from beginning of the study revealed that low educational level is associated with a three times higher risk of developing GDM compared with a high educational level\(^\text{23}\). Significant differences found between the educational state of the pregnant women with GDM and without GDM. In an observational register-based cohort study, the risk factors of GDM studied among 7750 women from the city of Vantaa. The result of the study showed that primiparous women who aged more than 35 years had significantly higher risk of GDM. There were no any significant differences found between vitamin D statususes of the both groups. In both groups of GDM and non-GDM almost 70 percent of the cases had serum vitamin D levels less than 20ng/mL in the numbers of studies it has been proposed that vitamin D deficiency can trigger the onset of diabetes during pregnancy and several mechanisms defined. The studies showed that active form of vitamin D (1,255 (OH)_2D) play a role in stimulation of insulin production and enhance sensitivity to insulin, thus vitamin D deficiency may involved in the development of GDM (25). The two cross-sectional studies showed that serum level of the vitamin D level is lower in GDM women compare to non-GDM women\(^\text{14,8}\).

**Conclusion**

Body mass index, education, residency, age at marriage, parity and Gravidity are the factors that affect the development of GDM. Socio-economic state has not been associated with risk of GDM.

Assessment of the Two-Glutathione S-Transferase Genotypes GSTM1 and GSTT1 Polymorphism Frequencies in Epithelial Ovarian Cancer in Nasiriya Province

ENAAS SALEH JAWAD1, HIBA ABUDL-ADHEEM2

1ASSIST. PROF. OBSTETRICS AND GYNECOLOGY DEPARTMENT, COLLEGE OF MEDICINE, UNIVERSITY OF THI-QAR, IRAQ,
2LECTURER, CANCER RESEARCH UNIT, COLLEGE OF MEDICINE, UNIVERSITY OF THI-QAR, IRAQ

Abstract

The family of glutathione S-transferases (GSTs) is composed of multiple isozymes with significant evidence of functional polymorphic variation. Glutathione S-transferase GSTM1 and GSTT1 are members of the GST family, responsible for metabolism of xenobiotics and carcinogens. Allelic variant of GST gene polymorphisms might impair detoxification function and increase the susceptibility to cancer. The null genetic polymorphism in the gene encoding GST Class µ, GSTM1 and GSTT1, has been reported to be significantly elevated in cancer patient. This study aimed to investigate if these polymorphisms are useful markers for predicting ovarian cancer susceptibility. 30 cases of epithelial ovarian cancer and 30 controls was used to investigate the frequency of GSTT1 and GSTM1 genotypes by using multiplex conventional PCR protocol. The frequency of GSTM1 null allele was significantly elevated (100%, \( P = 0.004 \)) compared with GSTT1 active allele (13% \( P = 0.037 \)). GSTT1 null showed no significant effect in prognosis epithelial ovarian cancer (17%, \( P = 0.551 \)). We conclude that the GSTs might affect in both risk to ovarian cancer.

Keywords: GSTM1, GSTT1 Polymorphism, Epithelial Ovarian Cancer, Nasiriya Province.

Introduction

Ovarian cancer is the main cause of death with gynecological malignancies\(^1\). It is a disease of premenopausal and postmenopausal women; however, no age exempt from ovarian neoplasm. Here is no socio-economic bar for ovarian malignancies but epidemiologically it is more frequent in higher socio-economic and industrially developed countries\(^2\). Risk factor of ovarian carcinoma include inflammation, excessive number of lifetime ovulation, increase in steroid. Hormone levels, infertility, age, asbestos, talk and reproductive factor such as nulli-parity\(^3\). Oxidative stress is due to disturbance in the balance between the production of reactive oxygen species (ROS) and deficiency of antioxidant defense. In other words, oxidative stress results if excessive production of ROS overwhelms the antioxidant system or if there is a significant decrease or lack of antioxidant defense \(^4\). Numerous genetic polymorphism that may be involved in deferential enzyme function or expression, cancer risk\(^5\). Our study postulated that lack of detoxification, which is determined genetically, might be risk factor of ovarian cancer. Glutathione S-transferase (GSTs) are a family of enzymes responsible for the metabolism of xenobiotics and carcinogens. GSTM1, one member of GST family was formerly termed GST1 or GST class “µ”\(^6\). GSTM1 is critical in the detoxification of the oxidative stress product during ovulation\(^7\). Because of detoxification properties of GST enzymes, it is logical to suspect the role of GSTM1-related gene in ovarian cancer patients\(^8\). Glutathione S-transferase theta 1 (GSTT1) is located in long arm of chromosome 22 (22q11.23). Some studies reported that GSTT1 protein was involved in the conjugation of ethylene oxide and halogenated metabolites\(^10\). Glutathione S-transferase catalyze glutathione-mediated reduction of exogenous and endogenous electrophile with broad and overlapping substrate specificity\(^11\). It has been hypnotized GST functional variant associated with less effect detoxification of potential carcinogenesis may confer an increased susceptibility to cancer. Especially in the presence of environmental stress. Such as smoking
and exposure UV radiation\[12\]. Detection variant of null allele exist for GSTT1 and GSTM1 genes and these present biochemically as failure express protein\[13,14\].

Reported studies about the effect of GST polymorphism on risk of ovarian cancer are still few, due to many limitations. GSTT1 and GSTM1 null genotypes was shown to be associated with proper survival and progression free interval in ovarian cancer cases \[15\]. This study has been done because of the lack of genetic studies related to these cases in south of Iraq.

Materials and Method

Subjects: This case-control study was conducted between February 2016 and December 2017. Overall, thirty cases who recruited at Al-Habbobi teaching hospital were histopathological confirmed as epithelial ovarian cancer after surgery. Thirty healthy volunteers were chosen as control. Age ranged from 22 to 39 years in epithelial ovarian group and from 21 to 49 years in control group. Peripheral blood (5 mL) was drawn and collected into tubes containing ethylenediaminetetraacetic acid) EDTA) as an anticoagulant. The collected blood samples were frozen until DNA extraction and then PCR analysis was proceeded. A verbal consent had been taken from the patient and the control volunteer before engagement with the questionnaire.

Genotyping: Genomic DNA was isolated from whole blood as described previously\[16\]. Eight microliter of DNA of each sample was subjected to qualitative assay by 0.8% agarose gel electrophoresis (70V/150Ma for 20 min). The homozygous of GSTT1 and GSTM1 genes were detected by multiplex PCR reaction, using primer set sequences in the table 1. To check successful amplification, albumin gene was used as internal control. The absence of amplified GSTT1 or GSTM1 product (in the existence of the albumin PCR product) indicate the null genotyping for each respectively. Multiplex PCR reaction was proceed in a reaction volume 20µl which contain 5µl of master mix (Kappa, Korea), 1.25 µl of each primer (10 pmol), 3.5µl of genomic DNA. Amplification condition for this multiplex reaction was as follows : (94°C for 3 min, 30 cycles at 94°C for 1 min, 58°C for 1 min and 72°C for 1 min, and final cycle of extension at 72°C for 5 min). 10µl of each PCR product was loaded into 1.8% agarose gel containing ethidium bromide for electrophoresis (70V, 150 mA for 30 min) and visualized at room temperature under UV light.

Epidemiological Analysis: Relative association between studied genotypes and epithelial ovarian cancer risk were evaluated to calculate odd ratio (OR) and 95% confidence intervals (CI).

Results

Genomic DNA, which was extracted from blood leukocytes, was subjected to agarose gel electrophoresis assay as previously described, was illustrated in figure 1. Thirty samples of ovarian cancer and thirty samples of healthy volunteers (as control) genotyped by multiplex PCR assay for detection of GSTT1 and GSTM1 genes. Figure 2 represent multiplex PCR products which was analyzed by 1.8% agarose gel electrophoresis. The GSTT1 active genotype frequency was 43.3% which was significantly different from control (P=0.037, OR 2.75, 95%), whereas the GSTM1 null genotype frequency was 100% for all ovarian cancer cases (P= 0.004, OR 0.02, 95%). GSTT1 null genotype showed no significant effect in risk of epithelial cancer (P = 0.551, OR 1.3, 95), as illustrated in table 1.

Figure 1. Extracted genomic DNA analyzed by 0.8% agarose gel electrophoresis
Figure 2. Detection of GSTT1 and GSTM1 genotypes by multiplex conventional PCR. Arrows indicate the position of 480 bp GSTT1 product and 350 bp AIB1 product. Lane 1 is a 100 bp marker. Lane 2, 3, 5 refer to GSTT1 product, lane 4 was classified as GSTT1 null. All lane exhibit GSTM1 null at 215bp.

Discussion

This is the first study to investigate the association between GSTT1 and GSTM1 polymorphisms and the epithelial ovarian cancer in Nasiriya city. This study reported that GSTT1 active and GSTM1 null have significant effects in risk of epithelial ovarian cancer. Except the genotype GSTT1 null showed no significant effect of any examined cases. In the past several years, many studies have tried to illustrate the effects of genetic factors in susceptibility and development of ovarian cancer. However, the reported studies about frequencies mutation of previously mentioned genes were mostly not exhaustive\(^{17,18}\). Recently, many studies reported that the polymorphism of GSTs could effect in susceptibility and developing ovarian cancer due to their important role in modification of the biological effects of carcinogens\(^{19,20}\).

Deletion of GSTM1 and GSTT1 genes results in “null” genotype characterized by a general deficit in enzymatic activity\(^{16}\). Individuals homozygous of these deletions are thought to be at increased risk for malignancies as consequence of a decreased capacity to detoxify possible carcinogens\(^{21}\). GSTM1 gene deletion is a good marker for the early detection of many diseases, including, ovarian cancer, endometriosis\(^7\), cystic fibrosis\(^{22}\), bladder\(^{23}\), lung\(^{24}\) and stomach\(^{25}\) cancers. Null phenotype of GSTT1 exhibits decrease in catalytic activity and has been associated with increased risk of cancer of the head, neck and oral cavity\(^{26}\). Patients with GSTM1 null or GSTT1 null showed a better survival rate after chemotherapeutic treatment for the invasive ovarian cancer compared to other patients\(^{27}\).

Otherwise, this study found that the risk of ovarian cancer was increased in carrier of GSTT1-active genotype. This result seemed to be conflict, taking into consideration that several environmental carcinogens found in combustion products and tobacco smoke are among GSTT1 substrates\(^{20}\). However, there is proof that GSTT1 might also be involved in bioactivation, rather than detoxification of several bifunctional alkylating
agents, present in environmental pollution and certain occupational hazards\(^{[28]}\). As a conclusion, bioactive process can yield potent electrophiles that modify DNA and are potentially genotoxic\(^{[29,30]}\). Thus, out result in conformity with the study of Sgambato et al. they showed that \(GSTT1\) null is associated with decreased risk of cancer\(^{[31]}\).

In summary, these results suggest that \(GSTM1\) null and \(GSTT1\) active alleles increase risk to ovarian cancer in Nasiriya population, but further large sample studies need to confirm the genetic role of GSTs in epithelial ovarian cancer.

Histological Characteristic that Accompanying with Ovaryfolliculogenisis of Rabbits for Effectiveness Seeds of (Trigonellatibetana)

Hussein Bashar Mahmood, Walaa F Obead, Ghassan A Dawood

Abstract

Objectives: Alternative plants Medicine has been considered one of the world’s most important solutions to female reproductive diseases. The goal of the current study however, was to evaluate the mains histological changes that follow the use of seeds of (Trigonellatibetana) on ovary folliculogenisis.

Method: Twelve’s female healthy rabbits, in animal house all experimental animals have been adapted. For this study, animals were taken distributed into two groups, control administrated by distal water (5 ml/kg b.w) and treatment group was administrated by Trigonellatibetana extract at a dose of 2g/kgb.w/orally administration during 2 week for 3 time daily.

Results: The present study finding the numerous changes happened in the ovary, the mains variance has been noticed increase the numbers of primordial and atretic follicles in treatment group and increase in size of follicles. Moreover, the theca interna was thickness and has a thicker layers of collagen than control group.

Conclusions: Such results indicate that (Trigonellatibetana) was considered to be suitable for early fertility period arrival.

Keywords: Histological, Trigonellatibetana, folliculogenisis, rabbits.

Introduction

Nowadays, in world culture, the term alternate solution Medicine has become very popular, focusing on the concept of using the plants for medicinal purposes. But the present absolutely believe that the only medicines we can trust and use are those which come in capsules or medications. And though most of these tablets and capsules that we take and use come from plants during our everyday lives. Medicinal plants were used as raw materials for the extraction process components that were used in the utilization of various drugs. It includes products from plants, as in the case of sedatives, antibiotics and blood thinners. Moreover the active ingredients of Taxol, vincristine, and morphine isolated from foxglove, periwinkle, yew, and opium poppy, respectively. Medicinal plants are incredibly recognized worldwide as a synthetic anti-inflammatory or considered alternative medicine in the world. In addition there are numerous of plants has been used to treatment of ulcer and acidity in stomach as such as Inhibitor pump H⁺ proton. Herbal medicines have a great future as there are approximately half a million species worldwide and most of them have not yet indicted their medical activities and their medical activities may be crucial in the therapy of current or potential experiments. Trigonell is one of the principal family of herbal medicines. The plant’s effective medicinal part is its seeds which own fertility hormones such as estrogen and progesterone. It is also used for reduce dysmenorrhea occurrence and wound repair, GIT. Furthermore, the administration herbal plants in laboratory animals due to decrease the number of cystic follicles and increase the number of normal follicles. In addition to metabolic modification, there are related changes in the production of reproductive hormones, including the significantly
increased luteinizing hormone (LH) to follicle-stimulating hormone \(^6,7\). Fenugreek conserved good general health, apparently hyperactivity and elevated intake of food, but no major changes in the value in body mass. High doses however significantly decrease the improvement in mature body weight for rats. Fenugreek seeds increase folliculogenesis in mature, perimeter and mature groups but do not affect follicular growth and development likewise, these seeds have estrogen like action \(^8\). Eventually, the medical plants have a great effectiveness to improve of histological characteristics and due to recover disadvantage in organs. The goal of this study to follow the main stages evolve the follicles and arriving to maturate period early.

**Materials and Method**

Twelve healthy female rabbits were chosen and divided in to two groups (control and treatment group). The average weight were [1100-1300] g, breed locally, and were used in this study. Control group [5ml/kg b.w] administrated by distilled Water and treated group have been given mix of (2g) from Trigonellatibetana with 5 ml of distal water after that administration [5 ml/kg b.w] orally during 14 day for 3 time daily \(^9\). Ovary samples were then kept for 72 hours in 10% formalin. Hematoxyline, eosin and Masson’s trichrome stain were used in the samples with routine histological technique: to differentiate tissue components, connective tissue fibers (collagen), fibrin, and muscles\(^{11}\). Themeasuring of theca interna was performed using the average of (4) microscopic fields for each histological section representing 1.13 mm\(^2\) below 10X, selecting (5) histological section . After which end up taking the arithmetic mean in all fields and convert the 1 mm\(^2\) arhythmically\(^{10}\).

**Results and Discussion**

**Histological Features:** The anatomical features for the rabbit ovary were elongated shape, located in pelvic region and pushed slightly to the abdomen cavity. Likewise, the ovary in control rabbit had smooth texture and longer while the ovary in treatment group was rough surface, these result akin with \(^{11}\) in female Rabbit and\(^{12,13}\) in female Hamster who stated that the effect of medicinal plant in anatomical characteristics. While this results contrasting with\(^{14,15}\) in Albino rat which finding different results and considered these medicinal plant not affecting on anatomical features.

Generally, during inspection of all histological sections of ovary observed many variances between two groups: The stroma of ovary in the control group was distinguished by existence a numbers of primordial follicles closed to germinal layer, these follicle were a less number moreover, more follicles in this group were primary and secondary stage and atretic follicles observed rarely (Figure,1). The ovary in treatment group had a large numbers of primordial follicles which, spread a long sheet of germinal layer. On the other hand the ovary of treatment group was distinguished by the presence of large numbers of mature follicles that distributed in all region of stroma (Figure, 2). These results occur as high level sexual hormones as Estrogen and Progesterone this consequences similar with\(^{16}\) who show that trigonellaseeds with relatively normal follicular maturation increase the normal of folliculogenesis. Mature ovaries secrete adequate quantities of oestrogen reinforce by crude trigonella seeds, resulting in significant increases in growing follicles, with increase in total ovarian structures.

The present study was finding the theca interna in normal ovaries have a thin and consist of (3-6) coil around ovarian follicles, thickness about (50 µm) while the theca interna in treatment ovaries became a thick layer about (10-12) coil and thickness about (100 µm). These finding akin with\(^{17}\) which mention that the administrated medical plant in female rats this process lead to increase size of the ovaries structures (Figure, 3,4).

The present study was showing the variance in quantity of collagen fibers through distribution of connective tissue beneath germinal layer and intermingled with theca interna. There are massive amount of collagen fibers in treated ovaries while the control ovaries have less quantity (Fig, 5,6). These result was happing probably for impact increase the follicles size to support Graafian follicles, this finding akin with \(^{18}\)who has reported that the increase in the thickness of theca interna shown in can play a role in steroidogenysis. This is because of ovarian estrogen, is secreted by theca interna,
Figure, 1: Control group showing the stroma of ovary have premordial (black arrow), primary and secondary follicles (yellow arrow). H&E stain. 40X.

Figure, 2: Treatment group showing the ovary have a large number of perimordial follicles (black arrows) and early atretic follicles (yellow arrow) H&E stain. 40X.
Figure, 3: Control group showing the mature follicle surrounded by a thin of theca interna (yellow arrow) with spherical oocyte (black arrow). H&E stain. 100X.

Figure, 4: Treatment group showing the ovary have a thick layer of theca interna (black arrow) H&E stain. 100X.
Figure, 5: Control group showing the amount of connective tissue spread under germinal layer and blood vessels (black arrow). Masson trichrome stain. 100X.

Figure, 6: Treatment group showing the ovary has a large amount of connective tissue intermingled with theca interna (black arrow). Masson trichrome stain. 100X.
Conclusion

Such results indicate that (Trigonellatibetana) was considered to be suitable for early fertility period arrival.

Serum Macrophage Migration Inhibitory Factor Levels in Patients with Ischemic Stroke in Iraqi Populations

Manal M. Kadhim\textsuperscript{1}, Ali S.Shakir\textsuperscript{2}

\textsuperscript{1}Professor of Clinical Immunology Department of Medical Microbiology, College of Medicine, University of Al-Qadisiyah, Diwaniya, Iraq, \textsuperscript{2}Assistant lecturer, Department of Medical Microbiology, College of Medicine, University of Al-Qadisiyah, Diwaniya, Iraq

Abstract

\textbf{Background:} Stroke is one of the leading causes of permanent disability worldwide. The most common cause of stroke is the occlusion of blood circulation by a thrombus (or embolism) although it can also be produced by the rupture of a vessel and subsequent bleeding in a certain region of the brain. Strokes can, therefore, be classified as ischemic or hemorrhagic.

\textbf{Aim:} The present study was conducted to investigate whether serum MIF levels are associated with severity in patients with ischemic stroke.

\textbf{Method:} A total of 40 patients with ischemic stroke were included in the study who were admitted to hospital from the period between March to August 2019, and other groups consist of 40 apparently healthy individuals. Two blood sample were taken from each patients one during attack (within 24 hours) and the other sample during follow up (within 1-3 months) for serum concentration of MIF by ELISA technique.

\textbf{Results:} Mean serum concentration of MIF in Ischemic stroke during attack (within 24 hours) was significantly higher than that of Ischemic stroke during follow up (within 1-3 months) and healthy control group; 17.094±2.25ng/ml versus 12.83± 4.16ng/ml and 6.407± 3.33ng/ml respectively.

\textbf{Keyword:} Ischemic Stroke, MIF, NIHSS, ELISA.

Introduction

Stroke is one of the leading causes of permanent disability worldwide. The most common cause of stroke is the occlusion of blood circulation by a thrombus (or embolism) although it can also be produced by the rupture of a vessel and subsequent bleeding in a certain region of the brain. Strokes can, therefore, be classified as ischemic or hemorrhagic\textsuperscript{(1)}. Ischemic stroke (IS) accounts for 85\% of overall stroke and its pathophysiology are regulated by a combination of lifestyle, environmental, and unclear genetic risk factors\textsuperscript{(2)}. Ischemic stroke is a heterogeneous multi-factorial, polygenic, complex disease resulting from the combination of vascular, environmental and genetic factors\textsuperscript{(3)}. Ischemic Stroke often causes severe neurological and motor deficits, leading to decreased quality of life; stroke also has significant clinical and socioeconomic impacts\textsuperscript{(4)}. Annually, approximately 800,000 people in the United States have a stroke, and 130,000 die. It has accounted for nearly 5.7 million deaths worldwide, and 87\% of these deaths occur in low and middle-income countries\textsuperscript{(5)}. Numerous studies have focused on the inflammatory reactions after stroke and identifying the roles of important inflammatory signaling molecules, mainly cytokines\textsuperscript{(5)}. Cytokines are up-regulated in the brain after stroke and are expressed not only in immunological cells but also in glial cells and neurons\textsuperscript{(7)}. However, the mechanisms leading to increased release of inflammatory cytokines in patients with stroke remain unclear. Macrophage migration inhibitory factor (MIF) a central cytokine of the innate immunity, includes 114 amino acid with a molecular weight of 12.5-kDa and is expressed in a diversity of cell types, including T cells, macrophages, monocytes, endothelial cells and also in...
activated platelets\(^{(8)}\). Furthermore, it is recognized as a multifunctional cytokine participating in both immune and inflammatory responses\(^{(9)}\). MIF is up-regulated in the brain after cerebral ischemia and is involved in neuro-inflammation\(^{(10)}\). One study demonstrated that serum MIF levels at admission were positively correlated with infarct volume and long-term outcome in patients with acute ischemic stroke (AIS)\(^{(4)}\), while another study confirmed that elevated plasma levels of MIF at admission were associated with increased risk of post-stroke depression (PSD) in the next 3 months\(^{(11)}\).

**Materials and Method**

The current study was carried on 40 patients (18 males, 22 females) age range between 45-85 years from March to August 2019. Other groups consist of 40 apparently healthy individuals (20 male and 20 female) without any history of systemic disease were clinically considered as healthy also included in this study as a control group. We used NIH Stroke Scale to determine the severity of the disease in ischemic stroke patients. We excluded patients with hemorrhagic stroke, stroke associated with surgery, severe trauma or organ ischemia. A six ml of blood samples were collected and withdrawn from each patient within 2 different period including three ml during attack (within 24 hours) and three ml during follow up (within 1-3 months) and three ml from healthy control by vein puncture using disposable syringes under aseptic technique were transferred to sterile Gel tube, and allow to clot at room temperature and centrifuge at 2500 rpm for 10 minutes and the separated serum was saved in Eppendorf tubes and immediately frozen at -20 C till further use to avoid repeated thawing and freezing for MIF ELISA Kit (Elabscience USA) test. This study was in agreement with ethics of Al-Diwaniya Teaching Hospital and verbal informed consent was obtained from all participants.

The National Institutes of Health Stroke Scale, or NIH Stroke Scale (NIHSS) is a tool used by healthcare providers to objectively quantify the impairment caused by a stroke. The NIHSS is composed of 11 items, each of which scores a specific ability between a 0 and 4. For each item, a score of 0 typically indicates normal function in that specific ability, while a higher score is indicative of some level of impairment\(^{(12)}\). The individual scores from each item are summed in order to calculate a patient’s total NIHSS score. The maximum possible score is 42, with the minimum score being a 0\(^{(13)}\).

**Results**

Forty Ischemic stroke (IS) patients included in this study. The risk factors distribution of the study population are summarized in Table (1). There were no significant differences in smoking status as (P>0.05). The prevalence rates of hypertension, diabetes, alcoholism and heart disease were significantly increased in the IS group compared with those in the control group. Mean serum concentration of MIF in Ischemic stroke during attack (within 24 hours) was significantly higher than that of Ischemic stroke during follow up (within 1-3 months) and healthy control group; 17.094±2.25ng/ml versus 12.83± 4.16ng/ml and 6.407± 3.33ng/ml respectively, P-value was (P < 0.0001), figure (1). Table (2) showed highly significant correlation between serum levels of MIF and severity of ischemic stroke (NIHSS) (P<0.001, r=0.512). Where serum levels of MIF increased with increasing severity of ischemic stroke as defined by the NIHSS score.

* NS : No significant association (P>0.05), S : significant association (P<0.05).
The current study showed that 29 (72.5%) of the patients with ischemic stroke had hypertension, and these results indicate high significantly increased in patients with ischemic stroke compared with those in the healthy control group (P = 0.003, OR = 3.95) table (1). This leads us to believe that hypertension is highly non-diagnosed in population due to the lack of an active non-communicable disease screening program, failure to take routine blood pressure measurements, and a general lack of awareness among health practitioners about hypertension and their complications\(^{(14)}\). The present results are generally in accordance with previous studies where indicated that hypertension reduction being associated with a reduced rate of ischemic stroke\(^{(15)}\). These results consistence with results of Li et al\(^{(4)}\), who found that 91 (62.3%) with hypertension and indicate that hypertension significantly increased in the ischemic stroke group compared with those in the control group. In our results there are 22 (55%) of patients with ischemic stroke had diabetes, and these results indicate

### Discussion

The current study showed that 29 (72.5%) of the patients with ischemic stroke had hypertension, and these results indicate high significantly increased in patients with ischemic stroke compared with those in the healthy control group (P = 0.003, OR = 3.95) table (1). This leads us to believe that hypertension is highly non-diagnosed in population due to the lack of an active non-communicable disease screening program, failure to take routine blood pressure measurements, and a general lack of awareness among health practitioners about hypertension and their complications\(^{(14)}\). The present results are generally in accordance with previous studies where indicated that hypertension reduction being associated with a reduced rate of ischemic stroke\(^{(15)}\). These results consistence with results of Li et al\(^{(4)}\), who found that 91 (62.3%) with hypertension and indicate that hypertension significantly increased in the ischemic stroke group compared with those in the control group. In our results there are 22 (55%) of patients with ischemic stroke had diabetes, and these results indicate
significant correlation between diabetes and ischemic stroke when compared with healthy controls groups (p <0.05, OR=2.53). Diabetes is a recognized independent risk factor for stroke and is associated with higher morbidity and mortality. The physiology underlying the increased risk of ischemic stroke in diabetics may be attributable to the increased prevalence of intracranial stenosis in this population. Vasculopathy induced by chronic diabetes related endothelial damage results in acceleration of atherosclerosis inherent to diabetes. Which in consists in old studies that showed diabetes can commonly causes small infarcts which less likely to lead to a fatal stroke.

Although our results indicate 17(42.5%) from individuals with ischemic stroke are active smokers, but these results shows there is no significant correlation between the active smokers and ischemic stroke when compared with control groups, although the smokers are high in ischemic stroke groups (p > 0.05, OR=1.23) table(1). Although our study indicates non-significant association between the smokers and ischemic stroke when compared with control groups, but remain the smoking as important risk factors for ischemic stroke. The mechanism by which passive smoking can increase the risk of stroke has been reported in many studies. Passive smoking can lead to carotid atherosclerosis, and the levels of homocysteine, fibrinogen, and oxidized low-density lipoprotein cholesterol can also be elevated by smoking. About 8 (20%) of patients with ischemic stroke were alcohol consumption, as table (1), and there is a significant correlation between the ischemic stroke and alcoholism when compared with healthy control group (P= 0.038, OR= 1.6). Ischemic stroke is caused by a number of different pathophysiological mechanisms and alcohol drinking might have contrasting effects on ischemic stroke. For example, moderate and high alcohol consumption is associated with an elevated risk of atrial fibrillation, which is a risk factor for ischemic stroke. The risk for ischemic stroke was significantly higher for binge drinkers than for subjects with no heavy drinking pattern. The present results consistence with that of Xu et al(11), who found that 52 (15.6%) with alcohol consumption.

The frequency of heart disease among the ischemic stroke patients are 12(30%) as in table (3-5), and these results indicate significant association between heart disease and ischemic stroke when compared with healthy control groups (p < 0.05, OR= 3.85). Previous study showed that approximately 10% to 24% of patients with stroke have heart failure. Our study indicate frequency lower than Yalcin et al, which showed (57.5%) of the stroke patients had history of ischemic heart disease, and it may be due to short longevity of our patients after developing ischemic heart attack as compared to others in the developed countries, and short longevity after developing coronary heart disease. Furthermore, increasing evidence that heart disease is independently associated with cognitive impairment exists; and cognitive impairment is associated with decreased survival among hospitalized stroke patients.

Figure (1) showed that mean serum concentration of MIF were highly significantly increased among cases with ischemic stroke during attack (within 24 hours) 17.094± 2.25 ng/ml as compared to apparently healthy controls 6.407± 3.33ng/ml, these results revealed a significant association between the concentration of MIF and the ischemic stroke (P <0.001). A study by Inacio et al(19), (2011), indicated that MIF promotes neuronal death and aggravates neurological deficits after experimental stroke. They found that MIF promoter activity was significantly upregulated by hypoxia during ischemic stroke and that MIF protected neurons against oxygen–glucose deprivation. Thus, the reason why serum MIF levels are increased in ischemic stroke patients remains unknown. Serum MIF levels were found to be decreased with blood-sampling time, with the highest levels of serum MIF at ischemic stroke during attack (within 24 hours) (17.094 ± 2.25 ng/ml), and this levels decrease at cases with ischemic stroke during follow up(within 1-3 months) (12.83± 4.16ng/ml), these difference in serum MIF levels between ischemic stroke during attack (within 24 hours) and ischemic stroke during follow up(within 1-3 months) was statistically significant (P<0.001), figure (1). These results indicate that MIF might play an important role in inflammatory process of central nervous system. However, serum MIF levels were highly significantly elevated in any time of ischemic stroke when compared with the controls (P <0.001). Table (2) showed positive correlation between serum MIF levels and severity of ischemic stroke (NIHSS) (P<0.001, r=0.512, where serum levels of MIF increased with increasing severity of ischemic stroke as defined by the NIHSS score, were highest MIF levels in the severe group (18.229 ± 2.45 ng/ml) as compared to moderate and mild severity (16.891± 3.12 ng/ml and 14.98 ± 4.33 ng/ml respectively). The present results are consistence with results of Xu et al(11), which indicated there was a positive correlation between levels of MIF and the NIHSS (r = 0.248, P<0.001).
Conclusions

Our study demonstrated that the serum level of MIF significantly increased following ischemic stroke. The serum MIF levels at admission were positively correlated with the infarct volumes and the severity of patients with IS. In this study we found increased inflammatory response after ischemic stroke compared with healthy control, represented by increased levels of MIF.

Abstract

The study was carried out in Kirkuk city, from 20th January to September to November 2019 included 40 Diabetic patients with retinopathy and 40 healthy persons within the range of age: 45-75 years of old. The information about patients in this study was retrieved from patient’s itself. The diabetic patients with retinopathy were diagnosed by analysis RBS and HbA1c and fundoscopical examination by the ophthalmologist. The criteria of exclusion include non-diabetic and malignant disease. The results of the patients groups were compared with healthy individuals nearly comparable age and BMI. Four ml of blood were collected from patients and for determination of irisin, vaspin and HbA1c. The study showed that the mean serum level of irisin was significantly elevated in DR patients compared to control group (27.57 ± 4.22 and 17.57 ± 5.9 pg/ml) respectively at a P value < 0.01. This study showed that the mean serum level vaspin was higher in DR patients especially in persons with high BMI and decreased in lower BMI persons (75.1, 59.3 and 48.3 ng/ml) respectively but still higher than healthy ones (P<0.01), as compared with the control group (32.17ng/ml). The study showed that, HbA1c was elevated significantly (P<0.01) in diabetic retinopathy patients (10.17%) compared with healthy control (5.17%),. The study concluded that, vaspin and irisin levels were highly elevate din diabetic patients with retinopathy.

Keywords: Malondialdehyde; Diabetic retinopathy; Oxidative stress; HbA1c.

Introduction

Diabetes mellitus (DM) is expected to affect around 550 million people all over the world according to global estimates of the prevalence of diabetes (1). DM is characterized by constant hyperglycemia that damages various organs and manifests in macro vascular complications like premature atherosclerosis resulting in strokes, peripheral vascular disease, and myocardial infarctions and micro vascular complications such as nephropathy, neuropathy, and retinopathy(2). Diabetic retinopathy (DR) is the number one cause of blindness in people between 27 and 75 years of age. Prevalence of DR is around 25% and 90% at 5 and 20 years, respectively, from diagnosis; it is calculated that 191 million people will be diagnosed with this micro-vascular complication by the year 2030(3). Through the last three decades, extensive scientific reports have shown ROS to play an important role in DM complications such as diabetic neuropathy, nephropathy, and retinopathy due to alterations on the biomechanisms involved in the instauration and progression of micro-vascular complications(4). These three micro-vascular complications share high glucose levels as a starting point; such condition is necessary, but may not be enough to initiate the damage present in the peripheral nervous system (neuropathy), kidneys (nephropathy), and retinas (retinopathy) of diabetic patients(5,6). Hyperglycemic states favor the activation of alternative pathways leading to reactive oxygen species (ROS) formation and augmented concentrations locally and in the rest of the body even at the point of surpassing the antioxidant capacity, a state known as oxidative stress affecting retinal integrity(7,8). The study aim of this work was to evaluate the level of Malondialdehyde (MDA) in diabetic patients with and without retinopathy and healthy controls.

Patients and Method

The study was carried out in Kirkuk city, from 20th January to September to November 2019 included
40 Diabetic patients with retinopathy and 40 healthy persons within the range of age: 45-75 years of old. The information about patients in this study was retrieved from patient’s itself. The diabetic patients with retinopathy were diagnosed by analysis RBS and HbA1c and fundoscopy examination by the ophthalmologist. The criteria of exclusion include non-diabetic and malignant disease. The results of the patients groups were compared with healthy individuals nearly comparable age and BMI.

Four ml of blood were collected from patients and controls in plain tubes without any anticoagulant at room temperature for 10-15 minutes and allowed to clot. The tube then were centrifuged (3000 rpm) for 15min. The clear serum was pipetted into clear dry Eppendorf’s and stored at (-20°C) until used for the various investigations. The levels of malondialdehyde, HbA1c were measured by using immunofluorescence technique.

The study showed that, HbA1c was elevated significantly (P<0.01) in diabetic retinopathy patients (10.17%) compared with healthy control (5.17%), Figure 1.

**Discussion**

In several studies, women had significantly higher rate of DR than men, as it seems that females may take care about their general health more than males, which is similar to a study in Sweden where women had a higher rate than men (1-3). Esteghamati et al (10) also established that, there was significant relation of irisin and vasoin with occurrence and development of diabetic retinopathy. While Choi et al (11) in recent study reported that the rate of diabetic retinopathy was significantly associated with elevation of vaspin in obese DR patients. In agreement with the current results, Jeong et al (12) indicated a highly significantly increased irisin levels, in cases with respect to controls, point towards a role of free radicals in causation of diabetic complications like retinopathy. In addition, Rickhamet et al (13) showed that, serum irisin has been found to be significantly associated with the severity of DR in patients with type 2 insulin-dependent DM. Taal et al (14) reported that increased vaspin is associated with oxidative stress and poor antioxidant defense, which promotes the progression of DR to its proliferative form. Some other studies speculate that retinal microvascular complications are closely related to the severity of oxidative stress, as expressed as increased level of MDA among DR patients (7,8). Indeed, the exact mechanism by which the oxidative stress contributes to diabetic complications remains unclear, but all biochemical alterations due to DM lead to anatomical and functional impairment in the retinal microvascular network, such as changes in blood flow in the retina, disruption of the blood-retina-barrier and consequently capillary occlusion and ischemia (15). Moreover, El-Mesallamye at al (16) showed that, serum vaspin was significantly higher in DR patients and the lowest mean was in the control group. Al-El-Lebedy et al (17) in their study showed that, HbA1C was elevated significantly in DR group followed by DM patients indicating that poor glycemic control is a strong predictor for the development of DR. Our findings were also consistent with that stated by other studies in the world (17,18). The elevated levels of HbA1c in DR patients may be due to their induction of retinal inflammation and vascular leakage due to their effect on blood vessels which may lead to retinal cell death (7). The positive association between DR and duration of diabetes is noted in the literature. The retinopathy rate in Southern India was 7% in individuals with short duration of diabetes (less than 10 years), 26% in those with 10-14 years duration and 63% in those with 15 years and more duration of diabetes (6). Our findings were also in agreement with the well established statement of several studies denoted that the severity of retinopathy is strongly associated with the duration of diabetes (19,20). Navnet et al (27) showed level OF Vaspin increased as the grade of obesity increased performed a similar study and reported that the concentration of MDA increased with increasing BMI, which was found to be statistically in overweight subjects.

**Conclusions**

The study concluded that, vaspin and irisin levels were highly elevate in diabetic patients with retinopathy.

**Financial Disclosure:** There is no financial disclosure.

Psychological Burden of Caregivers of Children with Cancer at AL-Amal Hospital in Baghdad City

Ahmad Shihab Ahmad

Ph.D. of Community Health Nursing Science/ALZahrawi College University

Abstract

Objectives: To assess psychological burden of caregivers of child with cancer at Al-Amal Hospital in Baghdad City

Method: Descriptive study conducted among 50 caregivers, they are using self-administration method to answer the psychological burden items. The data collection started from October 7th 2019 to March 9th 2020 at Al-Amal Hospital in Baghdad city.

Results: 50% of caregivers had moderate level of psychological burden and 44% had severe level of psychological burden. The grand mean was (2.21) at moderate level of assessment. There is no significant relationship between the caregivers psychological burden and their general information at P-value 0.05.

Conclusion: The care giver had moderate to severe psychological burden due to caring child with cancer. They are need for psychological support.

Keywords: Psychological Burden, Caregivers, Children, Cancer.

Introduction

Cancer is expected to rank as the leading cause of death and the single most important barrier to increasing life expectancy in every country of the world in the 21st century. According to estimates from the World Health Organization (WHO) in 2015, cancer is the first or second leading cause of death before age 70 years in 91 of 172 countries, and it ranks third or fourth in an additional 22 countries.(1) ‘Burden’ may be defined as a multidimensional concept with objective and subjective components. ‘Objective burden’ is defined as specific happenings and activities related to caregiving, for instance, financial problems or personal activity limitations. ‘Subjective burden’, on the other hand, encompasses affective responses to the caregiver experience, such as feelings and emotions related to fear, strain and guilt.(2) Family caregivers (FCs) are a pivotal source for quality of life, well-being and quality of care in terminally ill patients. However, they are also affected by caring for the patient and may thus be affected by significant physical and psychosocial burden. Psychosocial burden and anxiety are associated with the number of unmet needs in FCs of advanced cancer patients. Frequently unmet needs of FCs relate to information on caregiving and care planning, support in managing fear as the patient’s physical or psychological status declines, and preparing for the patient’s death and their own bereavement. Supportive needs can be summarized in four main categories: needs concerning the patient’s well-being, transfer of information, practical problems of caregiving, and emotional support. Some studies suggest that FCs’ needs might be better addressed if specialized palliative care is included during home or hospital care. In addition, FCs’ quality of life has been shown to be higher in patients receiving care in palliative care facilities rather than in acute care hospitals.(3) Cancer is a family experience, and often family members have as many problems coping with it as does the diagnosed patient. The family goes through different stages of adjusting to the disease. The emotional reactions may include anger, resentment, guilt and adjustment pain, and may or may not lead to the acceptance of the disease. The cancer’s diagnosis, as well as the subsequent phases of the disease and its treatment, may be a source of intense stress both for the patient and for the family. Patients and their relatives need to
face the challenge of a life defined with uncertainty; treatment routines, the threat of recurrence or the failure of the treatment.\(^{(4)}\)

Caring for a child with cancer can be profoundly distressing to parents and in turn, parental psychological distress (PD) can affect child and sibling wellbeing. Caring for a child with advanced cancer is likely to be even more distressing, yet very few prospective studies have evaluated parent PD among these families. Understanding the degree of PD and contributing factors among parents with children with advanced cancer has the potential to better enable clinicians to identify higher risk families and optimize outcomes.\(^{(5)}\)

Family caregivers often feel overloaded with the additional obligations and roles they have to pick up. They find it increasingly burdening to care full-time for the household and provide emotional support for the patient. The family’s problems and the way family members regard the disease may be also a result of the family system they are in.\(^{(6)}\)

The role of a family in the course of cancer changes according to the needs of the patient and the cancer’s phase. In the diagnosis phase, depending on the type of family, a big mobilization, with readiness to give support to the patient, is observed. Family members try to get information about the diagnosis, treatment and chances of survival. Other family types may avoid talking about the cancer to avoid creating an additional stress for the patient. Also, very often both the patient and family members try to search for the reasons for the sickness. Looking to find some sense in the universe is a very common tendency, which results from the conviction that everything in the world has its place and reason. Depending on the family’s coping style, if it is a task concentrated family, attitude towards the sickness may promote healthy behavior or strengthen the will of the patient to fight.\(^{(7)}\)

Taking care of a sick patient, most caregivers share some common needs which unfortunately are not always possible to be fulfilled. All of them have a need for information, for feeling close to and needed by the patient, and to have a chance to get external support whereby they can speak about their own problems – to ‘ventilate’ their emotions.\(^{(8)}\)

Method

Descriptive study design was conducted to assess psychological burden of caregivers of child with cancer at Al-Amal Hospital. The data collection started from October 7th 2019 to March 9th 2020 at Al-Amal Hospital in Baghdad city. The study carried among 50 caregivers selected by a non-probability (purposive sample). The study tool was used constructed questionnaire tool psychological burden of care givers of child with cancer. The questionnaire consists of two parts:- Demographic data of sample composed of (5) items that represent the sample demographic data such Age, gender, level of Education, relative to the child and socio economic status and the psychological burden consisted from 14 items constructed to measure the phenomena, rating and scoring according to 3 likert scale answered by 3 key answer always (3), sometimes (2) and never (1), which assessed by cutoff point (0.66) due to scores (1, 2 and 3) respectively. level of assessment: (1-1.66) = low = L, (1.67-2.33) = moderate = M, (2.34-3.00) = severe = S. The data collected after taken the sample agreement to participate in the study and using self-administration method to gathering data. The data analysis by using descriptive and inferential data analysis (SPSS version 20).

There is no significant relationship between the caregivers psychological burden and their general information at P-value 0.05.
Conclusion

Parenting a child with advanced cancer is strongly associated with moderate to severe levels of psychological burden. Interventions aimed at aligning prognostic understanding with concrete care goals, and easing child suffering and financial hardship may mitigate parental psychological burden. Suggestions for further research are presented to support efficient psychosocial interventions and minimize the psychosocial problem experienced by pediatric caregivers over the course of onco-hematological treatments.

Abstract

This paper reviews the legal regulation of the dietary supplement turnover in Russia. Since dietary supplements are an independent object of civil commerce, they must have certain qualities that distinguish them, most importantly, from medicines. According to the authors, the dichotomy in the definition of dietary supplements in the Russian legislation does not allow fully preventing dietary supplements from being confused with other food products, medicines, international non-proprietary names of medicines. The authors also examine the relationship of dietary supplements with such concepts as comestibles and food products.

Method: The authors used the method of comparative and systemic analysis, synthesis, and scientific research of the object as an element of civil legal relations.

The purpose of the study was to look at dietary supplements as a subject of civil legal relations, to identify problems of protecting dietary supplements as objects of intellectual property law.

Results: Although since the mid-1990s, active distribution of dietary supplements has begun in Russia, to date, the legal doctrine has not developed the scientific concept of dietary supplements, and the definitions contained in regulatory acts are contradictory. The analysis of the regulatory framework and judicial practice gives reason to conclude that dietary supplements are recognized as objects of civil legal relations in Russia. They are sold in free circulation, they are movable property, and legislators have established mandatory registration for putting these objects into commodity circulation.

Keywords: Object of civil legal relations; dietary supplements; medicines; food products; product life cycle.

Introduction

The history of the development of the legal regulation of dietary supplements (further referred to as DS) in Russia has developed in line with the legal regulation of the entire pharmaceutical market. In the mid-1990s, the country began an active distribution of nutritional supplements, with Herbalife as the largest supplier. In 1991, the Russian legislators adopted law No. 1034-1 “On the sanitary and epidemiological well-being of the population,” of the Russian Soviet Federative Socialist Republic (RSFSR) which was the foundation for the legal regulation of DS production and circulation. However, this was the first step, not entirely successful, to create a legal framework for the DS production and civil commerce.

Currently, Russia is completing the implementation of the Strategy for the Development of the Pharmaceutical
Market of the Russian Federation until 2020. The goal of the strategy was the transition to an innovative model for the development of the pharmaceutical industry of the Russian Federation. This is expected to be achieved through consistent technical and technological re-equipment of enterprises and the release of innovative products, including DS, demanded by the population. As a result, by 2020, the export potential of Russian pharmaceutical products should exceed the figure of 2008 by 8 times. However, not all goals have been achieved, which forces us to carefully study the ongoing processes and draw the right conclusions.

Today, the Federal DS Register of the Federal Service for Surveillance on Consumer Rights Protection and Human Wellbeing (Rospotrebnadzor) lists about 9,500 DS. For example, in 2018 alone, Rospotrebnadzor issued 2,302 certificates of state registration for DS. For many years now, the Evalar company has remained the market leader. The second place is occupied by Pharma-Med. According to data for 9 months of 2018, there were more than 52 thousand facilities in the Russian Federation engaged in the production and commerce of DS, including 180 enterprises engaged in DS production and 52,029 enterprises engaged in DS circulation (including 735 warehouses, 5,569 retail network enterprises, 45,725 pharmacy chain facilities). At the same time, according to the results for 9 months of 2018, the territorial agencies of the Rospotrebnadzor of the Russian Federation had revealed 1997 violations. These figures convincingly demonstrate that the market for the production and distribution of DS in Russia is vast, but there are no clear legal mechanisms for regulating this market.

Violations of the mandatory requirements of the law were identified in 77% of facilities producing DS. During inspections of organizations involved in the implementation of DS (trading enterprises, storage depots, pharmacy chains), violations of the established requirements were found in 47% of the facilities. 2,412 decisions were issued on imposing an administrative penalty in the form of an administrative fine for 17,114.61 thousand rubles. 1,404 DS batches were withdrawn from commerce. The volume of rejected products amounted to 1,133.16 kg.

These figures convincingly demonstrate the need to study DS as the object of legal regulation, and to search for a mechanism for the effective regulation of the DS civil circulation in the Russian Federation.

**Method**

In the research process, we used the following method: comparative and system analysis; scientific research of an object as an element of civil legal relations; synthesis; structural-functional and statistical analysis, as well as the empirical cognition method.

**Results**

Russia is a member of the Codex Alimentarius Commission. Codex Alimentarius is a code of accepted international standards and related texts concerning food products presented in a unified format. First of all, these are accepted international standards, guidelines, norms, and rules. The Codex standards are based on reliable scientific data provided by independent international risk assessment bodies or through special consultations organized by the World Health Organization (WHO).

Although the concept of DS is an integral part of the regulatory framework in the field of sanitary and hygienic regulation, the legal doctrine does not contain a scientifically based concept of DS. Legislators define DS as follows: DS are compositions of natural or identical to natural biologically active substances intended for direct intake with food or incorporation into food products to enrich the diet with individual nutritional supplements from plant-based, animal or mineral raw materials, as well as chemical or biologically active substances and their complexes. It seems to us that this definition lacks the most important thing, namely, the purpose of their application. Should there always be a positive effect on the body when taking DS? The history of Russian pharmaceuticals is full of cases where certain medicines did not have any medical effect, and the health of patients improved only due to the placebo effect.

DS registration takes place at the federal level and the state controls all stages of the DS circulation. A study of the dynamics of the development of legislation shows that it follows a chaotic gradual tightening of the order of the DS circulation, and there are no uniform rules for the civil circulation of DS in Russia. As a result, selling DS makes one balance between legal and illegal activities. The similarity of DS to medicines in many respects has predetermined the complex nature of legal relations regulation in the circulation of DS.

The subjects of civil legal relations enter into relations to satisfy their needs. The objects of civil legal relations are various tangible (including material)
benefits and intangible (ideal) benefits or the process of their creation, which are part of the activities performed by subjects of civil law. DS can have a great impact on human health, not always with positive results. Therefore, the problem of DS turnover is relevant in Russia, as the population’s health leaves much to be desired.

Legislators define DS as an object of the material world. This follows from Article 1 of Federal law No. 29-FZ “On food quality and safety” dated 02.01.2000 which defines DS as natural (or identical to natural) biologically active substances.

According to Paragraph 2.1 of Sanitary Rules and norms (SanPiN) 2.3.2.1290 — 03, DS are used as an additional source of food and biologically active substances, to optimize carbohydrate, fat, protein, vitamin and other types of metabolism in various functional states, to normalize and/or improve the functional state of organs and human body systems, including products that provide a restorative, soft diuretic, tonic, sedative and other types of effect under various functional conditions, to reduce the risk of diseases, as well as to normalize the microflora of the gastrointestinal tract as enterosorbents.

The technical regulation of the Customs Union “On food safety” (TR TS 021/2011) defines DS as natural and (or) identical to natural biologically active substances, as well as probiotic microorganisms intended for consumption with food or incorporation into food products. This inclusion of probiotic microorganisms highlights the inconsistency of the concepts defined by various regulatory enactments.

If we turn to the Guidelines of the Chief Sanitary Doctor of Russia on determining the safety and effectiveness of biologically active nutritional supplements, then we will see another definition of DS as compositions of natural or identical to natural biologically active substances intended for direct intake with food or introduction into food products to enrich the diet with individual DS from plant-based, animal or mineral raw materials, as well as chemical or biologically active substances and their combinations.

Moreover, it is worth noting that legislators introduced DS in two different concepts: as “comestibles” in the law “On the basic norms of state regulation of trade activities in the Russian Federation” and “food products” in the law “On the quality of products”.

According to the law “On trading activities”, comestibles are products in natural or processed form, which are commercially available and used by humans for food (including baby food, diet food), bottled drinking water, alcoholic beverages, beer and beverages made based on it, soft drinks, chewing gum, nutritional supplements and DS. Based on this normative act, one can conclude that DS is a kind of comestible.

According to the law “On food quality”, food products are products in a natural or processed form used by humans for food (including baby food, diet food), bottled drinking water, alcoholic beverages (including beer), soft drinks, chewing gum, as well as food raw materials, nutritional supplements and DS.

Based on the foregoing, we can conclude that the concept of food products includes everything that includes the concept of comestibles, except food raw materials. The term “food raw materials” itself does not have legal significance since it is not used in regulatory acts and judicial practice. Therefore, we can say that in general food products and comestibles constitute almost identical concepts. At the same time, a comparison of DS with food products, in our opinion, violates the balance of interests between the consumer and the manufacturer in favor of the latter. This has been repeatedly indicated in the literature more than once. It seems to us that a DS release on the market should be preceded by an investigation of the positive effect of this particular DS.

The dichotomy in the definition of DS in the Russian legislation does not allow fully protecting DS from being confused with other food products or medicines, including international nonproprietary names of medicines (INPNs).

Let us review the question of the correct legal qualifications and the legal regime of DS as an object of civil rights.

In scientific literature, the ability to serve as an object of property turnover (various transactions) and change its owners (holders) is called turnover ratio. From this point of view, all things are divided into three groups (permitted in circulation, restricted in circulation, and prohibited in circulation or withdrawn from circulation). Most of the things belong to the first group, i.e. permitted in circulation. They can freely move from one person to another as a result of civil transactions, without special permission.
Objects restricted in circulation belong only to certain participants in the turnover. These include ammunition, radioactive substances, etc., or things that are in circulation by special permission of the public authority (for example, currency values, mineral resources, etc.).

The third group of objects withdrawn from circulation consists of things that cannot serve as the subject of transactions and change the owner (Russian Federation or its subjects). These objects, for example, include some land plots that are in federal ownership.

DS are usually classified as objects in free circulation. Legislators do not require a license from legal entities, individual entrepreneurs, and citizens whose activities are associated with the design, construction, reconstruction, operation of organizations for the production of DS, or import and circulation of DS. However, SanPiN2.3.2.1290-03 establishes requirements for the location, arrangement, layout, sanitary condition of organizations involved in the production, import, and circulation of DS, as well as working conditions in their production.

There are requirements for the registration of the new DS. Based on Paragraph 2.8 of SanPiN 2.3.2.1290-03, the launch of new DS, production, and circulation of DS is allowed only after confirmation of their compliance with applicable regulatory documents and technical regulations (registration) in the manner prescribed by applicable law. Paragraph 5, Part 1, Article 24 of TR TS 021/2011 classifies DS as specialized food products subject to state registration. According to Part 6, Article 24 of TR TS 021/2011, the fact of state registration of DS is confirmed by the inclusion of information about it in the Unified Register of Specialized Food Products. Thus, on the one hand, legislators classify DS as things that are free to trade, on the other hand, this trade is placed in a tight framework that restricted it. Nevertheless, DS do not appear in Decree No. 179 “On types of products (works, services) and production waste, the free sale of which is prohibited” of the President of the Russian Federation dated February 22, 1992, therefore they can be distributed in free circulation.

Legislators have also established requirements for the sale of DS. For example, DS can be sold in retail by pharmacy organizations (pharmacies, medicine stores, pharmacy kiosks, and others), specialized stores selling dietary products, food stores (special departments, sections, kiosks) (Paragraph 7.4.1 of SanPiN 2.3.2.1290-03). At the same time, the remote retail sale of DS is not allowed (Letter No. AK/17858/16 “On advertising the remote sale of DS” of the Federal Antimonopoly Service (FAS) of Russia dated 22.03.2016).

Another basis for the classification of objects is their separation into movable and immovable ones. Moreover, the Civil Code of the Russian Federation (CC RF) includes all things not classified by law as real estate in the concept of movable property. Movable property, as a general rule, is not subject to state registration. However, as an exception, legislators may establish the registration of transactions with certain types of movable property (Paragraph 2, Article 164 of the CC RF). Therefore, the fact of registration is not the basis for dividing objects into movable and immovable.

Real estate in Russia includes land, buildings, structures, and all things that are firmly connected with the land, i.e. inseparable from it without disproportionate damage to their economic purpose (immovable by nature). Besides, the CC RF lists aircraft and sea vessels, inland navigation vessels, and space objects as immovable property subject to state registration. As one can see, real estate is a legal category, and state registration of real estate rights is an integral part of the legal regime of real estate, while movable property registration is an exception to the rule.

DS are registered in the prescribed manner. Rospotrebnadzor reveals the compliance of information about the new DS with regulatory documents and the requirements for the quality of DS (Paragraph 2.2 of SanPiN 2.3.2.1290-03). The fact of state registration of DS is confirmed by the inclusion of information about it in the Unified Register of Specialized Food Products. Information from the Unified Register of Specialized Food Products is publicly available.

The procedure for registering a DS consists of several stages: Formation and submission of a registration dossier for the examination of DS at the Scientific Research Institute of Nutrition of the Russian Academy of Medical Sciences (RAMN);

Product testing and examination;

Drawing up an expert opinion;

Submission of documents and their approval in the agencies of Rospotrebnadzor.
Since DS are not medicines, they do not undergo large multi-year international independent clinical trials.

Examination of DS includes the assessment of the accompanying documentation of DS, conducting microbiological, sanitary and chemical studies, studying the toxicological and metabolic effects that may be caused by the use of DS, clinical analysis of the effectiveness of DS and a comprehensive assessment of the results based on the data obtained. Thus, DS, being movable property, undergo serious testing and registration as immovable property, but this does not make them real estate.

The CC RF allows for the registration of rights with movable property. Thus, Article 130 of the CC RF provides for registration on the movable property in cases specified in the law. Paragraph 2, Article 164 of the CC RF establishes state registration of transactions providing for a change in the terms of a registered transaction.

However, in this case, the state registration of DS does not contradict the current legislation of the Russian Federation and it can be assumed that DS, like money and securities, can be attributed to movable property. At the same time, physical properties of objects as a legal regime are not so important for a commodity circulation, namely the ability (impossibility) to make various transactions with these objects, as well as protecting such a regime from possible violations.

The CC RF protects the results of intellectual activities and equivalent means of individualization of legal entities, goods, works, services. The protection of the results of intellectual activity and means of individualization is carried out under the current legislation of the Russian Federation (Paragraph 2, Article 1225 of the CC RF). For the violation of intellectual property protected by law, various types of liability can arise, such as civil liability (Articles 1253, 1301, 1311, 1472, 1515, 1537 of the CC RF); administrative liability (Article 7.12 of the Administrative Code of the Russian Federation (AC RF) “Violation of copyright and related rights, inventive and patent rights”, Article 14.10 of the AC RF “Illegal use of a trademark”) and criminal liability (Article 146 of the Criminal Code of the Russian Federation (CrC RF) “Violation of copyright and related rights”, Article 147 of the CrC RF “Violation of inventive and patent rights”, Article 180 of the CrC RF “Illegal use of a trademark”).

Since DS are allowed to be produced and circulated only after confirmation of their registration (Paragraph 2.8 of SanPiN dated 04.17.2003), the right to name the DS, and the right to labeling or designation of goods start to function from the moment of registration of the corresponding biologically active supplement in the Federal Register of Permissible DS. Such a register will allow all consumers to obtain information about the manufacturer, the scope, and expert opinion based on which the certificate was issued. Until the registration, the means of individualization of the right to the name of the supplement is not of an exclusive legal nature. However, it seems to us that in this case, the right to a name can be protected concerning the rules governing unfair competition.

The legal significance of the DS registration is supported by judicial practice. Thus, the court upheld the conclusion that a trademark in the form of a verbal designation cannot be registered to a similar verbal designation of the name of a DS since in this case the trademark was capable of misleading the consumer regarding the location of the manufacturer of the product, and therefore it violated the provisions of Paragraph 3, Article 1483 of the CC RF. In this case, the applicant had applied with priority on December 28, 2009, for registration of the word “TRIBUSTERON” as a trademark. Rospatent refused to register. The applicant appealed against this refusal to a court. All courts supported the decision of Rospatent on the following grounds: a similar designation is used by a limited liability company based on a certificate of the Rospotrebnadzor dated April 17, 2009, and May 26, 2010, before the priority date of the disputed trademark that the manufacturer wanted to register as a DS name.

Courts, guided by the provisions of Articles 6 and 7 of law No. 3520-1 “On trademarks, service marks and appellations of origin” of the Russian Federation dated September 23, 1992, and Articles 13, 1248, 1483, 1484, 1486 of the CC RF, Paragraph 6 of the Decision of the Plenum of the Supreme Court of the Russian Federation concluded that the designation claimed did not comply with Paragraph 3, Article 1483 of the CC RF.

It is worth noting that the registration of DS in the register protects the right to the name, but DS with a self-registered trademark acquire greater security. Legislators understand a trademark as a designation used to individualize goods, the right to which is certified by a certificate for a trademark (Paragraph 1, Article 1477 of the CC RF). Most manufacturers register verbal, graphic, three-dimensional, and other designations or their combinations as a DS trademark.
It is also worth noting the practice in the Russian Federation of interpreting norms by the Patent Rights Chamber in addition to court interpretations.

In Russian legislation, as well as in the legislation of most foreign countries, the main sign of trademark eligibility is the presence of distinctive character. At the same time, in judicial practice, it is normal to take into account not only the data of the registers allowing to introduce DS into circulation but also the open data contained in these registers. In this case, the basis for refusal of state registration, the relevant authorities indicate Paragraph 3, Article 1483 of the CC RF, where state registration of designations that are an element or contain an element that is false or is capable of misleading the consumer regarding the product or its manufacturer is not allowed. To such designations, legislators refer to designations that generate in the consumer’s mind a false idea of a certain quality of the product, its manufacturer, or place of origin.

The protection capacity of a trademark is limited, as for all means of individualization (for a commercial designation, this is a territorial sphere (Article 1539 of the CC RF), for company names, it is a field of activity (Article 1474 of the CC RF), for trademarks, it is the production of certain groups of goods). In Russia, when registering a trademark, it is necessary to indicate the list of goods according to the International Classification of Goods and Services for the Registration of Marks (hereinafter ICGS). DS belong to Class 5 of ICGS.

Legislators prohibit registration as trademarks of signs that are identical or similar to the point of confusion with the trademarks of others concerning similar goods and having an earlier priority.

It is widely known that legal protection of a trademark as a means of individualization is provided to classes of goods for which state registration of a designation is requested. If a competitor uses a controversial designation for homogeneous goods, the exclusive right to a trademark is subject to protection under the procedure established in the fourth part of the CC. According to the ICGS, DS belong to Class 5. Class 5 of this classification includes pharmaceutical and veterinary medicines; hygiene products for medical purposes; diet food and substances for medical or veterinary purposes, baby food; nutritional supplements for humans and animals; plasters, dressings; materials for dental fillings and manufacturing of dental casts; disinfectants; preparations for the destruction of harmful animals; fungicides, herbicides.

However, even with the inclusion of DS in Class 5 of the ICGS, the law enforcement difficulties are not over. In particular, the question arises about the possibility of applying the registered designation to all types of goods included in one class of ICGS, or about the possibility of equating goods from different classes to DS. On the one hand, the Intellectual property court (IPC) emphasized that in a specific trademark dispute regarding DS, it was necessary to analyze the homogeneity of goods entered into civil commerce by the plaintiff (in a specific case: DS, fruit filler, jelly, ice cream raw materials), products for which trademarks of the defendant had been registered and in respect of which a requirement had been made for the early termination of legal trademark protection (baby food, teas, dietary substances for medical purposes). When establishing the homogeneity of goods, one needs to determine the fundamental possibility of a consumer having the idea that these goods belong to one manufacturer. To establish the homogeneity of the goods, one takes into account the kind (type) of goods, their purpose, the type of material from which they are made, the conditions for the sale of goods, the circle of consumers, and other characteristics. When establishing the homogeneity of goods (services), courts should take into account the following circumstances: the kind (type) of goods (services), their consumer properties and functional purpose (volume and purpose of use), the type of material from which they are made, complementarity or interchangeability of goods (services), conditions for their sale (including the general point of sale, sale through a retail or wholesale network), the circle of consumers, the traditional or predominant way of using goods (services). However, in another case, in its decision, the Chamber of Patent Disputes Board noted that baby food, or wound dressings, or herbicides and fungicides were not pharmaceuticals, and when deciding on the registration of a trademark, it was not necessary to take into account the uniformity of those products.

Another problem of DS safety is the question if DS are homogeneous to medicines or ordinary food products. How closely is homogeneity related to a particular class of ICGS?

The initial jurisprudence focused on the fact that the homogeneity of goods was determined primarily within the framework of one class of ICGS. Therefore, identical trademarks could be registered for various goods
included in various classes of ICGS. Thus, the scope of legal protection depends both on the list of specific goods indicated in the trademark certificate and on the general indication of the class of ICGS. At this stage of the development of the institution of trademarks, the concept of "homogeneity" may cover goods related not to the same, but different classes of ICGS.

In addition to the similarity to the degree of mixing, homogeneity of the goods, the name of the DS should not be similar to the well-known active substance (Paragraph 16, Article 4 of the Federal law “On the circulation of medicines” introduces the concept of the INPN of the medicinal product, i.e. the name of the active substance of the pharmaceutical substances recommended by the WHO). It should be noted that judicial practice supports this legal position. Thus, the Decree of the Presidium of the Supreme Arbitration Court of the Russian Federation indicated that the KARNITON trademark was registered for a wide range of goods, including pharmaceuticals, and we can conclude that the registration of this trademark, which is similar to the degree of confusion with the INPN Carnitine used for medicinal products, leads to misleading the consumer who may think that a non-medicinal product marked with this trademark is a medicine.

DS are often presented in a package quite similar to medicines, with similar release forms and similar instructions for use. They are sold through the pharmacy network, sometimes they have a similar composition of active substances. There are frequent cases where the names of DS are indistinguishable or have significant similarities with the names of medicines (usually substances for medical use). The vast majority of dispute cases are related to the means of individualization of DS introduced into commodity circulation.

Thus, DS are recognized in the Russian Federation as objects of civil legal relations, free in civil commerce. Besides, DS are movable property, but legislators have established mandatory registration for entering these objects into commodity circulation. However, DS names can be mixed with other food products, medicines, INPNs of medicines. In this connection, it is necessary to study the life cycle of DS, to develop additional requirements and rules for the rational choice of DS. The practice of assigning names of medicines followed this practice.

What is the DS life cycle? Without a definition of a life cycle, it is difficult to ensure the safe circulation of DS.

Recently, the phrase “life cycle” is increasingly found both in normative acts and in the scientific literature.

The board and council of the Eurasian Economic Commission define the “product life cycle” as all stages of the product’s life from the initial development, its circulation until the product ceases to exist and also defines the concepts of “equipment and (or) coating life cycle” and other life cycles. The legal concept of “product life cycle” is also contained in other normative acts and is defined as a set of interrelated processes of successive changes in the state of the product from the formation of the initial requirements for the product to the decommissioning of the product, its disposal and (or) dumping.

In the scientific literature, there is currently no single approach to the concept of “life cycle”. The number of stages that a product goes through during its life on the market is also not defined in the doctrine.

Often in normative acts, one can find such terms as “turnover” or “circulation of goods”. Under Article 1 of law No. 29-FZ “On food quality and safety” dated January 2, 2000, the turnover of food products means the sale and purchase (including export and import) and other method of food transfer (sale), its storage, and transportation.

Legislators include the following stages in the process of “medicine circulation”: development, preclinical studies, clinical trials, examination, state registration, standardization, and quality control, production, manufacturing, storage, transportation, import into the Russian Federation, export from the Russian Federation, advertising, delivery, sale, transfer, use, destruction of medicines. As we see, in this context we are talking only about medicines, which do not include DS.

If we analyze the terms used in the Customs Union, then the circulation of food products means buying and selling and other method of transferring food products in the Customs Union (TR TS 021/2011).

Thus, the analysis of the current legislation of Russia shows that there is no unity in the regulatory acts of various levels in the use of the terms “turnover” and “circulation”.

However, for the legal regulation of the circulation of DS, it is important to trace all stages of the life of
DS, not only from the moment of sale. If we turn to common vocabulary, the “cycle” is a process consisting of a succession of various stages over a certain period. For any object, it is important to have a period, starting from birth, functioning, and ending with the cessation of existence. Therefore, under the “life cycle” we mean all the processes from the moment of the development of new DS to their introduction into circulation, the turnover itself, and its termination.

In the absence of a normative act on the life cycle of DS from production to disposal, the provisions of various norms of national standards apply, especially the ones concerning food products.

The norms of SanPiN 2.3.2.1290-03 2.3.2. establish requirements for the composition of DS, the development, registration, production, storage, transportation, labeling, sale, disposal, and supervision. The methodological guideline (MG) norms 2.3.2.721-98 are applied at the stages of examination and registration of DS as well as in the development and putting them into production, industrial production, storage, transportation, procurement, import into the country and sale, in the development of regulatory and technical documentation governing the issues of handling DS.

The quality, safety of DS in food, and their ability to exert the effect declared by the manufacturer are determined by their compliance with hygiene standards established by SanPiN 2.3.2.1078-01. Food raw materials must meet the hygiene requirements of the safety and nutritional value of food products. Here one can give two dozen different regulatory acts regulating the life cycle of DS in Russia as an example.

Based on such an extensive regulatory framework that governs the various stages of the life cycle of DS, we have identified the following: development of new DS, examination, state registration, manufacturing (production), storage, transportation, sale, supervision (control) and disposal. The definition of such stages in the life cycle of DS will allow us to study the legal regulation of DS in general and at a specific life stage of DS.

On January 1, 2019, a new national standard of the Russian Federation was introduced, namely “Specialized food products, biologically active nutritional supplements. Method for the determination of quartzetin” GOST R 57990-201723.

Under GOST R 56202-2014, at the earliest stages of development of DS, a risk assessment must be performed to eliminate or minimize potential risks and implement effective control. According to Article 16 of Federal law No. 29-FZ “On food quality and safety” dated 02.01.2000, developers of new food products are obliged to justify the requirements for the quality and safety of the product, develop programs for production control over the quality and safety of products, establish test method, and shelf life. By GOST R 56202-2014, at the earliest stages of development of DS, a risk assessment must be performed to eliminate or minimize potential risks and implement effective control. Thus, when developing DS, the company conducts scientific and technical activities to obtain scientific and technical products for subsequent implementation.

To develop an original medicine, first one needs to decide what the effect of the DS will be (whether it will improve the functioning of the gastrointestinal tract, promote the functioning of the nervous system, etc.) or find a substance that somehow effectively affects the human body. During the initial screening, options are screened in the laboratory, and the non-effective ones are screened out. It is determined whether the selected substance works. If there are few side effects and the tested substance has a positive effect, then the documentation for the registration of a new DS can be prepared.

It is not allowed to buy or sell DS that:

- do not meet the requirements of regulatory documents;
- have obvious signs of poor quality that do not raise doubts among representatives of agencies exercising state supervision in the field of ensuring the quality and safety of food products (hereinafter referred to as state supervision agencies) when checking such products, materials, and goods;
- do not correspond to the information provided and in respect of which there are reasonable suspicions about their falsification;
- do not have established expiration dates (for food products, materials, and goods, for which the establishment of expiration dates is mandatory) or are past their expiration dates;
do not have labeling containing the information prescribed by law or regulatory documents, or for which there is no such information.

Such DS are recognized as low-quality and dangerous and therefore cannot be sold. They are disposed of or destroyed, withdrawn from circulation by their owner or by order of organizations engaged in state sanitary and epidemiological surveillance, and are also not subject to sale for their intended purpose.

Discussion

1. In international law, in particular, in Decision No. 880 “On the adoption of technical regulations of the Customs Union “On safe food products” of the Commission of the Customs Union dated December 9, 2011, DS are defined as natural and/or identical to natural biologically active substances, as well as probiotic microorganisms intended for consumption at the same time as food or incorporation into food products. This document also contains implicit criteria for classifying substances as DS. In this regard, the doctrinal and (or) legislative consolidation and refinement require a single concept of DS, which includes the mandatory features (criteria) and allows distinguishing between this object (product) and other (medicines, other food products, etc.).

2. Since currently such concepts used in regulatory legal acts as “releasing DS to the market” and “circulation of DS” have different lexical meanings, it is necessary to use a single terminology in regulatory legal acts that would cover both of these concepts. It seems to us that the wording “releasing DS to the market” which is enshrined in Article 6 of the Directive of the European Parliament and the Council of the EU 2001/83/EC of November 6, 2001, deserves attention. The concept “On the Code of the medicines for human use community” covers not only circulation as trade in the market but also other life cycles of DS.

Conclusion

As a result of the study and analysis of the regulatory framework and judicial practice, we can draw the following conclusions:

1. DS are recognized as objects of civil legal relations in Russia. They have free turnover, are movable property, and legislators have established mandatory registration for entering these objects into commodity circulation. Requirements for use in the development and production of DS, their import, storage, transportation, and sale in the Russian Federation are established by SanPin.

2. At present, in Russia, there are no clear criteria to clearly distinguish between DS and medicines. DS are often presented in civilian circulation in packaging quite similar to medicines, with similar release forms, and similar instructions for use. They are sold through the pharmacy network, and sometimes they have a similar composition of active substances. This is the reason for the overwhelming majority of cases of disputes concerning means of individualization of DS introduced into civil commerce.

3. In determining the life cycle of DS, the following stages should be distinguished: the development of new DS, examination, state registration, manufacture (production), storage, transportation, sale, supervision (control), and disposal. The definition of such stages in the life cycle of DS will allow us to study the legal regulation of DS in general and at a specific life stage of DS.

4. To develop a new kind of DS, one first needs to decide what this DS will influence (whether it will improve the functioning of the gastrointestinal tract, promote the functioning of the nervous system, etc.) or find a substance that somehow effectively affects the human body. During the initial screening in the laboratory, it is necessary to look at the non-effective options and find out if the selected substance works. If there are few side effects and a positive effect is present, then such a DS can be registered.

5. Since DS are allowed to production and circulation only after their registration, the right to name DS or the right to labeling or designation of goods arises from the moment of such registration in the Federal Register of Permissible DS. Until the registration, the means of individualization of the right to the name of the supplement is not of an exclusive legal nature. However, in this case, the right to the name may be protected based on the law on the Protection of Competition

Abstract

Background: Major adverse cardiovascular events (MACE) are the leading cause of death in chronic kidney disease (CKD) patients. The relationship between the initiation of peritoneal dialysis (PD) and MACE is unclear.

Objective: This study compared the incidence of MACE in PD patients when the estimated glomerular filtration rate (eGFR) is calculated using the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equation with the Thai eGFR equation.

Method: The study was conducted among 684 end-stage CKD patients in a referral hospital in Thailand between 2011-2018. The first occurrence of cardiovascular events related MACE was defined as dependent variable. Logistic regression was used to identify the relationship.

Results: The incidence of MACE was different between CKD-EPI group (10.9%) and Thai eGFR group (12.4%). After adjusting for other factors, the PD initiation using eGFR calculated by CKD-EPI equation did not affect the incidence of MACE when compared to those from Thai eGFR equation (Ajd.OR: 1.11; 95%CI: 0.68-1.82, P-value = 0.685).

Conclusion: There was no effect on incidence of MACE when PD was initiated based on eGFR calculated using the CKD-EPI equation compared with the Thai eGFR equation.

Keywords: Late stage, end stage kidney disease, PD, CVD, advanced stage, CKD.

Introduction

End-stage renal disease patients are at high risk for major adverse cardiovascular events (MACE). It is the most common cause of death in this group of patients whose illnesses frequently worsen over time as kidney function declines[¹-⁴]. Early accurate detection CKD and monitoring of renal function can reduce MACE...
complications by implementing treatment and lifestyle interventions to help slow the progression of disease, and delay need for renal replacement therapies (RRT). Glomerular filtration rate is the best reflection of kidney function however it is difficult to measure with routine clinical laboratory method. As a result, GFR is estimated based on serum creatinine, and is the measurement nephrologists use to decide when to initiate renal replacement therapy (RRT) for their ESRD patients⁵,⁶. GFR estimates also play an important role in CVD risk screening⁷. The Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI equation, 2009) is the most widely used method to estimate GFR globally⁸. The CKD-EPI equation includes variables related to race and ethnicity. For this reason, many countries have developed new eGFR equations that are based on data from their population⁹-¹³.

Peritoneal dialysis (PD) is one of the RRT options to reduce mortality in ESRD patients. Use of life-extending treatments like RRT should consider both physical and spiritual benefits for patients to maximize the benefit for individual patients and their families. In 2008, the Thai government developed the “PD First” policy for ESRD patients as a strategy to balance the use of clinical resources, treatment outcomes and medical expenditures¹⁴. There are several issues to consider before initiating PD; one of the most important ones is timing. Starting PD can provide significant improvement in symptoms. However, it increases the risk of dialysis related complications. PD requires significant effort on behalf of patients and families and impact quality of life¹⁵. Starting PD before it is necessary can also result in increased costs for the patient and the health care system. The global issue of kidney disease reported the need for more research into the management of CVD risk factors in CKD patients¹⁶,¹⁷. In 2011, the Thai eGFR equation was developed. This was followed in 2015 by the recommendation by the Nephrology Society of Thailand that it be used for the evaluation and management of the adult-CKD patients in Thailand¹⁸, even though it uses an unconventional method compared to the CKD-EPI equation¹⁸,¹⁹. The GFR estimated by Thai eGFR is generally higher than the CKD-EPI-eGFR, there have not been any studies to compare the clinical outcomes of using eGFR calculated by either method to decide when to initiate PD. This study compared the incidence of MACE in patients starting PD based on the eGFR calculated using the Thai eGFR equation with the CKD-EPI equation. MACE is a major complication affecting on high mortality in CKD¹,⁷,²⁰. By using MACE as the clinical outcome of interest, rather than mortality, this study aims to understand the cause of the comorbidity resulting in mortality in ESRD patients.

Materials and Method
Study design and variables: A total of 684 out of 828 ESRD patients from a referral hospital in Thailand between 2011-2018 were included in the study, 144 patients excluded due to MACE that occurred before initiating PD. Participants were divided into two groups based on the results of eGFR recalculated by the CKD-EPI equation and the Thai eGFR equation. The data of each patient were retrieved from the hospital information system which included: gender, age at time PD was started and diabetes mellitus status. Physical examination results of body mass index and blood pressure were obtained. Laboratory results collected were serum creatinine (SCr) during the 3-month period before starting PD, albumin, hemoglobin, bicarbonate and the presence or absence of hypokalemia, defined as a serum potassium level of less than 3.5 mEq/L (3.5 mmol/L. The first CVD-related disease (coronary artery disease, peripheral vascular disease or stroke) that occurred after PD initiation was a dependent variable.

The nephrologists of that hospital used the CKD-EPI eGFR equation to make decisions regarding when to initiate PD. In order to select the equations, a data set for the SCr of a 60-year-old male was generated for eGFR calculation. In the generation process, SCr was varied while gender and age were fixed. The results showed that the eGFR calculated by the Thai eGFR equation was higher than that by CKD-EPI equation (Figure 1). Two groups were then defined: the CKD-EPI equation group which included those with eGFR ranging from 5 to 14 ml/min/1.73m² and the Thai eGFR equation group which included eGFR ≥ 4 ml/min/1.73m² and eGFR < 4 ml/min/1.73m² obtained from CKD-EPI equation.
The formulas used to recalculate the eGFR are displayed in Figure 2. The required parameters (age, gender, and SCr) in the CKD-EPI equation and the Thai eGFR equation were selected. Each participant was allocated to the defined group based on their recalculated eGFR results.

**CKD-EPI equation:**

- $\text{Scr} \leq 0.7$ eGFR = $144 \times \left(\frac{\text{Scr}}{0.7}\right)^{-0.329} \times 0.993^{\text{Age}}$ (Female)
- $\text{Scr} > 0.7$ eGFR = $144 \times \left(\frac{\text{Scr}}{0.7}\right)^{-1.209} \times 0.993^{\text{Age}}$ (Female)
- $\text{Scr} \leq 0.9$ eGFR = $141 \times \left(\frac{\text{Scr}}{0.9}\right)^{-0.411} \times 0.993^{\text{Age}}$ (Male)
- $\text{Scr} > 0.9$ eGFR = $141 \times \left(\frac{\text{Scr}}{0.9}\right)^{-1.209} \times 0.993^{\text{Age}}$ (Male)

**Thai eGFR equation:**

$375.5 \times \text{Scr}^{(-0.848)} \times \text{Age}^{(-0.360)} \times 0.712$ (If female)

**Data Analysis:** Data analysis was performed using StataCorp Stata MP 16.0. We displayed the baseline characteristics of both CKD-EPI eGFR and Thai eGFR equations groups to demonstrate the balance of attributes between the groups using frequency and percent for gender, and presence or absence of diabetes mellitus and hypokalemia. For other continuous variables, mean and standard deviation, median and range (Minimum: Maximum) were used.
Outcome variable was the first occurrence of MACE - coronary arterial disease (CAD), peripheral arterial disease (PAD) or stroke - after starting PD. Univariate analysis was employed to understand the magnitude of the overall MACE alongside each event of CAD, PAD and stroke. Simple logistic regression was performed in bivariate analysis to produce results of association between MACE and each candidate variable. All candidate factors were included in the initial model of multivariable analysis using multiple logistic regression. Each variable was then eliminated from the model. No difference between the models with and without that variable (a result from likelihood ratio test produced a probability of greater than 0.05). The final model presented all factors as crude ORs and adjusted ORs corresponding to their 95% confidence intervals (CI). All hypothesis testing was considered as statistically significant at p-value less than 0.05.

Results

Baseline information of participants: In the 684 end-stage renal disease patients who had not experienced MACE prior to initiating peritoneal dialysis, there was no significant difference between both equation groups except the presence of DM and hypokalemia, which was higher in CKD-EPI group (Table 1).

MACE major adverse cardiovascular event; CAD coronary arterial disease; PAD peripheral arterial disease

**Relationship between different eGFR levels and major adverse cardiovascular events:** Using the 684 observations in the fitting model, the different equations did not have a statistically significant effect on MACE occurrence. A MACE event (CAD, PAD or stroke) was 1.11 times more likely to occur after PD initiation in the Thai eGFR group than EPI-CKD group.

Age refers to age at initiated PD; DM refers to diabetes mellitus; BMI refers to body mass index

**Discussion**

This study aims to compare the incidence of MACE among 684 PD patients from a large provincial hospital based on eGFR recalculated by the CKD-EPI equation and Thai eGFR equation using serum creatinine and other data obtained 3 months prior to initiation PD. No significantly difference in the incidence of MACE was found when comparing the CKD-EPI equation group and the Thai equation in calculating eGFR (adj.OR: 1.11; 95%CI: 0.68-1.82; P-value = 0.685).

Patients in the Thai eGFR group (recalculated eGFR $\geq 4$ ml/min/1.73m² using the Thai eGFR and eGFR<4 ml/min/1.73m² using the CKD-EPI) appear to be at greater risk of MACE than those in the CKD-EPI group (recalculated eGFR 5 to 14 ml/min/1.73m² using CKD-EPI equation). The percentage of patients with diabetes and hypokalemia was higher in the Thai eGFR group. Diabetes is a known risk factor for MACE as well as hypokalemia. Coronary artery disease and stroke were also found to be higher in Thai eGFR group. However, these differences are minor and not statistically significant (P-value = 0.685) in a multivariable analysis that adjusted for age at PD initiation, DM, hypokalemia, and other variables.

A study from Japan compared two equations between the coefficient-modified CKD-EPI equation and their own developed GFR-estimating equation (JPN-eGFR) on CVD events, suggested that CKDEPI-eGFR was more likely to detect some CVD event (cardiac disease or stroke, or both) other than kidney dysfunction when compared with JPN-eGFR. Stroke is one of consequence of malfunctional kidney supported by Kimoto et al., demonstrated that kidney dysfunction related to elevated arterial, particularly aorta, stiffness in type-2 DM patients. In this study, the CKD-EPI and Thai eGFR estimating equation are both based on serum creatinine (Scr) which varies based on the ability of the kidney to excrete waste products, muscle mass, age, and gender. The Thai eGFR equation does not account for all parameters related to the fluctuation of Scr compared with the CKD-EPI equation. People are more likely to lose muscle mass with the increasing age or ill health, especially if they have ESRD. Therefore, they are more likely to have a lower GFR estimation. It is noteworthy thatCKD-EPI estimates GFR was based on specific Scr according to male or female, this brings eGFR lower than Thai eGFR. Hence, gaining high eGFR in the Thai eGFR seems not have significant different effect on MACE in Thai ESRD patients compared with CKD-EPI calculation.

The strengths of this study include the large number of ESRD patients on PD who have not experienced any MACE prior to PD initiation and completeness of the variables strongly associated with MACE. Another strength is that the data come from a large provincial hospital with one of the largest populations of chronic kidney disease in Thailand, and therefore is a large sample representative of the diversity of patients in a lower level of health care facilities. This article also focuses on a
major complication (MACE) which is a more practical outcome in the evaluation and management of the adult-CKD patients than overall mortality and can avoid “lead time bias” in clinical care. In developing the algorithm concerning the classification of both equations, we allocated recalculated eGFR by covering both early and late PD start according to the IDEAL Study definition (Figure 1), however, decision to start PD is recommended based on a careful discussion with the patient of the risks and benefits of the treatment, considering patient’s symptoms and signs of renal failure in addition to the eGFR[23].

**Conclusion**

There was no effect on major adverse cardiovascular events (MACE) either using CKD-EPI eGFR estimating equation or the Thai eGFR equation to initiate peritoneal dialysis. Nephrologists can consider using the Thai eGFR as comparable as the CKD-EPI, while considering the patient’s clinical symptoms and patient opinion as part of the decision making.

**Ethical Considerations:** Ethical approval was obtained from the Ethics Committee of KhonKaen University (reference number HE622214) and use of the data was approved by the administrative board of the study hospital (EC number: 22/62).

**Acknowledgement:** The authors acknowledge the support from the administrative committees of Chaiyaphum Hospital for providing data for the analysis.

**Conflict of Interest:** No conflicts of interest were disclosed.

**Source of Funding:** Faculty The authors declare that no grants were involved in supporting this work.

Abstract

Background: Glomerular filtration rate (GFR) is the gold standard for the detection and monitoring of chronic kidney disease (CKD). Controversy is remaining in the timing of peritoneal dialysis (PD).

Objective: This study compared all-cause mortality and technique failure between early-late and very late start PD in stage-5 CKD patients.

Method: A cohort of 828 stage-5 CKD patients from a tertiary hospital was reviewed and analyzed. Patients were categorized into groups of early-late or very late start PD according to their estimated-GFRs. The outcomes were all-cause mortality and technique failure. Survival analysis was performed.

Results: Median time to all-cause mortality was 35 months in early-late group, 40 months in very late group, while technique failure was found identical in both groups (25 months). There were no statistically significant association in cox regression models.

Conclusion: No clinical benefits were found by starting dialysis based on eGFR at the timing of PD (early or very late start PD plan). Asymptomatic patients with stage-5 CKD may be safely managed by very late start PD plan and patients may benefit from the delayed PD initiation.

Keywords: End-stage renal disease, end-stage kidney disease, delayed PD, formula, equation.

Introduction

Chronic kidney disease (CKD) patients often remain asymptomatic until the late stages of disease when the loss of renal function has already reached 90%[1]. Glomerular filtration rate (GFR) is considered the best clinical parameter to determine renal function but is not useful in clinical practices because it cannot be measured directly in an individual[2-4]. As a result, clinicians often use serum creatinine to diagnose and monitor renal disease. However, serum creatinine varies with age and muscle mass making it imperfect for determining renal function[5-9]. Current clinical practice guidelines recommend using eGFR to detect early kidney damage[3], diagnose chronic kidney disease...
(CKD), monitor renal function\cite{43} and guide decision making about initiation of dialysis \cite{3}. The decision to initiate dialysis requires consideration of multiple factors, including clinical symptoms, eGFR, rate of decline of eGFR, and patient preferences. The IDEAL study conducted in 2009 found early vs. delayed dialysis initiation made no difference in mortality \cite{10}. Several guidelines recommend considering renal replacement therapy (RRT) when patients reach CKD stage-5 or eGFR <15 ml/min/1.73m\(^2\)\cite{11,12}, and vary from country to country. Patients in Taiwan (5 ml/min/1.73m\(^2\)) and New Zealand (6.4 ml/min/1.73m\(^2\)) have a mean pre-dialysis eGFR level in the lower end of the spectrum, when compared with Australia (7.3 ml/min/1.73m\(^2\)), the United Kingdom (8.5 ml/min/1.73m\(^2\)) and the United States (11 ml/min/1.73m\(^2\))\cite{13}. A systematic review reported the average GFR when starting dialysis in several East Asian countries including Hong Kong (9.1 ml/min/1.73m\(^2\)), Korea (7.8 – 8.2 ml/min/1.73m\(^2\)) and Japan (5.0 ml/min/1.73m\(^2\))\cite{14}. While eGFR is very helpful in monitoring rate of decline in renal function and can provide parameters for decision making, clinical symptoms play a significant role in the initiation of RRT. Initiation of dialysis also occurs urgently when patients develop life threatening congestive heart failure which cannot be corrected with other therapeutic interventions. Monitoring the eGFR plays a key role in guiding nephrologists so they can plan and avoid emergent dialysis, or worse yet, a fatal event.

Despite yielding different results from eGFR calculation along with several formulae, treatment decisions based on CKD stage and eGFR such as the initiation of dialysis and other treatments are impacted. In the absence of clinical situations requiring dialysis, asymptomatic patients may experience a decrease in quality of life, and risk of complications due to the premature initiation of dialysis. It can also result in unnecessary health care expenditures. Therefore, this study intended to compare all-cause mortality and technique failure between early-late and very late start PD in stage-5 CKD patients.

Materials and Method

Study Design: This was a retrospective cohort study utilizing data from the hospital information system of a tertiary hospital in the Northeast Thailand. There were 996 CKD patients who underwent PD at the hospital from 2011 to 2018. All patients at least 15 years old with stage-5 CKD, were included regardless of gender. Patients with incomplete data required for analysis were excluded, resulting in a total of 828 study participants (Figure 1).

**Dependent Variables:** The primary outcome variable was all-cause mortality, including patients who died after switching from peritoneal to hemodialysis. The secondary dependent variable was the composite outcome of technique failure which comprised of discontinuation of dialysis, change from PD to hemodialysis, kidney transplantation and death. Patient survival rates were calculated from the date of initiation of continuous PD until the date of death or up to 31 December 2018. Time from initiation of PD until technique failure was calculated from the date of commencing PD until the first date change to hemodialysis, kidney transplantation or death, or up to 31 December 2018.

**Independent Variables:** The following information was collected for each patient at the time PD was initiated: age, gender, body mass index, blood pressure, diagnosis of diabetes or cardiovascular disease (CVD). Laboratory results including albumin (g/dL); hemoglobin (g/dL); bicarbonate (mmol/L) and hypokalemia (yes/no), were also collected.

**Definition of Comparing Groups:** The early-late group and the very late group were defined by a well-known randomized, controlled trial of early versus late initiation of dialysis \cite{10}, the range of eGFR for PD initiation plan was explained as eGFR = 10.0 to 14.0 ml/min/1.73m\(^2\) (early start), eGFR = 5.0 to 7.0 ml/min/1.73m\(^2\) (late start). Therefore, we set the eGFR 5.0 ml/min/1.73m\(^2\) as a cut-of-point to divide group, patients who had eGFR 3-month before starting PD > 5 ml/min/1.73m\(^2\) were included in the early-late group, while those who had eGFR < 5 ml/min/1.73m\(^2\) were assigned in the very late group. All eGFR were calculated by CKD-EPI formula in the hospital.

**Statistical Analysis:** Categorical variables were reported as number and percentage. Mean and standard deviation, median and range (Minimum: Maximum) were used to describe continuous variables.

To answer the research question, all-cause mortality and technique failure were considered individually. Time to events were reported as incidence density rate of events in 100 per patient-month. Survival probability was presented using Kaplan Meier method comparing both groups. Test of equality was employed using log-rank test.
A Cox proportional hazard model was performed to estimate the effect of the start PD on each outcome variable adjusting for gender, age, DM, hypertension, CVD, BMI, blood pressure, albumin, bicarbonate and hypokalemia. Hazard ratios (HR) with their 95% confidence interval (CI) were reported. Data analysis was performed using StataCorp Stata MP 16. All statistical tests considered a probability of 0.05 as statistically significant level.

**Results**

**Baseline Characteristics of the stage-5 CKD patients**: The demographic information, health and disease conditions of the stage-5 CKD patients were presented in Table 1.

Incidence rates of all-cause mortality and technique failure

**All-cause mortality rate:** Of the 828 patients revealed the overall mortality rate as 1.9/100 patients per month (95% CI: 1.7-2.1) (Figure 1). Patients with DM had highest mortality rate. Patients at early-late start PD was slightly higher mortality rate (2/100 patient-month (95%CI: 1.8-2.3)) than those beginning PD at very late (1.7/100 patient-month (95%CI: 1.4-2)).

**Technique survival rate:** Patients in early-late group had similar rate of technique failure 2.8/100 patient-month (95%CI: 2.5-3.2) compared to those in very late group, 2.7/100 patient-month (95%CI: 2.4-3.1) (Figure 2). Technique failure rates were higher in diabetic patients and in patients with CVD. While the overall technique failure rate demonstrated somewhat difference from other attributes (2.8/100 patients per month; 95%CI: 2.6-3.0).
Survival probability of all-cause mortality and technique failure: Kaplan-Meier survival curves of all-cause mortality demonstrated a slightly lower median survival time (35 months) in early-late group than that in very late group (40 months) (Figure 3). The median time to technique failure in both groups were similar (25 months). The log rank test of the two curves were not statistically significant different.
Association between two equations on all-cause mortality and technique failure: There were no statistically significant association between two groups for outcome variables (Table 2). Adjusted HRs of both all-cause mortality and technique failure were 0.92 (95%CI: 0.74-1.14, P-value = 0.45) and 1.01 (95%CI:0.84-1.23, P-value = 0.88), respectively. The analysis also demonstrated that low albumin level, diabetes were risk factors for death and technique failure.

### Table 2 Association between two equations on all-cause mortality and technique failure

| Characteristics | All-cause mortality | | | Technique failure | | |
|-----------------|---------------------|----------------|----------------|----------------|----------------|
|                 | Crude HR            | Adj.HR** (95%CI) | P             | Crude HR       | Adj.HR** (95%CI) | P             |
| **Group**       |                     |                 |               |                 |                 |               |
| Early-late      | 1                    | 1               |               | 1               | 1               |               |
| Very late       | 0.86                 | 0.92(0.74-1.14) | 0.45          | 0.96            | 1.01(0.84-1.23) | 0.88          |
| **Gender**      |                     |                 |               |                 |                 |               |

**Adjusted for gender, age, DM = diabetes mellitus, CVD = cardiovascular disease, BMI = body mass index, SBP = systolic blood pressure, DBP = diastolic blood pressure, albumin, hemoglobin, bicarbonate in mmol/L, hypokalemia. Early-late = eGFR of >5 ml/min/1.73m², Very late = eGFR < 5 ml/min/1.73m², P = P-value. 95%CI = 95% confidence interval.

**Discussion**

This is the first observational study utilizing real world nephrology data from a tertiary referral hospital in Thailand. It compares all-cause mortality and technique failure based on the time of peritoneal dialysis initiation in a large cohort of stage-5 CKD patients. Our results found no statistically significant difference in median time from initiation of PD to mortality or technique failure comparing between patients who early-late started PD (eGFR>5 ml/min/1.73m²) and those whose eGFR less than 5 ml/min/1.73m². The mean pre-dialysis eGFR in the early-late group was 7.5 (range: 5.0 to 14.0) ml/min/1.73m² and was 3.2 (range: 1.0: 4.0) ml/min/1.73m² in the very late group.

Mean pre-dialysis eGFR in patients who start PD at >5 ml/min/1.73m² is higher than some countries
including Taiwan (5.0), New Zealand (6.4), Australia (7.3), and lower than the United Kingdom (8.5), the United States (11.0), Hong Kong (9.1) and Korean (7.8 – 8.2)\[13\]. While mean pre-dialysis eGFR before starting PD of less than 5 ml/min/1.73m² seems very low, however, it is closely in comparison with some Asian countries that it covers the ranges of 3.29 to 8.9 ml/ min/1.73m²\[14\]. These differences may be due to various estimated-GFR formula used and racial differences across country.

Several studies suggested that when the GFR falls less than 6 ml/min/1.73m² recommend initiation of dialysis with no consideration of uremia or malnutrition, or should be initiated before the GFR has fallen to 6 mL/ min/1.73 m², even if optimal pre-dialysis care has been provided and patient is asymptomatic\[15\].

While the guidelines recommend that PD consideration be taken as soon as 6 mL/min/1.73 m² or less, the absence of difference in the effect on mortality or technique failure comparing from very late PD start to early-late PD start planning was observed. Since the higher eGFR, nephrologists and patients may feel more comfortable deferring the start of RRT knowing there with no significant difference in rates of all-cause mortality and rates of technique failure. Both peritoneal and hemodialysis have a significant impact on the quality of life of patients and their caregivers. Both forms of RT also have potential complications such as infection, blood pressure instability, and metabolic abnormalities. Previous studies have shown that starting dialysis with high eGFR could be a cause of death \[14\], however, considering patients’ clinical conditions should be taken into this critical decision\[10, 11, 13-18\]. Although the current study found no benefit on clinical outcomes compared between initiating PD at very late or at early-late, clinical symptoms were not included in the analysis. Another potential benefit is reduction in resource utilization, which could reduce the financial burden to the health system. This is an especially important consideration in Thailand where the government health system covers the cost of renal replacement therapy for many patients, and the prevalence of chronic kidney disease patients is growing.

Our study has several strengths. We have a large sample size, with data was obtained from the largest database of stage-5 CKD patients in Thailand, which also contained information about important confounders such as diabetes and cardiovascular diseases that included in the analysis. There were no patients lost to follow-up. Our mortality rates and cause of death are reliable as they were confirmed with data from the Ministry of Interior, Thailand.

A limitation of our findings is that they are based on an observational study using eGFR values. However, it provides a compelling evidence for further studies of using the GFR-estimating formula between the popular use in healthcare setting in Thailand to compare with the Thai eGFR formula to inform decisions regarding the initiation of dialysis.

**Conclusion**

We found that there are no differences in the time from initiation of dialysis to death or technique. The high eGFR calculated by CKD-EPI formula is more likely to provide the same treatment results comparing to the very low eGFR. Therefore, nephrologists should plan to start PD for patients based on eGFR and patients’ symptoms or without symptom. Asymptomatic patients with stage-5 CKD may be safely managed with eGFR <5 ml/min/1.73m², by doing this, patients may benefit from the delayed PD initiation.

**Ethical Considerations:** The Ethical Committee of KhonKaen University approved the exemption for obtaining informed consent in this study with the reference number of HE622214. The administrative board of a participant hospital allowed the research to use the data (EC number: 22/62).

**Acknowledgement:** The authors appreciate the support from the administrative committees of the participating Hospital for allowing us to utilize the precious data from the hospital information system.

**Conflict of Interest:** No conflicts of interest to declare.

**Source of Funding:** No grants were involved in supporting this work.

Abstract

Background: Early-onset peritoneal dialysis-related peritonitis (EOP) increased technique failure and mortality among peritoneal dialysis (PD) patients. However, whether hypokalemia is the risk of EOP remains unclear.

Objective: This retrospective cohort study aimed to identify the association between hypokalemia within the first 3 months after PD initiation and EOP.

Method: A total of 947 PD patients registered at the Kidney Unit in Chaiyaphum regional hospital from January 2011 to December 2018 were recruited and followed up. The first EOP episode within 6 months after the initiation of PD was a primary outcome. Logistic regression was used to identify the association.

Results: Of the total, 485 experienced hypokalemia. 90 patients, developed EOP, 61 were from the hypokalemic group (12.6%). Hypokalemia was a significant risk factor of EOP (OR, 2.36; 95% CI, 1.42 to 3.94; P=0.01), as well as decreased serum bicarbonate level (OR, 0.90; 95%CI, 0.82 to 0.99; P=0.026) and decreased hemoglobin level (OR, 0.72; 95% CI, 0.57 to 0.90; P=0.004) and elevated sodium (OR, 1.07;95% CI, 1.00 to 1.15; P=0.046) while controlling other covariates.

Conclusions: Hypokalemia within the first three months after PD initiation was a significant risk factor of EOP.

Keyword: First episode of peritonitis, hypokalemia, EOP.

Introduction

PD-related peritonitis and malnutrition are serious complications among peritoneal dialysis (PD) patients¹. PD-related peritonitis has impact on both patient survival and technique failure²⁻⁴. In addition, early-onset PD-related peritonitis (EOP) was identified as an important risk factor for mortality and technique failure in peritoneal dialysis patients²⁻⁵.

A recent observational multicenter study reported that EOP was more likely predictor of technique failure⁶. Risk factors of PD-related peritonitis are the main focus of the PD community because reducing the risks indicates improvement of quality of care. Many modifiable medical factors were identified as risks for PD-related peritonitis such as hypoaalbuminemia, hypokalemia, obesity, depression, absence of vitamin D supplementation, and invasive intervention⁷. The known
risk factors of EOP are early use of PD catheter, male, hypoalbuminemia, and higher Charlson Comorbidity Index score\(^7\text{-}^9\). The influence of hypokalemia on EOP has not been observed in these studies\(^6\text{-}^8\text{,}^9\).

PD situations in Thailand, nutritional indicators which are serum albumin and hypokalemia were found the poorest in the Peritoneal Dialysis Outcomes and Practice Patterns Study (PDOPPS)\(^10\). Eventhough the facility peritonitis rate was comparable with those in the UK and AUS/NZ\(^11\), we wonder whether these nutritional factors might contribute to peritonitis rate in our population. In PD patients, hypokalemia is a common electrolytes disorder. Hypokalemia caused by a variety of factors, including poor nutritional status, low potassium intake, intracellular shift and loss into the dialysate\(^12\text{-}^13\). The association between peritonitis rate and hypokalemia was not clear and inconclusive\(^14\text{-}^17\).

Thus, we retrieved the data from the retrospective observational study to evaluate whether hypokalemic episode within the first three months of PD initiation increased the odds of EOP.

**Materials and Method**

**Inclusion and exclusion criteria:** Adult PD patients who survived after 90 days of PD initiation in the Universal Health Coverage scheme of Chaiyaphum Hospital were enrolled from January 2011–December 2018. The Exclusion criteria were aged younger than 15 and had incomplete laboratory data. The patients who experienced hypokalemic episode within three months after PD commencing was grouped to compare the odds of having EOP with another group by using multiple logistic regressions to adjust the effect of potential confounders.

The prescription PD dose was three bags of 2 liters 1.5% dextrose solution per day. We titrated dosing to 4 bags per day in some patients depending on clinical conditions. Blood chemistry was tested before PD catheter placement, 1-2 weeks after PD initiation (titrated to achieve maximum dose), at four weeks later and then every eight weeks until reaching six months. Blood chemistry was performed by colorimetric method.

**Hypokalemia and EOP definitions:** The serum potassium level within three months of PD commencing was used to define hypokalemic status if the level was less than 3.5 mEq/L. The patients who had a hypokalemic episode at least once were classified into a hypokalemic group. Therefore, misclassification that might occur if using mean serum potassium can be avoided. In order to explore the nature of serum potassium in our patients, we calculated the mean value of potassium of every visit within the first three months of PD commencing, as well as the median value of potassium.

Peritonitis episodes were recorded in local data registry system by fulfilling at least 2 out of 3 criteria: 1) clinical features consistent with peritonitis, i.e. abdominal pain, and/or cloudy dialysate effluent; 2) dialysis effluent white cell count > 100/uL or > 109/L (after dwell at least 2 hours), with > 50% polymorphonuclear; and 3) positive dialysis effluent culture. Relapsing peritonitis case (an episode that occurs within four weeks of completion of therapy of a prior episode with the same organism or one sterile episode) was excluded. According to the previous literature, the early-onset PD-related peritonitis is PD-related peritonitis occurring within the first six months of PD commencing.

**Data Collection:** Demographic, clinical characteristics, laboratory data, peritonitis, diabetic status, body mass index (BMI), date of start and stop PD, and peritonitis date were retrieved from the Peritoneal Dialysis Registry of the hospital. All laboratory data were electronically transferred from the Hospital Information System in order to lessen human error. Baseline data were collected at the first date of PD commencing included age, gender, body weight and height for BMI and diabetic status. Pre-dialysis baseline serum creatinine was collected for eGFR calculation using CKD-EPI formula\(^18\). Laboratory data collected within 1-6 months of PD commencing included bicarbonate, serum sodium, BUN, uric acid, serum phosphate, calcium, albumin, haemoglobin, and total lymphocyte count. Due to its multiple measurement conditions, we used the mean value of these biochemical parameters from the PD at the start date until the day before EOP episode for the patients who had experienced EOP, and the mean of all 6-months measurements of the patients who had never experienced EOP.

In the study period, 947 from 1,215 PD patients had been enrolled for analysis. Of these patients, 268 patients were excluded due to being younger than 15 years (12 patients), had no laboratory data (140 patients), and withdraw from PD before 90 days (116 patients). 485 experienced hypokalemia, while 462 were not. Total EOP were 90 patients, 61 were in the hypokalemic group (12.6%).
Results

Sample Characteristics: Patient characteristics are shown in Table 1. Per the study design, the hypokalemic group was similar to the normokalemic group regarding age, BMI, pre-dialysis eGFR, TLC, bicarbonate, hemoglobin, calcium, phosphate, BUN, uric acid, and sodium but was more predominate of female, more diabetes, and lower serum albumin. The median (min: max) of mean serum potassium level of the hypokalemic group and the normokalemic group was 3.45 (2:5.44) and 4.3 (3.5:6) meq/L, respectively. Noticed that some patients in the hypokalemic group had mean serum potassium higher than 3.5 meq/L. However, they had experienced a hypokalemic episode at least once within the first three months. That is why they were classified.

Table 1: Clinical characteristics of total population separated by serum potassium level < 3.5 meq/L

The multivariable analysis (Table 3) confirmed that hypokalemia was a statistically significant risk factor of EOP (OR, 2.36; 95% CI, 1.42 to 3.94; P=0.01) after adjustment for age, gender, diabetes status, albumin, eGFR, TLC, BMI, calcium, phosphate, BUN, and sodium. EOP was also significantly associated with decreased serum bicarbonate level (OR, 0.90; 95% CI, 0.82 to 0.99; P=0.026), decreased hemoglobin level (OR, 0.72; 95% CI, 0.57 to 0.90; P=0.004) and elevated sodium (OR, 1.07; 95% CI, 1.00 to 1.15; P=0.046) while controlling other covariates.

Discussion

The result showed that hypokalemic episode within the first three months after PD commencing is a significant risk factor of EOP. Our finding was both similar and different from previous studies. The possible explanation might be the difference in defining hypokalemic status. In addition, the association in some studies were not adjusted for important confounders.

Firstly, the majority of studies identified hypokalemia based on time-average potassium levels, measured repeatedly throughout the observational period, while some did not clearly define how it was classified hypokalemia\textsuperscript{(14,17)}. Our study is the first analysis using the clearly defined process of hypokalemic episode identification. In the study, the patients who had a hypokalemic episode (less than 3.5 mEq/L.) at least once were classified into a hypokalemic group. We considered that the averaged serum potassium level might not reflect the actual status of hypokalemia because the hypokalemic status in some patients might be concealed by post-correction normokalemia, and
hypokalemia can recurrent even after being cured. As we can see in the table 1, some patients in the hypokalemic group might not be classified as hypokalemia if we used time-averaged serum potassium because their mean serum potassium level was higher or equal to 3.5 mEq/L.

Secondly, some literatures indicated the association between hypokalemia and PD-related peritonitis. However, some were more likely to insufficiently adjusted for confounding factors. Hypokalemia may relate with malnutrition and poor general conditions. Besides serum albumin level, total lymphocyte count is one of the nutritional indexes that should be enrolled in the multivariable adjustment to lessen the influence of malnutrition and hypokalemia on PD-related peritonitis. We adjusted for the nutritional index such as total lymphocyte count which rarely considered in the same research question. These findings support the proposed mechanism of hypokalemia affecting intestinal dysmotility and increasing the risk of peritonitis.

The averaged serum albumin level before EOP has not shown is a significant risk factor in our analysis. It might be that serum albumin at baseline might not be affected much at the early period but can be progressively declined after PD commencing because of peritoneal protein loss and long-term associated nutritional factors. On the other hand, low serum bicarbonate and decreased hemoglobin level were significantly associated with EOP. Therefore, the time-average serum bicarbonate before the day of EOP event is more likely to be the sign of systemic inflammation in individual patients or an early sign of EOP. The mechanism is still unclear and needed to be further determined. Besides, the time-averaged hemoglobin might not be a real risk factor of EOP but rather a coincidentally correlated factor with malnutrition or inadequacy, which strongly associated with peritonitis.

To confirm that hypokalemia has an influence on PD-related peritonitis via intestinal dysmotility, Enterobacteriaceae should be the significant pathogens in our population. Unfortunately, we did not include the pathogen profile into the analysis. Moreover, the study cannot explore technique contamination which is one of the factors involving the PD-related peritonitis. Furthermore, it is the single center analysis which lacks information of dialysis adequacy, residual renal function, diuretic usage, angiotensin-converting enzyme (ACE) inhibitors and angiotensin receptor blockers (ARBs) usage in the analysis.

For advantages, the study applied electronically transferred data from HIS to analysis which help reducing human error. Additionally, the study included objective nutritional indexes in a routine lab for adjustment. Either applying 6-months averaged biochemical values, or at baseline values, hypokalemia still observed as a significant risk factor of EOP.

**Conclusion**

Hypokalemia within the three months of PD commencing was a significant risk factor of EOP. It is a warning sign that should be seriously concerned. More frequent follow-up, exploring the causes, and continuous supplement administration in complicated cases.

Psychological Forensic of Political Party Court Judges: Analysis of the Political Party Court Judges’ Independence Based on the Law No. 2 of 2011 on the Change of the Law No. 2 of 2008 on Political Parties

Sultan Alwan¹, Rachmad Safa’at², Sihabudin³, Aan Eko Widiarto⁴

¹Student Doctoral of Law, Universitas Brawijaya, Indonesia, ²Professor of Law, Universitas Brawijaya, Indonesia, ³Associate Professor, Universitas Brawijaya, Indonesia, ⁴Associate Professor, Universitas Brawijaya, Indonesia

Abstract

The Political Party Court has been given a mandate by the Law No. 2 of 2011 on Political Parties to resolve the party’s disputes. The research results show that there is an unclarity in the constitutional law on the requirements of the Political Party Court Judges and the mechanism to appoint them, which gives room for the parties to create their own mechanisms. Practically, this has caused problems, as the party’s administration contributed in determining and appointing the Political Party Court Judge, even though those administrators have the potential to be one of the parties in the dispute trial due to the party’s policies. This condition causes psychological and psychic pressures to the Party Judges. Thus, they cannot be independent in making verdicts in a trial. This fragility makes the Political Party Court Judge powerless in making verdicts in the internal level of the political parties.

Keyword: Psychology, Party, Court, Judge, independence, Law.

Introduction

The presence of political parties is a must in democratic and modern politics.¹ This is because a democratic state is built upon a system of parties.² A democratic mechanism which is carried out through direct election has changed the democratic paradigm in Indonesia, where there are the great desire and determination to choose the president and the vice in the parliament with the basis of every citizen’s civil and political rights, as guaranteed in the constitution.³ This change of paradigm cannot be separated from the roles of the parties.

Political parties on one hand have the position as one of the democratic buffers for the governmental stability.⁴ On the other hand, they also become a facility for the citizens to channel their political aspirations and interests, both by being directly involved as the committee or as sympathizers.⁵ In the momentum of the democratic event, there are four general elections in every five years, which are the general election to choose legislative judges and the president, the election of governors, the election of regents/mayor, which are inseparable from the roles of the political parties.

In consequence, there are structural disputes, dismissals as party managers, laying off of judges without clear reasons. The party’s structural disputes have happened since the pre-independence era, post-independence in the Old Order Era⁶, in the New Order Era⁷, and even in the Reformation Era. Yet, the political parties have not produced a strong construction of democratic politics in terms of its organization and in terms of a democratic public spirit⁸, especially in resolving internal political party disputes.

Since the issuing of the Law No. 2 of 2011 on the Change of the Law No. 2 of 2008 on Political Parties, and also as stated in the Republic of Indonesia Fascicles of 2011 No. 8, the resolution of political party disputes is carried out at the Political Party Court or that of other names which have such authority. This Court is formed internally, with the foundation of the party’s basic budget and budget of the party’s affairs.
There are many problems caused by the placement of the Political Party Court as an internal part of the party and also the filling of the Political Party Court by the party’s committee. On one hand, the Political Party Court gives the power to make a verdict on cases. But, on the other hand, it is an internal part of the party, thus there may be a conflict of interest, where there is the desire to protect their colleagues. Apart from that, the appointment of the Political Party Court judges involves the party’s administrators. Ironically, the political party’s administrators will be one of the parties which will have disputes and will process cases in the Political Party Court. Thus, this will produce a relation of patron-client, which has the potential to create an unequal attitude in the process of the political party dispute resolution.

The Political Party Court judges may experience psychological pressure in giving a verdict on the cases which involve the party’s administration and also the party’s leaders. The position of the Political Party Court as a member of the party under the administration of the Chairperson creates an unhealthy psychological condition. The problem of this research is, “Can the Political Party Court judges be independent in giving a verdict on the party’s disputes in unhealthy psychic and psychological conditions?”

**Research Method**

This is a socio-legal type of research. This type of research is based on the normative-legal knowledge (the constitutional regulations) which then adjusts and compares with the reality, as the law in action. This means that apart from analyzing and observing the research objects from the positive law point of view, it also analyzes the legal phenomenon in the society or the social facts.

Experts of psychology in the past defined their field of study as the “study of mental activities.” With the development of the behaviorism paradigm at the start of this century, where the emphasis of study is only things which may be measured objectively, psychology is then defined as “a behavioral study.” The definition of psychology from the Great Indonesian Language Dictionary as quoted by Atkinson is the study which is related to mental processes, both normal and abnormal ones, and their influence towards the behavior.

The psychological approach towards the judges have the aim to analyze the judges’ behaviors as legal subjects in seeing the occurring legal phenomena. This approach towards the judges emphasize the humans’ ability in law, including from the laws and the judges’ verdicts. The psychology of law assumes that the characteristics, the participants, and the condition may influence how a judge issues a verdict. In those characteristics, it includes the capability of those people as judges, their perspectives, their values, their experiences and also all factors which influence their behaviors. For example, will a judge personnel give a “guilty” verdict to a thief due to hunger? Will a judge from the A tribe have more sympathy towards a perpetrator whose tribe is also A?

In the psychological perspective of the judges, the behaviors of the participants in the legal system are not only results from their internal quality, but also from the environment where they worked at. The Political Party Court judges have the same dilemma, where they are psychically and psychologically influenced by the environment. Political parties have the obligation to form a Political Party Court or that of other names to resolve disputes which happen internally in the parties. Such disputes are resolved at the Political Party Court, by the Political Party Court judges, with all of their problems.

**Data processed from the Indonesian Ministry of Law and Human Rights:** Based on the table above, there are different names of the dispute resolution institutions formed by Indonesia’s various parties. There are also different numbers of the Political Party Court judges, or that of different names. The 2011 Law on Political Parties obliges all parties to submit the structure of the Political Party Court, or that of other names, to the Ministry of Law and Human Rights.

The Political Party Court judges who were appointed through the internal mechanism of the parties must be reported by the party to the Ministry of Law and Human Rights. According to A. A. Teohari (Head of the Political Party Sub-Directory of the Republic of Indonesia’s Ministry of Law and Human Rights) in a conversation (February 17th, 2020), in practice, there are two types of such reports: “First, the political party only reports it as according to the stipulations of Article 32, where the Chairperson and the General Secretary sign a letter which delivers the Political Party Court structure. The second variety is, sometimes the Party will insert the Political Party Court structure to be included in the management structure.”

The Political Party Court judges’ scope of authority, as stipulated in Article 32 clause (5)No. 2011 of the Political Party Law are as follows: resolving management disputes, laying off cadres without clear reasons, misuse of power, financial accountability, objections on the party’s decrees. It even states that in management disputes, the Political Party Court judges’ verdicts are final and binding.

Then, in the practical level, the political party cadres have the perception that it is difficult for the Political Party Court judges to carry out their roles and functions by applying the principles of impartiality, justice, and objectivity. Such pessimistic attitude was uncovered from the statement of a Party Judge, Y. B. Badeode, a member of the Demokrat Party Court in a conversation (February 28th, 2020):

... so that the Political Party Court may exist, it must be acknowledged by the party, and must be independent. It cannot be controlled by the Central Board nor the Chairperson. Yet, there is the concern that if the Political Party Court is too strong, it will be regarded as a second power, even though the Political Party Court is an internal part, thus it should be independent.

Then, M. Wahid, a Legislative member of Ternate City, a cadre of PPP, in a conversation (December 23rd, 2019) stated that:

... there is the potential of a conflict of interest when the Political Party Court issues a verdict. The term is “jeruk makan jeruk”, which means that the Political Party Court is filled by people of that party, and the objects put on trial at that court are verdicts of the Political Party leaders, which means that they are the verdicts of that party itself. Then, there is a room for cadres to seek justice at the Political Party managers through the Political Party Court. This is where the objectivity is tested.

The political party members’ perceptions influence their choice in determining the institution to resolve political party disputes who are believed as able to bring justice. The Political Party Court judges’ psychological condition which are suspected as not independent makes the problematic cadres or administrators choose to resolve their issues through mechanisms other than through the Political Party Court, which is through a lawsuit to the District Court.

Source: Data processed from the Republic of Indonesia Supreme Court

Based on the data of the five political parties which were participants of the general election above, the problems are dominated by the case of dismissal of the parties’ members, where there were 86 cases. Then, there were 13 cases which were related to the management. The data above show that in resolving the parties’ cases, the cadres do not choose to resolve them through the Political Party Court. But they choose to send a lawsuit directly to the District Court. Then, according to Sulistiyono and Isharyanto the most basic form of courtly independence is the independence in issuing a verdict, which has reference to the judges’ capabilities to decide upon a case independently according to the law, without the influence of other parties or other institutions.

The personal independence of the Political Party Court judges is influenced by the relations between the party who appoint and the party who is appointed (patron-client). In this case, Political Party Court judges were chosen and appointed by the party’s management. Thus, there is a high chance for a tolerant attitude to return the favor. This will influence the personal independence. This creates an unhealthy psychological condition for the Political Party Court judges as they cannot be objective.

According to Sulistiyono and Isharyanto, the impartial behavior in a courtly process may only be established if the judge may release him/herself from the conflict of interest or the collegial spirit with the parties in the trial. If a judge sees the potential for a conflict of interest in handling a case, thus that judge must step down.

That is why, one of the requirements which must be fulfilled by a judge in handling a case is that there cannot be a conflict of interest. If there is a potential for it, that judge has the obligation to step down. The resignation of a judge in a District Court in handling a case where there is a conflict of interest is facultative. If the judge does not step down, it will imply to the invalidity of the verdict.

Principally, the main job of a court is to accept, investigate, judge, and resolve all cases which are proposed. According to Mertokusumo, “It is not an easy job to explore, follow, and understand the legal values which live in the society.” Thus, the profession as a judge is a job which needs adequate expertise, time, and knowledge to explore, understand, and judge a case based on the values of justice. That is why the law on Judicial Power gives very tight requirements to the judges.

Even so, the tight requirement to be appointed as judges, the noble task and the great responsibility in upholding the law and justice are not applied in filling the profession of judges in the Political Party Court. This is because the procedures in filling the Political Party Court judges are fully up to the party’s mechanism. Thus, there is the tendency for a dominant subjective consideration in appointing the Political Party Court judges. Those who are appointed are the people who can work together with the party’s managers. At least, those who are chosen have the tendency to make verdicts which side the interests of the party’s managers.
This patron-client relation in filling the Political Party Court judge position is against the _nemo judex in rexsua_ principle, which believes that there is no good judge for him/herself. As an _ius constituedum_ there needs to be a law on filling the Political Party Court judge position in the constitutional level by limiting the double position for the Political Party Court judges and accommodating Political Party Court judges from elements outside of the party who are independent, and who are appointed through the highest forum in making the party’s decisions.

**Conclusion**

The Political Party Court judges experience psychological and psychic pressures which make them unable to act or give a verdict on the case in a party independently. The Political Party Court judges may be pressured by the party’s managers or administrators due to their status as a party member, which may be laid off anytime.

Such unhealthy psychological and psychic condition of the Political Party Court judges is very clear. Thus, the party members prefer resolve disputes in the District Court rather than bringing it to the Political Party Court. They realize the Political Party Court judges’ tendency to not be independent, and that as members of the party, they must comply with the party’s leadership. But on the other hand, they must resolve disputes or conflicts which involve the party’s administrators or managers.

Protection for Trafficking Victims: The Perspectives of Law and Psychological Health

Sulistya Eviningrum¹, Hartiwiningsih², and Moh. Jamin³

¹Doctoral of Law Student Universitas Sebelas Maret Surakarta, ²Professor of Law Universitas Sebelas Maret Surakarta, ³Associate Professor Universitas Sebelas Maret Surakarta

Abstract

Human trafficking is a crime carried out by a dark society of some people, and its network is between countries and in international borders. Most victims come from developing countries. The main aim of this crime is to force young boys and girls to work in sexual sectors. There is economic oppression as they are exploited for the interests of the agents, distributors, and crime syndicates as what is similar to other illegal activities which regard trafficking, such as trafficking of domestic workers, fake marriage, illegal jobs, and illegal adoption. This research analyzes the legal protection for human trafficking victims and the health impacts. This is a doctrinal legal research, strengthened by the qualitative field research. It uses the constitutional and case approaches. Based on the results of the study and the discussion, it can be concluded that there are some impacts of the child trafficking in the aspects health and other aspects for the children. The government needs to formulate and to refine the constitutional regulations regarding the health protection for victims of child trafficking.

Keywords: Health impacts, legal impacts, child trafficking, protection, psychology.

Introduction

The phenomenon of child trafficking has long developed in countries such as Saudi Arabia, Japan, Malaysia, Hongkong, Taiwan, Singapore, and even Indonesia. No country is immune from trafficking. Each year, it is estimated that 600,000 until 800,000 men, women, and children are internationally trafficked for sexual exploitation¹.

They use the threat of violence and even the violence itself. They kidnap, undergo fraud, forgery, and misuse of power and position. They give payments or benefits so that they receive the agreement of the people who have control of the victims².

One of the urgencies of this child protection is encouraged by the understanding that children are still inherently and relatively weak in their growth and development processes². Even, if viewed from the victimological perspective, Finkelhor⁴ in his book entitled “Childhood Victimology” stated that children are human beings which are most prone to become victims of criminal activities in the society, not only the conventional crimes which target adults, but also specific crimes which happen only to children. Child trafficking is one of the worst actions of power experienced by women and children.

It is also a criminal action which is a violation of the human rights². Human rights ignorance becomes very clear when relating to children and their rights. The violence against children is so massive that a lot of them become victims of child trafficking. There are tens of thousands of women under the age of 18 in Indonesia who wander day and night as sex commodities. On top of that, millions of Indonesian children are also forced to work improperly, such as becoming beggars, peddling newspapers on the streets or scavenging⁵.

Arif gives the definition that victims are those who suffer physically and mentally as a result of other

e-mail: eviningrumsulistyaa@yahoo.co.id
people’s actions who seek the fulfillment of their own interests or other people’s, which is against the interests and the rights of the people who experience the loss. The human trafficking issue often become the discussion topic in the field of legal studies and social studies. There has been quite enough interventions, policies and formulations of the constitutional regulations regarding this problem to minimize the case prevalence of the human trafficking in the future.

This is actually a very good thing, apart from the fact that there are legal aspects which handle this issue, it also proves to the society that human trafficking is a crucial issue which must be faced together. The cases of human trafficking often start from document fraud.

The cases of sexual exploitation which happen in Indonesia increase by 30% each year. Victims of the commercial sexual exploitation to children are underage children who have high risks in being infected with diseases due to free sexual activities. From time to time, some opinions which relate the human trafficking with the issue of the human rights violation emerge. Starting from that time, new policies were issued, which start to pay attention to the aspect of the victims in human trafficking.

Some efforts have been carried out by the government, non-governmental organizations, and various social movements. These efforts include the preventive and controlling efforts in various situations where human trafficking is prone to happen. According to the statement the problem is how do the child sexual workers who are victims of human trafficking in a prostitution site assess the reproductive health and the psychological health?

**Research Method**

The method of this research is qualitative, using the case study design with the method of profound interview to some informants, which consist of children and guardians of children. This research aims to dig into the physical and health impacts of the trafficking victims. This research obtains information on the knowledge of the child informants regarding the physiology and the reproductive health. The victim suffered syphilis, or what they usually call kapatil. Meanwhile, about HIV/AIDS, they believe that it is a disease which may be infected through the nose and mouth, and that to prevent oneself from being infected. They also suffers stress and trauma after the incident even after several years.

**Discussion**

There needs to be an adequate legal protection for crime victims, as it is not only a national issue, but also an international one. Generally, prostitution is defined as someone’s involvement in a sexual behavior or activity, in this case intercourse, with the aim to trade that activity with something else, usually in the form of some amount of money. Even, the majority of the trafficking victims who were exploited sexually became pregnant, which leads them to undergo abortion. This condition often threatens their lives. Based on the Governmental Decree No. 16 of 2014 regarding Reproductive Health, abortion is a prohibited activity, and is only allowed in certain conditions, such as the indication of medical urgency, like a pregnancy which threatens the health of the mother and the fetus; pregnancy due to rape (it may only be carried out if the pregnancy age is at most 40 days from the first day of the last menstruation period).

This Governmental Decree regulates on how abortion may be done only in certain conditions, and how abortion is carried out safely with the help of doctors. With this Governmental Decree, it is hoped that abortion is no longer carried out carelessly. It is also to minimize the number of extramarital pregnancies or unwanted pregnancies.

This is where the familial strength becomes an important thing, because it can give mental support to the victims. Quoting from an article, it is said that generally, a family has these functions: 1) Replacement of the population, the function to continue its offspring; 2) Care of the young, the function of caring for children; 3) Socialization of new members, the function to socialize cultural values, norms, and language to family members; 4) Regulation of social behavior, the function of regulating sexual behavior; 5) Source of affection, the function to give affection. Child trafficking is a phenomenon indicating that the family does not function well. A similar thing was stated by Kramer as cited in Lehmiller, where sexual workers suffer some diseases which regard the physical and the psychological condition.

From the numerous diseases they suffered, sexually-transmitted diseases and HIV/AIDS are the categories which receive the highest attention, as they have the highest correlation towards the health of the sexual workers, in this case the reproductive and the sexual health. Apart from that, the sexual workers are regarded as one of the mediators in the infection of that disease.
The basic principles of the public health are promotive, preventive, curative, and rehabilitative, where this is certainly in line with the initiating movement which carry the background of the human rights approach. Human trafficking may be regarded as a public issue, as it influences the social and the mental aspects of an individual, a family, and even the whole community of various generations. The many cases of human trafficking and the complexity of this issue makes the policy-makers face difficulties in finding the right method to prevent it.

Human trafficking is very worrying, but the crime increases with diverse modus operandi year by year. This is because the public still lacks of understanding of human trafficking. Moreover, the law enforcers often consider human trafficking as a common crime. On top of that, legal policy products are still unable to give attention to victims of trafficking.

In Indonesia, prostitution is regarded as a morality/decency crime, and it is an illegal activity which violates the law. In the ratification of the Republic of Indonesia’s Constitution No. 7 of 1984, women trafficking and prostitution is regarded as violence towards women. Prostitutes are workers who turn themselves in, who sell the service of carrying out sexual activities to the public, and receiving payment according to the initial agreement. Prostitution is the sale of sexual services, such as oral sex or sexual intercourse. Someone who sells the sexual services are called prostitutes or what is usually called commercial sexual workers. The activity of prostitution is an activity which must be regarded as taboo, as it is morally contradictory to the values, religion, and norms. Prostitution is one of the social problems which raises concerns.

There are many factors which cause prostitution to be part of a child’s life. One of them is the low knowledge of the child on prostitution. Apart from that, important factors include the lack of attention from parents, lesbianism which is visible in a woman, the influence of alcohol, the reading materials of children on prostitution, and even the current sophisticated communication technology. The most influencing result of this social problem is the increase of unwanted pregnancies.

According to the World Health Organization, there are some health and other impacts of human trafficking to the human beings. These are the impacts which results from the human trafficking cases: The victim’s terrible mental health condition is the dominant health effect and it clearly brings loss. The psychological consequences include: depression, post-traumatic stress disorder, and other anxiety disorders; thoughts of suicide; and somatic conditions including physical disfunction.

The victims are socially isolated. For example, they are prohibited from contacting their families, and their space for mobility is also restricted. This is used to maintain the power over the children in a trafficking condition, such as emotional manipulation using threats and empty promises.

The victims are also exploited economically. The children who are sold do not have the power to make decisions of what they can do. They are not paid for their services. Even, the traffickers may impose fees to the victims for housing, clothes, food, or transportation.

There is a legal insecurity for the people who undergo interborder travel, especially when the trafficker or the illegal business owner confiscate the identification documents, or if they give fake information regarding their rights, including regarding the access to health services. This condition does not only limit the society’s use of the health facilities. Yet, it may also cause unjust deportation or imprisonment. It is impossible for the trafficked victim to be regarded as crime victims. Unfortunately, they are regarded as violators of migration regulations, workers or prostitutes who are against the law. They may be imprisoned in the correctional centers or imprisoned as illegal immigrants. When they come back home, the trafficking victims may have the same trouble as when they were trafficked overseas. Plus, they must deal with new health problems and other challenges, including stigma and psychological problems. Meanwhile, for the children who try to stay in that location, they often face discomfort or pressures.

In the first three months of 2019, the Indonesian Commission for Women and Children has supervised and watched over eight cases. The ones which stand out are handled by the police force. The cases are spread out almost evenly in all parts of Indonesia, with the average number of three victims in each case. On January, five children were involved in a storefront sex prostitution in Bali, as stated by Solihah, Commissioner of Child Trafficking and Exploitation, the Indonesian Commission for Women and Children), in Menteng, Central Jakarta, March 29th, 2019.

Based on the results of study, 30%-87, 8% of
victims accessed health services during the period of exploitation. Most of them are illegal workers or blue-collar workers, children, and women. We know that there are risk factors, signs, and symptoms\textsuperscript{16} of a trafficking case. In the efforts to make the medical aspect as one of the keys in developing the identification tool of human trafficking, the health workers must be equipped with the knowledge that the risk factors which exist in a population do not always indicate that human trafficking is happening\textsuperscript{17}. But, the increasing risk factors of a population may cause that population to become prone to human trafficking.

The symptoms which are found during the anamnesis period or the physical examination may become an indicator that human trafficking has happened or is happening. These signs and symptoms may be in the form of sexually transmitted diseases which are not treated, the patients do not know where they are, there are abnormal physical wounds, and when the patients come, they are accompanied by someone who has the tendency to be dominating during the anamnesis process between the patients and the doctors. The existence of these signs and symptoms must lead to interventions from some parties. Yet, it is unfortunate that there are not enough trainings on this case from the various sectors (the medical, legal, and social sectors). This causes the loss of the signs and symptoms which may identify trafficking, which may then lead to an intervention from the health workers.

Other studies also found that the trafficking victims tend to open up more to health workers as opposed to police officers. This strengthens the fact that the medical sector has a unique position to identify these signs and symptoms and treat them. Even though the trafficking victims are regarded as a hidden population due to the complexity of this issue, as it is connected to criminality and violation of rights by the regulation policies which are currently developed, yet at some point of time, these victims will interact with the outside world through the medical sector. Because of that, the existence of the trafficking signs and symptoms may become the ideal intervention point to initiate an identification and further services.

**Conclusion**

The victim’s terrible mental health condition is the dominant health effect and it clearly brings loss. The psychological consequences include: depression, post-traumatic stress disorder, and other anxiety disorders; thoughts of suicide; and somatic conditions including physical disfunction. Victim need a social, health and psychological care to recover their physical and psychological health. The collaboration between the public health discipline and the medical aspect carried out by the doctors and nurses in hospitals, private clinics, and other medical service offices may become the new holistic solution in handling the human trafficking problem.

A Comparative Study of Some Physiological Variables between People with Obesity and Non-obesity

Atheer Abbas Mustafa¹, Ahmed Abdulameer Ahmed¹

¹Asst. Prof., Dept. of Students Activities/University of Basra-Iraq

Abstract

The tremendous technological progress that led to the dependence of individuals on the machine in the modern age and in all different fields led to the lack of human movement and thus the lack of its physical and physiological efficacy, which made it vulnerable to infection with many diseases, which are called diseases of lack of movement The ideal body weight is a vital subject for the human being during the stages of his life and the development of his maturity. As well as, it is one of the necessary indicators to follow the health, functional and psychological state in which researchers and specialists work in the medical, sports and psychological fields. The importance of study is to have knowledge regarding the physiological variables of obese and non-obese people and making comparisons between them to understand the positive effects of the ideal weight of individuals, which is reached through the practice of physical activity and constantly on the physiological variables and work to develop and improve these variables in a way that serves the health aspect. The researchers used the descriptive method in the survey. It is the best approach in achieving the study goals. The study sample was chosen in an intentional way. It was represented by the students of the third stage of the College of Physical Education at the University of Basra, where the sample size reached (30) students from the College of Physical Education and Sports Science. It was divided into two groups, and the size of each group was (15) participants, after excluding the female students who were (5). Dividing the sample into two groups, one that suffers from an increase in weight and another of normal weight according to the body mass index, measuring blood pressure, the number of heartbeat and measuring some physiological variables. The researchers concluded that people without obesity are healthier and more active than infected people who suffer from many disorders and problems in their physiological variables.

Key words: Body weight, physiological variables, blood variables.

Introduction

The tremendous technological progress that led to the dependence of the individual on the machine in the modern era and in all different fields led to the lack of human movement. Thus, it causes the lack of its physical and physiological efficacy, which made him vulnerable to many diseases, as the muscles move by converting chemical energy into mechanical energy. This cooperation determines the efficiency of the physical movement and thus advances the level of performance whenever these changes are positive in order to achieve the process of physiological change and the response of the body’s systems to the performance of pregnancy(1).

The ideal body weight is a vital subject for the human being during the stages of his life and the development of his maturity. The physiology is concerned with studying the effect of the change in body weight in every part of it and its relationship to changes in the body’s internal organs and organs. The degree of these changes is related to many factors including the level of physical activity of individual. “Even if we worked to improve and develop a person’s fitness level, whether athletic or non-athletic, so that each element of fitness was developed without working to measure and define the components of his body, and more specifically determining what a person carries from his fat mass, it must be a program...
that lacks accuracy scientific and that leads us to the optimal elements.”

The Problem: The physical measurements of the weight and proportion of the fatty component are considered a basic for building the individual. That is, physical and motor activity lead to maintaining weight. Thus, it constitutes a critical importance in reducing or reducing physical and health deterioration. All studies indicate that non-athletic people have increased their weight and increased their blood pressure and have increased fat percentage in the blood. While those who exercised have maintained their cholesterol level, pressure of blood and their average of weight too, especially in adulthood, as this stage is considered one of the important stages in which the rate of obesity increases. Hence, it affects some physiological variables in the body.

The significant of the Study: The importance of the study lies on knowing the physiological variables of obese and non-obese people and making comparisons between them to understand the positive effects of the ideal weight of individuals, which is reached through the practice of physical activity and constantly on the physiological variables and work to develop and improve these variables in a way that serves the health aspect.

The aims of the Study: Identify the values of some physiological variables and compare these variables between obese and non-obese people.

The Procedure: The researchers used the descriptive method in the survey method. It is the best method to facilitate the achievement of the study aims. The descriptive approach is “an accurate visualization of the interrelationships between society, attitudes, tendencies, desires and development. The research gives an image of real life, setting indicators, and building future predictions.” The aim of selecting the sample is to obtain information about a given society. As for the study population, it is the group through which researchers wish to generalize the results of its study. The sample of study was chosen in the intentional way. It was represented by the third stage students of the Faculty of Physical Education at the University of Basra, where the sample size reached (30) participants from the students of the College of Physical Education and Sports Science. The sample was divided into two groups and the size of each group was (15) participants after excluding the students sample of exploratory experience whose number was (5). The researchers used multiple tools as means by which they can reach the required data.

The devices used to make the measurements are:
1. An electronic medical scale for measuring the German made weight to the nearest (50 g).
2. A tape to measure the length.
3. Medical syringes to draw blood (40) syringes and sterile materials.
4. Plan tube
5. Cool box

This procedure is consistent with most studies and research conducted in the same field which was “under the conditions of the sample abstaining from food at least 12 hours before drawing blood”. The blood drawing process was performed in the laboratory of Al-Jumhori General Hospital in Basra city, where the amount of blood withdrawal from each individual of the sample (five cc). The measurements that the researchers measured are (hemoglobin, blood sugar, and York acid, and blood viscosity, number of heart beats, number of breaths, systolic blood pressure, diastolic blood pressure). Before conducting the above measurements, the researchers conducted a survey experiment on Monday 12/03/2018 on a group of five female students and they were excluded from the main measurements of the study.” The exploratory experiment is a scientific training for the researcher to determine the positives and negatives that occur during the test procedure to avoid them.”

In order to achieve homogeneity among the individuals of the sample for each of the two research groups (obese and non-infected), the Law of Coefficient of Twist was used as their grades were limited to (+3), which indicates the good distribution of the sample and its homogeneity in the study. This indicates the good distribution and homogeneity of the sample in the research. The statistical program (spss) version 22 was used by researchers to treat the results statistically.
Displaying and analyzing the results of some physiological variables for students with obesity and non-obesity:

Table (1) includes the presentation of some of the results obtained by the researchers through measurements of the indicators of blood variables under study. It analyzes these results and discusses them after conducting statistical treatments for them. Through the results that the researchers reached, they found the significance of the differences for the hemoglobin variable, the significant difference between female students without obesity and obesity in the variable (hemoglobin). Thus, it affects the daily activity of persons. Low levels of hemoctylene that transport oxygen to working muscles affect performance, which leads to a build-up of lactic acid and an inability to continue functioning (muscle fatigue).<sup>7</sup>

The amount of hemoglobin in blood is more for boys and adults than for girls.<sup>8</sup> From the foregoing, we conclude that there is an inverse correlation relationship between the increase in the percentage of fats (obesity) and the percentage of hemoglobin, since most times the increase in obesity is offset by a decrease in blood hemoglobin levels, and this is the reason for the significant difference between female students without obesity and those with obesity in the variable. For the benefit of other students, the women attribute the reason for this increase in the percentage of (S. Uric acid) in the blood of female students with obesity and the normal rate due to the unhealthy diet followed by obese women, which was a major reason for increasing their weight. It contains a lot of meat and fat.<sup>11</sup> As one of the reasons for the high level (S. Uric acid) is eating meat in large quantities. As well as, the exercise of sports activities has a role in reducing levels (S. Uric acid) by stimulating blood circulation work to regulate the percentage of salts in the body and work to get rid of excess salts by putting them out by way of recognition. This is confirmed by Bahaa El Din Salama that increased activity of hormones, enzymes, and energy materials that participate in the metabolism process.<sup>12</sup>

we find the indicates that there is a significant difference between female students without obesity and those with obesity in the variable and for the benefit of students who are not infected and researchers attribute the reason that the level of blood viscosity is related to the number of red blood cells in one cubic milliliter of blood. “The viscosity and density of the blood are related to the amount of red blood cells, hemoglobin and protein plasma components.”<sup>13</sup> In the case of immobility and activity, the degree of blood viscosity increases, which hinders the ease of its flow into the blood vessels.<sup>14</sup>

</table>

As for Table No. (2), it presents some of the results that the researchers reached through measurements of some physiological variables under study. Through it, we find that the number of heartbeats significant difference between students without obesity and those with obesity in the variable for the benefit of other students injured. The researchers attribute the reason to the lack of physical activity and the inactivity of female students with obesity. Moreover the lack of activity works to increase the heart rate because the heart muscle needs greater effort, constriction and extroversion, and then it increases Fatigue of the arteries(15).

We find significant difference between female students without obesity and obese women in the variable and for the benefit of female students Non-infected. There searchers attribute the reason to the lack of fat for students without obesity, which leads to maintaining the average number of breathing times within normal limits, unlike female students with obesity. (Al-Hamoud et al., 2002) notes that “the breathing rate represents the number of breathing times and for athletes.”

The rate is lower because training works to enhance the efficiency of the breathing process, as the athlete needs a smaller number of breaths to transport the same volume of air.”Having a look on the variable systolic blood pressure rate, we find significant difference between female students without obesity and those with obesity in the variable and in favor of female students who are not infected. To overcome this pregnancy, the heart muscle compensates for this by increasing the volume. “Nayef Magdy and Sobhi Ahmed” stress that “exercising regularly and eating low-cholesterol and fat food makes blood pressure natural in some cases, so there is no need to take medicines or their amounts can be reduced.”

Goldberg (1988) indicates that using the appropriate aerobic training method, following the conditions for feeding and controlling other healthy habits leads to a systolic blood pressure drop of 10 mm Hg from the mean(16).

As for blood pressure, we find a significant difference between female students without obesity and those with obesity in the variable and for the benefit of other students women suffer from. the researchers attribute the reason to the fact that female students without obesity are more active and active than the affected female students. “That sports activity affects in two ways the first is improving the level of physical fitness and the second is helping to strengthen the heart muscle itself. Therefore, we notice in individuals who exercise sports regularly low heart rate. There is a decrease in the blood pressure rate by comparing them with idle individuals with little movement because the people who are more mobile have flexibility in the arteries. This helps in maintaining its elasticity at the same time, maintaining the economical work of the heart(17). The injured and those who suffer from many disorders and problems in their physiological variables in general and blood variables in particular, which may be the beginning of many diseases related to obesity.

Abstract

At our review we will discuss the definition of infertility according to the World Health Organization (WHO), types of infertility, factors determine fertility, factors affecting infertility in both men & female as Body mass index (BMI), hormones and life style changes that are increasing in the current years and factors as (stress and smoking). Also discuss the role of Growth Hormone (GH) in management of women infertility.

Keywords: Infertility; Body mass index; Growth Hormone.

Introduction

Infertility is a major health problem that couple faces during their life. Reproduction helps the community to produce new generation for continuity of human beings in life also some communities have social concerns about reproduction as they considerate as a fortune and the couples may undergo social pressure from their families and society to have their own offspring’s. Sterility is an illness concerns the propagative device determine via fiascos to accomplish gestation afterward 12 months or additional (¹). Men infertility may be due to impaired sperm count, motility and morphology (²). Infertility may be primary or secondary infertility. Primary infertility, when pregnancy is not achieved more than 1 yr. Secondary infertility where 1 or more pregnancies in the past, but are having difficulty conceiving again (³).

Factors Determining Fertility: Factors that determine man fertility ejaculation of motile sperm (40-250 million per ml). Every sperm takes ten weeks to be created by spermatogenesis, when sperm count fall beneath 14-40 million for each ml will impairs fertility (Fig.1) (⁴), at every low sperm counts (under 5 million for each ml) in these men, may have abnormal morphology (⁵), the number of sperm of sperm created every day is controlled by number of Sertoli cells (⁶, ⁷). Sertoli cells number is the main factor that affects sperm counts (⁷, ⁸) (Fig1). The male reproductive organs inside (testes, prostate gland, vas deferens and epididymis) and externally (scrotum). The descent of testis in scrotum occurs by birth, in complete descent of testis (cryptorchidism) because low sperm count and increase risk of testicular cancer (⁶, ⁹ and ¹⁰).
Fig (1): Sperm counts affect male fertility depend mainly on amount of Sertoli cells in the testes, propagation from Sertoli cells is influenced through regulatory substance, environmental factors as sperm count below 40 million per ml decreases fertility.

In woman, fertility depend on monthly ovulation of oocyte Fig (2) within female reproductive organs (Ovary, fallopian tubes & uterus), production of mature oocyte able to be fertilized by menstrual cycle\(^ {11, 12}\), five hundred oocytes might be ovulated in puberty. The elementary oocyte in fetal ovary captured in first meiotic prophase and stay dominant till maturation resume activity in puberty triggered by follicle stimulating hormone (FSH) that stimulate follicle maturation producing estrogen to start growth of endometrium of uterus then section luteinizing hormone (LH) in mid cycle stimulate ovulation Fig (2).

Fig (2): Female hormonal regulation with changes endometrium and corresponding changes in the ovary during regular menstrual cycle without fertilization.
Factors affecting infertility

Body mass index (BMI): Body-mass-index (BMI) has minimum impaction on male semen enumeration, however ability own major possessions at feminine fecundity(13). within a womanly of regular weighing & nutrition (Fig.3a), control of follicle maturation and ovulation by LH and FSH liberate from the pituitary gland. The emission of LH and FSH is directed by gonadotropin emission hormone. FSH in addition LH adjust maturation about cavities within the ovary, whose

stimulate production of (testosterone, estradiol and progesterone) these hormones act on the uterus. Women with anorexia nervosa (Fig.3b) scarcely have normal and regular menstrual cycle(14). The action of ovaries starts to diminish due to fall in GnRH production, causing gonadotrophin concentrations very few to sustain ovarian function. Leptinconcentricity are least within below a weight lady such might be the agent such diminishes emission about GnRH (Fig.3b). Obesity on the other hand leads to sexual problems (Fig.3c)(15).

Fig (3): Regulation the secretion of GnRH causes secretion of LH& FSH from pituitary gland. Nutrition play role in female fertility by effect of Leptin hormone from fat cell& insulin from pancreas that alter presence of estradiol & testosterone (T).

Deficiency about these gender sex hormone results in an nonappearance about follicular development, on the other hand, in overweight ladies or potentially with polycystic ovary syndrome (PCOS), raise leptin and insulin scale and an expansion within LH, rather than FSH scale result infraction al expansion of cavities such excrete supernormal scale from testosterone, nevertheless scarcely ovulate (consequently least progesterone ovaries testosterone manufacture/activity to PCOS[4]. The link between overweight and polycystic ovary syndrome as ovary contains immature follicles is one of the prevalent reasons for infertility cause an ovulation (16). Its etiology is mysterious, but genetic factors are important, polycystic ovaries are linked with hormone abnormalities (overabundance emission of testosterone by the ovary). Be that as it may, there is additionally an interaction with nutrition. Polycystic ovaries are described by metabolic disturbances, including an intestinal obesity, in addition to resistance to and over-excretion of insulin(17). The outcomes of abdominal obesity in ladies with polycystic ovaries incorporate an expanded possibility of anovulation and infertility,
increased testosterone (bringing about undesirable male pattern hair) and, danger of creating type-2 diabetes in later life\cite{17}.

**Hormones:** GnRH is released from neurons in hypothalamus and stimulates the secretion of LH and FSH from the anterior pituitary gland. LH activates the interstitial cells of testes for testosterone release. FSH activates sustentacular cells of the seminiferous tubules to increase spermatogenesis and to secrete inhibin. In research done in Iraq by\cite{18}, about the effect of hormones on infertility among men & women.

Table 1 shows no significant difference between BMI in healthy men (26.11±2.31) or infertile ones (25.45 ±1.34) kg/m$^2$. But there were absolute variations between serum LH and serum FSH. The mean serum LH level of these infertile men (7.895±0.85) mLU/ml in comparison with (2.12±0.31) mLU/ml of the normal men. This outcome is high of thanormal LH value and also it significant. The serum FSH was (9.89±1.12) mLU/ml in the infertile men in contrast with the values in the control group which were lower (3.39± 1.45) mLU/ml. This result is supported by\cite{19} which showed that the plasma FSH scalewas 26.40±1.43 mLU/ml within the check collection in contrast with the scale within the monitoring group was 3.71± 1.25 mLU/ml, yonder was a remarkable link ($r= 0.67$) amongplasma FSH besides the semenamount. Serum prolactin increases in the infertile men and reach to (13.33±2.15) ng/ml compared to the monitoring assembly (5.65±3.34) ng/ml. This result agrees with\cite{19} who showed that the mean serum prolactin in test group was (18.01±1.28) ng/ml, compared to (5.43± 2.02) ng/ml of the monitoring assembly, these results is extra than double the control prolactin worth and is highly considerable ($p< 0.01$). Also,\cite{20} showed that the prolactin may suppress the production of GnRH and leading to testicular dysfunction in associated with spermatogenic arrest and decreased serum testosterone concentration. On the other hand,\cite{21} showed that any insult in the hypothalamus or pituitary (hypogonadotropic-hypogonadism) whose results in lower serum FSH & LH through increase within plasma prolactin scale may possibly causes sterility. Hyper-prolactinemia occur when excess secretion from lactotrophs in anterior pituitary.\cite{20} Prolactin induce apoptosis in spermatogonal stage of the testes but FSH to these tissue societies switches these progressions, increases secretion for a long time of FSH can induce sperm production, inazoospermia is reversible\cite{22}.

</tbody>
</table>

Data expressed as mean±SD ** $P< 0.01$: Highly significant difference.

The level of testosterone hormone (ng/ml) has low significant difference (3.91±0.51) ng/dl in test group in comparison with control group (21.76±1.45) ng/dl\cite{23}. This result agrees with\cite{19} who found that testosterone levels markedly less(4.10±2.23) ng/dl within exam assemblage in comparison with the monitoring collection (14.02±2.48) ng/dl. Low levels of testosterone hormone may be resulted from the conversion of testosterone to estradiol by the aromatase enzyme effectfrom adipose tissue. Obese males who are rich with aromatase activity have more androgens converted into estrogen causing rise in estrogen level and a drop of androgen in the serum\cite{23}. Serum leptin has highly significant ($p<0.01$) increase in the infertile (9.40±0.44) μg/L compared with normal men values (2.95±0.35) μg/L. Leptin is an important adipose tissue derived hormone, takes a
role in regulating body weight, immune function and reproduction (24). As a result, leptin levels increases with obesity (23). Male obesity not only impact negatively on male reproductive potency by lessens sperm quality, but also adjusting the physical and cellular structure of germ cell and eventually full-grown sperm (25).

Development hormone in the arrangement of womanly sterility: Growth hormone is secreted not only from the pituitary as well as locally by the ovaries. It attaches to growth hormone receptors on surface of granulosa, the thecal and luteal cells, inducing steroidogenesis and gametogenesis (26). Growth hormone play role in ovulation process in variable steps and can growing ovarian sensitivity to receive gonadotropin and promotes follicular formation (27).

When GH receptor-deficient the development of the follicle is delayed, growth hormone besides IGF-I together a function within the secretion from the follicle from his association, and this causes eventually monofollicular development in female (26). In case of lower growth hormone, this leads to decreased plasma scale of IGF-I inhibit the follicle after rising IGF-I scale. Such averts of somewhat variance within the susceptibility to FSH of the various association follicle, and permiss similar multifollicular evolution. Through GH remediation, a variantsusceptibility to FSH amongst that follicle in addition her association are gained backvia advanced IGF-I scale, promptingmonofollicular development. In place of the follicle develops, atomic and cytoplasmic happen take place inside the oocyte to permit oocyte fertilization.

Dosage of GH co thereby: Doses utilized have run from 0.9 to 1.8 Milligrams per week, and growth hormone is ceased once conception is accomplished (28). Past investigations have utilized a lot higher doses. GH has been given every day or on interchange dates in doses running from (12 to 24 international unit) (26). One researcher has recommended an everyday weight-based dose (0.1 international unit per kilogram) (29) whereas else has compared 4 international unit every day and 12 international unit day by day (30). GH co-therapy has an unmistakable task to carry out isovarian incitement, and is viable in suitably selected cases; more studies should be done to recognize effective and efficient GH treatment regimen too improve quiet determination. Attempts should also be made to examine the impact of growth hormone treatment on oocyte fertilization and endometrial susceptibility.

Infertility is a multifactorial health problem may be affected by nutrition’s: Nutrition plays an important role infertility and undernutrition may be associated with stress or obesity that may affect female by causing (PCOs) and in male affecting semen parameters (31), we recommend having health balanced diet with doing activates. Hormones as FSH, LH, prolactin & testosterone may cause hormone disturbance for both male and female. Life style changes as smoking and alcohol will have negative impact on aspects of fertility in both sexes.

Some causes of infertility in both sexes preventable by many ways as

- Stop smoking.
- Limitation of alcohol consumption.
- Practice daily activities.
- Avoid thing lead to prolonged heat for testicles.
- Avoid exposure to pesticides, heavy metals and other toxins.

**Conclusion**

Reproduction helps the community to produce a new generation for continuity of human beings in life also some communities exert social pressure on inertial couples although it’s a saved simply by seeking medical care to exclude the multifactorial causes and care the causing problems.

Detection of Copy Number of Mitochondrial DNA in Iraq Population

Suhair M. Jabbar¹, Nihad A.M. Al-Rashedi²

¹Post Graduate, ²Prof., Department of Biology, College of Science, Al Muthanna University, Samawah, Iraq

Abstract

Mitochondrial DNA copy number (mtDNA-CN), a measure of the number of mitochondrial genomes per cell. A cell contains two copies of genomic DNA compared to a single copy of DNA per chromosome. The quantitative real-time PCR (qPCR) is the gold standard method for measuring mtDNA-CN, the quantification after DNA extraction it is an important step, the quantitation of DNA plays a central role in medical and forensic DNA analysis, which provides the information about the amount of DNA present in unknown samples. In this study the quantitative results showed that the higher value 74941 and the lower value 190. A multiplex quantitative PCR assay developed to amplify target sequences of different length, which allows for the assessment of DNA degradation in samples of forensic interest. The quantification of DNA by qPCR relies on the detection of amplified product (amplicon) at each cycle of the PCR.

Keywords: Mitochondrial DNA, copy number, qPCR, Iraq population

Introduction

Mitochondrial DNA copy number (mtDNA-CN) is increasingly used to assess the role of mitochondria in forensic field and is applicable when samples that fail to yield successful nuclear DNA profiles, in cases where nuclear DNA is significantly degraded, cannot be isolated or is present in extremely limited amounts, [1, 2].

Quantitative real-time PCR (qPCR) has been the most widely used method for measuring mtDNA-CN, partly due to its low cost and quick turnaround time. However, these advances, it is important for the field to evaluate these method in the context of the current gold standard.

In addition to the method for determining mtDNA-CN, it is important to consider the impact of DNA extraction method on mtDNA-CN, particularly due to the small size and circular nature of the mitochondrial genome. Previous research has shown organic solvent extraction is more accurate than silica-based method at measuring mtDNA-CN, which is unsurprising as column kit parameters are typically optimized for DNA fragments ≥ 50 Kb[3]. However, as all DNA extraction method have bias in the DNA which they target, measuring mtDNA-CN from direct cell lysate may prove to be a more accurate method.

Method and Materials

The study recruited 100 individuals from different south regions of Iraq between 18 and 65 years. In workflow of experiment, DNA isolated from whole blood, the copy number of mitochondrial DNA (mtDNA) was estimated by QPCR analysis using the mitochondrial gene NADH dehydrogenase subunit 1 ND1 and ND5. ND1 and ND5 copy number were normalized to half the level of GAPDH since each cell contains two copies of genomic DNA compared to a single copy of DNA per chromosome. Each sample was run in triplicate, and QPCR analysis was performed.

The qPCR reactions were performed by using the SYBR- Green qPCR, Real-time PCR analysis of two mtDNA targets and one nuDNA targets relative quantification of the copy number of mtDNA using

DOI Number: 10.37506/mlu.v20i4.2105
calculate the copy number of mtDNA from the Ct values obtained for each of the three target genes.

**Calculation:**

a. Determination of the difference in the Ct values for the ND1/GAPDH pair
   \[ \Delta C_{t1} = C_{t} \text{ for GAPDH} - C_{t} \text{ for ND1} \]

b. Determination of the difference in the Ct values for the ND5/GAPDH pair in the same manner.
   \[ \Delta C_{t2} = C_{t} \text{ GAPDH} - C_{t} \text{ ND5} \]

c. To Find \(2^{\Delta C_{t}}\) for the values for \(\Delta C_{t1}\) and \(\Delta C_{t2}\).
   Relative mitochondrial DNA content = \(2 \times 2^{\Delta C_{t}}\)

d. Use the average of the 2 values found in step c. as mtDNA copy number\(^4\).

**Results and Discussion**

The DNA yield of extraction was subject to estimated copy number of mitochondrial DNA (mtDNA) to nuclear DNA (nuDNA) ratio for each sample. The qPCR analysis was by using the mitochondrial gene NADH dehydrogenase subunit 1 (ND1) and ND5, the nuclear gene Glyceraldehyde 3-phosphate dehydrogenase (GAPDH). In this study the differences of Ct values both mtDNA and nuDNA Ct values was measured from real-time PCR, and average the CT values from triplicate reactions mtDNA copy number to relative nuDNA amounts were calculated the copy number by using the following equations:

\[ \Delta C_{T} = (\text{nuDNA CT} - \text{mtDNA CT}) \]

Relative mitochondrial DNA content = \(2 \times 2^{\Delta C_{T}}\)

The design of the mitochondrial qPCR assay selected a region of the ND1 (NADH dehydrogenase subunit 1) gene corresponding to bases 3485-3553 of the Cambridge Reference Sequence (CRS) in order to improve the accuracy and precision of DNA quantifications \(^5\). The reason for chosen this target was previous cross-species sequence homology studies to indicated this sub region of the ND1 gene to be significantly non conserved a promising feature for developing a species specific assay and because this region of ND1 has few known SNPs especially when compared to the HV1, HV2 in control regions using a number of web based searching tools and avoiding any well-known disease associated SNPs such as the LHON associated SNP at CRS3460 designed and evaluated several assays at the ND1 target\(^6\).
In order to process a successful duplex qPCR assay it is necessary to identify reaction conditions that effectively allow two amplifications to occur independently in the same tube the goal is to avoid the predicament in which one of the amplifications reduces the PCR efficiency of the second amplification such as situation can lead to a delayed amplification for the second assay an artificially large CT value and a corresponding underestimation of the quantity of target DNA measured by that assay one strategy for avoiding this situation is to develop duplexed qPCR assay to run under conditions that limit PCR amplification of the more abundant target sequence for example by limiting the primer concentrations for this amplification [7].

Genotyping Diversity of *Pseudomonas aeruginosa* Isolates, Isolated from Baquba City

Aghadeer Sarmad Najeeb\(^1\), Hadi Rahman Rasheed Al-Taai\(^2\)

\(^1\)Post Graduate, \(^2\)Prof., Department of Biology, College of Science, Diyala University/Iraq.

**Abstract**

This research aims to assess the similarities and variances between MDR *Pseudomonas aeruginosa* clinical isolates from different infections using MLST molecular typing technique in Baquba city. One hundred-eighty clinical samples were collected from urinary tract, wounds and burns infections, included (110) urine, (50) wounds and (20) burns. Twenty isolates (11.11%) of *Pseudomonas aeruginosa* were diagnosed based on microscopic, morphological, biochemical tests and confirmed by VITEK-2 system. Antibiotic susceptibility test for the twenty isolates was performed against six antibiotics using disk diffusion method, the results showed (100%) resistance for Cephalothin, Ceftazdim (60%), Colistin (35%), Amikacin (25%), Ciprofloxacin (20%), while (0%) resistance for Imipenem. The results also showed that 16 (80%) of isolates were produced extended spectrum beta-lactamase (ESβL) and did not show their production for Metallo-beta-lactamase (MβLs). Biofilm was detected by Micro-Titer Plate method and the result showed that all the isolates (100%) were biofilm producers. Multi-locus sequence typing (MLST) was used because broadness and ease of access of MLST database. Seven housekeeping genes (*acsA*, *aroE*, *guaA*, *mutL*, *nuoD*, *ppsA*, and*trpE*) were sequenced and the results were compared with MLST database and allele profile for each isolate was used to determine sequence types (STs). New Iraqi bacterial strain has been identified and recorded in database of MLST (PubMLST) under the name (AS-85U).

**Keywords:** *Pseudomonas aeruginosa*, Biofilm, MLST.

**Introduction**

*Pseudomonas aeruginosa* is known as an opportunistic pathogen with a range of virulence factors in humans including biofilms formation, toxins that causing broadtissue damage hence, access to bloodstream and spreading to body tissue, as a role of colonization, invasion and persistence in human host\(^(1)\). *P. aerugenosa* represents a phenomenon of resistance to many antibiotics creating hard to treat infections. This bacteria has natural resistance such as chromosomal expression, changing outer membrane permeability \(^(2)\), and have many groups of efflux pumps\(^(3)\). In addition to production of many enzymes able to antibiotics lysis especially \(\beta\)-lactams such as Metallo \(\beta\)-Lactamases (MβLs), Extended spectrum \(\beta\) -Lactamases (ESβLs) and Ampier molecular class (AMPC)\(^(4)\).

Due to its ability to develop multidrug resistance (MDR), extensively drug resistant (XDR), and pandrug-resistant (PDR) *P. aeruginosa* has gradually become a prevalent in nosocomial infections\(^(5)\). The plasticity and complexity of the large *P. aeruginosa* genome (6.3Mbp) reveals the evolutionary adaptations conversed to this species\(^(6)\). It comprises conserved core genome with strain definiteregions that permit strains to gain or shed genomic fragments for improvement of survival traits in a wide range of environment\(^(7)\).

In order to distinguish between the isolates and clonal groups of *P. aeruginosa*, some molecular typing schemes have been described\(^(8)\). Multilocus sequence typing
typing (MLST) is an alternative method for molecular typing which is a global and accurate strain-typing system that concentrates entirely on conserved housekeeping genes and the combination of each allele\(^9\). This is aimed to define the sequence type (ST) for each isolate and provide information in the relatedness of bacterial isolates at the core genome level. MLST scheme has been first advanced for \(P.\ aeruginosa\) by Curran et al\(^{10}\) and had the most analytical value (100\%) in labeling strains as unique\(^{11}\). The standardization of MLST has given increase to databases which allow comparative analysis of allele sequences and documentation of distinctive sequence types\(^{12}\).

**Materials and Method**

**Isolates activation:** All the twenty \(P.\ aeruginosa\)'s isolates from different infection sources have been activated, and diagnosed depending on morphological, biochemical tests, and confirmed by VITEK-2 system.

**Antimicrobial susceptibility testing:** Antimicrobial susceptibility test was performed using (Kirby-Bauer standard disk diffusion method) on Mueller-Hinton agar plates against six antibiotics according to Franklin et al.\(^{13}\) based on CLSI\(^{14}\).

**Biofilm detection**

The Micro Titer Plate method (MTP) was used as following:

\(P.\ aeruginosa\) isolates were cultured on nutrient broth for 18-24 hr at 37°C aerobically. After incubation 2-4 colonies were picked up and cultured in nutrient broth until the turbidity equivalent to 0.5 McFarland (1.5×10\(^8\) CFU/ml). 200 μL of the bacterial suspensions were transferred into polystyrene micro-titer plates containing 96 flat-bottom wells and a broth without bacterial inoculum was used as the negative control. The plate was sealed and incubated for 24 hr. The bacterial suspensions then removed, and each well was washed three times with sterile saline solution (0.9% NaCl). Next, the cells stuck on the walls were fixed with 200 μL of methanol for 10-15 minutes. The methanol was removed, the plates were left at room temperature to dry and they were stained with 200 μL of crystal violet 0.5% for 10-15 minutes. The plates then washed with distilled water 2-3 times and dried at room temperature\(^{15}\). The absorbency were taken in an ELISA reader at wavelength of 630 nm, according to Tang et al\(^{16}\). The value of the optical densities for each isolate (ODi) was obtained by averaging the three wells, and this value was compared to the optical density of the negative control (ODc). The isolates were classified into four categories, according to the mean optical densities (ODi) in relation to the ODc results.

- If ODi ≤ ODc; considered non-adherent,
- ODc≤ODi≤2*ODc; considered moderately adherent and
- if 2*ODc≤ODi which considered strongly adherent.

The formation degree of biofilm production = 

\[\text{Optical density of tested isolates - Optical density of control.}\]

**Production of ESβLs detection:** ESBL production in \(P.\ aeruginosa\) was identified by the double disk synergy test (DDST) as described by Jarlier et al\(^{17}\). Mueller–Hinton agar plates were streaked with inoculum (equivalent to 0.5 McFarland) using a sterile cotton swab. An Augmentin (20 μg amoxicillin and 10 μg of clavulanic acid) disk placed in the center of the plate and, ceftazidime (30 μg), aztreonam (30 μg) ciprofloxacin (30 μg) were placed 15 mm separately center to center on the plates with a sterile forceps\(^{18}\). The plates were then incubated for 18-24 hr at 35-37°C. An enhanced inhibition zones from 5 mm or more in the presence of Augmentin is suggested as positive result for the production of ESBL enzyme\(^{19}\).

**Molecular typing**

**Selection of loci for MLST:** The seven housekeeping genes for \(P.\ aeruginosa\) were chosen according to MLST scheme firstly designed by Curran et al\(^{10}\) based on their biological function (mismatch repair, DNA replication and amino acid biosynthesis), size, location (a minimum of 6 kbp upstream or downstream from known virulence factors, lysogenic phage, or insertion sequence elements), and suitability for nested primer design and sequence diversity\(^{12}\).

**DNA extraction:** Genomic DNA was extracted according to the protocol of ABIOPureTM Total DNAExtraction kit/USA.

**PCR primer for MLST:** MLST was performed on four selected isolates out of twenty in order to investigate which sequence types of \(P.\ aeruginosa\) were present in Baquba city. The PCR primers described by Curran et al\(^{10}\) were used and prepared according to the manufacturer’s instructions installed in the working method of equipped company (Macrogen, Korea) to
become a primer in the final concentration 100 pmol/μl. Primers for the housekeeping genes used in the MLST scheme were mentioned in (table 1).

**Amplification of loci:** All extracted DNA from the four isolates went through PCR procedure in order to target the seven genes under study. Each reaction components contained 2 ng/μl chromosomal DNA, 1μl forward primer (10 μM), 1μl reverse primer (10 μM), 12.5μl master mix (2x) and 8.5μl nuclease free H2O. The reaction conditions were: initial denaturation at 95ºC for 5 min, denaturation at 95ºC for 30 sec, primer annealing at 55ºC for 30 sec, extension at 72ºC for 1 min and the final extension at 72ºC for 7 min. The amplification product was purified before sequencing process.

</table>

**Sequencing and blasting:** Sequencing was performed for all 7 genes of the 4 isolates. PCR product were sent for Sanger sequencing using ABI3730XL, automated DNA sequencers, by Macrogen Corporation – Korea. The results were received by email then analyzed using genus software. To get an allelic profile, the results were blasted in the *Pseudomonas aeruginosa* MLST Database (http://pubmlst.org/paeruginosa), and then the database was used to search for the STs defined by those specific allelic profiles. The sequences were confirmed through individual BLAST searches to determine their correspondence with previously sequenced *P. aeruginosa* genomes. Then the full aligned sequences were saved in FASTA format.

**Allele and sequence type assignment:** Based upon the allele numbering system in the *P. aeruginosa* MLST database, an allele number was appointed for every gene in each isolate. Alleles that differed by even a one base pair from those present in the database were denominated as “new.” Each distinct combination of seven numbers (denoting the seven alleles) was assigned a number denoting its sequence type (ST) according to the MLST database. Combinations not present in the database were considered “new” STs.

**Results**

**Antibiotics sensitivity test:** Isolates under study showed 100% resistance for Cephalothin (KF), this result agree with Hameed (20) which was 100% resistance. Ceftazidime (CAZ) showed 60% resistance which is similar to Kaur and Singh (21) finding. The resistance to Amikacin (AK) and Ciprofloxacin (CP) was 25% and 20% respectively, this result agree with Fattma et al (22) 25% and 35% respectively while Colistin showed 35% resistance. Finally, the resistance to Impinem was 0% (100% sensitive) and this result is consistence with Hameed (20) finding which was 0%, table (3).

Biofilm production: The results showed that all the isolates included in the study had the properties of biofilms formation and the absorbency value was ranged from (0.186 – 0.21) and 25% of isolates were strongly biofilm forming this agree with Hameed\(^{(20)}\) finding which was 25%, 75% for moderately biofilm forming.

Extended Spectrum β- Lactamase Enzyme (ESβLs): The results showed that 16 (80%) of isolates under study were ESβLs producer and 4 (20%) non-producing. This result is nearly to Hyford\(^{(23)}\) result which was 88% of clinical isolates were producing these enzymes.

Multi locus Sequence Typing (MLST) and allelic profile: Allele profiles and STs can be found at (http://pubmlst.org/paeruginosa). By comparing the sequence and combination of genes the clonal relationship between isolates can be assessed\(^{(10)}\). It has been reported that isolates with the same sequence types (ST) can be considered as members of the same clone, and P. aeruginosa isolates that share at least five of the seven numbers within their allelic profile were regarded as members of the same clonal complex\(^{(24)}\) table (3).

*In MLST database any allele not contained within database was designated as “new”

Nucleotides Sequencing of MLST: In an effort to compare MLST genes heterogenicity, polymerase chain reaction products of seven genes for P. aeruginosa isolates were sent for determining the nucleotide sequence. Sequencing was determined by an automatic sequencer. DNA sequences were analyzed and similarity were accomplished among genes of local P. aeruginosa and standard strains with Basic Local Alignment Search Tool (BLAST) in National Center for Biotechnology Information (NCBI). A subsequent BLAST search showed a 99-100% match to P.aeruginosa genomes present in GenBank for acaA sequences of these isolates, which confirmed their identity as P.aeruginosa.

New bacterial strain identification: One bacterial isolate (P7) was identified as global new Iraqi strain for differences in some nucleotide position. This new strain AS-85U was published in the MLST database https://pubmlst.org/paeruginosa/
Conclusions

Pseudomonas aeruginosa has several genetic elements that support their pathogenicity (virulence and antibiotics resistance) and the resistance of Pseudomonas aeruginosa to most antibiotics in the study indicating a correlation between multidrug resistance to antibiotics and the production of (ESβLS) enzymes and biofilm formation. Molecular techniques provide sensitive and rapid analytical tools for identification, sequencing and increases the excellence of epidemiological investigations. The newly-developed MLST method for multi locus typing of P.aeruginosa suggests an accurate diagnosis of the bacteria and detection of the source of infections and treatment.

Motivation for Choosing Neurology as a Career, among Students of Baghdad Medical College

Zuhair A. Al-Johar¹ FIBMS(Neurology), Aqeel Kareem Hatem², FIBMS (Neurology), Hadeel Mohammed Abbas³, Hajer Waleed Khaled³, Maha Tayib Othman³

¹Specialist of Neurology, Lecturer of Neurology, Department of Medicine, College of Medicine, University of Baghdad, Baghdad, Iraq, ²Consultant Neurologist, Lecturer of Neurology, Department of Medicine, College of Medicine, University of Baghdad, Baghdad, Iraq, ³Students at College of Medicine/University of Baghdad, 4th Year/Iraq

Abstract

Purpose: To test the influence of specific factors on motivation for neurology career and especially the effect of taking neurology course, and the effect of gender on them.

Materials and Method: This is an observational cross-sectional, self-administered questionnaire-based study. Structured online surveys were offered to a random sample of 170 final year students of College of Medicine/University of Baghdad from July to September 2018. Assessment included factors that might influence students’ choice of neurology as a future career, gender effect on those factors, and especially evaluating the impact of exposure to neurology course on their determination for choosing neurology.

Results: A total of 150 students responded to this survey (88% responder rate). About 35.3% of the participants anticipated that they would choose neurology as their future career. The strongest motivational factors were: passion in neurology (50%), role model (38%), and prestige (36%). Family and friend’s effect and having an illness in the family were less motivating factors. Taking the neurosciences module did motivate the students to choose neurology as their future career (p=0.001).

Conclusion: Neurology is generally well-regarded by students in our college. There was a statistically significant association between choosing neurology as a future career and the influence of studying neuroscience module. Other significant associations were: will to help neurologically ill patients, having passion in neurology, role model, prestige and family pressure.

Keywords: Neurology, career, medical students, neuro-module, Baghdad.

Introduction

It is often thought that undergraduates do not make their career preferences until after they have graduated from medical school. However, not only entrants of medical schools¹, but even applicants to medical schools, often have strong preferences for or against some medical careers.² ³ ⁴ Neurology, it appears, has a reputation among medical specialties of being particularly hard. Particularly interesting is the concept of “Neurophobia,” i.e., perception that neurology is a difficult and complicated subject to understand.⁵

Little is known about the factors that motivate medical students to seek careers in Neuro-medicine. Their choice has been associated with multiple factors, the main ones were intellectual property, helping people with neurological disorders, passion in neurology, role model. Other less chosen factors were prestige, family

Corresponding Author:

Specialist of Neurology, Lecturer of Neurology, Department of Medicine, College of Medicine, University of Baghdad, Baghdad, Iraq
e-mail: zaljohar@comed.uobaghdad.edu.iq
and friends influence, having a neurological illness in the family or among friends, and controllable lifestyle. Academic exposure to neurology course has a very prominent effect on promoting choosing neurology as a future career whether that course was taken before or after graduation.

Age was seen to affect motivation, older applicants having experience with neurology chose intellectual property over interesting in helping people, while younger ones chose the latter.

Factors that deterred students form choosing neurology were: difficulty of the subject, perception of non-interference, poor quality of life and excessive clinical activities.

As regards gender issue, there is an increase in the number of women in neurology in the United State ‘US’, but even in the US, woman are still facing gender issues when working in neurology, mostly related to underestimation of their skills, and adverse social expectations.

No study on students’ selection of neurology as future specialty was conducted before in Iraq.

This study was conducted with the objectives to evaluate the known factors that influence the student’s choice of neurology as a future career, the effect of gender on those factors, and to evaluate the impact of exposure to neurology course on their determination of choosing neurology.

**Material and Method**

An observational cross-sectional survey study was conducted from July to September of 2018 at the College of Medicine, University of Baghdad. Initially 10 students were chosen for a pilot study to assess the accuracy and reliability of the questionnaire, then 170 students were randomly selected from all final (6th) year medical students. Consent was taken from the participants and they were informed of the confidential nature of the survey. Participation was voluntary and unpaid.

Inclusion criteria: 6th grade [final year] medical students of Baghdad University/College of Medicine.

Exclusion criteria: Students who were unwilling to participate or those who incorrectly/incompletely filled the questionnaire were excluded.

The questionnaire gathered information about: Demographic data: including gender; if the students would choose neurology as a career in the future (yes or no); factors related to choosing neurology as a career (family/friends influence, family/friends doctor, family/friends with neurological disorder, being influenced by role model, being influenced by prestige, passion in neurology, interest in helping people with neurological disorders, other cause). Questionnaire about the effect of neurology module included: score of neurology course in second academic year, score of neuroscience module in fifth academic year, did neurology courses in second, fifth academic years affect your motivation for choosing neurology as a future career?

**Data management and statistical analysis:**

Initial survey forms for the pilot study were on paper and distributed manually to the students, while the final survey forms included in our study were prepared via Google forms, and were distributed online by using Facebook to all of the respondents. The data was encoded and submitted into SPSS (version 24). All the data were set as categorical variables and the descriptive statistics were presented in frequencies, percentages and 95% standard deviations, and confidence intervals. Chi-square test [and fisher exact test when applicable] were used to analyze the significance of association between different variables. Unless otherwise noted, statistical significance we set as p<0.05.

**Results**

A total of 150 students were included in this study. A responder rate of 0.88. Male respondents totaled 41 (27.3%) and 109 (72.7%) were females. About 53 (35.3%) of the participants said that they’ll choose neuroscience as their future career and the remaining 97 (64.7%) preferred to choose other specialties. Of 109 female participants 40 (36.7%) were going to choose neurology compared to 13 (31.7%) of 41 males, a non-statistically significant difference (χ² = 0.3247, p= 0.569)

**Factors related to choosing neurology as a career:**

The number of students motivated by each factor in the survey and its percentage from the whole sample was as follows: interest in helping people with neurological disorder 125 (83%), passion in neurology 77 (51%), role model 57 (38%), Prestige 54 (36%), family/friend with a neurological disorder 49 (33%), family influence 37 (24.7), presence of family/friend doctor 36 (24%).
Figure (1) displays the percentages of students choosing each motivational factor from the sample of students who were willing to choose neurology as a future career.

Descriptive statistics for motivational factors for choosing neurology per the two choice groups and significance of differences were calculated and are depicted in Table 1.

</table>

Of males: 5,10,14,10,2 in 2nd grade and 1,6,18,6,10 in 5th grade had excellent, very good, good, average and borderline scores respectively. The respective results for females were 15,29,44,12,9 in 2nd grade and 4, 33,32,26,14 in 5th grade (p<0.05 for both grades).

The student’s perception of the motivational effect of taking the neuroscience module of the fifth year, and of both the second and fifth year, on their perceived choice of selecting Neurology as a future career was calculated and depicted in Figure 2. The difference was found be statistically significant (\( \chi^2 = 62.060, p<0.001 \)).
Discussion

Neurology was the career of choice for 35.3% of students in this study, suggesting that neurology is generally well-appreciated by our students. In comparison to Gupta N. etal study\(^6\) in which only 19% of students were willing to choose neurology.

The percentage of female students in our college is very high, constituting 54.4% in a prior study\(^13\) and around 72.7% in this study. Therefore gender related motivational issues to neurology must be addressed.

Analyzing the factors that are related to choosing neurology: 24.7% said that their families had an influence on their interest, whereas Gupta N. et al study showed that only 2% of the students reported family influence and pressure.\(^6\) This rather big difference could be due to cultural difference and differences in family involvement in students’ life between different societies. There was not gender difference regarding this factor.

For the family/friend neurologist influence, 24% agreed that having a family/friend neurologist doctor motivated them to pick neurology. After extensive research this was not tested by other studies as a relating factor, although it shows a large effect on students in this study. However this study didn’t reveal any significant association between this factor and the will to choose neurology as a future career. However this study did show that males are more prone to be affected by that factor than females (\(p=0.027\)).

Students who have a family/friend with a neurological disorder were 32.7%, this was also not tested by other studies. However this study didn’t show any significant association between this factor and choosing neurology as a future career at 0.05 level of significance, however the result was significant at 0.10 level. No gender difference was found in this study.

Having a role model influenced 38%, which is consistent with the findings of Thomas R. which had 37% influence on the students.\(^8\) This factor is consistently reported in most studies about motivation in neurology.\(^6,7,8\) This came here as the third highest factor that motivated students in our sample before prestige and family/friends impact, which largely agrees with earlier studies.\(^6,7,8\) This equally affected both genders in this study.

Considering neurology as a prestigious job inspired 54 (36%), on the other hand Gupta N.\(^6\), showed that 18% considered neurology as a prestige job. This might be because considering neurology as prestige might signal cultural grounds for this difference. In our study this significantly affected males more than females (\(p=0.017\)).

Passion in neurology was shown to affect more
than half of the students and without gender related differences, this agrees with the findings of Gupta N., in which also about more than half of the students (52%) were passionate and interested in neurology as a job. Passion in neurology was one of the commonest factors related to picking neurology among students in this study. Also this agrees with most studies.6,7,8

Students who reported having an interest to help people with neurological diseases were 83.3%. Also 82.6% were interested in helping people with neurological diseases in the study of Albert D.10 This agrees with most studies.6,7,8 In our study this included all students who would and wouldn’t choose neurology as a future career, males and females alike, but surprisingly it was much lower in the group who didn’t will to choose neurology as a future career that the difference was significant! Interest in helping people game first before passion in neurology, this agrees with older studies about younger students being motivated by interest in helping people as contrasted with older more experienced trainees in neurology which preferred intellectual content.7

Meanwhile, for the effect of neuroscience modules and the students’ choice of neurology, there was no statistically significant association between students’ score and their choice of neurology as a future career, and the same applies to gender effect on scores, this finding agrees with Goni U. et al which also stated having no gender associated difference with different scores.14

This study revealed a statistically significant association between choosing neurology as a future career and the influence of neuroscience of 2nd and 5th grade. These findings are supported by all prior studies6,7,8,10 all of which reported the effect of undergraduate or postgraduate courses in neurology on future choice of neurology as a career.

**Conclusion:**

Neurology is generally well-regarded by students of our college.

There was a statistically significant association between perception of choosing neurology as a future career and factors of: will to help neurologically ill patients, having passion in neurology, role model, prestige, and family pressure, in a descending manner.

There was a statistically significant association between the perception of choosing neurology as a future career and the influence of studying neuroscience module.

Outcome of Biliary Fistula After Liver Hydatid Cyst Surgery

Nasser M. Meazher¹, Fadhil Abbas Al-Janabi², Haider Nadum Obaid³

¹FICMS, Dept. of Surgery, Medical College/Kufa University, Iraq, ²CABS, FACS, Dept. of Surgery, AL Sadder Medical City, Al-Najaf Health Care Center/Iraq, ³CABS, FICMS, Dept. of Surgery, Al-Khadymia Teaching Hospital, Baghdad/Iraq

Abstract

Background: Biliary fistula after liver hydatid cyst surgery was occur in about 17.8 percent of patients in our center.

Objective: To study the outcome of biliary fistula regarding factors related to its causes and management.

Patients and Methodology: This is a prospective study of 241 cases submitted to liver hydatid surgery in Al-Sader teaching hospital in Al-Najaf city, from October 2015 to April 2019. A total of 43 patients who underwent surgery complicated with persistent leakage of bile from external drain. Prospectively collected database were gathered from patients medical records, sent for essential investigations, and treated either conservatively to give a chance for spontaneous closure, or by intervention with ERCP.

Results: Forty three patients who develop postoperative biliary fistula after hydatid cyst surgery from 241 patients (17.8 %), 230 patients treated with conservative surgery (95.4 %), 2 patients treated with radical surgery (0.82 %) and 9 patients treated with percutaneous aspiration injection reaspiration (3.7 %). All the 43 patients in this search treated with conservative surgery. Size more than 15 cm is a risk factors. Intraoperative risk factor is mainly presence of cystobiliary communication which occur in 16 patients (37.2 %). Treatment is conservative in about 23 patients (53.4 %). Treatment with ERCP in 19 patients (44.1 %). Time of intervention is from 9 – 15 days.

Conclusion: Most of patient with external biliary fistula after hydatid liver surgery can be treated conservatively and resolve spontaneously specially low output fistula.

Keywords: Hydatid cyst, biliary fistulae, Outcome, surgery.

Introduction

Hydatid disease is a zoonosis, caused by tapeworm Echinococcus infestation in its larval or cyst stage. The dogs transmit the disease to the Humans, and there is no human-to-human transmission. Three known forms of echinococcosis in humans; E. granulosus, E. multilocularis and E. vogeli.¹²

The typical hydatid cyst has a three layer wall containing a fluid. The outer one is the pericyst, the outer layer of the cyst itself is the laminated membrane (ectocyst) and the inner one (endocyst) is the germinal membrane, responsible for the production of clear fluid.³

Clinical Features: Mostly asymptomatic until complications occur. The commonest presentations: dyspepsia, abdominal pain and vomiting. Most common sign is hepatomegaly. The commonest complication is intrabiliary rupture of hydatid cysts, or may rupture to bronchial tree, or free rupture into cavities (peritoneal, pleural, or pericardial). Free ruptures can result in a potentially fatal anaphylactic reaction or disseminated echinococcosis.³

Diagnosis: The diagnosis of hydatid disease is based on an immunological test for echinococcal antigens [enzyme-linked immune sorbent assay (ELISA)], in approximately 85% of patients is positive. In approximately 30% of patients, Eosinophilia is seen. For detecting hydatid cysts, abdominal Ultrasonography

DOI Number: 10.37506/mlu.v20i4.2108
and CT scanning are both sensitive. Abdominal MRI may be helpful to assess the characteristics features of pericyst, cyst matrix, and daughter cyst.\textsuperscript{4}

**Treatment:** Medical with benzimidazole compounds is currently indicated in

(a) primary hepatic and pulmonary cystic echinococcosis in inoperable patients.
(b) cysts in two or more organs.
(c) small multiple (5 cm) hepatic cysts.
(d) deep cysts in hepatic parenchyma.
(e) secondary prevention.
(f) recurrent.
(g) unfit elderly with unilocular cysts.
(h) specific sites (such as brain, bone, eye)

**Contraindicated for:**

(a) large cysts (10 cm).
(b) honeycomb cysts.
(c) superficial cysts that are prone to rupture.
(d) infected one.
(e) inactive one.
(f) calcified cysts and asymptomatic.
(g) chronic hepatic disease(sever).
(h) bone marrow depression.
(i) pregnancy(early).
(j) Diabetes is a relative contraindication.\textsuperscript{5}

**Minimally Invasive Techniques:**

**Percutaneous Drainage of Hydatid Cysts (PAIR)** indicated for:

(a) inoperable patients,
(b) patients who refuse surgery,
(c) Gharbi type I and II,
(d) relapse after surgery,
(e) infected cysts,
(f) failure of chemotherapy,
(g) cysts of greater than 5-cm diameter and in different liver segments,
(h) possibly pregnant women (chemotherapy contraindicated).
(i) possibly children less than 3 years old.

**Contraindications for PAIR are:**

(a) inaccessible cysts,
(b) superficial cysts,
(c) honeycomb cysts,
(d) cysts show hyperechogenic solid patterns,
(e) cysts communicating with bile ducts,
(f) partially or totally calcified cysts,
(g) cysts in the lung.

**Surgery:** Surgerical intervention in the management of liver hydatid is still the “gold standard”.

**Indications for open surgery are:**

(a) large one with multiple daughter cysts,
(b) superficial cysts that may rupture,
(c) infected cysts,
(d) cystobiliary communication,
(e) cysts with pressure effect on adjacent organs,

**Contraindications for surgery are:**

(a) patients refusing surgery,
(b) extreme age,
(c) pregnant women,
(d) concomitant severe diseases,
(e) numerous cysts,
(f) difficult to access,
(g) dead cysts,
(h) calcified cysts,
(i) small cysts <5 cm (wait and see policy).\textsuperscript{5}

**Postoperative Complications:** The incidence and significance of postoperative morbidity after conservative procedures has been exaggerated in many reports. The most frequent postoperative complications are:

(a) wound infection,
(b) chest problems,
(c) subphrenic abscess,
(d) biliary leaks, and
(e) liver abscess.

**Biliary leak and fistula:**

Biliary fistula is bile flow along an abnormal epithelial connection from bile duct into nearby hollow structure, it is either classified as

- **External** or **internal**, external mean connection to the abdominal wall through the wound of its surgery, internal type is the connection to small bowel (bilioenteric) or pleural space (thoracobiliary) or classified as

- **Primary** or **secondary**, primary type which caused by biliary lethiasis or neoplasia, secondary type caused by iatrogenic injury during cholecystectomy or other biliary surgery.

Biliary leak is bile escape the bile duct through a perforation e.g rupture hydatid cyst (internal type) or faulty surgical anastomosis. In postoperative hydatid cyst surgery, bile leakage is drainage of bile through abdominal drains, regardless of quantity, no longer than 10 postoperative days. Persistent, stable external drainage of bile for 10 days or more, is a biliary fistula.

The most frequent causes are

(a) An overlooked cystobiliary communication,
(b) Injury to a bile duct,
(c) Inadequately managed cystobiliary communication,
(d) Calcified pericyst,
(e) Hydatid debris obstructing the CBD.

**Patients and Method**

This is a prospective study of 241 cases submitted to liver hydatid surgery in Al-Sader teaching hospital in Al-Najaf city, from October 2015 to April 2019. Postoperatively, 43 of those patients develop biliary fistula.

Prospectively collected database were gathered from patients medical records including: personal data, medical history of disease, main symptoms and sign, radiological finding (site and size of cyst, single or multiple, primary or secondary, other organs involvement), and ultrasonographic findings, CXR, preoperative complications (dilated biliary tree, jaundice, cyst rupture), type of surgical intervention, presence or absence of cystobiliary communication at operation time and type of its treatment, postoperative follow-up, daily fistula output, time of spontaneous closure, time of intervention, hospital stay postoperatively and mortality.

A biliary fistula is heralded by early postoperative external drainage of large quantities of bile.

Investigations that done to the patients include: liver function test, blood picture, ultrasonographic examination of an abdomen, computerized tomography (not used routinely).

Treatment of patients with biliary fistula includes either conservative management to give a chance for spontaneous closure, or by intervention with ERCP and sphincterotomy with or without stent.

**Results**

241 patients with hydatid cyst of liver who undergoes different surgical modalities include;

1. Conservative procedures by deroofing and omental patch in 230 patients (95.4 %).
2. Radical procedures by radical cystectomy and liver resection in 2 cases (0.80 %).
3. Percutaneous aspiration injection reaspiration (PAIR) done in 9 patients out of 241 patients (3.73 %).

There are 43 patients out of 241 patients were developed external biliary fistula (17.8 %) subjected to different types of management either surgically or conservatively (Table I):

Discussion

Surgery play an important role in treatment of liver hydatid. Operative options include radical surgery or conservative surgery as the patients in current study were treated. In this study there are 43 patients whose develop biliary fistula after surgery.

Female more common than male, 24 (55.8%) for female and 19 (44.18%) for male, in other research we found (73.2 %) for female and (26.8 %) for male, this is may be related to dealing with vegetable more regarding female side, age incidence is ranged from 18 to 55 years old with mean age (36.4 ± 7.6). In other research it was found similar range, Yang X et al.

Intraoperative cystobiliary communication was found in 16 patients (37.2%), only 6 of them treated with direct suturing and omental patch before they develop biliary fistula, similar percentage in other research was found; Demircan O et al. In comparison with other study; Bhattarai et al, about 13 patients from thirty patients were found with intraoperative cystobiliarycommunication which is close percentage.

A correlation between biliary fistula and site(right, left or both) in this research as it is more common in right lobe in 27 patients (62.79%) than the left lobe with 12 patients(27.9%) as it found in a similar research Gokhan et al. Kayaalp et al. of 113 patients showed that the site of the liver hydatid close to the hilum is a risk factor for a cystobiliary communication.

The cyst size was recognized as a predictive factor in the biliary fistula development. In literature, suggested size more than 10 cm plays a role in a cystobiliary communication development, compared to our study it found that the great percentage is when the cyst is more than 15 cm which was in 26 patients (60.4 %).

Multiple studies reported a history of cholangitis, high bilirubin and ALP level,a cyst size more than 10 cm and the presence of suggestive radiological findings as clinical predictors of intrabiliary rupture, and an ERCP was indicated in these cases to delineate the cyst-biliary communication.

In our study, spontaneous closure without any intervention was occur in 23 patients of 43(53.48%) in time ranged between (19-35) days, all of them with low output fistula.

In Balik AA et al a review of 304 cases, spontaneous closure in time ranged between 2-4 months inall the 10 cases with external biliary fistulae. In other studies, 7 of 12 fistulae closed spontaneously, with the closure time up to 38 days. In this study the closure time of fistula was ranged from 19 to 40 days in cases of low output fistula with gradual reduction in the amount of bile in the drain which was in 23 patients, in cases of high output fistula, closure time was ranged from 19 to 117 day with intervention. Time of intervention in low output fistula with no reduction in amount ranged form 19-28 days in other study.

Skroubis G, et al it was found that ERCP was used for the management of high-output fistulas of more than 1 week’s duration without reduction and low-output fistulas of more than 3 weeks’ duration without reduction of leakage.

19 patients in the other hand have been treated by ERCP, they have high output fistula, 2 cases of these 19 patients submitted to more than one ERCP and bigger size stent, in this search the time to intervene is ranged from 9-15 days.

In other cases when there are low output fistula but there is no decrease in amount of output, so intervention is mandatory and not to delay more than 28 days. The time from intervention to closure of fistula also ranged from 10 to 101 days.
Conclusions

Conservative treatment is the first method of treatment in low output fistula. High output fistula better not to delay intervention and treated by ERCP and sphincterotomy with or without stenting.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the Dept. of surgery and all experiments were carried out in accordance with approved guidelines.

Abstract

A comparative prospective study was conducted in the High Institute of Infertility Diagnosis and Assisted Reproductive Technologies/Al-Nahrain University, from September 2019 to March 2020. The study included 60 women who attended the infertility clinic of the High Institute of Infertility Diagnosis and Assisted Reproductive Technologies/Al-Nahrain University. Follitropin Alfa ampoules 75 IU, subcutaneous, from 7th day of menstrual cycle and the dose was adapted according to the ovarian response to the dose of treatment. Other twenty females were treated with Femara (Letrozole). The study showed that the highest mean of LH (in the day of triggering of the follicle) was recorded in women under Clomid +FSH treatment (13.52±7.22 mlU/ml) followed the control group (10.1±4.21 mlU/ml) and the lowest mean was in women received Letrozole+ FSH (8.67±4.54 mlU/ml). The study also demonstrated that the mean of E2 was elevated significantly in women under Clomid +FSH treatment (280.5±191.4 pg/ml) followed by in women received Letrozole+ FSH (214.2±141.4 pg/ml) and the lowest mean was in the control group (164.7±102.7 pg/ml). The maximum mean of progesterone was recorded in in women under Clomid +FSH treatment (4.15±3.2 ng/ml) followed by women received Letrozole+ FSH and the control group.

Keywords: Clomid; Female infertility; Letrozole; FSH.

Introduction

Infertility is a disease of the reproductive system, It can be defined by the failure to achieve a pregnancy after at least one year of regular unprotected sexual intercourse in women < 35 years not using contraception and after six months in women > 35 years or due to an impairment of a person’s capacity to reproduce, either as an individual or with his/her partner, it affects about 10-15% of couples¹,². According to the World Health Organization (WHO) definition, a couple is considered infertile if, after 2 years of regular sexual intercourse, without contraception, the woman has not become pregnant³. Infertility is classified as primary (no pregnancy in the past) or secondary (pregnancy has occurred in the past not necessarily leading to live birth)⁴. The causes of infertility can be generally classified into four groups: male, female, combined(both male and female) and unexplained⁵. Some additional factors that may contribute to female infertility are behavioural factors such as diet, exercise, smoking, alcohol and drug use⁶. Combined infertility arises from the combination of male and female causes and it may be that each partner is independently fertile but the couple cannot conceive together without assistance. Nowadays, progress in ART has enabled the clinicians to treat many types of infertility⁷.

Endometrial receptivity is defined as a temporary unique sequence of factors that make the endometrium receptive to the implantation of the embryo⁸. It is the window of time when the uterine environment is conductive to blastocyst acceptance and subsequent implantation⁹. The process of implantation may be separated into a series of developmental phases starting with the hatching of the blastocyst and attachment to the endometrium and sustained the formation of the placenta. The steps start with apposition, and progress through adhesion, penetration and invasion¹⁰. The aim of the study was to evaluate the use of clomid plus gonadotropin versus letrozole plus gonadotropin stimulation of infertile women.
Patients and Method

A comparative prospective study was conducted in the High Institute of Infertility Diagnosis and Assisted Reproductive Technologies/Al-Nahrain University, from September 2019 to March 2020. The study included a total of 60 women who attended the infertility clinic of High Institute of Infertility Diagnosis and Assisted Reproductive Technologies/Al-Nahrain University from September 2019 to March 2020. All couples subjected to a full history taking, complete general examination, complete gynecological examination and infertility workup including: husband’s seminal fluid analysis, basal hormonal analysis, uterine cavity assessment by ultrasound and tubal patency evaluation by hystrosalpingogram. The females were divided into two groups each consisting of 20 females. 20 females were stimulated with clomiphene citrate + gonadotropin and other 20 were stimulated by letrozole + gonadotropin. The ovarian stimulation protocol was chosen for each patient according to the following criteria: age, history and hormonal assay.

Evaluation of thickness and pattern of endometrium, size and number of mature follicles was performed by transvaginal ultrasonography in the 2nd day of menstrual cycle and cycle day 11-14 before HCG injection (ovulatory phase). Pregnancy outcome was used as a main comparative parameter between selected groups.

Ethical Approval: Written informed consent was given to every patient included in this study gave her written informed consent before taking part in the study, it was approved by the Ethics Committee and according to questionnaire forms designed.

History: The history was used to identify variables that affect the outcome of the ovarian induction program. The following variables were chosen for the initial analysis: age, type of infertility (primary or secondary), duration of infertility, menstrual history, any previous pregnancies, details about frequency of intercourse, use of vaginal douches after intercourse, and presence of any sexual dysfunction, chronic illnesses, surgery, and fertility investigations and or treatment. Etiology of infertility (unexplained infertility, male factor, minimal to mild endometriosis or ovarian dysfunction

Physical Examination: From external appearance of the patient obesity or low weight, acne or increased facial hair which may be a result of androgen excess. The thyroid gland was examined, abdominal examination for any surgical scars, mass and striae (Tkaczk-Wlachet al., 2016). Gynecological examination was performed through vaginal examination to exclude any palpable pelvic mass or discomfort, normal vagina and cervix, the size, shape, position and mobility of the uterus was assessed.

Hormonal Analysis: In ART, correct diagnosis of the cause of infertility is a pre-requisite to successful treatment. Hormone tests are essential monitoring tools which were done in this study. In this study basal hormonal analysis was performed to all females included in the study on the 2nd or 3rd day of the menstrual cycle before starting control ovarian hyperstimulation COH. These hormones include FSH, LH, Prolactin, E2, and progesterone. Blood samples were drawn from each patient (5ml) for hormonal assay, from median cubital vein by disposable syringe (Becton Dickinson company, USA), into a plain tube (AFCO, Jordan) allowed to clot for 30 minutes and centrifuged at 3500 rpm within 10 minutes to separate the serum by using hormone analyzer.

Hysterosalpingography: Tubal patency and uterine cavity regularity were confirmed by hysterosalpingography, women with defective tubal patency or cavity deformity were excluded from the study.

Induction of Ovulation: Twenty females were treated by Clomiphene Citrate (CC) (Clomid, 50 mg/ tablets, Aventis Company, France) two times daily for five days from day two of menstrual cycle after basal transvaginal ultrasound to sixth day. Follitropin Alfa ampoules 75 IU, subcutaneous, from the 7th day of menstrual cycle and the dose was adapted according to the ovarian response to the dose of treatment. Other twenty females were treated with Femara (Letrozole) [Novartis] Film-coated tablets contain 2.5 mg Letrozole two times daily for 5 days from second day of menstrual cycle it is used to treat failed multiple cycles with ovulation induction by clomiphene citrate as used by other investigators. Follitropin Alfa ampoules 75 IU, subcutaneous, from the 7th day and the dose was adapted according to the ovarian response. Endometrial wash done at day of trigger for hyaluronic acid assessment.

Results

In this study, the majority of women enrolled in this study belonged to rural area and below 30 years, parity below 1 and infertile between 2-4 years, as shown in Table 1.
The study showed that the highest mean of LH (in the day of triggering of the follicle) was recorded in women under Clomid + FSH treatment (13.52±7.22 mlU/ml) followed by the control group (10.1±4.21 mlU/ml) and the lowest mean was in women received Letrozole+FSH (8.67±4.54 mlU/ml). The study also demonstrated that the mean of E2 was elevated significantly in women under Clomid + FSH treatment (280.5±191.4 pg/ml) followed by in women received Letrozole+FSH (214.2±141.4 pg/ml) and the lowest mean was in the control group (164.7±102.7 pg/ml). The maximum mean of progesterone was recorded in in women under Clomid + FSH treatment (4.15±3.2 ng/ml) followed by women received Letrozole+ FSH and the control group (Table 2).

**Discussion**

In this study, the majority of women enrolled in this study belonged to rural area and below 30 years, parity below 1 and infertile between 2-4 years. These findings were close to that reported by Ahmeid(7), who found that the mean age of women under IVF was 30.36 year, his study also found that the mean of BMI was 25.9 (kg/m$^2$). Hameed and Ahmeid, (8) in recent study included 45 women who enrolled in ART programs in infertility center for in-vitro fertilization (IVF) and found that the mean age of infertile women was (31.80 ± 5.38 years), his study also found that the mean of BMI was 25.36 ± 1.99 (kg/m$^2$). Moreover Al-Dujaily et al(9) found that the mean age of infertile women (31.0 year) and BMI 25.3 (kg/m2) Due to body mass index (BMI) has an adverse effect on reproduction, a higher incidence of menstrual dysfunction and anovulation was found in overweight women, possibly because of the alteration in secretion of gonadotropin releasing hormone, sex hormone binding globulin, adrenal and ovarian androgen, and luteinizing hormone and also because of altered insulin resistance(10). Being a cheap, safe, and reasonably effective drug; Clomiphene citrate (CC) has withstood the test of time despite its all drawbacks. Therefore, the use of other protocols of ovulation induction in PCOS, including letrozole, has been limited to cases of CC resistance, failure, or intolerance (11). Effectiveness and cost-effectiveness of other protocols were also compared to CC. This approach is rational when costly, hazardous, or invasive interventions like gonadotropin stimulation or laparoscopic ovarian drilling (LOD) are considered (1). Letrozole, however, is similarly safe, relatively inexpensive, and reasonably effective drug. The drug, therefore, deserves a fair comparison with CC. Letrozole was the first aromatase inhibitor to be used for this indication. Studies on letrozole were mostly conducted on clomiphene resistant cases, and
because of its short history in this respect, concepts like letrozole resistance (12). The largest study comparing Clomiphene citrate to Letrozole was by Badawy et al. (13) demonstrated that the mean of E2 was significantly elevated in women under Clomid comparing with women who received Letrozole. Ibrahim et al. (14) also demonstrated that serum estradiol was significantly greater in the CC group. In an agreement with this study finding, Wu et al. (11) showed no significant difference in pregnancy rates and ovulation was found between the two drugs. Ibrahim et al. (14) also demonstrated that the clinical pregnancy rate was significantly higher in letrozole group (23.07 vs 10.68 %, P < 0.001). There was significant increase in endometrial receptivity in letrozole group as assessed by endometrial thickness and Doppler flow indices of uterine and subendometrial vessels statistically. No harmful side effects were reported in either group. Moreover, Majeed (15) proposed that, Letrozole appears to be a suitable ovulation inducing agent in PCOS women with CC failure and a significant higher pregnancy rate was observed in letrozole co treatment with gonadotropins. The finding of current study was also a good agreement with previous reports which conclude that letrozole has a better ovulation and pregnancy rate in patients with PCOS (16,17). Letrozole administration in early follicular phase blocks estrogen syntheses, and causes temporary accumulation of androgens in ovarian follicles, the accumulation of androgens may increase the sensitivity of the growing follicles to FSH by increasing the expression of FSH receptors (13). In addition, Dehbashi et al. (4) showed that no significant increase in pregnancy rate was observed in the letrozole group. A non-significant increase in pregnancy rate was observed in patients receiving the letrozole treatment (10). Moreover, Sammour et al. (18) concluded that the pregnancy rate per cycle was 11.5% in the letrozole group and 8.9% in the clomiphene group (similar pregnancy rate) in they studied total 238 cycles of IUI and superovulation in women with idiopathic infertility. Patients were randomized to receive 7.5 mg of letrozole or 100 mg of clomiphene daily. There was no significant difference between the total number of developing follicles in both groups the letrozole (5.7±3.7) and in the clomiphene groups (4.8±2.3).

Conclusions

It was concluded that, the number of follicles, Hyaluronic acid concentration, and the mean of Estradiol2 level at the day of trigger elevated significantly in women received letrozole than clomiphene as a treatment for non ovulatory infertility in women, and the pregnancy rate also is higher in letrozole plus gonadotropin group.

Characterization and Outcome of Patients Presented with Unilateral Nasal Disease to ENT unit at Hillah, Iraq

Safaa Hussain Alturaihy

M.B.Ch.B./F.I.B.M.S. ENT/Assistant Professor/Department of Surgery/College of Medicine/Babylon University/Consultant ENT in Hillah General Teaching Hospital at Department of Surgery

Abstract

Background: A common finding during daily otolaryngological practice is a patient with unilateral nasal symptoms, nasal polyp or mass. The causes behind most cases of unilateral nasal disorder are inflammatory in nature and responds well to medical intervention and rarely there is need for surgical management. The possibility of neoplastic nature is high when there is unilateral nasal complaint or pathology as neoplastic conditions during their early stages may mimic inflammatory pathologies.

Aim of the Study: The aim of the current study was to highlight the causes of unilateral nasal disease, their most frequent mode of presentation, management strategies and outcome in a sample of Iraqi patients.

Patients and Method: The current prospective study included 96 patients, 42 males and 54 females, with signs and symptoms suggestive of unilateral nasal disease. The study was carried out at Hillah General Teaching Hospital, Babel province, mid-Euphrates region of Iraq and the work with this study has extended from January 2014 to August 2019. All enrolled patients were subjected to routine ENT examination and office flexible endoscopy. Patients were managed by functional endoscopic sinus surgery for purpose of excisional or incisional biopsy.

Results: The current study included 96 patients with a mean age of 49.09± 7.43 years and an age range of 39 to 67 years. There were 42 males and 54 females. The resultsof complete evaluation have shown the following pathologies at the end of the study: nasal polyposis (31, 32.3 %), chronic rhinosinusitis without polyp (16, 16.7 %), antrochoanal polyp (14, 14.6 %), inverted papilloma (11, 11.5 %), frontoethmoidal mucocele (7, 7.3 %), concha bullosa (4, 4.2 %), squamous cell carcinoma (3, 3.1 %), rhinolith (2, 2.1 %), fibrous dysplasia (2, 2.1 %), adenocarcinoma (2, 2.1 %), malignant melanoma (1, 1.0 %), cavernous hemangioma (1, 1.0 %), pyocele in concha bullosa (1, 1.0 %) and non Hodgkin’s (1, 1.0 %). Therefore, in the current study, nasal polyposis was the commonest cause of unilateral sinonasal disease followed by chronic rhinosinusitis without polyp, antrochoanal polyp and inverted papilloma. The rate of malignant neoplasms was low.

Conclusion: Differentiating the neoplastic nature form non-neoplastic nature of unilateral nasal pathology is the most critical management step and in the current study, nasal polyposis was the commonest cause of unilateral sinonasal disease followed by chronic rhinosinusitis without polyp, antrochoanal polyp and inverted papilloma. The rate of neoplastic malignant conditions was low.

Keywords: Unilateral nasal poly, Hillah, Iraq.

Introduction

A common finding during daily otolaryngological practice is a patient with unilateral nasal symptoms, nasal polyp or mass. The causes behind most cases of unilateral nasal disorder are inflammatory in nature and responds well to medical intervention and rarely there is need for surgical management. The possibility of neoplastic nature is high when there is unilateral nasal complaint or pathology as neoplastic conditions during their early stages may mimic inflammatory pathologies.
Actually, the mission of an otolaryngologist is to discover neoplastic conditions in association with unilateral nasal complaint in order to offer the best management options that can assure cure with high rate\(^1\). Despite the fact that unilateral nasal complaint is a frequent finding in daily clinical practice, literature dealing with the characterization and outcome of these conditions is relatively scanty\(^1,4-6\).

Unilateral nasal discharge, nasal congestion and nose bleeding in addition to dysosmia, migrane, and facial swelling are most common presenting clinical complaints in patients with unilateral nasal disease (7-9). Clinical characterization of a patient complaining of single-sided nasal symptoms mass is an essential challenging health issue because they are often accompanied by multifactorial underlying etiology (1, 8, 9). Evaluation of such health issue should include good history taking, thorough local examination and endoscopic investigation in addition to radiologic evaluation (1, 7). Findings on imaging play a significant role in the diagnosis and workup of sinonasal pathology. Bilateral versus unilateral involvement is a key feature that can differentiate between different etiologies (10).

The poverty of national and international publications dealing with clinical presentation and pathologic characterization of unilateral nasal complaint justified the planning and conductance of the current study in Hillah General Teaching Hospital, mid-Euphrates region of Iraq.

**Patients and Method**

The current prospective study included 96 patients, 42 males and 54 females, with signs and symptoms suggestive of unilateral nasal disease. The study was carried out at Hillah General Teaching Hospital, Babel province, mid-Euphrates region of Iraq and the work with this study has extended from January 2014 to August 2019. All enrolled patients were subjected to routine ENT examination and office flexible endoscopy. Patients were managed by functional endoscopic sinus surgery for purpose of excisional or incisional biopsy.

The ethical approval was issued by the ethical approval committee of the local health institute and a verbal consent was obtained from all participants following full illustration of the aim and the procedure of the study. The principal outcomes were the clinical presenting features and the type of pathology.

Data were transformed into SPSS (statistical package for social sciences) software (IBM, Chicago, USA, version 23) for purpose of statistical description. Categorical variables were expressed as number and percentage, whereas, quantitative data were expressed as range, mean and standard deviation.

**Results**

The current study included 96 patients with a mean age of 49.09± 7.43 years and an age range of 39 to 67 years. There were 42 males and 54 females. The results of complete evaluation have shown the following pathologies at the end of the study: nasal polyposis (31, 32.3 %), chronic rhinosinusitis without polyp (16, 16.7 %), antrochoanal polyp (14, 14.6 %), inverted papilloma (11, 11.5 %), frontoethmoidal mucocele (7, 7.3 %), concha bullosa (4, 4.2 %), squamous cell carcinoma (3, 3.1 %), rhinolith (2, 2.1 %), fibrous dysplasia (2, 2.1 %), adenocarcinoma (2, 2.1 %), malignant melanoma (1, 1.0 %), cavernous hemangioma (1, 1.0 %), pyocele in concha bullosa (1, 1.0 %) and non Hodgkin’s (1, 1.0 %). Therefore, in the current study, nasal polyposis was the commonest cause of unilateral sinonasal disease followed by chronic rhinosinusitis without polyp, antrochoanal polyp and inverted papilloma. The rate of malignant neoplasms was low, as demonstrated in figure 1.

The presenting clinical features are shown in figure 2. The most frequent clinical symptom was nasal obstruction which was seen in 81 cases (84.4 %), followed by rhinorrhea (69 cases, 71.9 %), then postnasal drip (33 cases, 34.4 %) and anosmia (23 cases, 24.0 %). Other manifestations included: epistaxis, facial pain, otologic symptom, visual problem and toothache in 8 (8.3 %), 8 (8.3 %), 4 (4.2 %), 3 (3.1 %) and 3 (3.1 %), respectively.

The radiological findings of some patients have been demonstrated in figures 3 through 5.
Figure 1: Bar chart showing the frequency distribution of patients with unilateral nasal disease according to etiology.

Figure 2: Bar chart showing the frequency distribution of patients with unilateral nasal disease according to clinical features.
Figure 3: Computed tomogram findings in a patient with unilateral chronic rhinosinusitis

Figure 4: Computed tomogram findings in a patient with unilateral nasal polyposis
Figure 5: Axial view patient with unilateral nasal disease

Figure 6: Computed tomogram findings in a patient with antrochoanal polyp
Discussion

One of the frequent presenting features of patients visiting ENT units is the complaint of unilateral nasal problems. Indeed, it is a challenging presentation to the ENT specialist because of the high possibility of a neoplastic disorder to be seen in association with unilateral nasal presentation than with bilateral nasal presentation; however, overall, the proportion of neoplastic disorders is low in either presentation 11,12.

In the current study, which has extended for more than 3 years, we were able to categorize 96 patients with unilateral nasal disease. The most frequent pathologies were nasal polyposis, chronic rhinosinusitis without polyp, antrochoanal polyp and inverted papilloma. In order to accomplish this mission, we followed the rule of comprehensive clinical evaluations of patient’s age, presenting clinical features, examination using nasoendoscopy, and radiological investigations, computed tomography (CT) in particular. In accordance with current study findings, it has been stated that the majority of pathologies in the sinonasal region are reactive inflammatory disorders and that the minority of them are neoplastic disorders 12.

The problem with neoplastic malignant sinonasal pathologies is that they mimic inflammatory disorders in their early stages, so that the diagnosis of these disorders is often made late. Delay in the diagnosis of such malignant disorders is usually accompanied by poor prognosis; therefore, meticulous evaluation of unilateral nasal presentations is of prime importance to exclude malignant neoplastic disorders 1.

With respect to age, benign neoplasms are often seen in children and young adults (1). The average age at time of detecting unilateral choanal polyps is around 27 (13). Fifth to 7th decade is the usual time for detecting neoplastic disorders in patients with sinonasal disorder with a male predominance and low socioeconomic status 14. Indeed, one of principal observations in the current study was that males were more often affected by neoplastic disorders than women and that inflammatory conditions were mainly seen in younger patients.

A variety of clinical manifestations are associated with unilateral nasal lesions, such as nasal discharge, nasal obstruction, anosmia, headache and epistaxis. In the current study the major presenting symptoms in order of frequency were nasal obstruction which was seen in 81 cases (84.4 %), followed by rhinorrhea (69 cases, 71.9 %), then postnasal drip (33 cases, 34.4 %) and anosmia (23 cases, 24.0 %). These findings are approximately the same as the findings of previous authors 1.

Facial pain, dental complaint and visual and otologic manifestation have also been seen in our study in accordance with previous observations made by several authors 1,4.

Comprehensive understanding of intranasal structure and characterization of intranasal pathologies have been made easy and amenable following the introduction of nasal endoscopy 1. Therefore, in the current study, the use of nasal endoscope provided both diagnostic and therapeutic tool since a number of conditions were treated by total excision of nasal pathology. The nasal mass lesions may be seen as single of multiple masses, sessile or pedunculated polyps.

Inflammatory conditions like acute and chronic CRS, either from bacterial or fungal origin were the commonest histopathological diagnosis in our study. Inflammation was the commonest form of nasal pathology in the current study and this is in accordance with previous reports 1. In our study, the commonest benign neoplasm was inverted papilloma (11.5 %) and this finding is supported by previous similar findings 1,15. On the other hand, the most common malignant neoplasm in our study was squamous cell carcinoma which is the same observation as the observation of some previous authors 1,16. In our study, a single case of Non-Hodgkin lymphoma was identified. Previous studies have also documented the rarity of Non-Hodgkin lymphoma in this clinical setting 1,17.

Conclusion

Differentiating the neoplastic nature form non-neoplastic nature of unilateral nasal pathology is the most critical management step and in the current study, nasal polyposis was the commonest cause of unilateral sinonasal disease followed by chronic rhinosinusitis without polyp, antrochoanal polyp and inverted papilloma. The rate of neoplastic malignant conditions was low.

Acknowledgement: We would like to express our deep thanks to all patients who participated in the current study to be a baseline report about the anatomical and the pathological presentation of unilateral sinonasal disease in Iraq.

Genetic Mutation Detection of IL-4 Gene in Patients with a Topic Dermatitis in Iraq Population

Aseel Kasim Kareem¹, Alaa Jawad Hassan²

¹Lecturer, Department of Biology, College of Science, University of Babylon, Iraq, ²Prof. Dr., Department of Biology, College of Science, University of Babylon, Iraq

Abstract

The aim of this study is to detect mutation in IL4 gene in atopic dermatitis patients in Babylon province, Iraq. The current study was performed on (50) Samples of patients with atopic dermatitis and 40 samples represents healthy subjects as control group, their ages ranged between 1-20 years old. The results of the PCR, with newly designed primers, showed 502bp amplicon as well as there were no mutations detected in nucleotide sequences for all samples including control. Therefore, when compare the results of identity for any isolate; it was appeared that there are no differences in nucleotides sequences and atopic dermatitis is not necessarily associated with IL4 gene mutation.

Keywords: IL4 gene, atopic dermatitis, PCR, sequencing.

Introduction

As a common chronic skin disease, atopic dermatitis (AD) affects over 20% of children with stress and economic impact on the family¹,². The first step in the prevention and treatment is to investigate the etiological factors of AD because it has multifactorial mechanisms including personal and environmental factors like food and environmental allergens as strong factors during youngest age³. Polymorphisms of various immune pathway genes are associated with an increased risk of AD through alternations in the T-helper type 2 signaling pathway⁴. Up regulation of certain interleukin (IL-4 and IL-13) lowers FLG expression, which leads to skin barrier defects, furthermore, a gain of functional polymorphisms of Th 2 cytokine receptors IL-4R and IL-13R are also implicated in AD pathogenesis⁵,⁶. Additionally, the expression/immune expression level of IL-4 is functionally dependent on genetic variants of IL-4 (SNP). In light of the association studies, it can be hypothesized that some IL-4 SNPs may lead to an overexpression of IL-4 gene and thus influence the immunological reaction⁷. Therefore, the aim of current study was to determine the association between IL4 gene mutation and AD.

Materials and Method

Collection of blood samples: About 2ml of venous blood was collected directly in EDTA tubes from 50 patients with AD and 40 healthy persons.

DNA extraction and purification: DNA was extracted from patients and control individuals using genomic DNA extraction blood DNA Mini Kit (Favorgene, Korea). The DNA concentration and purity at 260/280 nm were measured using Nano Drop spectrophotometer (OPTIZEN POP, Korea). DNA was stored at -20°C till use.

Primer design and PCR: PCR Primer (F: 5’-GAAACCTCAGAATAGACCTACC-3’) and (R: 5’-TGTCCTGTGAAATCAGACC-3’) were designed from the sequences reported (GenBank accession No. BC022894.1) in order to amplify a 502bp fragment of the IL4 gene. The PCR reaction consisted of 5µl DNA, 12.5µl 1X Master Mix (Promega), 2µl of 10pmol
of each specific primer (Macrogen, Korea) and the volume completed to 25µl by DNase free water. The PCR reaction was performed according to conditions mentioned in Table (1).

Electrophoreoses was accomplished using 1.5% agarose gel, stained with ethidium bromide, for 45min at 75 volt then, viewed by UV transilluminator and photographed.

DNA sequencing: Sequence similarity was accomplished using the forward primer previously designed through sequence alignment using BLASTN 2.2.27+ program.

Results

The results show that the presence of a single band (502bp) of the target sequence of IL4 gene (Fig. 1). The sequencing data for samples that takes from the same product of PCR were revealed the heterozygous among patients in location \(-11903\) of the samples A5 & A8 (TC), whenever the risk factor is C allele for the disease, but for the samples A7 & A9 the homozygous were (TT) as shown in Table (2) and Figure (2).

Also The results of samples for product of PCR amplification that sent to Sequencing reading appeared the frameshift mutation (deletion) of thymine base in location \(-12259\) in regulatory area of IL4 gene and this mutation is recorded in the NCBI data base with accession number as shown in Figure (3). From the results, this mutation might have an effect on gene expression level and as a result on disease severity.

**Figure 1: Electrophoresis patterns of PCR product 502bp for IL4 gene loci, lane M DNA 100bp marker, lane 1- 10 PCR product of patient, lane 11-16 PCR product of control, 1.5 % agarose, 75 V, 20 Am for 45 Minutes. (10µl in each well)**
Discussion

The current study agreement with Malaisse et al.,(2014) whom noticed the IL4 promotes that development of atopic diseases through effects on multiple cell types. Despite its critical role in AD, how IL4 alters gene expression in keratinocytes has not been completely defined. In this report its used high-throughput transcriptomic analysis to identify IL4 induced changes in keratinocyte gene expression at early and late stages of differentiation.
Acute and chronic IL4 stimulation resulted in extensive changes in gene expression profiles that spanned a variety of functional modules, including wound healing, a biological response impaired by IL4.

The results of heterozygous (TC) for IL4 gene using sequencing technique when the C allele that represented risk factor for disease disagreement with Zahran et al. (2013) that conclusion, the IL4 gene polymorphism (C-590T) had no relationship with the development of both types of dermatitis, but the C allele was risk factor for disease.

**Conclusion**

There were many mutations detected in nucleotide sequences for all samples including control. Therefore, when compare the results of identity for any sample; it was appeared that there are many differences in nucleotides sequences and atopic dermatitis is necessarily associated with IL4 gene mutation.

The Accuracy of Computed Tomography in Blunt Abdominal Trauma in Unusual Times

Muslim Kandel Kadeem¹, Mohanad Abdulretha¹

¹Assist. Prof., Department of General Surgery, College of Medicine, University of Thi-Qar, Iraq

Abstract

Background: A potential research for the evaluation of CT scan accuracy in blunt abdominal trauma was carried out by comparing operative and CT scan observation. About 60 patients undertook the blunt abdominal trauma in three years. CT scan was performed on these stabilized patients for its further comparison with operative results. Moreover, all the documented data comprised of scan results, sex, age and type of injuries.

Aim of Study: The objective of our current research was to discover the accuracy of CT scan results for blunt abdominal trauma which was evaluated by surgeons in duty compare with operative findings.

Results: From 60 patients, 40 pts (66.6 %) underwent surgery. 20 pts (33.3%) were conservatively managed. 5 pts were died. Hemoperitoneum was perceived in fifty five patients. The patients having little hemoperitoneum on CT scan along with reasonable clinical observations were conventionally managed whereas those patients having huge hemoperitoneum needed surgical investigation. Out of all the patients involved in study, 13 had splenic, 3 pancreatic, 15 hepatic, 4 vascular and 5 renal injuries, however, 12 showed retroperitoneum hematoma.

Conclusion: In comparison between clinical monitoring, CT in the evaluation of blunt abdominal trauma with accuracy 86-100% (over all accuracy 94%).

Keywords: Computed Tomography; Blunt Abdominal Trauma.

Introduction

The abdominal trauma is categorized in penetrating and blunt kinds. The penetrating abdominal trauma (PAT) is frequently diagnosed on the basis of clinical symptoms. Whereas, the blunt trauma get missed or postponed due to unclear clinical signs.[1]

Thus, it can create problems for individuals of all ages. The recognition of severe intra-abdominal pathology is sometimes perplexing as it is difficult to acknowledge various injuries in initial evaluation and treatment [2].

Diagnosis: The most significant concern in evaluating the blunt abdominal trauma is the estimation of hemodynamic stability [3]. Moreover, a quick estimation for hemodynamically unstable patients can be achieved with FAST (Focused assessment with sonography trauma) and diagnostic eitoneal lavage (DPL) for hemoperitoneum evaluation. The inconvincible physical examination results leads to the abdominal radiographic studies of stable patients[4,5].

FAST: The FAST examination done in 4 windows of ultrasound: (perihepatic, pelvic, pericardiac, perisplenic) along with the supine patients to detect free fluid or bleeding in any of this 4 windows (2,3,4,5)

Computed Tomography: The outcomes of CT scans are essential for solid organ injuries’ detection such as liver, kidneys, spleen, as well as for retroperitoneum involving colorectum, pancreas, bladder, diaphragm, and small bowel [6].Likewise CT scan can further expose other related injuries for instance, thoracic cavity injuries, vertebral and pelvic fractures as well.

Scans illustrate brilliant imaging for genitourinary system, pancreas and duodenum by revealing blood quantity in abdomen & precisely each individual organ.
But it has some limitations such as marginal sensitivity for hollow viscous, pancreatic and diaphragmatic injuries’ diagnosis. These are also considered as costly, time taking and need oral or intravenous contrast which may lead to the severe reactions [7,8].

Thus, the CT scans in contrast to the FAST and DPL investigation have capacity for the haemorrhage source determination. Besides this, various retroperitoneal injuries get ignored with DPL & FAST evaluation [9].

Figure 1. Blunt abdominal trauma. Right kidney injury with blood in perirenal space. Injury resulted from high-speed motor vehicle collision.

Method

This prospective study, done in Al Hussain Teaching Hospital in Nassyriah IRAQ during 3 years (from January 2012 to December 2014), used abdomen CT scan to assess abdominal blunt trauma to most stable patients arrived emergency room in holidays and daily after 10 pm till morning by surgeon in duty and technician (because unavailable radiologist at hospital at this time).

About sixty stabilized blunt abdominal trauma patients went through this examination. The patients included 36 males (60%) and 24 females (40%). The age range was 7 – 68 years.

Clinical examination and diagnostic peritoneal tapping was done for most of them. The patients who weren’t admitted or the ones who got discharged after short examination were devoid of any more investigation were omitted from our research.

We are usually looking for any hemoperitonium and solid organ injuries. Hence, the CT of hemoperitoneum was categorised as defined by Federle and Jeffrey et al.[10]

- Fluid in one space = Small (100-200 cc)
- Fluid in tow spaces or more = Moderate (250-500cc)
- Fluid in all spaces or pelvic fluid anterior\superior tourinary bladder = Large ( > 500 cc)

The Organ Injury Scale (OIS system) was used to grade the solid organ injuries. from simple organic contusion grade I to avascularisation of one organ grade V., then these CT observations were related to the operative discoveries of forty patients who underwent explorative laprotomy.

Results

Most of patients involved in this study whom
suffering from abdominal trauma are male, the Male:female ratio is 1.5:1 look table 2 they extend from different age groups ranging from 7 years to 64 years.

The commonest mode of injury in blunt abdominal trauma, is RTA (road traffic accident) in 48 from 60 patients (80%). look table 1.

Another group with normal CT scan no collection no solid organ injury with stable general condition they discharge home this group not involve in this study

All the 9 patients with large Hemoperitoneum required surgical exploration., while All 10 patients with small fluid on CT scan started with conservative management in spite of one severely injury in head and chest, 3 of them (30%) deteriorated with in 24 hours of follow up.

The moderate fluid group indicated that thirteen (13) were conservatively managed who were stable general condition and the other 28 patients underwent surgical exploration that were either unstable haemodynamically and/or had deterioration of their conditions like unexplained abdominal rigidity, therefore, the explorative laparotomy’s rate in moderate hemoperitoneum patients was observed to be as 68% on CT scan as presented in table (2).

**Discussion**

The primary inspection of abdomen can distinguish the major intra-abdominal haemorrhage symptoms. Whereas, the secondary investigation is important to spot a continuous bleeding or haemorrhage subsequent to the normal blood pressure restoration \[11\].

The blunt abdominal trauma patients lack the substantial physical symptoms of organ participation. In case of instability of patients having numerous injuries, there is an ambiguity about abdomen being a shock source, thus a FAST investigation might be helpful. In case of stabilized patient and easy approach to CT scan,
abdomen and head scan should be performed. The stable patients having several injuries including occult organ injuries which are not threat of life then CT estimation is essential.[12] in this study we start with clinical assessment of all patients had abdominal blunt trauma who arrived emergency room, the stable patients sent to CT scan assessment , if negative or minimal collection they treated conservatively and most of them go home so not involved in this study, but patents whom admit hospital for follow up 60 patients 40 from 60 patients, (66.6%) underwent surgery about, while 20 patients (33.3%) continue on conservative managed without any complications.

Most of patients involved in this study whom suffering from abdominal trauma are male, the Male :female ratio is 1.5 :1 look table 2 they extend from different age groups ranging from 7 years to 64 years.

The severe wound caused because of blunt force trauma are reliant on transferred kinetic energy amount and tissue whom energy is transmitted. Thus the kinetic energy is related to the object movement which is equivalent to the one half of the object mass while multiplying with the square of object velocity such as $\frac{1}{2}mv^2$. Therefore, generally, the lighter objects moving with a high speed are more dangerous as compared to the heavy object roving at lower speed. [1- 4] However, unluckily 5 patients expired and out of them two deaths were caused due to postoperative complications. But the other two deceased patients were associated with sever extra abdominal injuries within first 24 hours . there was one patient not operated because severely injured head and chest, and autopsy reveal no significant intra abdominal injuries so all deaths due to severity of trauma look table 1.

Haemodynamically, the CT accurateness in stabilized blunt trauma patients is well recognised. Moreover, among the patients of emergency CT, the specificity of about 98.7% while sensitivity of about 97% & 92% have been testified[13,14] which is near the range of this study table 9 accuracy for solid organs between 84 – 100 % median range may be because reading by surgeon in duty himself who is not provisional in radiology, and also not use contrast at this time of day but any how if compare its nearby, Various researchers endorse being admitted and observed subsequent to a negative CT[15,16]to repeat CT scan with or without contrast and reassessed by radiologist to exclude farther injuries as CT is particularly insufficient to diagnose the mesenteric wounds while it might skip some hollow visceral wounds. Thus, for the hollow visceral or mesenteric prone patients, the most suitable test is DPL [17]. And negative results of CT scan for these patients do not consistently eliminate the intra-abdominal wounds. So we depend on hemoperitoneum or fluid collection we found the accuracy of CT scan was 100%, the overall nine patients having great hemoperitoneum need surgical examination. Whereas, the group of moderate fluid have conservatively managed thirteen patients who were stable general condition and the other 28 patients underwent surgical exploration. More than 68% patients of moderate fluid were investigated. Taylor et al. presented a report of an experience of 50%[18] we think this relatively higher percentage because exclude most of stable patient with negative CT and stable those discharge on their responsibility and not involved in this study, and of course less experience of surgeon in CT scan assessment without contrast at night or holidays.

CT was executed in forty four haemodynamically stabilized patients of blunt trauma succeeding DPL by Kane. The scan of sixteen patients exposed an essential retroperitoneal or intra-abdominal wounds which DPL could not identify. Finally, the results of scans helped 58% patients in modifying the original plan of treatment.[19]

About grading of solid organ injury in this study we cannot assess by CT scan because lack of experience, but during surgery show a lot of patients have multi-organ injuries 25 from 40 patient was explored 62.5%, and 12 patents 30% have single organ injured, another 3 patients only free fluid no solid organ injured, the injured organs in different grades II, III, IV or V injuries they required surgery. While the rest of the injuries were managed conservatively, and according to follow up clinical finding if deteriorated go to surgery.

The high grade injury of solid organs upsurge the surgical management. While the low grade wounds were insufficient for management protocol prediction because some time hypo or hyper assessment of CT scan by surgeon.

**Conclusion**

We conclude that the CT scan is accurate test for diagnosis of intra-abdominal hemoperitoneum or fluid collections, and solid organ injury after blunt trauma and has all the attributes to make it an initial investigation of choice in haemodynamically stable patients even
done by surgeon in duty (but it’s better to be done with contrast and assessed by provisional radiologist) Thus, the negative laparotomy’s rate is decreased by abstaining from unnecessary surgical interference, also reduce missed injury by early discover of internal bleeding or organ injury in cases of conservative management.

Analysis and Compare of Cardiac Functional Efficiency Level and the Circulatory System for Short, Middle and Long-Distance Runners

Lamyia Yihia Atwan

Assist. Lecturer, Al-Ayen University, Thi-Qar, Iraq

Abstract

The aims of this study are knowing of cardiac functional Efficiency level and circulatory system for the short, middle and long-distance runner and knowing the differences of the cardia physical efficiency level and circulatory system for the long-middle and shirt-distance runners. Thus, continuing of the sport training operation may lead to take place some of the physiological changes in body, as the track and field games is definitely distinguished that runners. The athletes may face a various kind of functional changes resulted by various training resilience. While the Heartbeat size increases with the physical efficiency level at the relation time. Thus, we may say that physical efficiency level increases and reflects with the Heartbeat increasing and lowering of the cardiac Heartbeat during relaxation. As the track and field races are dividing athletes into short, middle and long-distance runners. Generally, the athletes participating may face in various games, therefore, the research importance is based on knowing the cardia physical efficiency level and circulatory system for the short, middle long-distance runners, then attempting to know the best set in fitness in raspatory circulatory system among the athletes in these activities.

Keywords: Cardiac, Efficiency Level, Circulatory System, Distance Runners.

Introduction

The physical activity is deeply linking with the vital systems as it being an attempt to developing the individual capacities and progressing his aptitudes in order to achieve a better level in performance as well as creating the functional endurance for the human systems which is directly connected or indirectly with the present activity. One of the most important systems is circulatory system and respiratory. And the heart will be the main part of the circular system and the Heart activity of muscuarlr contraction and relaxation in succession. This succession in Heart activity will ensure the blood reaching to the veins and cardiccirculatory. It will contain contraction and relaxation. And a time of stopping of heart contraction, which is consequence tunes to relaxations of Atriums and Ventriclees, and stopping is the rest between the relaxation of Atriums and ventricles. The measures and functional tests are considered one of the most important factors which to accompany the treatment program. In order to ensure resilience training of for the runner and having the increasing resilience, either fix it or lesson it to be able by finding out any shortage unnormal in the normal state for the athlete at the beginning. Before is multiplied during the training process and increasing of resilience degree to the body, without noticing the healthy and functional training state. The means of the test and measure have been developed to include all the data of the athlete during relaxation time and at the physical resilience and later. And these tests and measures also provide to follow up the training runner state during the training seasons which makes is a precursor to prophecy of the an indicate do of better future level

The distinguished tests of the functional state for Heart and Circular system: The cardiac efficiency and circulatory system are considered of the important mark for the physical fitness. The cardiac functional and circularity system are based on the ability for this part. And this system in order to fill up the boys needs of
blood during exercises and ant ability to return back to the natural state after a short period of relaxation.

**Cardiac functional state and its relation to the physical ability:** The term of body efficiency is one of the greatly distributed terms in athletic physiology field and work. The experiments conclude that body efficiency is increased in level and connected with the circulatory system efficiency as the size of the Heartbeat is increased with the body efficiency level and reflected on the Heartbeat size increasing and lesson Heartbeat average during relaxation.

**Circulatory system:** The circulatory system is divided into two parts: the cardiac circulatory system which included the heart which is the main member and bloody lymph veins, and lymph glands so the heart circulatory system pushes the oxygen and various food material into the body cells. and at the same time attempting to get rid of $\text{CO}_2$.

Of $\text{CO}_2$ the remainmetabolism processs of the all human cells. It also provides transporting hormones from endocrine glands into its limited cells. This system also keeps the interior body heat degree at roughly (37$^\circ$C) and the ability to keep an amount of the liquids in body in order to save the body out of damage at the dryness state and help of saving from infections by germs and microbes which attack and occupied the body.

**Activities of Track and Field Games (Running):**

**Activities of Short- Distance:** Short-distance running is considered one of the activities which required a great amount of physical and psychological capacities. And the short -distance running is distinguished of being reliable of airless energy system in which the body woks during oxygen shortage. And the short-distance activities are considered of the activities which in excitement is important as it is distinguished of surprises. Thus, these activities are considered totally competing and not-entertainment (1). The short-distance activities are including competitions (100m, 200m, 400, 100 fences female. 110 fences male, 4100 m post, 400m post)

**Activities of middle-distance:** The middle- distance running is distinguished in the ongoing time with high acceleration performance level in the last years. The difficulty of trespassing the world numbers in this field is very hard to obtain, in order to reach to a higher level

The middle-distance runners is described of gathering amid the long-distance an short-distance runners (1). It included of the middle activities (800 m. 1500 m)

**Activities of Long-Distance:** These activities are named the long running distances or the endurance running. Thus, the higher rate of the values to ensuing the energy is oxygen rate is amount between (70-80)

The long -distance activities are considered of the simpler distances in the track and field games technically. The athlete can learn by himself as not need to the technical parts in the running performance and organize the respiratory operations with the step tunes. And this is an important operation so the athlete will not feel of tiredness (2) and the long -distance activities of (3000 m, 3000 fences, 5000 m, 10000 m).

**Research Method and its field measures:**

**Research Method:** The researcher used the description method of scanning style due being the best method and easily done in making the research aims

**Research Society:** The aims which the researcher may do for his research and the measures he used will repeat the sample nature which he has chosen (1) therefore the research society for the long, middle and short -distance runners as it is seen in the table 1.

Instruments and the ways of data gathering

* Foreign and Arabic Resources.
* Cardiac functional measure state and circulatory system.
* tests and measure.

**Used Tests:**

Tests of functional state measure and circulatory system

**Test name:** Step test for Basra university.

**Reason for test:** Cardiac functional state measure and circulatory system

**Used instruments**

Stage at 15 inches
Instrument for record sounds
Result registration form

**Method of performance:** The student stands in the front of the device while he is holding the crossbar of the device. When the starting signal is given, the expert will climb on the right foot and then the left foot and then the right foot and then the left foot go down and the process of going up and down the foot is done according to the sound rhythm specified for that bump thus the performance continues until the end of time which is 3 minutes.

**Registration:**

Calculating performance seconds numbers
Calculating Heartbeat for 30 minutes period after giving the player a rest period for 30 minutes

**Evaluation:**

Player’s activity is evaluated according to following equation

**Player’s Efficiency:** performance seconds number \times 100

6.5 \times Heartbeat for 30 seconds

**Exploratory Experience:** The researchers conducted a exploratory experiment on 2/7/2020 on a sample of track and field runners for young men. The aim of this experiment was to identify the efficiency of devices and tools, as well as knowing the work obstacles and the time needed for testing, and the exploratory experiment has achieved its goals.

**Main Experience:** After making sure of the efficiency of the devices and tools, the players were notified of the test dates. Also, it has been prepared the devices and tools, and the assistant staff were also informed. Later the study experiment has been carried out on 17/2/2020.

**Statistical means:** The test results have been statistically treated by using the statistical program (spss) version 20 and by using computer, Lenovo, with speed processor 2,8 Gb. according to following rules:

| Percentage | analyzing parallel variance (ON WAY ANOVA) |
| L.S.D rule | Arithmetic mean |
| Standard deviation |
| Showing experiment, analyze and discuss |
| Showing, analyzing, and discussing the test results of cardiac functional state and circulatory system for the short, middle, long distance runners. |

**Table (2). Showing the Arithmetic Mean and Standard deviation the test results of cardiac functional state and circulatory system for the short, middle, long distance runners.**

</tr>
<tr>
<td>Long distance players</td>
<td>3,86 94,78</td>
</tr>
</tbody>
</table>

- From table 2 we find that arithmetic mean for testing the cardiac functional state and circulatory system for short-distance players which reached to (91,13) with standard deviation reached to (3,6). While the arithmetic mean for short-distance runners (75,89) with standard deviation (2,8). While the arithmetic mean for the long-distance runners reached to (94,78) with (3,87). Therefore, we find out the variation in the level of Cardiac functional and the circulatory system between the short middle and
long-distance runners. And in order to identify these differences, the researcher carried out an analysis (on way a nova) and it shows in the following table:

**Table (3): Data analysis shows the level of the cardiac functional state and the circulatory system at Short, middle and long distances**

<table>

</tbody>
</table>

By knowing table 3 we find out the calculated value of F which reached to (5,527) and this value its bigger than value tablet adults (4,10) under degree freedom (10,20). Thus, there will be nominal differences amid the short, middle and long-distance runners in testing the cardiac state and circulatory system. For this, in order to learn if there any effect which may record for the sake of the runners in these three activities, the researcher has carried out an operation to find out the less nominal value (L. S. D). and for knowing on the best group in this test, as the less nominal value using the best group in it, just to learn the best performance, there has to be a difference in the results of difference analyzation. In this way, (L. S. D) is calculated when there will be differences in the value of (F) more of calculated (F)

**Table 4: It represents the less nominal difference value and the differences for the average to the short, middle and long-distance runners:**

By seeing table 4 we can find out the difference amid the calculated media amid the long and short and middle-distance runner which reached to (15,240). This difference amid the medians is the larger of value and calculated (L.D.S) this concluded of presenting a nominal difference in selecting the cardiac functional level and circulatory system for the sake of the middle -distance runners due the calculated media for the middle -distance runners is the lessor value than the cleated media for the

While the difference of the calculated media between the short and long-distance runners may reach to (18,89) and the difference between the calculated media value are larger than the calculated value of (L.S.D). That leads to find out a difference in choosing the Cardiac Functional State and Circulatory System for the sake of the short-distance runner.

The researcher may explain the reason that makes the used test distinguished in what accelerated performance and to the continuous effort in performance which leads the middle-distance runners to better than he long and short -distance in this test.

The researcher may explain the reason that makes the middle-distance runner of having a large lynx ability and for distinguishing of having larger cardiac muscle size which reached to average of ability (1200 cm³) also to the pulmometry size which reached to average (4700-5300) (1).

The middle-distance running distinguishes in the present time with huge acceleration. Thus, the middle-distance runners need to acquiring a natural special talent due the highly required performance in the last years. Therefore, we may find out of highly training programs which serve of developing the psychological, physical
and bodily qualities. And some of the middle-distance runner may be described of gathering performance between the long distance and short-distance runners.

**Conclusions and Recommendations**

1. Cardiac functional Efficiency Level and circulatory System for the middle-distance runners are in better Functional Efficiency Level for the Short and Long distance runners.

2. There will be no difference in functional efficiency level in testing the cardiac functional state and circulatory system amid long and short-distance runners.

Interleukin-6 (174G/C) Gene Polymorphism and Serum Levels of IL-6, their Association with Risk of Obesity in Iraqi Childhood Populations

Manal M. Kadhim¹, Intesar A. Salman²

¹Professor of Clinical Immunology, Department of Medical Microbiology, College of Medicine, University of Al-Qadisiyah, Diwaniya, Iraq. ²Assistant Lecturer, Department of Medical Microbiology, College of Medicine, University of Al-Qadisiyah, Babil, Iraq

Abstract

Background: Childhood obesity is one of the most serious public health challenges of the 21st century.

Aim: The present study was conducted to investigate the association of CD14 genotype and serum levels of IL-6 with risk of ischemic stroke.

Method: A total of 60 patients with obesity were included in the study who were admitted to hospital from the period between March to August 2020, and other groups consist of 60 apparently healthy individuals. A five ml of blood samples were collected, 3 ml of each sample for polymerase chain reaction amplification and detection of IL-6 technique. The remaining (2 ml) for IL-6 serum levels by ELISA assay procedure.

Results: IL-6 (-174G/C) genotype was significantly associated with increased risk of obesity (P = 0.004). However, IL-6 serum levels were higher in subjects with GG genotype compared with those with CG or CC genotype (P < 0.001).

Conclusion: A significant correlation between IL-6 genotype and IL-6 levels were higher level in subjects with GG genotype compared with those with CG or CC genotype.

Keyword: Childhood Obesity, BMI, IL-6.

Introduction

Childhood obesity is one of the most serious public health challenges of the 21st century. It is widely known that obesity reduces child health-related quality of life and is associated with several health and social consequences. These include the risk of premature death, as well as developing diabetes, cancer, heart disease. It also causes undesirable psychological consequences, such as anxiety, depression, sleep disorders and low self-esteem, which affects the social and educational relationships of children. A pooled analysis of 2416 population-based measurement studies showed that from 1975 to 2016 there was a rising trend in children’s and adolescent’s body mass index (BMI). In 2016, 124 million children and adolescents, aged 5–19 years, were estimated to suffer from obesity worldwide and 213 million were overweight. The number of obese children and adolescents (aged five to 19 years) worldwide has risen tenfold in the past four decades. If current trends continue, more children and adolescents will be obese than moderately or severely underweight by 2022. Researchers believe that the increased prevalence of obesity is the result of changes in the life-style of societies, such as the inactivity, unhealthy eating patterns, collapse of energy balance, short sleep duration, increased use of fast food and animal proteins, and increased use of technology. Interleukin-6 (IL-6) is an immune-modulator pro-inflammatory cytokine, secreted by many types of cells, mainly T cells, macrophages, endothelial cells, smooth muscle cells, adipocytes, and hepatocytes. IL-6 is critical in the inflammatory signaling pathway and is involved in the development of obesity and insulin resistance.
Furthermore, IL-6 regulates/stimulates production of cell adhesion molecules, acute phase protein, and mediates the release of other cytokines that amplify the inflammatory response which influence the function of adipose tissue\(^9\). The human IL-6 gene is located on chromosome 7p21, and the -174G/C polymorphism consists of a single nucleotide change from G to C at position -174 in the promoter region\(^10\). The association of the IL-6–174G/C polymorphism with obesity risk has been evaluated in several genetic studies. Some studies have suggested that IL-6–174G/C increased the obesity risk\(^11\), while some found no association between IL-6–174G/C and obesity\(^12\).

**Materials and Method**

The current study was carried on 60 patients (25 males, 35 females) age range between 4-18 years from March to August 2020. Other groups consist of 60 apparently healthy individuals (30 male and 30 female) without any history of systemic disease were clinically considered as healthy also included in this study as a control group. We excluded patients have obesity secondary to a genetic or medical condition, such as diabetics, polycystic ovarian syndrome, hypothyroidism, Cushing’s syndrome, growth hormone deficiency, insulinoma, hypothalamic disorders (e.g., Froelich syndrome, Bardet-Biedl syndrome, Prader-Willi syndrome), or medication use (e.g., antipsychotics). A five ml of blood samples were collected by vein puncture using disposable syringes under aseptic technique 3 ml of each sample were transferred into with EDTA tube and immediately frozen at -20 C till further use to avoid repeated thawing and freezing for polymerase chain reaction amplification and detection of IL-6 (RFLP-PCR) technique. The remaining (2ml) were transferred into sterile test tubes (Plain tube) and allow sample to clot for few minutes at room temperature then followed by separation of serum from the clot by centrifugation for 10 minutes at 2500 r.p.m. and stored at -20°C for ELISA assay procedure. This study was in agreement with ethics of Al-Imam Al Sadiq Teaching Hospital and verbal informed consent was obtained from all participants.

**Results**

Sixty Childhood obesity patients included in this study. The socioeconomic and lifestyle variables distribution of the study population are summarized in Table (1). There were no significant differences between daily duration of sleep and risk for obesity (P = 0.138). The present study found a statistically significant between family income and obesity (p= 0.007). The frequency distribution of obesity further increased with the number of hours per day spent watching television (33.4% of childhood patients spent more than four hours per day in watching television), although the relation was not significant (P = 0.175). The frequency distribution of childhood patients and healthy controls according to physical activity indicated the prevalence of obesity was lower among childhood who practiced physical activity (P= 0.003). Distribution of IL-6–174G>C polymorphism was detected by RFLP-PCR technique, at this locus there are three genotypes, CG, GG and CC with band sizes 198/140/158 bp, 140/158 bp and 198 bp respectively, table (2), figure (1). The genotype distribution had no deviation from Hardy-Weinberg equilibrium in all study groups and agree with the reports of Ibrahim et al\(^13\).Both groups were comparable in Median serum concentration IL-6 table (3), figure (2). Median serum concentration of IL-6 in obesity patients was significantly higher than that of healthy control 127.32 (62.43) ng/L versus 89.44 (29.75) ng/L and P-value was (P < 0.001).Median serum concentration of IL-6 were statistically significantly higher in patients bearing the GG genotype (p< 0.001) compared with heterozygotes (CG) and those homozygous for the CC genotype, and this indicate serum level of IL-6 was highly significant associated to IL-6 genotype polymorphism in childhood patients group, table (4).

</table>
Table (1) revealed that 24 (40%) of the patients with obesity with sleep duration more than ten hours and 14 (23.4%) of healthy control with sleep duration more than ten hours, and this result suggested increased obesity with increased sleep duration, but these results indicated no significant difference in the frequency distribution of patients and control subjects according to sleep duration (P = 0.138). The results of present study agree with results of El-Kabbaoui et al., (14) (2018), which indicated 78 (38.6%) of patients has had more than ten hours sleep duration and these result indicate no significant association between the daily duration of sleep and risk for overweight or obesity (P = 0.75). We found a statistically significant relation between family income and risk of obesity, where the obesity increasing with increasing family income 30 (50%) of patients have had high average family income. Several explanations have been proposed. The low prevalence of obesity in groups of low socioeconomic status in developing countries is related to food scarcity, patterns of high energy expenditure and the greater capacity of the elite to obtain adequate food supplies (15). The correlations may be due to the benefits of economic growth, notably better access to food and high energy expenditure by poorer social groups, difficulty in acquiring more expensive, less energy-dense foods and a trend towards less leisure time and fewer opportunities for exercise (14).

A similar finding was reported in a study of Moroccan adults, in which family income, used as a determinant of socioeconomic status, was strongly associated with obesity (16).

Table (1) revealed that 20 (33.4%) of the patients with obesity was had more than four hours Television viewing, although watching television daily for ≥ 4 h was not significantly associated with obesity in our study when compared to healthy controls (p= 0.175). Watching television may reduce energy expenditure by replacing physical activity and also increase snacking, which is further encouraged by advertisements for energy-dense foods (17). Our results agree with results of El-Kabbaoui et al., (14), which indicated non-significant correlation between watching television daily for ≥ 4 h with the risk of childhood for obesity (p= 0.32). The present results found inverse statistically significant relation between the prevalence of obesity and physical

**Discussion**

Figure (2): Distribution of patients with obesity and control subjects according to the level of Serum Interleukin-6
activity (P = 0.003), where the frequency distribution of childhood obesity patients according to physical activity was as following: 26 (43.3%) patients having physical activity and 34 (56.7%) don’t having physical activity. Inadequate physical activity has been hypothesized to be an important contributing factor to the development of childhood obesity. The influence on energy expenditure can explain this relationship. Physiologically, sedentary posture lowers energy expenditure, and this in turn promotes weight gain. A review of the influence of physical activity on adiposity among 5–18-year-olds showed that adiposity was reduced and aerobic capacity increased with more time spent in intense physical activity. The present results in consistence with results of several studies. For instance, a study in Saudi Arabia showed that intense physical activity was inversely associated with adolescent obesity, and a strong negative association was reported between vigorous physical activity and total and central body fat in Spanish adolescents.

Obesity is caused by several genetic, metabolic, social, and environmental factors. Among these internal and external factors, the contribution of genetic factors has been recognized widely, but the genes involved have not been fully elucidated. Genetic variants, especially functional polymorphisms in the promoter region of genes, may alter the function and expression of genes associated with energy intake and energy expenditure. Several indications of the linkage between single nucleotide polymorphisms (SNPs) and obesity phenotypes have been found. Interleukin-6 polymorphisms have been investigated in many populations for associations with various chronic diseases. For example, single-nucleotide polymorphisms (SNPs) rs1800797(-597 G/A), rs1800796 (-572G/C) and rs1800795 (-174 G/C), located in the promoter region of IL6, have been shown to be associated with obesity and metabolic traits in different ethnic groups. Accordingly, IL-6 -174G>C were selected and their genetic associations with obesity risk were evaluated using RFLP PCR analysis to identify if genetic variants in IL-6 might be a potentially genetic marker to predict the susceptibility of obesity. Overall, highly significant differences can be found in the distribution of the genotype and allele frequencies of IL-6 (rs1800795) between the obesity patients and control subjects (P = 0.004). The present results consistence with results of Nelson et al., which indicated IL-6 -174G>C polymorphism was highly associated with the risk of obesity.

The results of present study showed high frequency of (GG) genotype among patients when compared to healthy controls, these result identify (GG) genotype is associated with increased risk of obesity with statistically significant (P = 0.002), and may be considered as the etiological factor for obesity. The results of present study consistence with result of Yang et al., which found the GG genotype was significantly higher in patients with obesity than in those without ($\chi^2 = 10.63$, $p = 0.005$). The present study are relatively conflicting with previous reports which revealed that the IL-6 rs1800795 SNP in the genotype GG play a protective role and present predominated in the control group (95.3%) with a statistically significant difference compared to that of obese children (28.2%). Moreover, the present result revealed frequency of allele C was more in healthy control compared to obesity patients. Also showed that (CC) genotype frequency in patients (20%) lower than in healthy controls (48.3%) and this results disagree with results Oana et al., which found that the G allele at IL-6 as being more common in lean subjects and observed the C allele to be associated with indices of obesity.

Higher serum concentration of IL-6 may be due to its important role in pathophysiology of obesity. The adipose tissue is a major source of circulating IL-6, and the excessive secretion of IL-6 appears to be directly related to obesity. IL-6 also can influence adipocyte function, lipid metabolism and thus play a major role in the development of obesity. Other theory Saied IL-6 exerts strong effects on hormonal balance and may induce some endocrino logical disturbances. It is suggested that IL-6 may affect the increase of free fatty acids level. IL-6 concentration is elevated in patients with lipid disorders and insulin resistance. The increased IL-6 levels in obese individuals may result in a state of insulin resistance and increased risk of cardiovascular complication. Our results agree with results of Ibrahim et al., which found The mean serum level of IL-6 in obese children was significantly higher as compared to those of control children (7.7±0.46 pg/mL and 5.46±0.40 pg/mL respectively (P=0.003).

Table (4), showed significant association between serum IL-6 levels and IL-6 Polymorphism in patients with obesity (p < 0.001), were we found higher median serum IL-6 levels in the GG genotype 149.86 (60.7) ng/L as compared with CG or CC genotype (122.87 (37.57)ng/L and 93.4 (10.41) ng/L respectively). The present study found higher promoter activity of the rs1800795 G-allele compared with the C-allele, where
CC homozygotes genotype had lower serum IL-6 levels when compared with G-allele carriers in both obesity patients and healthy controls. This suggests that rs1800795 G-allele carriers with higher levels of IL-6 have a higher risk for obesity.

Conclusions

Our results confirm clinically relevant relationship of IL-6 gene polymorphism with risk of obesity. Childhood Patients who undergone obesity showed a higher level of IL-6 than healthy control. In this study we found a significant correlation between IL-6 genotype and IL-6 levels were higher level in subjects with GG genotype compared with those with CG or CC genotype.

Serum Macrophage Migration Inhibitory Factor Levels in Patients with Ischemic Stroke in Iraqi Populations

Manal M. Kadhim¹, Ali S.Shakir²

¹Professor of Clinical Immunology Department of Medical Microbiology, College of Medicine, University of Al-Qadisiyah, Diwaniya, Iraq, ²Assistant Lecturer, Department of Medical Microbiology, College of Medicine, University of Al-Qadisiyah, Diwaniya, Iraq

Abstract

Background: Stroke is one of the leading causes of permanent disability worldwide. The most common cause of stroke is the occlusion of blood circulation by a thrombus (or embolism) although it can also be produced by the rupture of a vessel and subsequent bleeding in a certain region of the brain. Strokes can, therefore, be classified as ischemic or hemorrhagic.

Aim: The present study was conducted to investigate whether serum MIF levels are associated with severity in patients with ischemic stroke.

Method: A total of 40 patients with ischemic stroke were included in the study who were admitted to hospital from the period between March to August 2019, and other groups consist of 40 apparently healthy individuals. Two blood sample were taken from each patients one during attack (within 24 hours) and the other sample during follow up (within 1-3 months) for serum concentration of MIF by ELISA technique.

Results: Mean serum concentration of MIF in Ischemic stroke during attack (within 24 hours) was significantly higher than that of Ischemic stroke during follow up (within 1-3 months) and healthy control group; 17.094±2.25ng/ml versus 12.83± 4.16ng/ml and 6.407± 3.33ng/ml respectively.

Keyword: Ischemic Stroke, MIF, NIHSS, ELISA.

Introduction

Stroke is one of the leading causes of permanent disability worldwide. The most common cause of stroke is the occlusion of blood circulation by a thrombus (or embolism) although it can also be produced by the rupture of a vessel and subsequent bleeding in a certain region of the brain. Strokes can, therefore, be classified as ischemic or hemorrhagic(1). Ischemic stroke (IS) accounts for 85% of overall stroke and its pathophysiology are regulated by a combination of lifestyle, environmental, and unclear genetic risk factors(2). Ischemic stroke is a heterogeneous multi-factorial, polygenic, complex disease resulting from the combination of vascular, environmental and genetic factors(3). Ischemic Stroke often causes severe neurological and motor deficits, leading to decreased quality of life; stroke also has significant clinical and socioeconomic impacts(4). Annually, approximately 800,000 people in the United States have a stroke, and 130,000 die. It has accounted for nearly 5.7 million deaths worldwide, and 87% of these deaths occur in low and middle-income countries(5). Numerous studies have focused on the inflammatory reactions after stroke and identifying the roles of important inflammatory signaling molecules, mainly cytokines(5). Cytokines are up-regulated in the brain after stroke and are expressed not only in immunological cells but also in glial cells and neurons(7). However, the mechanisms leading to increased release of inflammatory cytokines in patients with stroke remain unclear. Macrophage migration inhibitory factor (MIF) a central cytokine of the innate immunity, includes 114 amino acid with a molecular weight of 12.5-kDa and is expressed in a diversity of cell types, including T cells, macrophages, monocytes, endothelial cells and also in activated platelets(6). Furthermore, it is recognized as a multifunctional cytokine participating in both immune
and inflammatory responses\(^9\). MIF is up-regulated in the brain after cerebral ischemia and is involved in neuro-inflammation\(^{10}\). One study demonstrated that serum MIF levels at admission were positively correlated with infarct volume and long-term outcome in patients with acute ischemic stroke (AIS)\(^4\), while another study confirmed that elevated plasma levels of MIF at admission were associated with increased risk of post-stroke depression (PSD) in the next 3 months\(^{11}\).

### Materials and Method

The current study was carried on 40 patients (18 males, 22 females) age range between 45-85 years from March to August 2019. Other groups consist of 40 apparently healthy individuals (20 male and 20 female) without any history of systemic disease were clinically considered as healthy also included in this study as a control group. We used NIHSS Scale to determine the severity of the disease in ischemic stroke patients.

We excluded patients with hemorrhagic stroke, stroke associated with surgery, severe trauma or organ ischemia. A six ml of blood samples were collected and withdrawn from each patient within 2 different period including three ml during attack (within 24 hours) and three ml during follow up (within 1-3 months) and three ml from healthy control by vein puncture using disposable syringes under aseptic technique were transferred to sterile Gel tube, and allow to clot at room temperature and centrifuge at 2500 rpm for 10 minutes and the separated serum was saved in Eppendorf tubes and immediately frozen at -20 C till further use to avoid repeated thawing and freezing for MIF ELISA Kit (Elabscience USA) test. This study was in agreement with ethics of Al-Diwaniya Teaching Hospital and verbal informed consent was obtained from all participants.

The National Institutes of Health Stroke Scale, or NIH Stroke Scale (NIHSS) is a tool used by healthcare providers to objectively quantify the impairment caused by a stroke. The NIHSS is composed of 11 items, each of which scores a specific ability between a 0 and 4. For each item, a score of 0 typically indicates normal function in that specific ability, while a higher score is indicative of some level of impairment\(^{12}\). The individual scores from each item are summed in order to calculate a patient’s total NIHSS score. The maximum possible score is 42, with the minimum score being a 0\(^{13}\).

Results

Forty Ischemic stroke (IS) patients included in this study. The risk factors distribution of the study population are summarized in Table (1). There were no significant differences in smoking status as (P>0.05). The prevalence rates of hypertension, diabetes, alcoholism and heart disease were significantly increased in the IS group compared with those in the control group. Mean serum concentration of MIF in Ischemic stroke during attack (within 24 hours) was significantly higher than that of Ischemic stroke during follow up (within 1-3 months) and healthy control group; 17.094±2.25ng/ml versus 12.83±4.16ng/ml and 6.407±3.33ng/ml respectively, P-value was (P < 0.0001), figure (1). Table (2) showed highly significant correlation between serum levels of MIF and severity of ischemic stroke (NIHSS) (P<0.001, r=0.512). Where serum levels of MIF increased with increasing severity of ischemic stroke as defined by the NIHSS score.

Discussion

The current study showed that 29 (72.5%) of the patients with ischemic stroke had hypertension, and these results indicate high significantly increased in patients with ischemic stroke compared with those in the healthy control group (P= 0.003, OR= 3.95) table (1). This leads us to believe that hypertension is highly non-diaagnosed in population due to the lack of an active non-communicable disease screening program, failure to take routine blood pressure measurements, and a general lack of awareness among health practitioners about hypertension and their complications(14). The present results are generally in accordance with previous studies where indicated that hypertension reduction being associated with a reduced rate of ischemic stroke(15). These results consistence with results of Li et al(4), who found that 91 (62.3%) with hypertension and indicate that hypertension significantly increased in the ischemic stroke group compared with those in the control group.
In our results there are 22 (55%) of patients with ischemic stroke had diabetes, and these results indicate significant correlation between diabetes and ischemic stroke when compared with healthy controls groups (p < 0.05, OR=2.53). Diabetes is a recognized independent risk factor for stroke and is associated with higher morbidity and mortality\(^{(16)}\). The physiology underlying the increased risk of ischemic stroke in diabetics may be attributable to the increased prevalence of intracranial stenosis in this population\(^{(17)}\). Vasculopathy induced by chronic diabetes related endothelial damage results in acceleration of atherosclerosis inherent to diabetes\(^{(18)}\). Which in consistence with old studies that showed diabetes can commonly causes small infarcts which less likely to lead to a fatal stroke\(^{(19)}\).

Although our results indicate 17(42.5%) from individuals with ischemic stroke are active smokers, but these results shows there is no significant correlation between the active smokers and ischemic stroke when compared with control groups, although the smokers are high in ischemic stroke groups (p > 0.05, OR=1.23) table (1). Although our study indicate non-significant association between the smokers and ischemic stroke when compared with control groups, but remain the smoking as important risk factors for ischemic stroke. The mechanism by which passive smoking can increase the risk of stroke has been reported in many studies. Passive smoking can lead to carotid atherosclerosis\(^{(20)}\), and the levels of homocysteine, fibrinogen, and oxidized low-density lipoprotein cholesterol can also be elevated by smoking\(^{(21)}\). About 8 (20%) of patients with ischemic stroke were alcohol consumption, as table (1), and there is a significant correlation between the ischemic stroke and alcoholism when compared with healthy control group (P= 0.038, OR= 1.6). Ischemic stroke is caused by a number of different pathophysiological mechanisms and alcohol drinking might have contrasting effects on ischemic stroke. For example, moderate and high alcohol consumption is associated with an elevated risk of atrial fibrillation, which is a risk factor for ischemic stroke\(^{(22)}\). The risk for ischemic stroke was significantly higher for binge drinkers than for subjects with no heavy drinking pattern\(^{(23)}\). The present results consistence with that of Xu et al\(^{(11)}\), who found that 52 (15.6%) with alcohol consumption.

The frequency of heart disease among the ischemic stroke patients are 12(30%) as in table (3-5), and these results indicate significant association between heart disease and ischemic stroke when compared with healthy control groups (p < 0.05, OR= 3.85). Previous study showed that approximately 10% to 24% of patients with stroke have heart failure\(^{(24)}\). Our study indicate frequency lower than Yalcin et al\(^{(25)}\), which showed (57.5%) of the stroke patients had history of ischemic heart disease, and it may be due to short longevity of our patients after developing ischemic heart attack as compared to others in the developed countries, and short longevity after developing coronary heart disease. Furthermore, increasing evidence that heart disease is independently associated with cognitive impairment exists; and cognitive impairment is associated with decreased survival among hospitalized stroke patients\(^{(24)}\).

Figure (1) showed that mean serum concentration of MIF were highly significantly increased among cases with ischemic stroke during attack (within 24 hours) 17.094± 2.25 ng/ml as compared to apparently healthy controls 6.407± 3.33ng/ml, these results revealed a significant association between the concentration of MIF and the ischemic stroke (P <0.001). A study by Inacio et al\(^{(19)}\) (2011), indicated that MIF promotes neuronal death and aggravates neurological deficits after experimental stroke. They found that MIF promoter activity was significantly upregulated by hypoxia during ischemic stroke and that MIF protected neurons against oxygen–glucose deprivation. Thus, the reason why serum MIF levels are increased in ischemic stroke patients remains unknown. Serum MIF levels were found to be decreased with blood-sampling time, with the highest levels of serum MIF at ischemic stroke during attack (within 24 hours) (17.094 ± 2.25 ng/ml), and this levels decrease at cases with ischemic stroke during follow up(within 1-3 months) (12.83± 4.16ng/ml), these difference in serum MIF levels between ischemic stroke during attack (within 24 hours) and ischemic stroke during follow up(within 1-3 months) was statistically significant (P<0.001), figure (1). These results indicate that MIF might play an important role in inflammatory process of central nervous system. However, serum MIF levels were highly significantly elevated in any time of ischemic stroke when compared with the controls (P <0.001). Table (2) showed positive correlation between serum MIF levels and severity of ischemic stroke (NIHSS) (P<0.001, r=0.512). where serum levels of MIF increased with increasing severity of ischemic stroke as defined by the NIHSS score, were highest MIF levels in the severe group (18.229 ± 2.45 ng/ml) as compared to moderate and mild severity (16.891± 3.12 ng/ml and 14.98 ± 4.33 ng/ml respectively). The present results are
consistence with results of Xu et al\(^{(11)}\), which indicated there was a positive correlation between levels of MIF and the NIHSS (r = 0.248, P<0.001).

**Conclusions**

Our study demonstrated that the serum level of MIF significantly increased following ischemic stroke. The serum MIF levels at admission were positively correlated with the infarct volumes and the severity of patients with IS. In this study we found increased inflammatory response after ischemic stroke compared with healthy control, represented by increased levels of MIF.

Genotype and Haplotype of Interleukin-17F (IL-17F) in Peptic Ulcer in Iraqi Patients

Zainab Akbal¹, Abdalnabi J Abid², Ekhlas Al-Shareefi³

¹M.Sc., Student, Department of Biology, College of Science for Women, University of Babylon, ²Prof. Dr., Department of Biology, College of Science for Women, University of Babylon, ³Assistant Prof. Dr., Department of Biology, College of Science for women, University of Babylon

Abstract

A peptic ulcer can be described as a condition in which there is a discontinuity in the entire thickness of the gastric mucosa. The discontinuity can also involve the submucosa, and in some cases, the deeper layers of the muscle wall¹. Immunological serological and molecular factors play a great role in the susceptibility and diagnosis of this disease. IL-17F genotyping were reported to have an influencing in all types of peptic ulcer. The current study aims to detect some cytokine concentration (proinflammatory and Regulatory) in patients’ blood, and some cytokine polymorphism. During the time from July 2019 to November 2019, the case-control study enrolled 318 blood samples collected from the patients who attended the Marjan Teaching Hospital- Hilla, as well as 60 healthy people. IL-17F genotyping was performing for 55 patients with peptic ulcer, and 30 healthy people as control, by using the PCR-SSP method. All types of peptic ulcers were significantly associated with IL-17F. Associations were also observed with IL-12A and IL-CXCR2. In conclusion, IL-17F, haplotypes, and genotypes have related to peptic ulcers so it can be dependent as a genetic marker for the susceptibility of this disease in Iraq.

Keywords: Gastric ulcer, Doudenal ulcer, Oesophagus ulcer, genotype, haplotype, IL17 F.

Introduction

A peptic ulcer is a lesion that may develop in gastric mucosa and submucosa or duodenum. Peptic ulcers develop because of increased acid secretion due to alcohol use, nonsteroidal anti-inflammatory drugs such as sedatives and aspirin, continuous and prolonged hunger, continuous stress, infection with Helicobacter pylori, and poor diet. Anticholinergic drugs, antihistamine, prostaglandin-like drugs and antimicrobials, proton pump inhibitors, and antimicrobial and anti-H. pylori antibiotics are the most important treatment lines for a peptic ulcer (2). Most ulcers are caused by an infection with a type of bacteria called Helicobacter pylori (H. pylori). Patients with (PUD) caused by H. pylori infection were mostly in the middle age of <50 years (3). Infection with this microorganism plays a major role in the pathogenesis of gastric adenocarcinoma (GA) (4).

An ulcer in the stomach is known as a gastric ulcer while that in the first part of the intestines is known as a duodenal ulcer. The incidence varies with age, gender, geographical location, and is associated with severe complications including hemorrhages, perforations, gastrointestinal obstruction, and malignancy. Thus, this clinical condition represents a worldwide health problem because of its high morbidity, mortality, and economic loss (5, 6, 7). Gastric ulcer is one of the most common and serious chronic diseases of the upper gastrointestinal tract. The prevalence of gastric ulcers is 2.4% in the western population and maybe up to 6.1% in Asia (8).

Gastric ulcer (GU) disease results from an interplay of environmental, microbial (Helicobacter pylori), pharmacological (non-steroidal anti-inflammatory drugs), excessive gastrin production (Zollinger-Ellison syndrome) and genetic factors (9). However, other causes like stress, smoking, spicy food, and nutritional deficiencies, can result in GU (10). Diabetes is an independent risk factor for gastric ulcer bleeding (11). Duodenal Ulcer Occurs most often in the first portion of the duodenum) 12 (with ~90% located within 3 cm of the pylorus. Ulcers can be demarcated, with depth at times reaching the muscularispropria. The base of the
ulcer often consists of a zone of eosinophilic necrosis with surrounding fibrosis. Malignant duodenal ulcers (MDUs) are extremely rare and are more common than GUs in western countries. An esophageal ulcer is a distinct break in the margin of the esophageal mucosa. This mucosal damage to the esophagus is often caused by gastroesophageal reflux disease or from severe sustained esophagitis from other causes.

**Material and Method**

**Patients and Controls:** Three hundred Eighteen blood samples were collected from clinically diagnosed peptic ulcer patients who regularly admitted by medical committee specialized medicals center of the digestive system of Marjan hospital (Babylon) from July 2019 to November 2019, the age of patients between (≤10- 80) years including both sex male (156) and female (162), in addition to (60) samples were taken from apparently healthy human was taken from Babylon province as control. The study was approved by the Research Ethics Review Boards of the University of Babylon. Patients with peptic ulcers, including the newly and long-time diagnosed patients, were diagnosed according to the specialized physician, some of them were suffering from chronic diseases and others have a history with medication, in addition to other causes such as smoking, *H.pylori*, stress, etc.

**Blood Sampling:** The venous blood was collected from the patients and healthy persons by using (5ml) syringes, and then separated to (2ml) with anticoagulant tube and (3ml) without anticoagulant. The blood samples without anticoagulant allowed clotting at room temperature and then serum was separated by centrifugation at (3000 rpm) for (5min), and that was within 2-3 hours after collection (16). Blood samples with anticoagulants were used for the DNA extraction by using a specific DNA extraction kit, which performed according to the protocols recommended by the manufacturer (Favorgen/Taiwan).

**IL 17 F genotype analysis:** IL 17 F genotype was performed with PCR-sequence-specific primers (PCR-SSP). The total volume of PCR Eppendorf tube for 17 F was prepared of 25µl, by adding 2.5 µl DNA and 1µl from each reverse and forward 1, 2 of the primer to PCR Eppendorf tube containing 12.5 µl master mix then 8µl nuclease-free water was added for reach the final volume (25µl). The DNA amplification for IL17 F includes an initial denaturation of 5 min in 94°C, 32 cycles of amplification (every cycle consists of denaturation of 30 s in 95°C, hybridization of primers during 30 s in 58°C, and an extension of 30 s in 72°C), and a final extension of 10 min in72°C, then the PCR products were separated in 1.5 % agarose electrophoresis system using ethidium bromide then visualized with the gel documentation, with 100 bp-ladder (Bioneer, Korea) and photographed. The sequences of primers used for the amplification of the genes are presented in table 1.

**Table 1: Sequences of the couples of primers used for the amplification of the genes.**

**Statistical Analysis:** All data were statistically analyzed according to software program SPSS version 20 statistical software (SPSS version 20, Inc., Chicago, IL, USA). The identified Primer 17F and association between type of peptic ulcer, alleles, haplotypes, and genotypes were assessed using the odds ratio with its 95% confidence interval (OR, CI 95 percentage).

**Results**

The present study reveals a noticeable variety of IL17F haplotype among the type of peptic ulcers. IL17F discriminated by PCR assay.
The distribution of interleukin-17F according to the site of the ulcer: The distribution of interleukin-17F (IL-17F T>C) genotyping according to site ulcer show that high appearance in all types, for Gastric Ulcer, TT genotypes high appearance 9(32.14%) with high OR(4.926) (p. value 0.004) (CI 1.619-14.992) while CC show only 3(10.71%) with OR(1.282) (p. value 0.54) (CI 0.260-6.315), for Doudenal Ulcer, TT genotypes show 2(13.33%) with high OR(5.167) (p. value 0.001) (CI 2.824-8.464) while CC show 2(13.33%) with OR(1) (p. value 0.665) (CI 0.161-6.192), for Oesophagus Ulcer, TT genotypes show 2(16.66%) with high OR(11.66) (p. value 0.002) (CI 2.116-64.326) while CC show 1(8.33%) with OR(1.692) (p. value 0.554) (CI 0.169-16.912), so TT genotypes had a Risk factor in the type of Peptic Ulcer while CC genotypes had a protective effect in a type of Peptic Ulcer, Table (3).

The distribution of interleukin-17F according to the cause of the ulcer: The distribution of interleukin-17F (IL-17F T>C) genotyping according to cause ulcer show that high appearance in all types, Bacterial Ulcer TT genotypes high appearance 10(33.33%) with high OR(4.667) (p. value 0.004) (CI 1.571-13.866) while CC show only 2(6.66%) with OR(2.154) (CI 0.363-12.764), Active bleeding Ulcer TT genotypes show 2(13.33%) with high OR(5.167) (p. value 0.001) (CI 2.824-8.464) while CC show 3(20%) with OR(0.615) (p. value 0.429) (CI 0.119-3.191), Stress Ulcer TT genotypes show 1(10%) with high OR(12) (p. value 0.001) (CI 2.307-19.168) while CC show 1(10%) with OR(1.385) (p. value 0.633) (CI 13.6-14.071), so TT genotypes had a Risk factor in the type of Peptic Ulcer while CC genotypes had a protective effect in a type of Peptic Ulcer, table (4).

The distribution of interleukin-17F according to the gender of the ulcer: The distribution of the interleukin-17F (IL-17F T>C) genotyping according to the gender through the below table, notice that the genotype of the genes shows that the (C/T) gene in patient samples with percentage 65.45% was dominant, where the ratio was 36% divided by 21 females and 15 males, while the control was the same by 8 for each gender, while the (T/T) gene with percentage 23.63% ranked second in terms of genotype where 11% of the patients were divided into 8 females and 5 males, but the control was for females higher than males, while the third gene (C/C) constituted 10.9% of the total samples was the lowest in terms of genotype at 6% distributed for females by 4% males 2%. However, it is noteworthy that the percentage of control was higher than the previous percentage of genes, as it was shown that this gene was higher in females than males, table (5).

Table (5): Distribution patient samples of interleukin-17F (IL-17F) genotype and control according to gender.

The distribution of interleukin-17F according to the age group of the ulcer: The distribution of interleukin-17F (IL-17F T>C) genotyping according to age group, showed a significant moral difference in the following age groups (11–20) show genotype (T/T) high appearance with high OR(7) (p.value 0.029), (41–50) show genotype (T/T) high appearance with high OR(11.66)(p.value 0.024), (51–60) show genotype (T/T) high appearance with high OR(7) (p.value 0.029), so SNPs in samples show revealed high prevalence of (C/T) genotype in patient samples with
percentage 65.45% and (T/T) genotype in the second place with percentage 23.63%, while (C/C) constituted 10.9% of the total samples. As for his part OR we notice the overpowering T/T where was his highest value in age (11-20) (21), Table (6).

Discussion

The results showed a significant association of IL-17F (IL-17F C>T) rs (763780) polymorphisms with susceptibility to the peptic ulcer (especially Gastric Ulcer GU), TT genotypes high appearance (23.63%) while CC show (10.9%), so TT genotypes had a Risk factor in the type of Peptic Ulcer while CC genotypes had a protective effect in a type of Peptic Ulcer.

These results agree with each of: (18) by showing that TT appearance was at a high rate, (19) by showing that TT genotypes were at a high appearance (38.8%) while CC showed (27.3%), (20) by showing that TT genotypes were at a high appearance (89.3%) while CC showed (0.7%), (21) by showing that TT genotypes were at a high appearance (97.0%) while CC showed (3%), (22,23,24,25,26), show that TT appearance was at a high rate.

While the study of (27) showed CC genotypes high appearance (81.59%) and TT show (6.75%), (28) that showed CC genotypes high appearance (94.91%) while TT show (5.09%), excluded due to the relatively small sample size of our study. Previous studies have identified the IL-17 F polymorphism as a potential genetic marker for gastric cancer risk (29).

In Bacterial Ulcer (H. pylori), TT genotypes show a high appearance (33.33%) with high OR (4.667), while CC show only (6.66%) with OR (2.154). Active bleeding Ulcer TT genotypes show (13.33%) with high OR (15.167) while CC show (20%) with OR (0.615) (P. value 0.429) (CI 0.119-3.191), Stress Ulcer TT genotypes show (10%) with high OR (21) while CC show (10%) with OR (1.385).

Study of (27), for Bacterial Ulcer (H. pylori), TT genotypes were (57.67%). For active bleeding Ulcer, TT genotypes show (44.48%), while for stress Ulcer TT genotypes show (34.36%). It was shown that this gene was higher in females (60%) than males (40%). (30, 22, 19, 20, 26) shown that higher in females than males. While (18) show that was higher in males (41%) than females (17%), (27, 24) show that was higher in males than females due to a variety of environmental and host genetic factors.

The results showed a significant association of IL-17F (IL-17F C>T) rs (763780) polymorphisms with age groups (11-20) show genotype (T/T) high appearance with high OR (12) (P.value 0.001) and (31-40) show genotype (T/T) high appearance with high OR (7) (P.value 0.029). (18, 31) is associated with an increased risk for the severity of gastric mucosal atrophy in subjects younger than 60 years, (19) shown that was higher in ≥ 50 yr (82.9%) than < 50 yr (17.1%). While (27) show that was higher in <60 (56.13%) than ≥60 (43.87%) due to a variety of behavioral factor like smoking and a high salt diet.

Conclusion

This study was designed to assess the associations of IL 17F, haplotypes, and genotypes with the risk of developing a type of peptic ulcer in Iraq. Certain IL 17F,
haplotypes, and genotypes were related to peptic ulcers and may be used as genetic susceptibility markers to peptic ulcers. Further studies of IL17F and peptic ulcer in Iraq are needed to confirm the present results and to provide data for the development of screening assays and for better management of patients with peptic ulcers at the onset of disease.

Types of Evidence Before the International Criminal Court

Hayder Abd Mohsen Al-Jubouri¹, Nowrse Hadi Waheed²

¹Assistant Professor, Dr., University of Babylon/College of Law, Iraq, ²University of Babylon/College of Law, Iraq

Abstract

Evidence for proof that the international courts relied on varies, including the International Criminal Court. There is direct evidence to prove, and there is indirect evidence for proof, and direct evidence is intended to be evidence that is directly focused on the incident to be proven, and if the judge acquires his knowledge of the incident to be proven directly, it may be This evidence is anecdotal, and it may be material, and anecdotal evidence is known as the kind of deductive or inductive evidence that the mind perceives or that the thought concludes from its analysis of the facts, circumstances, or motives that cover the commission of the crime or the occurrence of the accident, it is what emanates from personal elements represented in what comes from others From sayings, which are represented in testimony and recognition, as for material evidence, it means everything that has an entity that can be perceived and disclosed, whether by human senses, that is, directly, or by means of modern scientific technology, that is, indirectly, and is represented in written evidence and electronic evidence, while indirect evidence is Evidence that is not focused directly on the incident to be proven, that is, it is focused on another incident with a close logical connection to it, so it requires the application of reason and For logic to deduce the event on which the evidence is directed and which it is intended to prove, when the event that embodies the content of the evidence requires some intellectual processes of examination, analysis, extrapolation and deduction. Here the evidence is indirect. Experience and clues.

Keywords: Evidence, Types, Criminal Court.

Introduction

Evidence generally represents the elements of criminal proof in the criminal case, and is embodied by the facts or things that the evidentiary procedures reveal and transfer them to the field of the case¹. The principle of judicial conviction which is adopted by all international courts, including the International Criminal Court. The judge has the right to take any evidence that he is comfortable with, meaning that the judge is not bound by a specific evidence, especially since there are multiple divisions of evidence, but the most important of these divisions is the division that is based on the relationship of evidence.² With the incident to be proven, which is the division of the evidence evidence into direct evidences and indirect evidence, so the evidence of proof shall be direct if the judge obtained his knowledge from him directly of the incident in question, the example of which is anecdotal evidence and physical evidence such as testimony, confession, written evidence and electronic evidence, but if the incident that represents The content of the evidence requires some intellectual and intellectual practical examination, scrutiny, analysis, extrapolation and deduction. Here the evidence is indirect. Experience and clues.

Research Importance: The importance of research shows that the issue of the types of evidence before the International Criminal Court has not been adequately studied and researched, and its importance in reaching the truth by helping the judge build his judgment, which he will issue on sound and correct foundations.

Research Problem: The problem of research is to know the legal basis of the evidence before the International Criminal Court, and the authenticity of this
evidence. Therefore, our study raises the extent of the legal value of evidence before the International Criminal Court.

**Research Methodology**

This research relied on the analytical and descriptive method, through which we analyze the legal texts that came in the Rome Statute, and from which it is inferred that the International Criminal Court relies on these evidence in issuing its rulings.

**The First Section:**

Types of evidence before the International Criminal Court

Evidence for evidence relied on by international courts, including the International Criminal Court, in issuing their judgments, some of which are direct evidence, and some are indirect evidence, and to clarify the types of these evidence we will divide this topic into the following two requirements: -

The first requirement: direct evidence before the International Criminal Court.

The second requirement: indirect proof of evidence before the International Criminal Court.

**The first requirement**

**Direct evidence before the International Criminal Court:** Evidence shall be direct if it is directed directly to the incident to be proven, and if the judge acquires his knowledge of it directly of the incident to be proven. This evidence may be anecdotal, or it may be material, and this is what we will discuss in the following two sections as follows: -

The first branch: anecdotal evidence.

The second branch: physical evidence.

**First branch**

**Anecdotal Evidence:** Anecdotal evidence means the kind of deductive or inductive evidence that the mind perceives or that the thought concludes from its analysis of the facts, circumstances, or motives that pertain to the commission of the crime or the occurrence of the accident, it is that which emanates from personal elements represented by the sayings of others, that is, they are non-moral matters Materialism needs clarification, and it bears a lot of interpretation and interpretation, and it does not necessarily relate to fixed material facts. It indicates it and the statements of another person who may be a witness or an accused if the evidence is a confession. The anecdotal evidence is represented in testimony and confession, and this is what we will discuss in turn: -

**First: Testifying:** Testifying means giving a person the information he has about the crime and which he perceives with one of his senses, whether that information is related to proving the crime, the circumstances of its occurrence, or the circumstances surrounding it. She is reassured about her and rejects her when she becomes suspicious and suspicious of her, for the matter in the end is due to the court's conviction and reassurance. With regard to a specific incident, and do not take it into account in another incident or with regard to a specific accused, nor take it into account in relation to another accused.

**Second: Recognition:** The confession is known as the defendant's admission that he has committed the accusation against him, and he is the master and the most influential of the same judge, and he claimed it towards his direction of conviction. If the conditions of its validity have been fulfilled, the court must verify its truthfulness and conformity with reality, and it is an objective matter that enters the authority of the court, so it may take it if it is satisfied with it. Taking into account its manifestations. This is what the legislation of the Latin system adopted, but the legislation of the Anglo-Saxon system deviated from this rule. In English legislation, if the accused made a confession that meets the conditions, it is considered legal evidence of the conviction that exempts the judge from searching for any other evidence, and the consideration begins In assessing the punishment, this exception does not change the principle of judicial conviction, and there are criminal legislation in some countries, such as France and the United States of America. Confession alone is not sufficient for a conviction, and other evidence must be present. She supports him, while in other countries, such as Britain, relies on confession alone to convict him, without the need for other evidence to support him.

**The second branch**

**Physical Evidence:** Physical evidence is defined as everything that has an entity that can be perceived and disclosed, whether by human senses, that is, directly,
or by means of modern scientific technology, that is, indirectly, and thus it is not required to disclose physical evidence through vision or directly through touch, as the evidence is material. Even if it is disclosed by scientific means and method. The physical evidence is represented in the written evidence and electronic evidence, and this is what we will discuss in succession:

First: Written evidence: Written evidence is defined as a paper that carries data regarding an incident of importance in proving the commission of the crime and attributing it to the accused. The written evidence may be documentary, and writing may be by hand, typewriter, printing, copies, pictures, or recording sounds or symbols, and this evidence In order for it to be suitable to prove the incident, it must be true in itself, meaning that the document is real and not forged. Its statutes give certain documents authentic before it. All documents and papers in the eyes of these courts are the same, as they are all subject to the conviction of the same court.

Second: Electronic Evidence: Electronic evidence, in general, is either paper output produced by printers or plotters, or it is paperless output or it is electronic, such as tapes, magnetic disks, video discs and other non-traditional electronic forms, or it is represented in the presentation of the outputs of computer-mediated processing. On its own screen, or the Internet through screens or a visual display unit. These evidence are digital evidence and open source evidence, as for the authenticity of digital evidence in criminal proof, this authenticity differs according to the evidentiary systems adopted by the legislation in terms of the restricted proof system And the free proof system in particular, under the restricted evidence system, the legislation that follows the Anglo-Saxon approach goes to the application of the best evidence rule, which necessarily requires submitting the origins of the document and not contenting itself with a copy of it. Thus, the writing on the computer disk in its electromagnetic form can be considered the original copy, and this does not clash with the base of the best evidence. At that time, the electronic documents are provided as an original copy, and as a result, the value of the computer output appears as an acceptable evidence for proof in criminal matters. As for the free evidence system, in which the judge has broad authority in evaluating the evidence in terms of its probative, so the judge may accept or reject the evidence according to his conviction. With regard to the authenticity of open source evidence, although there is no comprehensive international standard for the admission of video and photo evidence in international courts, the information is often accepted as evidence if it is proven that it is relevant remotely.

The second requirement:

Indirect proof of evidence before the International Criminal Court: Indirect evidence is defined as evidence that is not focused directly on the incident to be proven, meaning that it is focused on another incident with a close logical connection to it, so the introduction of this type of evidence requires the use of reason and logic to deduce the fact on which the evidence is directed and which it wants to prove, and then It is considered the lowest level of direct evidence, including evidence obtained by scientific method and means from the reality of the effects that are left behind at the crime scene, that is, those that emanate from technical expertise based on scientific and practical method. The following two are as follows:

The first branch: experience.

The second branch: the clues.

First branch

Experience: Experience is defined as a physical or mental estimate expressed by art or specialist owners in a technical matter that the person investigating the crime cannot know with his own information, whether that technical issue is related to the person of the accused, the object of the crime, the materials used in its commission or its effects. Criminal evidence, if a matter appeared during the proceedings and its course of the case that requires a scientific or technical opinion to clarify its truth, and the judge was not able to express his opinion on it, because it requires knowledge and knowledge of a scientific or technical field in the scope of certain sciences such as medicine, engineering, chemistry, social and psychological sciences, or a specific profession such as drafting and construction And mechanics and electricity, as is the case with knowledge of fingerprints and footprints, the real cause of death, the effects of firearms, the nature of stains and their analysis, as the experience is represented in specialized technical reports issued by the expert regarding his scientific opinion in certain facts, it is a scientific and technical assessment of a specific incident. Based on scientific criteria, and the judge touches this incident through technical appreciation of it, and through the judge’s assessment
of the expert’s opinion, he reaches the formation of his conviction.

The Nuremberg Tribunal has used medical expertise to clarify the health status of some of the defendants, despite the lack of legal texts regulating it.

As for the courts of the former Yugoslavia and Rwanda, the procedural and evidence rules for each of them included some judgments related to experience. The experience was taken before these two courts in many matters, including forensic medicine, ballistics, the accused’s medical health, historical conflicts, military matters and others.

International criminal courts consider experience a kind of testimony of opinion, influenced by the Anglo-Saxon system, which considers the expert as a witness, so he is subject, like other witnesses, to taking an oath, as they call the experts (expert witnesses).

As for the International Criminal Court, there are no texts related to experience, neither in the statute nor in the procedural and evidence rules, but according to the principle of judicial conviction that all international criminal courts adopt, it is possible to resort to experience whenever they find the court’s judges necessary, i.e. Whether or not to take experience within the authority of the discretionary court, as the statute of the International Criminal Court indicated that the court may order the submission of evidence in addition to evidence already collected before the trial or presented by the parties during the trial. Request the submission of all evidence deemed necessary for truth determination.

The expert is required to be neutral and impartial. The principle is that the expert is a neutral person who does not have a special interest in the lawsuit, but he may be biased towards the party of the case who requested and paid his fees, and this leads to a breach of justice, so what is followed in the international judiciary is the need to appoint Honorable witnesses are through the court, provided that they are subject to the protections established before the international criminal courts that protect them from any influences or pressures that affect their technical work and their testimony before the court. The expert also requires the availability of experience in the expert, as the person is not an expert in a specific field without being He possesses what qualifies him to be an expert, and this matter is appreciated by the court, as the competence of the expert is what leads to confidence in the evidence and its legitimacy, so the expert must have experience of a special kind and training at a certain level, so that the evidence has a great degree of credibility and then reassurance about it.

The international criminal courts require that the expert submit a report that includes his actions and the results he has reached, and the report is discussed in the presence of the expert by the parties to the case, and this is what is applied in the Latin system, in contrast to what is followed under the Anglo-Saxon system, especially in English law, whereby the expert is not allowed to submit a written report, but the expert is subject, like other witnesses, to the questioning system. As for the authenticity of the expert opinion, it is subject, like the rest of the evidence, to the court’s discretion, as international courts are not bound by the opinions of experts. To take it, it has the right to reject it completely, and it has the right to rely on parts of it only. Although the procedural rules and the rules of evidence of the International Criminal Court have emphasized that the court is obligated to explain the reasons for the decision it makes on matters of evidence.

The international criminal courts follow the rule of (expert expert judge) according to the nomenclature used in the Latin system. Or (expert judge in the case) according to the designation used in the Anglo-Saxon system.

In this, the former Yugoslavia court decided that expert reports are used to prove technical matters, and not to determine the incrimination of a particular accused.

The second branch

Clues: Clues are defined as the deduction of an unchanging matter from a fixed matter. Likewise, it is known as a link between an event and its outcome, in which the evidence of the incident is evidence of the occurrence of its result. It has a rule stipulated in an abstract form, and these are the legal presumptions, and in terms of their authority in evidence, they are divided into conclusive legal evidence whose opposite may not be proven. The clues are one of the technical means aimed at clarifying the truth and achieving justice between the conflicting parties, and at the same time it is one of the rational tools that the international judge uses in the matter of translating the mental legal principles into a reality that settles the parties’ disputes, and despite this importance, the dispute arose . In international
jurisprudence on the existence of legal presumptions in international law. As an opinion tended to deny their existence in international law on the grounds that there is no authority superior to states that can determine the legal presumptions and impose their application, in when another opinion went to the contrary, based on the fact that the evidence represents one of the method of proof before the international judiciary, and it is possible to find its sources in the original and reserve sources of international law. The range to a conclusive legal presumption.

Through our review of the legal texts of the international criminal courts, it became clear to us that they lack any text that includes a legal presumption.

As for the second type of evidence, which is what the trial judge deduces from the circumstances of the case, and individual conclusions are considered in special cases, and these are the judicial evidence. And that there is not the slightest suspicion, otherwise they are signs and Emirates that do not rise to the level of evidence, and therefore it is not permissible to rely on them.

Judicial evidence is considered evidence before the international criminal courts, as there are no legal texts in their statutes preventing it, as long as it falls within the principle of judicial conviction that allows the court to reach the truth by any legitimate means.

It is worth noting that judicial evidence finds its place before international criminal courts in proving the moral element in the crime of genocide, as there is great difficulty in proving this element.

The court of the former Yugoslavia decided that the private intent of the crime of genocide can be proven in the absence of clear and direct evidence from the circumstances of the case, such as the general context or the commission of other criminal acts systematically directed against the group itself, or the extent of atrocities committed, or the systematic targeting of victims because of their affiliation with a specific group, or repeated destructive and discriminatory acts.

The Tribunal of Rwanda also decided that the intent of genocide can be deduced from material acts and, in particular, the massive, widespread and systematic nature of the atrocities ... in the absence of an explicit confession by the accused, his intention can be inferred from a number of factual assumptions.

Prevalence of Bacterial Vaginitis in Women with Recurrent Abortion in Comparison with Normal Pregnant Women

Samira Sherzad Hussien¹, Shahlaa Abd-Alrahman Mohammed², Bushra Mohammed Salih³

Abstract

Across-sectional study was done on a total of 80 deep vaginal swabs (40 women with recurrent abortion and 40 pregnant women as control group) were collected from the September 2019 to the end of November 2019 from inpatients and outpatients women attended to Kirkuk general hospital to evaluate the prevalence of vaginitis due to bacterial causes and its relation with abortion in pregnant women. Vaginal swabs were inoculated in bacterial media whose were prepared and sterilized according to the manufacturer’s instruction. The prepared media were used for isolation, determination of the viable count, identification and susceptibility testing these media were carried out after being solidified. Swabs was inoculated onto MacConkey, nutrient and blood agars. Then the inoculated plates were incubated at 37°C for 24 hr. The included 40 women with recurrent miscarriage with age range (20-44 years), the study showed that 12 of 40 were within the age group 30-39 years and 12 were below 30 years with mean age (31.6 years) and their husbands mean age (35.43 years) and 65% of cases were rural. There was 60% of cases were with history of 3 miscarriage and 18.75% were 4 miscarriage. The study also revealed that majority of cases were parity 3-6. The study also indicated that majority of cases have history of miscarriage in the 1st trimester in pregnancy. The study demonstrated that 55% of women with recurrent abortion have positive HVS culture comparing with 48% of pregnant women (control group). The study showed that 77.27% of women had aborted in the 1st trimester of pregnancy and the lowest rate of abortion 3% was in the 3rd trimester. The study revealed that highest rate of isolated bacteria from the HVS culture of aborted women was Gardenellavaginalis (36.36%), E. coli (27.27%) S. aureus (22.73%) and the higher rates of isolated bacteria from pregnant women were 50% for E coli.

Keywords: Bacterial vaginitis; Gardenellavaginosis; Recurrent abortion; Pregnancy.

Introduction

Vaginitis is the most common gynecological infection among women of fertile age (¹). Bacterial vaginosis (BV) comprises the 50% of the all cases of vaginitis (²). To understand the pathological events related to vaginitis, it is necessary to understand the normal vaginal flora. In normal vaginal flora, there are Lactobacillus species in 95% and facultative anaerobic and anaerobic microorganisms, including: Gardenellavaginalis, Staphylococcus epidermis, Mycoplasma hominis, Streptococcal species, Bacterioides species, Prevotellabivius, Peptostreptococci species, in 5% (³). In most cases of BV, the predominant microbe is the facultative anaerobe Gardenellavaginalis. However, evidence from recent studies of the pathogenesis of BV suggests that this bacterium forms a biofilm in the vaginal epithelium that serves as a “scaffolding” to which other bacterial species adhere in a symbiotic fashion, colonizing the vagina (⁴). Though asymptomatic in at least half of affected women, this polymicrobial condition can produce a thin, white, homogenous discharge with a distinct “fishy” odor (⁵). The changes in the vaginal flora seen in BV are associated with serious sequelae, such as preterm delivery, spontaneous abortion, postpartum endometritis, and increased susceptibility to HIV and other sexually transmitted infections (⁶,⁷). The aim of this study was to evaluate the prevalence of vaginitis due to bacterial causes and its relation with abortion in pregnant women.
Materials and Method

Across-sectional study was done on a total of 80 deep vaginal swabs (40 women with recurrent abortion and 40 pregnant women as control group) were collected from the September 2019 to the end of November 2019 from inpatients and outpatients women attended to Kirkuk general hospital. Collection of vaginal swabs included:

1. The swab package was partially opened.
2. Carefully the swab was inserted into vagina about 2 inches (5 cm) past the introitus and gently rotated for 10 to 30 seconds.
3. When the swab touched the vagina walls and moisture and absorbed the moisture, it was withdrawn without touching the skin.
4. Swabs was delivered to the laboratory within 1 hour of collection.
5. The swabs samples were cultured in blood agar and MacConkey agar for 24 hour\(^8\).

    Media were prepared and sterilized according to the manufacturer’s instruction. The prepared media were used for isolation, determination of the viable count, identification and susceptibility testing these media were carried out after being solidified. Swabs was inoculated onto MacConkey, nutrient and blood agars. Then the inoculated plates were incubated at 37°C for 24 hr.

Results

The included 40 women with recurrent miscarriage with age range (20-44 years), the study showed that 12 of 40 were within the age group 30-39 years and 12 were below 30 years with mean age (31.6 years) and their husbands mean age (35.43 years) and 65% of cases were rural. There was 60% of cases were with history of 3 miscarriage and 18.75% were 4 miscarriage. The study also revealed that majority of cases were parity 3-6. The study also indicated that majority of cases have history of miscarriage in the 1\(^{st}\) trimester in pregnancy, Table 1.

Discussion

In agreement with these finding, Sundari et al (9) reported in their study that the majority of the sample was reported at first trimester of pregnancy. This result is in agreement with the study of Hassan et al (10) and Ali (11) who reported a similar results. Al-dorri(12) found in a study that aborted pregnant women with Listeria infection most common in 1st trimester (< 12 wk) was 54(60.68%) and at late (12–20 wk) was 35(39.32%). Jamshidi et
al (13) who reported pregnant women with abortion at gestational age of early (< 12 wk) was 54(60.68%) and at late (12–20 wk) was 35(39.32%). Ra’ad et al (14) in a study of vaginitis in married women in Tikrit city found that women with 1st trimester of abortion recorded the highest rate of abortion. In present study, the overall prevalence of vaginal infections (57%) was coherent with several studies done earlier. A study done in Kirkuk found that 33.2% of women with recurrent abortion have positive HVS culture(15). Chambers(16) displayed that 34.7 % of women in India had positive HVS culture. Go VF et al (17) revealed that, the prevalence of vaginal infection in Vietnam was 49.5 %. Bahram et al(18) found that HVS were positive in 27.6% Iranian women. This variation might be methodology difference in isolation and identification of etiologies of vaginal infections. Moreover, environmental factors and difference on the actual study participants might also explain the above discrepancy. Manges et al(19) demonstrated that the most prevalent G. vaginosis bacteria was with rate (45.61%). The study was inconsistence with a study done in Erbil by Mohammed(20) who found a high percentage (46.21%) of E coli in his study. This may be due to the differences of the sites of swabs being taken from the hospital as a whole in Erbil or may be explained by the level of health awareness of both, patients and health staff in different communities (21). Hayat et al(22) and found that causative organisms of vaginitis were E. coli in less than one-third of cases followed by Klebsilla less than one quarter and more than 5% were Proteus. Other studies denoted that G. vaginosis and S. aureus may just be organisms causing local vaginal infection as they did not occur in the endocervix and may not have been responsible for the ascending upper genital tract infection in septic abortions. The result of the current study was supported by several studies done earlier. Carlson et al(23) and Yong et al(24) presented that women who suffer from spontaneous abortion are in 1st trimester and 2nd trimester while some of the women were multigravida had previous stillbirth, preterm birth, multiple birth, and previous miscarriage.

Conclusion:

Bacterial vaginosis was common in aborted women and S. aureus was the most isolated species followed by G. Vaginosis and E. coli.

Financial Disclosure: There is no financial disclosure.

The Power of Exercise to Reduce the Risk Factors of Cardiovascular Disease in Obese Men Patients

Elham Abed Mahdi¹, Seenaa Kadhum Ali², Haider Fayyadh Hamad Alamiri³

¹Assistant Prof., Chemistry Department/Faculty of Education for Girl/Kufa University, ²Assistant Prof., Chemistry Department/Faculty of Education for Girl/Kufa University, ³Assistant Prof., Faculty of Physical Education and Sport Sciences/Kufa University

Abstract

Objective: Firstly To assess the incidence of cardiovascular disease (CVD) risk factors in obese men, and secondly to compare the effects of high intensity interval training (HIIT) and moderate intensity continuous training (MICT) of an 8-week exercise intervention on cardiovascular disease CVD risk factors.

Design and Method: Trails comparing (HIIT) and (MICT) in obese men participants aged 42-52 years and subdivided to two groups: first group consisted from 30 individuals subjected to (HIIT) while the second group comprised from 30 volunteers subjected to (MICT). Participants performed 12 weeks of exercise consisting of 30 min of exercise five times a week, and all parameters were repeated following the 12-weeks

Result: Both HIIT and MICT elicited significant (p < 0.05) reduction in body mass index (BMI), waist to hip ratio (WHR), metabolic characteristics such as fasting blood glucose (FBG), fasting insulin and lipids variables, as well as improving in insulin sensitivity and blood pressure, in addition to there were significant decline in c- reactive protein (CRP) in study groups after 12- weeks exercise intervention.

The present results show an inverse relationship between the lipoprotein lipase (LPL) activity and body mass index and observed the activity of this enzyme at baseline was less than those in HIIT and MICT, in addition to the activity of this enzyme In individuals with HIIT group was significantly higher (p < 0.05) than the value in those with MICT group.

Conclusion: There is much information about the impact of physical activity on reduction of cardiovascular disease (CVD) risk factors. This information derives from different population groups where sedentary then, physical activity reduced the risk of coronary heart disease and cardiovascular mortality in patients have one or more from CVD risk factors. Present study have shown that reduction in large risk factors CVD can be achieved by moderate or intense physical activity. The risk factors of CVD included: obesity, glucose intolerance, dyslipidemia, and high blood pressure.

Keywords: Obesity, Risk Factors of Cardiovascular Diseases, lipoprotein lipase activity, C-reactive protein.

Introduction

Cardiovascular disease is a wide term, it is used to describe all circumstances affecting the heart and blood vessels, including coronary heart disease, stroke, heart attack and aortic disease. CVD risk factors can be categorized into two classes: invariable and variable¹. Invariable CVD risk factors are those that cannot be changed. These include age, ethnicity and family history (genetics cannot be changed), among other factors. Variable CVD factors are those that can be lessening or controlled by altered particular habits, by changing certain lifestyle, examples, take off smoking, consumption healthy diet and doing a sport².

Obesity is one of important factors which associated with an increased risk of developing (CVD), particularly heart failure (HF) and coronary heart disease (CHD). The process which explain how obesity increases CVD risk involving the changes in body composition that can alter hemodynamics and effect on heart structure. In addition to adipose tissue produce the Pro-inflammatory
cytokines which can induce cardiac dysfunction and may be promote the formation of atherosclerotic plaques\(^3\).

There are several observations from human and animal researches confirming a beneficial role for exercise in the reduction and treatment of CVD. Sedentary life style and obesity/overweight are not only associated with a number of health correlated with risk factors, but are considered to be independent risk factors for CVD, type 2 diabetes mellitus and hypertension. Clinical experiments confirm that lifestyle mediations (dietary modification and increased physical motion) reduce the risk of impaired glucose tolerance and type 2 diabetes\(^4\). Moreover, epidemiological studies revealed that risk of hypertension enhancement when a person being overweight. Moderate exercise intensity and frequency have hypotensive effects in physical inactivity hypertensive patients. Long term exercise improves endothelium-dependent dilatation in the aorta and strengthening heart arteries, whereas short-term exercise improves endothelial function in coronary conduit arteries\(^5\).

In addition to, exercise have been related positively with increasing high density lipoprotein (HDL)-cholesterol, and that elucidate why physical activity can have a protective role against coronary heart disease. According to Roussell and Kris-Etherton\(^27\) changing in life style, physical activity and a healthy diet can raise blood HDL-cholesterol by 10%–13%, while training and active motion can independently decrease blood triglyceride concentration\(^27\).

The aim of the present study was to evaluate whether changes in sedentary lifestyle aspects with special moderate to intense exercise, were effected on the reduce levels of multi CVD risk factors.

**Materials and Method**

**Study Design:** In this study, 60 obese patients (BMI>30) aged 42-52 years were recruited during the period April–July 2019 and subdivided to two groups: first group consisted from 30 individuals subjected to (HIIT) while the second group comprised from 30 volunteers subjected to (MICT). participants were required to take part in an 12-weeks exercise intervention program, and complete a series of physiologic and biochemical test profiles before and after the intervention.

All participants had their height and weight, waist and hip circumference, BP (systolic and diastolic), maximal oxygen volume (VO2 max), total cholesterol, HDL-cholesterol, triglycerides, lipoprotein lipase activity and C- reactive protein levels determined before and following exercise training.

The exercise program for both groups consisted of 12-weeks of high intensity interval training (HIIT) for first group and moderate intensity continuous training (MICT) for second group, two type of exercise consisting of 30 min of exercise five times a week.

![Figure (1): Risk factors for incidence cardiovascular disease (CVD)](image-url)
**Blood Biochemistry Analysis:** All blood sampling was carried out under sterile conditions. Blood glucose measurements which included fasting blood glucose, post prandial blood glucose using certain kits from Spinract, Spain, fasting insulin levels using ELISA kit from Calbiotech, USA then determined HOMA-IR by certain equation. In addition to the measurement of blood lipid profiles were carried out, that included total cholesterol, HDL-cholesterol and triglycerides were obtained between 8 and 10 am following a 10-h fast, using kits from Biolabo, France. Estimates of LDL-cholesterol were calculated using the Friedewald equation. The activity of lipoprotein lipase enzyme and C-reactive protein were determined by applied ELISA method by Elabscience, China kit.

**Statistical Analysis:** The statistical analysis was achieved by the statistical package for the social science (SPSS) software for windows, version 20.0. the result were represented as mean±standard deviation (Mean±SD). Paired- sample t test was used to compare variables in same group before and after exercise period and independent- sample t test was used to compare variables between two groups (HIIT)and (MICT) after exercise period. The confidence interval was set at 95%, thus p values less than 5% (p<0.05) were considered statistically significant.

**Results**

A total of 60 participants were classified into two groups based on type of exercise: (HIIT) group (n=30, BMI > 30 kg/m$^2$) and (MICT) group (n=30, BMI > 30 kg/m$^2$). The mean values of the anthropometric parameters in both groups before and after the period of exercise (12-weeks intervention). pre- vs. post-intervention, statistical analysis of the BMI study persons showed highly significant decreases (p>0.005) when compared pre vs. post exercise intervention in two groups as well as present results pointed out to decline in BMI in (HIIT) group than those in (MICT) group.

The comparison results of WHR in the two groups demonstrated, in the HIIT group, had an average WHR of 0.820 and MICT an average of 0.819, whilst the two experimental group had significant differences (p=0.000) in WHR between pre and post training. Systolic and diastolic blood pressure were determined in post and pre training intervention, non-significant increase of systolic blood pressure in post training for both groups (HIIT) and (MICT) in comparison with these values in pre training, whereas, significant reduction were recorded in diastolic blood pressure when compared values in before and following 8- weeks of training, while no such results were noted when the systolic and diastolic blood pressure were tested between (HIIT) and (MICT) groups.

Maximal oxygen uptake is dependent on age and gender, and is a widely used as a predictor tool of cardiopulmonary fitness. Figure (2) shows the average of VO2 max values for both groups. For pre-exercise, the mean VO2 max for HIIT and MICT groups was within the poor-fair range of fitness, while, Post the 12-weeks training intervention, the VO2 max values climbed significantly (p < 0.05) for both groups when comparing before and after training. Present study pointed out After 12 weeks of training, the cardiopulmonary fitness of HIIT and MICT groups improved to the fair-good range. Results also showed a main differences between HIIT and MICT, suggesting that MICT had a lower fitness than HIIT. the average of all biochemical variables for both groups before and after the 12-weeks of exercise. A significant decrease in blood sugar levels in pre HIIT and MICT groups comparing with post HIIT and MICT intervention, while did not show significant differences between post HIIT and MICT intervention.

![Figure (2): The average VO2 max values measured in HIIT and MICT group before and after the 12-weeks training](image-url)
In the present study there were significant decreasing of lipoprotein lipase (LPL) in post HIIT and MICT group compared to pre training intervention, no significant were observed when post HIIT and MICT groups compared together (p=0.85). a significant decrease (p=0.000) of CRP levels in post HIIT and MICT groups when compared with those pre training intervention in both groups.

Fasting insulin level seemed to be significantly reduction (p=0.000) in the samples of pre HIIT and MICT intervention group comparison to pre training intervention, additionally there were significant variation between HIIT and MICT groups. The insulin resistance level was represented by the HOMA-IR and fasting insulin/glucose ratio (FIGR). The HOMA-IR values in HIIT and MICT groups baseline were 3.009± 1.45, 3.033±1.566; respectively. Results of t-test showed that IR in the HIIT group after exercise intervention was less than those in MICT group, and the differences were statistically significant (p<0.05). FIGR levels in the post HIIT and MICT groups seemed to be within their levels in the pre HIIT and MICT groups. Results of the present work failed to find significant differences in the levels of FIGR between post training in both groups HIIT and MICT.

The study reported a significant decreasing in the levels of cholesterol, triglyceride, low density lipoprotein binding cholesterol (LDL-C) and very low density lipoprotein binding cholesterol (vLDL-C) after 12 weeks of exercise intervention in HIIT and MICT groups when comparing with their levels before exercise intervention, in addition to there were significant variation in these levels of lipid parameters between post HIIT and MICT intervention. The present study shows that high density lipoprotein binding cholesterol (HDL-C) in serum of post HIIT and MICT groups are significantly increased (p<0.05) compared with that of pre exercise intervention in both groups HIIT and MICT.

**Discussion**

This study compared the effects of short-term HIIT and MICT programs on BMI, WHR, VO_{2}MAX, blood pressure, and several metabolic characteristics, such as fasting blood glucose and insulin in addition to blood lipoprotein levels in sedentary adults. The main findings were that both HIIT and MICT programs significantly improved the BMI, WHR, and diastolic blood pressure. However, there were only significantly improved in the HIIT group following 12 weeks of training.

Almost of the participants in present study were obese (BMI ≥ 30) as compared with a large waist circumference characteristic accumulation of the lipid layer in the abdomen (apple pattern), meaning they were classified as obese individuals. Central obesity as a marker of body fat, which can estimated by measuring body mass index (BMI) and waist circumference (WHR) that in turn might effectively predict the risk of metabolic syndrome. Obesity seems to be predominant underlying risk factor not only for the development of metabolic syndrome but also other cardiovascular risk factors. Results of many studies indicated for increasing in body weight and BMI associated with the elevation of ischemic heart disease in several populations. The present finding agreed with the study which mentioned to fact that HIIT has greater effectiveness on weight loss than MICT, indicating that exercise intensity have efficacy in regulation body composition and local fat exhaustion. 

HIIT is superior to MICT in enhancing the secretion of catecholamines, adrenalin, noradernalin, and growth hormone (GH), which elevate fat decomposition, to obtain effective weight loss.

Increasing evidences which elucidate that high blood pressure is associating with mortality and CVD. participating in training programs have been recommended as an effective non-medication approach to improve blood pressure, in the same regards, the present study showed that four weeks of HIIT and MICT programs decreased diastolic blood pressure in physically inactive adults. Other study demonstrated a mean reduction from pre- to post-intervention of 3.6 and 3.3 mmHg for resting diastolic bp in the HIIT and MICT intervention with no differences between these programs.

Exercise is an effective method to reduce insulin levels, HIIT intervention was more effective in reduction FBG and insulin resistance compared with MICT training. several studies demonstrated that HIIT can trigger the expression and translocation of glucose transporter 4 (GLUT4) on skeletal muscle cell membrane surfaces more than MICT. Over the last 6 ~ 19 years that the regulating and improving insulin resistance will diminishing without physical activity. thus HIIT can promote insulin transportation and insulin tolerance. Ostman et al 2017 reported the lessening in the FBG of patients with insulin resistance syndrome after 16 weeks of continuous training or
intermittent exercise. Gayda et al.2013 noticed that intermittent exercise is effective in the same way of continuous exercise reduction of FBG in patients with chronic heart failure. Obese individuals suffered from lipid metabolism abnormalities, then leads to raising risk of CVD. Trainings are known as an economic and efficient method to reduce fat accumulation, however, the previous results comparison between HIIT and MICT programs, indicated no significant variations in their effects on TG, TC, LDL, HDL. Other studies revealed no significant difference in the levels of TC, HDL, LDL, triglycerides, and C-reactive protein between HIIT and MICT. The effects of exercise on blood lipid levels in persons with obesity depend on blood lipid levels before training, training intensity, training duration, body fat, calorie intake, metabolic rate and. Several studies have shown that exercise stimulate fat decomposition especially HIIT and MICT are more effective method to reduce TC, as well as the outcomes of this study established that accumulation of LDL inside the blood vessels as a major cause of arteriosclerosis. Our results suggest that trainings especially HIIT help in control on the obesity, reduction the risk factors of CVD, then helping to prevent the development of CVD in obese individual

The main role of lipoprotein lipase is binding to the capillary endothelium of most tissues, to metabolize triglycerides in circulating system. Free fatty acids produced by this action, then uptake by peripheral tissues. Most studies report that aerobic exercise increases LPL enzyme expression and activity in postheparin plasma. Another sites of LPL activity include skeletal muscle, where lipolysis produce fatty acids that can be oxidized as an energy source, and adipose tissue, and adipose tissue where fatty acids released from circulating lipoproteins by LPL are reesterfied and stored as triglycerides. The Investigators in animal have generally identified increases in skeletal muscle LPL activity and decreases in adipose LPL with exercise, but human studies are indicated that exercise promote increases in LPL activity in both tissues. Muscle is the main place of triglyceride removal in humans, and if LPL is central to this process, LPL-stimulate lipolysis in muscle, wherefore, may be a basic factor in the generation of high-density lipoprotein-cholesterol (HDL-C) . In addition to, the catabolism of triglyceride-rich lipoproteins, raising the generation of HDL-C and HDL2-C in exercising human muscle. There are much evidences that fasting lipid alterations occur in response to exercise due to the stimulate of adipose tissue LPL activity, which correlated with weight loss, so in the morbid obese, weight loss is combined with increased LPL expression in adipose tissue.

A metabolic abnormalities in obesity patients associated with increase acute-phase response. C-reactive protein (CRP), is the important component of acute-phase proteins and considered a sensitive and major marker of bacterial infection, physical tissue damage, and other inflammatory conditions. CRP is controlled by the proinflammatorycytokines including interleukin-1 (IL-1), tumor necrosis factor-a (TNF-a), and interleukin-6 (IL-6), which produced by hepatocytes. Recent researches provide a proof that inflammation might play a role in the incidence of cardiovascular disease, CRP with other inflammatory markers being regarded as indicators of atherothrombotic disease.

Conclusions

There is much information about the impact of physical activity on reduction of cardiovascular disease (CVD) risk factors. This information derives from different population groups where sedentary then, physical activity reduced the risk of coronary heart disease and cardiovascular mortality in patients have one or more from CVD risk factors. Present study have shown that reduction in large risk factors CVD can be achieved by moderate (MICT) or intense (HIIT) physical activity. The risk factors of CVD included: obesity, glucose intolerance, dyslipidemia, and high blood pressure all of these parameters improving in good state. In addition to, the present research demonstrated that physical achievement is inversely correlated with levels of LPL and inflammatory marker (CRP) in obese patients and improve this parameters values after exercise programs.

The Impact of Breastfeeding on the Total Duration of the Third Stage of Labour among Women Attending Maternity Teaching Hospital in Sulaimani City

Mahabat Hassan Saeed1, Atiya Kareem Mohammed2

1Assist. Lecturer, Maternal Neonatal Nursing Department, College of Nursing, University of Sulaimani, 2Assist. Professor Dr., Maternal Neonate Nursing Department, College of Nursing, University of Sulaimani

Abstract

Background: Quick breastfeeding during the third stage of labour is considered the safest and most effective intervention to reduce the blood loss associated with labour, as it can naturally release the oxytocin to stimulate the uterine contraction. These contractions make it easier to dislodge the placenta and help reduce the total duration of the third stage of labour.

Aim of the Study: To evaluate the impacts of breastfeeding immediately after birth for the total duration of the third stage of labour.

Study Design: A quasi-experimental study, post-test only control design.

Material and Method: 300 pregnant women from the labour ward in their third stage of labour participated in this study, carried out between 26th of February 2020 and 30th of July 2020. Samples were selected by using a convenient sampling technique through the structured observation record sheet, onto which the beginning of breastfeeding time and placental delivery was recorded. The data were analyzed using descriptive and inferential statistics.

Results: Among the 300 mothers (34%) had delivered the placenta within 5 minutes, (46%) within 8-10 minutes, (13.3%) within 11-13 minutes and (6.7%) had 14-16 minutes in the experimental groups. While, in the control group the duration was longer (46.7%) between 11 and 13 minutes, (20%) within 14 and 16 minutes.

Conclusion: The study results show that early initiation of breastfeeding is an effective intervention to reduce the total duration of the third stage among the mothers during the third stage of labour.

Keywords: Impact, Immediate breastfeeding, Third stage of labour.

Introduction

Pregnancy and childbirth are physiologic processes with their developments specific to each woman, and under normal circumstances, they proceed without any problems1,2. The childbirth is a celebrated event worldwide and is usually have four stages, when the cervix is fully dilated is named as dilatation stages or first stages, in the second stages the born of the baby and in the third stages the placenta is delivered, final the fourth stages is the recovery stages3. A mother’s milk is the first and the most essential gift for the baby. Human milk is capable of providing for all the nutritional requirements of the infant and boosts the immune defenses of the suckling baby to protect it against a series of childhood diseases. The terms “suckling” and “nursing” are used interchangeably with the term “breastfeeding”, all of which refer to the act of feeding an infant or a baby with breast milk by holding the baby to the female human breast who proceeds to suck the milk out of it4. In the third stage of the labour (TSoL), uterus muscles contract sharply and the placenta begins to be separated from the uterus wall. This third stage can naturally carry out
passively or actively with human interaction. No matter which version takes place, the process is associated with a certain amount of blood loss. The amount of blood lost is primarily based on the duration of the separation process. That being said, any deficiency in the uterus muscle contractions would result in lack of uterine tonus, which in turn prevents it from contracting fully. This lack of contraction will prevent blood vessels from constricting fully and will result in more severe blood loss. Any unexpected and uncontrolled bleeding in this third stage might cause a serious health risk to the mother, and may even lead up to mortality. It has been noticed by competent midwives that, if the mother breastfeeds during this exact period, and if proper active management to the labour is provided, less blood will be lost overall.

The physical and cognitive interactions taking place during breastfeeding causes the secretion of oxytocin in the mother, which promotes the release of milk into the breast, from where it can be excreted through the nipple. This secretion of oxytocin is often accompanied by contractions in the uterus as well. It is believed that such uterine contractions can help reduce the bleeding that takes place in the TSoL. Combined with the shortening of the period, the additional contractions in the uterine muscles lead to less blood loss and lowers the risk for the mother associated with the labour. Nonetheless, ensuring increased levels of breastfeeding practices is employed worldwide has been decided as a global health goal for all nations, since human milk carries numerous unique components that are beneficial for the baby. In addition to being the most natural and beneficial nutritional source for the baby, mother’s milk also helps establish a strong foundation of health for it that will last its entire life. It has been reported breastfeeding alone can cause a 13% reduction in infant mortality rate. Because it helps reduce the blood loss due to labour, speeds up the separation of the placenta, and helps establish a bond between the mother and the baby, it is believed that placing the baby straight to its mother’s breast right after delivery is good practice. In this practice, many professionals believe the injection of syntometrine to stimulate womb contractions is unnecessary. This study was performed to evaluate whether immediate breastfeeding was sufficient in this regard.

**Material and Method**

**Study Population:** 300 pregnant women who are beyond their 37th week of gestation and belong to different age groups. The study was conducted between the 26th of February 2020 and 30th of July 2020. Inclusion criteria for selection of pregnant women were to be between 38th and 42nd weeks of gestation, to be pregnant with a singleton, to have a live foetus, and to be undergoing vaginal delivery with or without an episiotomy. Mothers also had to be without any complication during antenatal and intranatal period.

**Ethical Approval:** The study was approved by the ethical committee of the University of Sulaimani/ College of Nursing and by the ethical review committee of the Maternity Teaching hospital. The data for the study was collected through interviews. Verbal consent was taken from each pregnant woman.

**Data Collection:** Data collection was performed by direct interviews with the study participants. For this, a questionnaire was constructed which surveyed the socio-demographic characteristics, any previous obstetric history, and characteristics and duration of the TSoL.

**Data Collection Procedure:** All participants for the survey were selected using the convenient sampling method. These were then separated into two groups of 150 as the experimental and control groups from the Maternity Teaching Hospital. The Apgar scale was evaluated one minute after the delivery of the baby. The face of the baby was cleaned, who was then wrapped in sterilized linen cloth and placed into its mother’s breast. Helping the baby reach the areola, proper suckling was ensured during the entirety of the TSoL. After that, the time of placenta separation was noted in both groups, and documented in observation record sheet it includes time of delivery, duration of placental separation and lengthening of the cord, expulsion of the placenta on the third stage of labour.

**Statistical analysis:** Once the surveys and labour data were gathered, they were entered into an excel spreadsheet, and were analyzed using the SPSS software, version 25. “Chi-square test of association” was used to evaluate the nominal distribution of data. Fisher’s exact test was used in cases where the expected count >20% of the excel cells collective achieved a score of <5. Student’s t-test of two independent samples was used to compare two means. Binary logistic regression analysis was used to show the independent effect of breastfeeding. A p-value of ≤ 0.05 was considered statistically significant.
Limitations of the Study: Recording data on observation sheet was the difficulty that fell during the study.

Results

Table 1: shows that the highest proportion (53.3%) of the group was aged between 20 and 29 years, and only 3% was aged ≥ 40 years. It is evident that participants in the control group were older compared to the women of the other group as around 60% of them were aged 30 years or more, compared to the 19.3% of women of the experimental group (p<0.001). The average age of the women in the control group (30.77 years) was significantly (p < 0.001) higher than the mean age of the experimental group (24.52 years). The age of marriage of the control group was found to be higher than that of the experimental group (p<0.001), and the difference was statistically meaningful. The age of marriage of 28.7% of the women in the control group was 25 years or more compared to 9.4% of women of the experimental group. The findings show that no statistically significant variations are present between the groups regarding the educational level and residency.

Table 3 presents the characteristics of the TSoL as follows: Active management (97.7%), administration of a uteronic drug (96.3%), cord traction (53.7%), cord clamping (92%), and fundus massage (74%). The placenta was delivered in all the women. Regarding the time of the day, the majority (82.3%) of the women in the study delivered during the morning hours. The difference between the experimental and control groups regarding any of the mentioned characteristics were statistically insignificant (p > 0.05), as presented in Table 3.

</tbody>
</table>

Note: p-value was calculated by the Chi-square test.

The duration of the third stage of labour was longer in the control group where it is evident that the duration was between 11 and 13 minutes and between 14 and 16 minutes among 46.7% and 20% of the women in the control group, respectively, compared with 13.3% and 6.7% of the women of the experimental group (p < 0.001), as presented in Table 4.

Discussion

Three hundred women were included in the study. These women were placed either in the experimental group (n=150) who breastfed their babies during the TSoL or into the control group, (n=150) who did not breastfeed their babies during the labour.

In the present study, 66.7% of the participants in the experimental group were in the age group of 20 to 29 years, and most of them were housewives (88.7%). This distribution is consistent with the study conducted by Atiya K. Mohammed, 2020, who insisted the necessity for complete pregnancy and postnatal health recommendation for these women as a result of exposure to work outside the house provides ladies higher possibilities of contact with an experienced person and acquire valuable health and social information.

The present results show that there were no significant correlations between immediate breastfeeding and the educational level and residency. Similarly, Dashti et al (2010) reports that there no correlation exists
between the breastfeeding start point and any of the demographic properties they have investigated. On the other hand, a study performed in Egypt in 2018 report findings that a correlation exists between educational level and residential status of the participants with prompt breastfeeding. In the present study, (47.3%) of participants in the experimental group had primigravida, and 79 (52.7%) had multigravida. One-third of the women in the whole sample (33.7%) had a history of the previous breastfeeding. In the experimental group, the majority of subjects were on the 38th – 40th weeks of gestation, and nearly all parturient women (n=147, 98%) had a normal vaginal delivery. These results are consistent with the reports of numerous similar studies.

Our findings show that nearly all parturient women were provided with active labour intervention during the TSoL our, with n=148 (98.7%) and n=145 (96.7) respectively between two groups. In contrast, a quantitative study conducted in Sri Gokulam Hospital and Vijaya Hospital in Salem, where 60 parturient women were selected and separated into two groups of 30 members each (control and experimental), none of the women were provided with active management during the TSoL. The findings of the current study show that all participant women of both groups completely delivered the placenta (100%). ICM and FIGO have expressed that: “Every attendant at birth needs to have the knowledge, skills and critical judgment needed to carry out active management of the third stage of labour and access the needed supplies and equipment.”

**Conclusion**

Early initiation of breastfeeding during the third stage of the labour decreases the duration of the third stage, as can be seen by the comparison of results for the experimental control groups of our study. Therefore, early suckling is concluded here to be effective in reducing the duration of the TSoL among parturient women.

The Prevalence and Infectivity of 
*Entamoebahistolytica* in Baghdad Province

Safa Tawfeeq Waheeb¹, Braa A. Alshakir², Hasanain Sahib Salih¹, Faisal Ali Lattef², Rafal Salam Kadhim²

¹Lecturer, College of Pathological Analysis Techniques/AL-Bayan University Iraq,  
²Assistant Lecturer, College of Pathological Analysis Techniques/AL-Bayan University Iraq

**Abstract**

The present study aimed to explore the *Entamoebahistolytica* in 500 patients (human stool) selected from a private laboratory in Baghdad/Iraq during the period from 1st of April 2018 till the 31st of August, by using the iodine stain to detect the stages of parasite in all samples, evaluate the prevalence of the parasite between males and females and to evaluate the relationship of the parasite in selected months of this study. This study showed that the total number of infected patients is 394 from 500 taken sample. The high incidence (81.13%) is occurred in August and the low incidence (76.84%) is occurred in April. This result showed no significant differences appeared between the chosen months of the study (P<0.01). The result of this study showed no significant differences (p<0.01) appeared between the males and females of the study, the number of infected patients are (192 males out of 240 and 202 females out of 260).

**Keywords:** Prevalence, infectivity, *Entamoebahistolytica*, Baghdad province.

**Introduction**

*Entamoebahistolytica* is considered one of the intestinal parasites of the protozoa family which causes severe diarrhea (dysentery) in man.¹,² *Entamoebahistolytica* is considered one of the pathogenic parasites and leads to amoebiasis and considered one of the main causes of diarrhea in developing countries, the parasites have two stages to complete their life cycle, an active phase inside the host and an inactive phase there is outside a host.²

The World Health Organization has indicated that 3.5 billion people have intestinal parasites and about 450 million suffer from these parasites.³

The encapsulated phase (cyst stage) is the infected phase that exits with the droppings of the affected human and contains four nuclei and average 20 µm in diameter. As for the active phase with a size ranging from 10 to 60 µm, it is the one present in the large intestine of the host that causes damage to the intestinal wall and the appearance of blood with diarrhea.⁴,⁵

This parasite is transmitted in several ways, the most important of which is taking the cysts through contamination of water and food, through contact with two people, one of which is infected and the other is intact, contact with affected areas and finally swimming in water contaminated with the cysts of the parasite, clinical symptoms differ from one person to another, that is, the appearance of signs depends on the number of parasites present in the host, in simple cases, no symptoms appear, but in severe cases there is pain in the abdomen and bloody diarrhea.⁶,⁷

There are few reports of confirmed cases of amebiasis in the dog and even less information on amebicides, their dosages and side effects pertaining to animals.⁸

**Material and Method**

The samples were taken from a private laboratory in Baghdad governorate/Iraq during the 1st of April 2018 till the 31st of August. The number of Stool samples were 500, collected from (males and females) and added inside clean plastic bottles and then detected the stages of parasite by Lugol’s Iodine stain.

The preparation of Lugol’s Iodine is by Diluted 1:5 with sterile de-ionized water. (This working solution should be prepared fresh approximately every 3 weeks). Prepare a direct smear of the specimen, Place a coverslip over the sample and examine the wet mount preparation.
for the presence of motile protozoa. The organisms are very pale and transparent and are more easily observed under low light intensity, once the wet mount has been thoroughly examined, a drop of Lugol’s Iodine (working solution) can be placed at the edge of the coverslip, or a new mount can be prepared using iodine alone; examine the slide for the presence of brown parasitic structures.\(^{(9,10,11)}\)

**Result and Discussion**

This study showed that the total number of infected patients were (394) from 500 samples that had been taken and percentage was (78.8\%).

The high incidence was (81.13\%) that appeared in August and the low incidence was (76.84\%) that appeared in April as shown in the Table (1), this result showed a prevalence of parasite in Baghdad and no significant differences between the months during period of this study.

| 78.8%                     |

The reason of the absence of significant differences (p < 0.01) between months in this results it’s due to exposure the patients to the bad environment and low hygiene as well as food and water contamination with cyst of *Entamoeba histolytica*.

This research appeared that *Entamoeba histolytica* increased of incidence in hot months (from April to August), that agreed with\(^{(12,13,14,15,16)}\).

The cyst stage of *Entamoeba histolytica* was more active during hot months; our results agreed with\(^{(17,18)}\).

The incidence of this disease in hot months (from April to August) was without any significant variation as a result of the infected stage (cyst) of *Entamoeba histolytica* staying for weeks and resistance of the bad environment without destroyed the cyst besides the sample taken from symptomatic patients within the high temperature.
months and this condition considered good environment to survive the cyst, this study agreed with\(5, 6, 13\).

The reason of the absence of significant differences \((p < 0.01)\) between gender in this results it’s due to exposure both the gender to the same bad environment and low hygiene as well as food and water contamination with cyst of *Entamoebahistolytica*.

This study was disagree with other studies that recorded not important higher differences in proportions of infection between females and males in Baghdad \(19\) and Mosul city\(20\).

The reason for the different incidence of infection between males and females is attributed to the difference between body structure, immunity and addition to the physiology of the body for both genders, e.g. endocrine activity as male bodies are more tolerant than those of females\(21\).

Nurses’ Knowledge toward Procedure Nursing Care on Febrile Convulsions Patient in Emergency Unit Teaching Hospital in AL-Nasiriyah City

Suror H. Aneed, Fatima K. Naeem, Abbas F. Najee

1 Assist. Lecturer, Academic Nurse, Pediatric Nursing Department, University of Thi-Qar, Iraq/College of Nursing, Ministry of Higher Education & Scientific Research, 2 Assist. Lecturer, Academic Nurse, Maternal and Neonatal Nursing Department, University of Thi-Qar, Iraq/College of Nursing, Ministry of Higher Education & Scientific Research, 3 Assist. Lecturer, Adult Nursing Department, Highr Health Institute in Thiqar/Iraq

Abstract

Background: Febrile convulsion is seizure correlating with fever in the presence of central nervous system or a cut infection electrolyte imbalance child old one month of age without notice. It is commonly infected of (3% - 4%) of children under six years of age.

Objective: The study aims: 1-Assess knowledge of nurses toward nursing care procedure for children with febrile convulsions . 2- Find out- relation between nurses’ knowledge and demographic information (age, gender, marital status, level of education, Years’ experience in the domain pediatric nursing, Years’ experience in the neonatal intensive care unit, participate to training on Febrile convulsions).

Methodology: Descriptive design (cross sectional research design) performed on stage nursing care on febrile convulsions for patient . in order Knowledge Toward Procedure Nursing Care on febrile convulsions patient the study has been conducted for nurses in emergency unit in AL- Nasiriyah City Hospitals including Muhammad AL-Mawsawi pediatric Hospital, Bint Al -Huda Maternity & Children Hospital .starting from (20th September 2019) to (30th of August 2020).

A non-probability (Purposive) sample of (100) nurse from emergency unit in AL- Nasiriyah City Hospitals, including Muhammad AL-Mawsawi pediatric Hospital,Bint Al- Huda Maternity & Children Hospital . consisting study tool of two section : The first section is regarding that demographic characteristic of nurse and the another section is regarding that nurses’ knowledge toward procedure nursing care on febrile convulsions for Patient. The results by using SPSS (Statistical Package for the Social Sciences) software version 25 descriptive data analysis include) frequencies and percentages, mean and standard deviation). inferential analysis (D.F. and Chi-Square) at P value 0.05.

Results: indicates that nurses are within age group of (20 – 29) years were female. The majority of the sample are married . Regarding the level of education the majority participant of them college of nursing. Showed that non-significant correlation between the nurses’ knowledge with their demographic characteristic at (p > 0.05), except their gender and years’ experience them significant.

Conclusion: Majority of the sample are age group of (20-29) years old .There is non-significant correlation between the nurses’ knowledge with their demographic characteristic at (p > 0.05), except their gender and years’ experience in domain of pediatric nursing revealed significant differences relationship with their knowledge.

Keywords: Knowledge, Procedure Nursing Care, febrile convulsions, Emergency unit.
**Introduction**

Febrile convulsion is seizure it is associated with fever in the presence of central nervous system or acute infection electrolyte imbalance in babies older than one month of age without notice. It is commonly infected of (3%-4%) of children under six years of age and one of the commonly reasons for admission children’s hospital is repetition possibility of febrile seizure in the rate of 30%(1).

Results found for children with febrile convulsion is similar of pediatric control from school performance, behaviors and delay to procedure of health care although childhood febrile seizures are very common and generally seen, specially condition with good prognosis also, it’s very frightening and causes to family emotionally traumatic and anxiety when thinking them child febrile convulsion, parent them shocked and in many situation believe the child He could dies. Nurses may low awareness and willingness to provide every the first aid for children who has a seizure, the researchers stress must be measures taken to teaching nurses about febrile convulsion(2).

It is classification recently as complex or simple. Simple febrile convulsion is a general spasm that persists low than 15 minutes with no recurrence within 24 hours. Not It is caused by febrile illness or nerve problems. while complicated febrile convulsions cause one or more of the main symptoms. The symptoms cause a spasm in one arm or leg, and they last more than 15 minutes within 24 hours, it caused neurological malformations, for example, paresis Patient(3).

Febrile convulsions occur with simple disease or any diseases other and cause by fever and also, occurs with commonly diseases for example ear inflammation, colds, influenza, cough and or any Another viral infection. There are another diseases such as kidney diseases, meningitis and pneumonia is less commonly resulting entry into neonatal intensive care unit. Iron deficiency and zinc and some immunization such as (Diphtheria-Pertussis-Tetanus and Measles –Mumps-Rubella), genetic factor, this is importance factors for febrile convulsion. Febrile convulsion may occur before or soon after fever begins for some minutes with possibility of cramping rising with the child’s body temperature (4).

nurses must be provider of the family with hard copy and oral about them reasons of febrile convulsion and the danger the risk of subsequent events. In necessary know to high body temperature this is sign of infection and occurs not disease. Additionally, must to the nurse teach family of diagnosis febrile convulsion, family are fully, aware: the child is more to outgrow febrile convulsions(5).

**Objective of Study:**

1. Assess knowledge of nurses toward nursing care procedure for children with febrile convulsions.
2. Find out relation between nurses’ knowledge and demographic information (age, gender, marital status, level of education, Years’ experience in the domain pediatric nursing, Years’ experience in the neonatal intensive care unit, participate to training on Febrile convulsions).

**Methodology**

Research is descriptive design (cross sectional research design) performed on nursing care on febrile convulsions for patient. in order knowledge toward procedure nursing care on febrile convulsions patient. The study has been conducted for nurses in emergency unit in AL- Nasiriyah city hospitals including, Muhammad AL-Mawsawi pediatric Hospital, Bint Al- Huda Maternity & Children Hospital. A non-probability sample (Purposive) size of the sample (100) nurse from emergency unit in AL- Nasiriyah city hospitals, including, Bint Al- Huda Maternity & Children Hospital, Muhammad AL-Mawsawi pediatric Hospital. Inclusion criteria included all participating nurses work at emergency unit and nurses’ age (under 20 years to above 40 years), and all sex of the participants are females and males, were confirmed by specialists, completeness and reliability of the results. Exclusion criteria include who have not participate in any assess procedure nursing care on febrile convulsions for patient in emergency. the researcher were used data collection during the instrument designed and constructed by based on previous studies. The study final tool consists of two section: First section is regarding that demographic characteristic of nurse and the second section is regarding that nurses’ knowledge toward procedure nursing care on febrile convulsions for patient. Statistical analyses were conduct that use statistical package for social science (SPSS) version (25) data analysis was works through the implementation of descriptive and inferential statistical approaches which were performed by through the calculation the following: frequencies, percentage, (D.F. and Chi-Square) at P value 0.05.

</table>
This table show that there is non-significant association among the knowledge of nurses with their demographic characteristics at \( p > 0.05 \), except their gender and years’ experience in domain pediatric nursing revealed significant differences relationship with their knowledge.

### Discussion

The study sample consisted of (100) sample randomly selected nurses. This chapter systematic clarify the results and discussion are sensible with providing the literature and relevant previous studies of the research. The data was analyzed through the application of descriptive and inferential statistics to obtain the objective of the study.

In table (1) regarding to nurses and results of the study are indicated that. The most of individuals are in the age group and this table indicates that (76%) of the nurses fall within age group (20-29) years. The results of the current study agree with Kennard, (2017) which his study results indicated that most of the average age of the participant in nursing was 29 years (6).

The present study showed that (83%) of the nurses are female. The results of the current study agree with Mould,(2012) which the results of his study indicated that (92.6%) are females and (7.4%) are males (7).

Related to the marital status of subject’s, the most of sample (60%) are married. The results of the current study agree with Baran,(2018) which the results of his study indicated that most of the marital status is Married (60.3)Single (39.7) (8).

Regarding the level of education, the majority to college of nursing and they are (36%) from sample. The results of the study results agree with Kennard, (2017) which indication that the majority the participants reported their highest level of nursing education as a Bachelor’s degree (64%) of the sample . Baran,(2018) revealed in his study that the majority of the pediatric nurses in the sample (87.3%) were university graduates (6).

Present study show that (60%) regarding to years’ experience in the domain pediatric nursing have less than three years of experience of pediatric nursing. The results of the present study agree Mediani et al., (2019) which the results of his study indicated that most (38) nurses had experience working in the hospital for more than ten years, but the majority of 58% (42 nurses) had served in the pediatric ward for less than three years (9).

The majority of the nurses participate in the training of the neonatal intensive care unit and their answer is (Yes) and they are (75%) of the sample. This result differ from Mediani et al., (2019),who studied: The most prominent nursing care intensive care unit,(70%) of the nurses participant in this survey did not undertaken any Intensive Care Unite training , while it is found that participation in the teaching program with the sample (No) (9).

### Part II: Correlation between nurses’ knowledge and their demographic variables:

This table showed that there is non-significant association among knowledge of nurses with their demographic characteristics at \( p > 0.05 \), except their gender and years’ experience in domain of pediatric nursing revealed significant differences relationship with their knowledge. The Researchers’ opinion that decrease knowledge for nurses in nursing care of febrile convulsions patient and effected that gender and years’ experience in domain of pediatric nursing.

### Conclusion

Majority of sample are age group (20-29 years old), female, college of nursing. There is non-significant association between the nurses’ knowledge with their demographic information at \( p > 0.05 \), except their
gender and years’ experience in domain of pediatric nursing revealed significant differences relationship with their knowledge.

**Recommendation:** The study recommended that educational program related to nurses’ knowledge toward procedure nursing care on febrile convulsions for patient updating booklets, boosters and pamphlets should be given for nurses to improve and upgrading their knowledge about procedure nursing care on febrile convulsions for patient and providing an educational courses for nursing worked in emergency unite.

**Acknowledgment:** The researchers are very thanks to all the nurses which participated in this study and filled out the questionnaire to study their knowledge about spasticity. Also, researchers are very thanks to the medical staff in all specialties to provide assistance to complete the study.

**Financial Disclosure:** There is no financial disclosure.

**Conflict of Interest:** None to declare.

**Ethical Clearance:** All experimental protocols were approved under the pediatric Nursing Department and all experiments were carried out in accordance with approved guidelines.

In Vitro Study for Nano Hydroxyl Apatite and Chitosan Coated Surface after Immersion in Simulated Body Fluid

Saja Kareem Esmael 1, Raghdaa Kareem Jassim 2, Soodad Abdallah Al-Hiloh 3

1Lecturer in Department of Prosthodontics, College of Dentistry, Uruk University, Baghdad, Iraq, 2Professor in Department of Prosthodontics, College of Dentistry, University of Baghdad, Baghdad, Iraq, 3Lecturer Assistant in Department of Prosthodontics, College of Dentistry, University of Kufa, Najaf, Iraq

Abstract

Multiple attempts are made to develop coating layers on the implant surface to enhance ossiointegration and support implant functions. The mixture of chitosan with HA prepared by sol–gel process to make organic–inorganic hybrid composite that has the ability to make network with or without covalent bonds between components.

In this study the immersion of titanium disc coated via sol – gel technique by nano-HA and chitosan in simulated body fluid.

Materials and Method: Composite of nano hydroxyapatite/chitosan was prepared by sol – gel technique after preparation of two solutions of calcium nitride and phosphorous pentaoxide, then the magnetic stirrer was used for mixing of these solutions, then 3 mg of chitosan were added to the mixture and the mixture was stirrer for 15 hours to complete the mixing. Dip coated of titanium samples, then the samples were removed and dried by hot air oven, finally samples were sintered at 400°C for one hour. Coated samples were immersed in SBF in closed containers and placed in incubators at temperature 37°C for 30 days.

Analysis of the surface include thickness measurement, X-ray diffraction (XRD), scanning electron microscopy (SEM) and energy-dispersive x-ray spectroscopy (EDX).

The results of thickness measurement showed increase in thickness of the coated layer after immersion in SBF compared with thickness before immersion. The results of XRD showed the appearance of new peaks of HA, SEM showed there are additional accumulation of HA granules on the original coating layer. EDX test showed decreased in the concentration of the main ions component (Ca, Na, P, O and K) when compared with coated samples before immersion in SBF.

Keywords: Dental implant, dip coating, sol–gel, chitosan, hydroxyapatite, nanoparticles, simulated body fluid.

Introduction

The successful of dental implant depends on many factors; implant material, design of implant and design of implant surface (1). Multiple attempts are made to develop coating layers on the implant surface to enhance ossiointegration and support implant functions(2). The coating layer should be biocompatible and osteoconductive properties which mean that it must have the ability to attract osteoblasts to the implant surface and enhance bone formation to secure bone–implant interface(3). The widely use of Titanium and its alloys as dental implant due to its biocompatibility, good strength, resistance to corrosion and has the ability to enhance ossiointegration(4). Many researches have been done to modify titanium implant surface by coating with materials that enhance stabilization and ossiointegration(5). The hydroxy apatite is commonly used as coating for titanium implant; since it is biomaterial that resembles natural teeth and bones(6). Also because of its biocompatibility that enhance growth of bone when implanted inside the body and acceptable mechanical properties so it is widely used as coating
material in plastic and orthopedic surgery\textsuperscript{(7)}. The sol–gel process can be successfully used in the preparation of HA powder or thin film under specific conditions\textsuperscript{(8)}. Sol–gel is successful process to produce nano sized HA\textsuperscript{(9)}.

Several types of sol–gel coatings can be applied for examples; dip coating, spray coating, flow coating and spin coating, making it an ideal technique for production of biocompatible coating\textsuperscript{(10)}. The use of dip coating procedure to apply the coating materials on titanium substrate has the advantage to change surface properties of the substrate and retaining the favorable properties of the coating material to the implant surface to accelerate osseointegration\textsuperscript{(11)}. The mixture of chitosan with HA prepared by sol–gel process to make organic–inorganic hybrid composite that has the ability to make network with or without covalent bonds between components\textsuperscript{(12)}. Chitosan as an amiopolysacharide that gained from alkaline deacetylation of chitin, it is a natural compound that characterized by its biocompatibility, biodegradability, non toxic and osteoconductive, so it has many medical applications; as surgical, reduction of periodontal pocket\textsuperscript{(13)} and as a material for bone grafting\textsuperscript{(14)}. Many attempts have been made to develop chitosan hybrid by making composites that establish ability of forming bone–like apatite in simulated body fluid (SBF)\textsuperscript{(15)}. A cellular (SBF) that have ions concentrations almost similar to that of human plasma, it has the ability to formulate bone apatite on surface of the bioactive materials, therefore it used for in vitro estimation of the bioactivity of the materials and evaluation of the formation of bone like apatite on the implant surface\textsuperscript{(16)}. The procedure of measure the HA formation on the coated surface considered as in vitro procedure that has many advantages over the conventional in vivo procedure in that is simplest, cheaper, quicker procedure, reproducible method and less effected by experimental conditions\textsuperscript{(17)}. Fan et al, 2008 study the apatite formation on natural nano HA/chitosan composite in simulated body fluid (SBF)\textsuperscript{(18)}. Rhee et al, 2012 study the synergic effect of silanol group and calcium ion in chitosan membrane on apatite forming ability in simulated body fluid\textsuperscript{(19)}.

The study aimed to evaluate the formation of new hydroxyapatite after immersion of coated samples in SBF.

**Materials and Method:**

**Preparation of Sol–Gel:** The preparation of nano HA/chitosan composite was achieved according to (Esmael et al, 2020)\textsuperscript{(20)}:

1. A magnetic stirrer (SH – 3/England) was used for mixing of 125 ml of Ethyl alcohol and (10.78 gm) of Calcium nitride which was weighed by electronic balance (Germany, accuracy 0.0001g). Mixing was continued for one hour until completely dissolved of Ca(NO\textsubscript{3})\textsubscript{2} to prepare first solution.
2. Mixing of (5) mg phosphorous petaoxide P\textsubscript{2}O\textsubscript{5} with (125) ml of Ethyl Alcohol for one hour on magnetic stirrer for completion of mixing and preparation of second solution.
3. Mixing of the two solutions was achieved by drop wise of the first solution on the second solution on magnetic stirrer for 2 hours, at this time (5) mg of KOH was added to complete the reaction.
4. Chitosan (3) mg was added to the mixture then mixed on magnetic stirrer for 15 hours.

**Sample Preparation:** Rod of commercially pure titanium grade 2 (Orotig S rl EU company Italy) were cut into circular discs with 10 mm diameter and 2.5 mm in thickness, the by the use of carbide silicone with 500 micron roughness for 15 min to provide mirror polished surface of samples. Then these discs were placed in ultrasound ethanol water bath absolute ≥ 99.8% for 15 min to remove debris and infection, finally discs were washed by distilled water for 10 min and left to dry at room temperature\textsuperscript{(21)}.

**Dip Coating Procedure:** Titanium samples were immersed in the mixture of chitosan/HA sol–gel on slow speed magnetic stirrer and continue for 90 min. to complete precipitation of the coating layer on samples, then the samples were removed from the mixture and dried by hot air oven (0 _ 200 c) (IMS/406, France).

**Heat treatment (Sintering):** The coated samples were sintered by the use of tube furnace (carbolite type MTF 12/38A. BAMFORD, England). Samples were coated at gel stage and sintered for 400°C for 1 hour.

**Preparation of simulated body fluid (SBF):** SBF prepared according to Kokubo's protocol\textsuperscript{(22)} with some modifications, the chemical composition of SBF and there quantity are listed in table (1).

<table>
<thead>
<tr>
<th>Description</th>
<th>Quantity gm/L</th>
</tr>
</thead>
<tbody>
<tr>
<td>NaCl</td>
<td>8.036</td>
</tr>
<tr>
<td>KCL</td>
<td>0.225</td>
</tr>
</tbody>
</table>
At room temperature all salts that are listed in table (1) are mixed with 1L of distilled water on magnetic stirrer for 1 hour to ensure completely dissolving of salts in water, and then the PH of fluid was adjusted to 7.4 and checked by PH meter (Germany).

**Immersion of samples in SBF:** Coated samples are immersed in SBF, and then the containers should be closed and placed in incubator (Gallen bamp. England) at temperature of 37°C which is the temperature of human body\(^{(23)}\). And the fluid should be changed at the same time every day to preserve PH level (7.2–7.4) for 30 days, the early nucleation of apatite start after 24 hours of immersion\(^{(24)}\).

**Analysis of the coated layer:** After 30 days the samples were taken out of SBF and rinsed in distilled water and air dried then surface characterized by:

1. **Thickness measurement:** After removing of the coated samples from the SBF the coated layer was measured by microprocess coating thickness gauge (TF–C–UVIS–SR/U.S.A.), the mean of three readings was 90 um when compared with the thickness of coated samples before immersion in SBF was 60 um because of the formation of new layers of HA after immersion in SBF\(^{(25)}\).

2. **X–Ray diffraction analysis:** The chemical composition of crystallographic structure was tested by this analysis test, the indexing peaks based on the joint committee on powder diffraction standards. (JCPDS). The device used (SHIMAZU, XRD–6000, Japan).

3. **Structural surface characterization by SEM:**

   The device used for this test was (SEM TE scan vega 111, Czech). This test analysis was of two parts:

   - **Surface Analysis:** The surface morphology and topographical characteristics of coated sample was performed by scanning electron microscope (SEM) after 30 days of immersion in SBF.
   - **Material characterization:** By Energy dispersive spectroscopy (EDS) by the use of SEM machine for chemical analysis of the sample, it depends on interaction and excitation of x – ray by each sample.

**Results**

**X-ray diffraction analysis:** As appeared in fig. 3.1 a and b compared between coated samples before and after immersion in SBF for 30 days that illustrate the appearance of new peaks of HA. Peaks of HA were indexed according to the standard pattern (JCPDS09-0432).

![Fig. (3.1) X-ray diffraction of tested samples](image-url)
3.2. Scanning electron microscope (SEM): The surface feature of coated samples after 30 days immersed in SBF was compared with surface feature of coated samples before immersion in SBF. As appeared in fig. 3.2 a, b and c there are additional accumulation of HA granules on the original coating layer. The newly formed crystals of HA accumulated as layers of flaks which differed from the manner of accumulation before immersion in SBF which was spherical like granules, these differences in the manner of accumulation due to the differences in the condition, PH and temperature of HA formation. Also the sufficient time of immersion in SBF leaded to completely coverage of titanium samples with layers of HA even cracks areas and appearance of randomly accumulation of layers because of unrestricted formation and growth of HA crystals\textsuperscript{(26)}. This manner of nucleation and formation of new apatite is an indication of bioactivity of the coated sample\textsuperscript{(27)}.

![Fig. (3.2) a SEM (5 um)](image1)

![Fig. (3.2) b SEM (10 um)](image2)
Energy dispersive x–ray spectroscopy (EDX): This test depended on the interaction of x–ray with each element, as seen in fig. (3.3) a the main component of the plate Ca, Na, P, O and K. showed decreased in concentration of these ions when compared with fig. (3.3) b that showed EDX of coated sample before immersion in SBF.

**Discussion**

Chitosan material recently has been used in dental implant because of its biocompatibility and bioactivity with the natural tissue \(^{28}\). It has the ability to successfully coating of titanium but doesn’t have ability of new apatite formation, therefore hybridization of chitosan with nano HA prepared by sol – gel technique to form chitosan/HA composite to enhance formation of new apatite\(^{29}\). The nano HA prepared by sol – gel technique have hydroxyl groups on its surface that act as nucleation that promote nucleation of calcium and phosphate that facilitate osseointegration\(^{30}\). Coated samples were immersed in SBF to observe nucleation ability of biomaterials\(^{31}\).

Abstract

Gonadectomy is the most commonly utilized method for permanent contraception in small animals. But some negative side effects can be noticed after surgical castration, therefore finding safe and effective contraceptive substances can be so useful, medicinal plants have a long history of use in traditional medicine. The sperm cell count, motility, live/dead sperm cell ratio, morphology, LH, FSH and Testosterone level were used in this study to evaluate the effect of prolonged administration of ethanolic extract of Anethumgraveolens on male reproductive system in male rabbits. Twelve healthy adult male rabbit were randomly divided in to two groups. The rabbits in group 1 (control group) were administered normal saline (3ml), while rabbits in group 2 were administered ethanolic extract of Anethumgraveolens at dose 0.5 gm./kg B.W for 30 days. The treatment with extract caused significant decrease in sperm motility, live/dead, sperm count, sperm LH, FSH and testosterone level with significant increase (P≤0.05) of abnormal sperm. Histological study showed many pathological changes in testes. On the other hand, Prolonged administration of the extract could be a good source of drug for birth control.

Keywords: Anethumgraveolens, sperm, testes, LH, FSH and testosterone, Rabbit.

Introduction

Gonadectomy is the very commonly used method for permanent contraception in small animals. But several negative side effects can be observed after surgical castration, therefore finding safe and effective contraceptive materials can be very useful, medicinal herbs have a long history of use in traditional medicine. Anethumgraveolens L commonly known as dill belonging to the family Umbelliferae, the generic name Anethum is derived from the Greek word anethon and the common name dill comes from the Norse word dylla or dilla which probably means to soothe¹. Dill an annual herb growing in the Mediterranean region, Europe, central, southern Asia. The plant is used both medicinally and as an aromatic herb and spice and cookery. dill has been used traditionally for gastrointestinal ailments such as flatulence, indigestion, stomachache colic and to tract intestinal gas² it is used anticonvulsant, antiemetic, anticramp (in children) remedy and also recommended topically as a wound healers³, antispasmodic⁴, antimicrobial⁵, cardioprotective⁶, antihyperlipidemic⁷ and antiproliferative activity⁸ the aim of the present study is to evaluating the effect of ethanolic extract of Anethumgraveolens on fertility in male rabbits.

Material and Method

Collection of plant materials and extraction:
Fresh plant of dill was purchased from the local market at Basra-Iraq. The shade dried plant was finely powdered in chemical mixer, 50gm of powder were put in the round bottle flask, 200ml of ethanol (70%) were added to flask and extracted for 12 hours at 70°C the extract was filtered by using whatmann filter paper, then the extract were put in the petridish and left at room temperature under the shade, the collection extracts were kept in tight closed container and stored till using⁹.

Experimental Animals: Twelve healthy adult male rabbit weighting 1000-1500 gm. were used, the animals kept in suitable cages in the animal house of
veterinary medicine college/Basra university, rabbits were acclimated to holding facilities for two weeks prior to the experiment and were fed standard diet and water ad libitum.

The animals were divided into two groups, each group containing 6 animals as follow:

**Group 1:** Rabbits received oral administration of normal saline (3ml) for 30 days (served as control group).

**Group 2:** Rabbits received oral administration of ethanolic extract of *Anethum graveolens* at dose 0.5 gm./kg B.W for 30 days.

**Blood Samples:** At the end of experimental period, blood samples were withdrawn from all animals through cardiac puncture, then the blood samples were put in a screw tube without anticoagulant then centrifuged at 5000 rpm for 15 minutes to get serum for hormonal assay.

**Hormonal Assay:** Serum samples were assayed for testosterone, using the enzyme-linked immunosorbent assay (ELISA) technique using the Fortress kit.

The concentration of FSH and LH were measured by Enzyme Linked Immuno Assay (ELISA) technique according to kit (Monobind Inc. lake forest CA 92630 USA).

**Semen Collection:** The testes were removed along with the epididymis. The caudal epididymis were separated from the testes, blotted with filter papers and lacerated to collect the semen.

**Semen Analysis:** Progressive sperm motility: this was done immediately after the semen collection. Semen was squeezed from the caudal epididymis onto pre-warmed microscope slide 37° and two drops of warm 2.9% sodium citrate was added, the slide was then covered with a warm cover slide and examined under the microscope. The percentage of motile sperms was defined as the number of motile sperms divided by the total number of counted sperms.

**Sperm Viability:** Eosin and Negrosine stain was used to identify the live and dead sperms. The dead sperm stained with the eosin, while the live sperm did not. The stained and unstained sperms were counted and the percentages was calculate.

**Viability = No. of live sperm/No. of sperm count × 100**

**Sperm abnormality:** Sperm suspension 50 µl was put on one end of the clean and warm slide, then a drop of Eosin-Negrosine stain was added, mixed by using glass rod and spreaded all over the slide by another slide. The smear was left to dry and examined under oil immersion. The abnormal sperms were calculated in each slide by examining 200 sperms.

**% Abnormal sperms = No. of abnormal/No. of total sperm x100**

**Sperm Count:** This was done by removing the caudal epididymis from the right testes and blotted with filter paper. The caudal epididymis was immersed in 5ml formal-saline in a graduated test-tube and the volume of fluid displaced was taken as the volume of the epididymis. The caudal epididymis and the 5ml formal-saline were then poured into a mortar and homogenized into a suspension from which the sperm count was carried out using the improved Neubauerhaemocytometer under the microscope.

**Histological Examination:** After removing the testes, they immediately fixed in Bouin’s fluid for 12 hours and the Bouin’s fixative washed from samples with 70% alcohol. the tissues were dehydrated progressively in ascending ethanol concentration then treated with xylene and embedded in paraffin. Five microns thick section of paraffin embedded tissues were mounted on glass slide and stained with heamatoxylin and eosin stain. Sections were examined by mean of light microscope. The sections were made from the middle portion of the testis and the component and functional changes for tissue of testis slide were examined by using light microscope.

**Statistical Analysis:** The mean and standard deviation (mean±SD) were calculated for all values. comparison between the control and the treated group were done using the student’s t-test. Difference were considered statistically significant at (P ≤0.05).

**Result**

**Effect of ethanolic extract of* Anethum graveolens* motility, live-dead sperm ratio and Sperm abnormalities in male rabbits:** The obtained results in table (1) revealed a significant low (P≤0.05) in motility and live- dead sperm ratio in semen of male rabbits.
treated with ethanolic extract of *Anethum graveolens* compared with control group. Moreover, there is a significant increase (P≤0.05) in abnormal sperm morphology of treated group as compared with control group.

**Sperm examination:** In the control group the sperm was normal Fig. (1,a), but sperms of rabbit treated with ethanolic extract of *Anethum graveolens* showing large number of dead, and large number of different types of abnormal sperms were observed, coiled tail fig.(1,b), big head fig.(1,c) headless tail fig.(1,d) and tailless head fig.(1,e).

Figure 1: (a) Normal sperm in control group, various sperm defects (b-e) were observed. b: coiled tail, c: big head, d: headless tail and e: tailless head in treated group with ethanolic extract of *Anethum graveolens*. 
Histological Examination: Section of testis of rabbit in control group showing normal seminiferous tubules and spermatogenesis (fig. 2), while section of testis of rabbit treated with ethanolic extract of *Anethum graveolens* showing vacuolation of epithelial cells lining of seminiferous tubules (sertoli cells) with suppression of spermatogenesis, congested blood vessels, thickening in capsules, oedema and fibrosis in interstitial tissue with inflammatory cells, degeneration of basement membrane and fragment of nucleolus cells (fig. 3).

**Fig. (2):** Section of testis of rabbit (control), showing normal seminiferous tubules and spermatogenesis.

**Fig. (3):** Section of testis of rabbit treated with extract, showing vacuolation of epithelial cells lining of seminiferous tubules ( ), congested blood vessels (C) with suppression of spermatogenesis and thicken in capsules (T).

**Discussion**

In this study, Male rabbits administered ethanolic extract of *Anethum graveolens* has significant decrease (P ≤ 0.05) in sperm motility, live/dead and total sperm count when compared to the control group, which could be due to the effect of this extract on the cell cycle, cell division and expression of genes necessary for the spermatogenesis. It is also possible that these changes might be as a result of changes in the microenvironment of epididymis and creation of a toxic microenvironment presence in extract, thus influencing sperm count and motility.
In our study showed a significant decrease in the level of FSH and LH and testosterone concentrations in rabbits treated with ethanolic extract of *Anethum graveolens* compared with control group, this indicates that the active ingredients of the extract may alter the pituitary gonadotropins hormones like FSH and LH\(^{17}\), low levels of these hormones decrease endogenous testosterone secretion from the testis depriving developing sperm of the signal required for normal maturation and also it suppress testicular steroidogenesis and spermatogenesis\(^{17}\) since the pituitary-testicular axis is a central regulatory conduit for testicular function that culminates in the production of spermatozoa\(^{18}\).

Alteration of sperm cell morphology caused by *Anethum graveolens* in our study, as a result of a fundamental problem with the process of maturation where abnormal sperm cells are matured from damaged seminiferous tubules\(^ {19}\). Prolonged administration of the extract can be inferred to have harmful effects on the seminiferous tubules which is reflected in this study the high sperm cell abnormalities observed. This observation is supported by histopathological findings of the testes whereby rabbits administered with *Anethum graveolens* exhibit varying degrees of lesions of the seminiferous tubules theses alterations might be caused by cytotoxicity of extract. This study demonstrated that the ethanolic extract of *Anethum graveolens* have antifertility effect on testis of rabbits and could be further investigated for possibility of developing a cheap, acceptable and easy available male contraceptive.

DNN Based Plant Diseases Recognition Using Classification of Leaf Images

Rajaa J. Khanjar

Assist. Lecturer, Department of computer science, Baghdad University, Iraq

Abstract

Throughout the area of image processing, the new generation of convolutional neural networks CNNs has produced remarkable performances. The paper reflects on a new approach to the production of utilizing deep convolutionary networks of a model of the identification of plants centered on the picture classification of the surface. Throughout reality, a modern model of teaching and technique allows it simple and fast to introduce the program. With the ability to differentiate the plant leaves from the environment, the engineered model will recognise 13 specific forms of plant diseases from safe leaves. This approach for identifying plant disease was introduced for the first time, according to our understanding. The entire paper outlines all important measures possible for the introduction of this model for disease identification, beginning with the picture collection to establish a database reviewed by agricultural experts. The comprehensive CNN preparation was carried out by Caffe, a fundamental research system developed by Berkley Vision and Learning Center. On average, the experimental results of the built model were 91 to 98 percent reliable for separate class research.

Keywords: DNN, CNN, Leaf Image, Plant Disease.

Introduction

Plant disease is a common threat to yield and quality of global agricultural production and bears responsibility for a significant portion of production costs. It is reported that the loss caused by plant disease accounts for at least a 10% reduction in global food production. Most of disease damage evaluation and treatment are done by farmers in the field with the guidance of plant pathologists. Incorrect diagnosis and pesticide usage are very common. Therefore, the prevention and control of plant disease have always been widely discussed because plants are exposed to outer environment and are highly prone to diseases. Normally, the accurate and rapid diagnosis of disease plays an important role in controlling plant disease, since useful protection measures are often implemented after correct diagnosis. Many recognition and diagnosis method have been proposed by following the pipelined procedures of image segmentation, feature extraction, and pattern recognition. Recognition method following the pipelined procedures have made some progress. But these method are subject to two issues. First, the accuracy of these method greatly depends on the extraction and selection of visible disease features. Specifically, features of visible disease symptoms should be extracted accurately and proper features should be selected. Second, the method following the pipelined procedures are relatively complicated. The presence of noises is largely unavoidable in disease images captured under field conditions, such as uneven illumination and clutter field background. This can severely decrease the quality of the features and affect the results of recognition. Therefore, many efforts are spent on eliminating the noises in conventional method to achieve robust results. The recent trend in the development of computer vision and the use of various machine learning algorithms for plant disease classification has shown promising results in few selected diseases and crops. Evolution of deep Convolutional Neural Network (CNN) based architectures has further enhanced the accuracy of classification significantly.

Literature Review: In this paragraph, different schemes have been proposed in automatic recognition of plant diseases as shown below:

An automatic identification of plant disease utilizing the capability of the digital image-based algorithm. This
algorithm is proposed to cope with various diseases and it is easy to retrain it to include new diseases. Its histogram based structure enables it to be reasonably robust under different circumstances to capture images. The obtained results show that there is still a place for improvement. Many factors such as a considerable number of present disorders, heterogeneity of symptoms associated with the same disease and symptom similarities between different disorders may need the adoption of hybrid techniques combining expert systems, image processing, and other information gathering techniques may be the best hope to beat at least some of the disadvantages present in practice have been presented.

System generative models are used for text and faces combined with standard shaded and textured regions models. This method makes it possible to interact and collaborate with these various versions to classify the images input. This device allows objects to be segmented, faces detected, and text detected and read in urban scenes. This system showed many cases where shaded models helped discover the face and text by explaining the shadows and absence sun glasses. The face and text models, in turn, improved segmentation quality. The present limits of this methodology lie in the standard class of objects that we are presently modelling. This restriction was inspired by the purpose of our software to identify the text and faces of visually disabled persons. But, in principle, this approach can include broad types of objects that have been presented.

The method of detection depended on an analysing of the number of points clusters in combination with CNN as the final classification. The suggested method of evaluating clusters of dots depends on a combination of modelled fuzzy logic and graphics processing. The suggested detection and classification architecture has been tested and compared to other method in this field to demonstrate performance and to draw conclusions for further progress. The detection results combined with CNN enabled us to create a good classification of objects. In the case of face detection utilizing the large database, we attained the rate of about 83%, while in the case of other items such as people about 75%, animals about 55%, and cars about 80%. The performance showed the high potential of the technique proposed. correctly estimate the likelihood of ARX differentials in order to overcome these problems that have been presented.

A support vector machine is used to identify the object of the selected image. The suggested approach of object detection is compatible with KPCA feature vector reduction and detection utilizing the SVM classification system. The extraction method of the feature from the image’s global descriptors. General features are extracted and formed as a feature vector during the process of extracting an image. The vector parameter is developed for full-image training and utilizes KPCA to minimize dimensions. The SVM classifier is equipped using a reduced feature vector. Later test images are provided as input and the Classifier’s output is checked. Back Propagation Neural Network is used for object recognition to show the validity of the SVM Classifier. SVM classifier outperforms from the comparison have been presented.

The Proposed Method

The framework of the proposed system comprises two main phases: a training phase and a classification phase. These two primary phases share the fundamental modules of the system (pre-processing module and features extraction module), as shown in Figure (1).
In the training phase, after the pre-processing and feature extraction steps extracted features vector, for each training sample, the features vectors are saved in the system database. While in the classification phase the system should match these feature vector of input plant leaf image with all vectors listed in the database and return the file name in dataset classifier. Matching and decision steps in the proposed system have been done by using a convolutional neural network (CNN).

**System using Deep Learning Method:** Deep learning neural network plant leaf diseases by image classification method is consist of two main stages:

1. **Enrolment Phase:** In this stage, many steps will be done such as pre-processing, localization, extracted features, (and labelled objects).

2. **Matching Phase:** In this stage, many steps will be used such as pre-processing, localization, extracted features, and matching process. Figure (2) explained the main stages of the proposed system are work and Figure (3) explained the main stages of CNN are work.

![Figure (2): The main stages of the proposed system](image)

![Figure (3): The main stages of CNN](image)
Image Acquisition: Acquisition of the image is always where vision systems begin in order to complete their set task. Once obtained, there are several different processing methods which are able to be used in order to carry out several tasks in regards to the image. The reason why the image acquisition is always the first step in the workflow sequence is that if there is no image, processing is impossible. There are multiple methods to acquire images including but not limited to, the use of cameras or scanners. The image which has been acquired needs to retain all features.

A. Standard Dataset: The images for 6 different diseases and healthy samples of pepper crops were obtained from the Plant Village dataset. The resolution of these images is 256 x 256 pixels and all these images are available in jpeg format. Figure (4) is showing the sample of Standard Dataset (Plant Village Database).

![Figure (4) The sample of the Plant Village dataset](image)

B. Enrolment Phase: At this stage all enrolled features are passed to the system at the same time in order to train the system. The enrolment phase is consisting of other sub steps:

I. Preprocessing Image: The first step in this work is applied pre-processing image to improve the plant leaf images. This technique is used to improve the image for the purpose of showing the image detail well because sometimes the images may be taken in conditions that are inappropriate in terms of light, noise or the size of the image is very large and does not produce good results.

II. Feature Extraction: The most important stage in the identification system is feature extraction from samples such as plant leaf diseases. In the main proposed, the system uses the convolutional neural network (CNN) in which the convolutional layer is in the role of the feature extraction stage. Figure (5) shown architecture of CNN that employed and explain each layer in details:

A. Resize Image for Plant Leaf Diseases: Since the system aims to get a better style and the advantage of the picture of plant diseases will change the size of the image in a manner appropriate to the system. Because artificial neural network inputs are of a certain size, depending on the structure used in the network, the dimensions of the image are adjusted to fit the desired size. To achieve these dimensions, the method is applied to the image so that no information is lost from the image during the resizing process.
Figure (5): Architecture of Convolutional neural network

1. **Convolutional Layer**: Feature extraction layer, it operated by moving mask of weight slide over the original image and dot product multiplication is performed, to produce feature map. Weight is generated randomly, along with many iterations passes through BN, Pooling, RleU Layers, the Weight changes until reaching the best weight for this image, this weight represents the feature.

2. **Batch Normalization Layer (BN)**: This layer is used to increase the speed of the training process and eliminate sensitivity to network initialization, it minimizes a large number of each channel, firstly, the activation of each channel is normalized by subtracting mean of mini batch and divide on standard deviation of mini batch, after that, the layer input is shifted by offset $\beta$, and then scale by factor $\gamma$. This layer is used between the convolutional layer and RleU layer.

3. **Max Pooling Layer**: In order to get rid of excess and unwanted feature, max pooling layer has been employed, so it returns an important feature, it does that by sliding mask with known dimension over feature map that results from previous convolutional layer, but the max is empty, at each stride, the result is the highest value lie under this mask.

4. **RleU Layer**: Since the images are naturally non-linear, and contain non-linear features such as color and border, the rectifier function is applied to increase non-linearity of the image, i.e. RleU layer is used to ensure only robust feature by taking only positive numbers and convert all negative numbers to zero.

5. **Fully Connected Layer**: It’s represent feature vector that hold the most important information for the input, it is gather the feature from all previous convolutional layer during training operation that can be used for classification later. i.e. train hidden layer to give probability of each class.

6. **Softmax Layer**: The output of Softmax layer is probability number ranging between zero and one (0-1), each class has its probability, for example
(0.011, 0.005), give high probability to the candidate class and decrease other classes.

7. **Loss Function Layer:** The loss function is used to determine the loss (error) at each trading epoch, it is also an important factor that the update of weight during backpropagation depends on i.e. it shown the difference between predicted output and true label.

C. **Matching and Decision Stage:** To find the difference between objects coordinate is used Euclidian distance. therefore, determine the decision of the identification system used Matching operation based on Euclidian distance value. each class has its upper and lower limitations when the result of distance lies between the limitations of any class, this means the examined sample belongs to this class.

4. **Experimental Results:** This method of detecting objects works best with objects that display unrepeated patterns of texture, resulting in special matches of features. With uniformly color objects or items containing repeating patterns, this method is unlikely to work well.

a. **Pre-processing stage:** This is the important stage during which the original image is converted to a grayscale image and ROI is extracted as shown in Figures (6).
b. **Convolutional neural network (CNN):** Feature extraction is the essence (core) of the detection Plant Diseases Leaf system, convolutional layer (conv_) in CNN is feature extraction layer, it works by sliding the weight mask over the input image and perform dot product multiplication, the result is called feature map, feature map of first convolutional layer (conv_1) act as input to Batch Normalization Layer (batchnorm_1) which minimize the numbers of feature map (numbers that represent input image after convolutional layer 1) to speed up training process, the output is going forward to first max-pooling layer, that takes only an important feature (highest values) and ignores the other, to increase the difference between individuals feature. Figure shows the output of each convolutional layer on CNN next layer is RReLU that ignore the negative number to ensure only vital feature are remain, so the size of the feature map is minimized.
Conclusion

In this paper, the goal is to automatically identify and detect herbal diseases from leaf images via a new approach of deep education process. The model was established to identify the involvement of leaves and differentiate between stable leaves and 13 diseases, which can be visually identified. The full method was defined from the set of images used for testing and evaluation, the pre-processing and extension of images and finally the deep CNN testing and fine-tuning technique. Numerous experiments have been performed to verify the newly developed model’s efficiency. New picture archive of plants disease was developed with over 3,000 initial photographs taken from Internet sources accessible and expanded by correct transformations to more than 30,000. Regarding specific class checks, the experimental findings obtained accuracy between 91% and 98%. The average finish of the trainer qualified was 96.3%. Fine-tuning revealed no major improvements in average precision; however, the cycle of improvement had a stronger effect on the performance.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the Department of computer science and all experiments were carried out in accordance with approved guidelines.

Effectiveness of an Educational Program on Nurses’ Knowledge toward Burn Management

Hawraa Razzaq Kadhim¹, Rajha Abdul Hassan Hamza²

¹M.Sc. in Nursing, Department of Adult Nursing, Faculty of Nursing, University of Kufa, Iraq,
²Ph.D. in Adult Nursing, Dean of Faculty of Nursing, University of Kufa, Iraq

Abstract

Objective: To determine the effectiveness of an educational program on nurses’ knowledge toward burn management and To identify the relationship between nurses’ knowledge toward burn management and their socio-demographic data. Methodology: “quasi-experimental” loaded out to accomplish the golas of the study consisting of (40) nurses at specialized burn center in Al-Najaf City/Al-Najaf Al-Ashraf Health Directorate from October 6th, 2019 to August 23rd, 2020. Results: the study show that there are highly significant differences in the nurses’ knowledge between the study and control groups in the post-test and the program was positive for the nurses’ knowledge about burn care and that there was a good improvement in the nurses’ knowledge between pre and post test.

Keywords: Educational program; nurses; knowledge; burn management.

Introduction

Burn injury occurs as a result of destruction or loss of body tissue resulting from exposure or direct contact to any type of chemical, thermal, electrical, or radiation. Those injuries are one of the world’s most common and debilitating types of trauma. The burn is considered a significant cause of mortality and morbidity worldwide according to the World Health Organization (WHO), accounting for about 180,000 annual deaths.

In Iraq, burns are a common type of injury. According to the latest WHO report, about 6,000 fire-related deaths and 18,000 disability-related burns occurred in Iraq in 2015 (WHO, 2016). Also WHO reports that 3,390 fire-related deaths occurred in Iraq in 2004, which is corresponding to a death rate of 12.3 per 100,000 per year higher than the global average.

A study conducted in Baghdad showed that the incidence of burns increased in the period after the invasion, from 39 to 117 per 100,000 people, which may be linked to an growing number of cases of burns linked to violence. Moreover, another previous study in Basra showed that the death rate was 22%, which was lower than the rate reported in Sulaimaniyah and the city of Baghdad, but it is 8.9% higher than the rate recorded in neighboring countries like Iran.

Total number of burn patients in Iraq reached 92,734 patients annually, and one of the causes of death was related to side effects after burning such as bacterial and viral infections, ulcers and other diseases, which included about 37% of the total number of deaths.

Methodology

A quasi-experimental design was used. The accidental sample consists of 40 nurses, divided into two groups, and each group consists of 20 nurses. One of these two groups underwent the educational program and is the study group. The other group, namely the control, was not subject to the educational program at a specialized burn center in Al-Najaf City/Al-Najaf Al-Ashraf Health Directorate from October 6th, 2019 to August 23rd, 2020. To assess the nurses’ knowledge about burn care, a two-part questionnaire was used, part I regarding the nurse’s demographic data, and the part II consisting of (40) questions in the form of multiple choice question, including their information about the anatomy and physiology of the skin, classification of burns and its complications, and burn management.

Table (1) illustrate the statistical distribution and difference of study and control groups by their socio-demographic data. This table explains that the majority of the nurses in both groups are those with ages between (21-30) years old. In addition, the table shows that the high percentages of participant in both groups (55%) and (60%) are males for study and control groups separately. Concerning residency, the table demonstrates that the entire sample (100%) are urban. About the marital status, the high percentage is (65%) for study group and (75%) of the sample in control group are married. In regard to the level of education, (35%) and (40%) for study and
control groups respectively are graduated from nursing institute and nursing college. Besides, the table shows that the economic status for study group is (70%) and (60%) for control group are satisfied to some extent.

In regard to the years of experience in nursing, the table shows that (95%) of the sample in study group and (75%) of the sample in control group have (1-9) years. Concerning years of experience in the burn unit, (80%) for both groups have (1-4) years’ experience in burn unit. In relation to training about burn care (46.2%) for study group and (61.5%) for control group have only one training course. However, no one of the participants in both groups has a training course outside Iraq and all courses are inside Iraq.

Table (2): Differences in the assessment of knowledge between pretest and posttest study group

</table>

This table demonstrate differences in the assessment of knowledge between pretest and posttest study group; it shows that there a strong significant difference (P <0.01) among pretest and posttest assessment in the study group. This mean, there is amelioration in the nurses’ knowledge after program.

Table (3): Differences in the assessment of knowledge between pretest and posttest control group

NS: Non-significant, SD: standard deviation

Findings of above table shows the differences in the assessment of knowledge between pretest and posttest control group; it shows that there no significant difference (P >0.05) among pretest and posttest assessment in the control group. The assessment of knowledge is based on the statistical scoring system that indicated total score between (0-0.33) as poor knowledge; fair is between (0.34-0.66); while good knowledge is above (0.66).

Discussion

Concerning their age, the majority of study and control groups are at age groups (21-30) years. This result coincides with the result mentioned nearly three quarters of the nurses are in the age group 21-30 years old. This may be related to the willingness of young nurses to take part in more educational courses in order to obtain more expertise and practice, while most older nurses do not think they need more courses because they have achieved a degree of experience to serve as a mentor.

About the gender of the study subjects, the higher percentages of participant in both groups (55%) and (60%) are males for study and control groups respectively, which is in consistency with revealed in their study that more than half of the nurses were males. This is may be linked to the few numbers of female in the burn unit.

Relative to the residency, the present study demonstrates that the entire sample from urban. These results are consistent with those who stated in their study that (94.4%) of the sample are urban residents. This may be related with nurses who prefer to stay close to their workplaces especially when working in critical care units such as burn units.

Regarding the marital status, the current study shows that most of the nurses (65%) and (75%) in the study and control groups are married respectively. The results of this study are congruent with who stated in their study that the majority of nurses are married.

Concerning the economic status, the highest percentage of both groups is satisfied to some extent. This result may be related to their need for more expenses to bear the burden of life.

Regarding the level of education, the study shows that the majority of study and control groups were graduated from university and institute. These results are in agreement with who indicated that approximately three quarters of the nurses obtained a university education. Further, reported that more than half of the nurses graduated from medical institutes. This is may be associated that the burn center is considered one of the critical centers that require special care and a scientific nursing staff.

Concerning the years of experience in nursing, the result of current study revealed that the majority of nurses in study and control groups are between (1-9) years of experience in nursing. This result is compatible with where he showed that the percentage of nurses with 10 years of experience and less is (85.7%). It may be related that they want to benefit and increase their knowledge.

Regarding to the years of experience in the burn unit, the present study shows that both groups have between (1-4) years. This finding is harmonious with another study they indicated that more than half of the nurses had work experience less than 5 years. That can happen because the hospital policies from time to time use a special distribution program for staff to fill the vacant positions in the hospital with nurses from different place. Moving the nursing staff to another place of work will also impact their experience, which could be incomplete

About training sessions toward burn injury, the majority of the sample in both study and control groups 65% had one training sessions. These results are correspondent with They revealed that more than two thirds of the sample attended one or two seminars. Furthermore, the findings indicate that none of the nurses in both groups have training sessions outside Iraq, this refers to no chances offered to the participants in nursing field training out of Iraq because of the country’s unstable financial situation.

Nurses knowledge has been improved regarding nursing management for patients with burn injury in the study group after exposure to educational program. This is indicated by the significant difference between pre-test and post-test results, which is reinforced by a preceding study which indicated after execution of nursing guidelines programa significant statistical enhanced of nurses knowledge score stated that the program was effective and developed nurses’ knowledge.

The existing study exposes that there is no significant association between post-test and demographic data of study group in related to (age, residency, marital status, socio-economic status, years of experience, level of education, and training sessions). Except for gender, the current study found that there is a relationship between gender and knowledge, where it was shown that men have better answers than women, this result contrast with (Sudani & Ali, 2017) found no relationship between gender and knowledge. This may be due to the freedom and flexibility given to men in our society where he has more freedom by attending seminars or opening nursing
clinics and gaining knowledge. With regard to other results, there are many studies that match our results and among them the research conducted by (Kadhim et al., 2019; El-Sayed et al., 2015; Lam and Tuan, 2018).

**Financial Disclosure:** There is no financial disclosure.

Study the Role Serum Omentin-1 in Occurrence and Development of Diabetic Retinopathy

Hussein Inam Mustafa¹, Sami A. Zbaar², Marwan Salah Salman³

¹M.Sc. Student, Medical Biochemistry, Kirkuk Health Directorate, ²Ph.D. Medical Biochemistry, College of Medicine, Tikrit University, ³Ph.D. Ophthalmology, College of Medicine, Tikrit University

Abstract

Diabetic retinopathy (DR) is a retinal disease which is one of the most severe microvascular complications occurring due to diabetes mellitus and is a major cause of blindness. The aim of this work was to study the serum level of omentin-1 and its relation to diabetic retinopathy in type 2 diabetes mellitus. The study included 60 diabetic patients (30 patients T2DM complicated with DR and 30 patients T2DM not complicated with DR). The study also included 30 healthy control individuals defended as subjects who apparently haven’t any chronic diseases. Thorough history taking and physical examination with calculation of body mass index (BMI), investigations were done including HbA1c, C-reactive protein (CRP) and serum omentin-1. Fundus examination was carried out by an expert ophthalmologist. The study showed that serum omentin-1 was reduced significantly (P<0.001) in DM patients (15.29±3.69 ng/ml) as compared with the control group (24.95±4.22 ng/ml), Table 1. The study also showed that serum omentin-1 was reduced significantly (P<0.001) in DR patients (12.39±2.21 ng/ml), comparing with DM patients without retinopathy (17.52±2.28 ng/ml). The study revealed that the highest mean of HbA1c was found in DM patients (8.39±1.62 %) as compared by the control group (4.91±0.43 %) (P<0.001), Table 3. The study also found that HbA1c was elevated significantly (P<0.001) in DR patients (9.38±1.65 %) comparing with DM patients without retinopathy (7.66±0.79 %) (P<0.001). The study showed that, the highest mean of serum CRP was recorded in DM patients (7.89±1.76 mg/dl), as compared with the control group (4.51±0.72 mg/dl) (P<0.001), Table 5. The study also found that CRP was elevated significantly (P<0.001) in DR patients (9.37±1.11 mg/dl) as compared with diabetic without retinopathy patients (6.41±0.73 mg/dl), The study showed that 60% DR patients suffered from T2D for more than 9 years and 40% suffered DM for 7-9 years while all diabetic patients without retinopathy were suffered from T2D for ≤ 9 years with a significant relation between Dr and the duration of diabetes (P<0.001). The study showed negative correlation of serum omentin-1 concentrations with duration of diabetes, BMI, HbA1c and CRP. From this study we can conclude that serum omentin-1 levels are correlated with the presence and severity of DR.

Keywords: Omentin-1; Type 2 diabetes mellitus; Diabetic retinopathy; HbA1c.

Introduction

Diabetic retinopathy (DR) is a chronic ocular complication of diabetes that is seen to some degree in approximately one-third of diabetic patients(1). Approximately one-third of patients with diabetic retinopathy have vision-threatening retinopathy (i.e., diabetic macular edema, severe non-proliferative diabetic retinopathy, or proliferative diabetic retinopathy)(2). The rate of progression varies depending on the duration of the disease, glycemic control, hypertension, and genetics. Proliferative diabetic retinopathy (PDR) is diagnosed in the presence of retinal or disc neovascularization, a consequence of retinal ischemia(3). Overall, the rate of progression to PDR and severe vision loss has decreased in the last two decades, most likely due to improvement in diabetic care(4). The risk of developing advanced PDR correlates directly with markers of glycemic exposure (such as HbA1c, duration of diabetes), hypertension, cardiovascular disease events, and albuminuria and inversely with age at diabetes diagnosis and, surprisingly, smoking(5). Omentin-1 is a novel peptide adipocytokine which was first acknowledged from cDNA library
consisting of human omental white adipose tissue (WAT)\(^6\). It is an adipocytokine which is released from omental and epicardial adipose tissue; and also from blood vessels, intestinal and respiratory airway goblet cells, mesothelial cells and ovary. The major effects of this secretory adipokine are the positive influences on insulin sensitivity and reduction of inflammation\(^7\). In human adipocytes, it has been found to play a role in promoting insulin-induced glucose uptake via protein kinase B (PKB) phosphorylation \(^8\). It mainly acts by suppressing ERK/NF-KB pathway or p38/JNK pathway mediated inflammation. In patients with obesity, insulin resistance and DM, the circulating concentration of omentin-1 is found to be reduced. As it is a protective molecule against insulin resistance and inflammation, it is worthwhile to study the role of omentin-1 in the pathogenesis of diabetic retinopathy\(^9,10\). In this study, we aimed to assess and compare the level of omentin-1 in the serum of patients with type 2 diabetes mellitus with and without diabetic retinopathy.

**Materials and Method**

This case-control study was carried out in Kirkuk city from the period started from 1\(^\text{st}\) of December 2019 to the end of February 2020. The study included 60 diabetic patients (30 patients T2DM complicated with DR and 30 patients T2DM not complicated with DR), their age between 45–64 years, these patients who attended Kirkuk General Hospital. Diabetic retinopathy was defined according to Fundus examination which carried out to all participants by an expert ophthalmologist. The study also included 30 healthy control individuals defined as subjects who apparently haven’t any chronic diseases. All participants were subjected to thorough history with special emphasis on age, sex and duration of DM. Complete physical examination performed to all subject with estimation of weight and height to calculate body mass index (BMI). Investigations included HbA1c by immunofluorescence technique (i-chroma II), C-reactive protein by immunofluorescence technique (i-chroma II), urine albumin creatinine ratio by testing micro-albumin and creatinine in urine (manual biochemical kits), and serum omentin-1 level was measured using an enzyme-linked immune sorbent assay.

**Exclusion Criteria:** Type 1 diabetes, Diabetic nephropathy (UACR more than 30 mg/g), Diabetic neuropathy, Chronic inflammatory diseases (e.g. rheumatoid arthritis), collagen disease, and chronic infections, History of malignancies, Heart diseases.

**Statistical Analysis:** Computerized statistically analysis was performed using Minitab version 23 statistic program. Comparison was carried out using Chi-square \((X^2)\), T-Test probability and ANOVA (analysis of variance). The \(P\) value\(>0.05\) was considered statistically significant, while for those which its \(P\) value was greater than 0.05 considered non-significant statistically.

**Result**

The study showed that serum omentin-1 was reduced significantly \((P<0.001)\) in DM patients \((15.29\pm3.69 \text{ ng/ml})\) as compared with the control group \((24.95\pm4.22 \text{ ng/ml})\), Table 1. The study also showed that serum omentin-1 was reduced significantly \((P<0.001)\) in DR patients \((12.39\pm2.21 \text{ ng/ml})\), comparing with DM patients without retinopathy \((17.52\pm2.28 \text{ ng/ml})\), Table 2.

**Discussion**

The study revealed that the highest mean of HbA1c was found in DM patients (8.39±1.62 %) as compared by the control group (4.91±0.43 %) (P<0.001), Table 1. The study also found that HbA1c was elevated significantly (P<0.001) in DR patients (9.38±1.65 %) comparing with DM patients without retinopathy (7.66±0.79 %) (P<0.001), Table 2. In agreement, Al-Ramadhan(11) study showed that, HbA1c was elevated significantly in DR group followed by DM patients and indicating that poor glycemic control is a strong predictor for the development of DR. The elevated levels of HbA1c in DR patients may be due to their induction of retinal inflammation and vascular leakage due to their effect on blood vessels which may lead to retinal cell death(12).

The study showed that the highest mean of serum CRP was recorded in DM patients (7.89±1.76 mg/dl), as compared with the control group (4.51±0.72 mg/dl) (P<0.001), Table 3. The study also found that CRP was elevated significantly (P<0.001) in DR patients (9.37±1.11 mg/dl) as compared with diabetic without retinopathy patients (6.41±0.73 mg/dl), Table 4. Our findings were also in agreement with the study done by Du et al (13) and Yasir et al (14), they found the hsCRP level was elevated more frequently in DR patients followed by NDR patients as compared with the control group. Moreover, AL-Harbi (15) data indicated that, serum CRP level had significant increase in T2DM group compared with control group.

Based on the previous investigation of CRP, it has been hypothesized that elevated CRP levels may be beneficial in the pre-proliferative stages of DR by relieving ischemia, up-regulating the expression of vascular endothelial growth factor A and thus increasing retinal perfusion(16). Collectively, the role of CRP in the inflammatory process is rather complicated as this protein may initiate and/or modulate multiple responses of the host and in this current study it is suggested that CRP may play a protective role in the DR pathogenesis(17).

Table 5 shows that 60% DR patients suffered from T2D for more than 9 years and 40% suffered DM for 7-9 years while all diabetic patients without retinopathy were suffered from T2D for ≤ 9 years with a significant relation between DR and the duration of diabetes (P<0.001). Cheng et al (18) revealed that, the presence of DR is strongly related to the duration of diabetes, with an approximate three-fold increase in vision-threatening DR in those who have had DM for 10 years or more. Menzel et al (19) also studied association of various risk factors with diabetic retinopathy and found significant relation of HbA1c with DR (P<0.001). Zhou et al (20) showed in similar study a significant relation of diabetic retinopathy with duration of diabetes (P<0.03). There is a strong positive relationship between the duration of diabetes and prevalence and progression of DR(21). The prevalence of any DR increased from 21.1% in subjects with diabetes of 10 years duration to 54.2% with duration between 10 and 20 years to 76.3% with ≥20 years disease duration in the META-EYE study (22).

The study showed that serum omentin-1 was reduced significantly (P<0.001) in DM patients (15.29±3.69 ng/ml) as compared with the control group (24.95±4.22 ng/ml), Table 6. The study also showed that serum omentin-1 was reduced significantly (P<0.001) in DR patients (12.39±2.21 ng/ml), comparing with DM patients without retinopathy (17.52±2.28 ng/ml), Table 7.
Korany et al. (23) also found that, serum omentin-1 level was significantly lower in diabetic patients compared with the control, and in DR compared with diabetics without DR. Omae et al. (24) also found that, serum omintin-1 was reduced significantly (P<0.001) in DR patients, comparing with DM patients without retinopathy. Additionally, in recent meta-analysis study showed that serum level of omentin was significantly lower in T2DM compared to healthy controls (25).

The possible explanation for this phenomenon is that, as omentin-1 could increases insulin sensitivity, its decrease may be the cause of impaired glucose homeostasis in prediabetic patients (1,3).

Omentin-1 is important for glucose metabolism-invito, omentin-1 increases insulin signal transduction by activating the protein kinase B and enhances insulin-mediated glucose transport in adipocytes. A clinical study of patients suffering from diabetes mellitus, reported that serum and vitreous omentin levels were related to the severity of DR, and experimental investigations have shown that omentin has a potent vasodilatory effect in isolated vessels mediated by endothelium derived nitric oxide, a strong vasodilator of the retinal arterioles (26).

The study showed negative correlation between omentin-1 and duration of DM, Figure 1.

Korany et al. (23) also found that, serum omentin-1 level was negatively correlated with DM duration. Interestingly, El-Mesallamy et al. (27) also found that, omentin-1 was negatively correlated with duration of DM.

The study showed negative correlation between omentin-1 and BMI of DM patients, Figure 2.

In agreement with this finding, Korany et al. (23) found that, serum omentin-1 level had a negative significant correlation with BMI in DM patients. Some studies have also shown that omentin-1 serum levels were generally lower in obese groups with or without type 2 DM (28). In a study performed by de souza Batista et al. (29) plasma levels of omentin were measured in lean, overweight, and obese, otherwise healthy subjects. The authors found that plasma omentin levels were highest among the lean subjects and these levels were inversely correlated with BMI. Our results were agreed with the findings reported by other studies that demonstrated significant negative correlation between plasma omentin-1 concentrations and patients BMI (30-31).

Estimation Level of Leptin and Resistin in Sera Patients with Type Two Diabetes among Iraqi Peoples

Alaa Sami Husain¹, Ali Yakub Majid², Ahmad Sa,adi Hassan³

¹B.Sc. Medical Laboratory Science Technology, Baghdad/National Blood Transfusion Center/Medical City, Baghdad, Iraq, ²Ph.D. Biochemistry, Poisoning Consultation Center/Specialized Surgeries Hospital, Medical City, Baghdad, Iraq, ³Ph.D. Chemistry, Medical Lab Technique, College of Health and Medical Technical, Middle Technical University, Baghdad, Iraq

Abstract

Leptin is a protein hormone containing 167 amino acids, firstly discovered in 1994 by Jeffrey M. Friedman, It is secreted by adipocytes and has been found to regulate food intakes through central neuroendocrine mechanisms. Resistin has been found to be generated and released via adipose tissue to serve endocrine functions which are likely to be associated with insulin resistance.

Aim: The aim of this study determination of leptin and resistin hormone level in serum of male and female with type 2 diabetic patients and healthy control in Iraq.

Subject and Method: This respective study carried out at three main medical facilities in Baghdad; National Center For Teaching Laboratories, Poisoning Consultation Center/Specialized Surgeries Hospital and the National Blood Transfusion center in Medical City,Iraq during the period from November 2019 to February 2020. It was included 100 participants; divided into 2 groups(50 patient with type 2 diabetes and 50 healthy control).

Results: The result of serum leptin showed that there was highly significant difference when comparing the mean of total serum leptin of patient group with that of the control group. While the mean of total circulating resistin in T2DM patient and healthy with no significant difference between the two groups.

Conclusion: Increased serum leptin level in type 2 diabetes patient than healthy control and no significant difference in serum resistin level when compared between diabetics and control

Keywords: Type Two diabetes, Leptin, Resistin.

Introduction

Diabetes is a complex, chronic disorder requiring continuous medical care. It is a serious, long-lasting or chronic disorder that occurs when there are raised levels of glucose in a person’s blood because their body cannot produce any or enough insulin, or cannot effectively use the insulin it produces. Insulin is an essential hormone produced by the beta cells in the islets of Langerhans in the pancreas. It allows glucose from the bloodstream to enter the body’s cells where that glucose is converted into energy. The main function of this hormone is to lower the level of glucose in the blood by promoting the uptake of glucose by the adipose tissue and skeletal muscle, known as glycogenesis. Ultimately to the homoeostasis of glucose which leads to complications like retinopathy, atherosclerosis, cardiovascular diseases, nephropathy and peripheral neuropathy. Type II diabetes usually affects people aged over 40 years. This metabolic disorder is characterized by target tissue resistance to insulin, It is epidemic in industrialized societies, and is strongly associated with obesity, Thus obesity is generally considered to be a strong risk factor for the later development of T2DM, and at times, they frequently occur together. Statistics show that 60%–90% of all patients with T2DM are or have been obese. Leptin originates from of the Greek root leptos, meaning...
Leptin is predominantly derived from white adipose tissue and released as a 16 kilo Dalton [kDa] Non-glycosylated protein with LEP encoding gene, also referred LEP gene in human. Leptin binds to its receptor (LEPR) expressed in the central nervous system and peripheral tissues and performs its biological acts. Generally, hyperleptinemia has been linked with T2DM, insulin resistance and complications of the vascular diabetes. Antidiabetic medicine can reduce leptin levels including sitagliptin, metformin, pioglitazone and liraglutide. Resistin is a putative adipocyte-derived signaling of polypeptides hormone(ADSF) the Molecular weightis 12.5kDa, with a length of 108 amino acids That is generated and released into the bloodstream from white adipose tissue, primarily by macrophages in human Resistin functions as the pathogenic factor which results in insulin resistance by antagonizing the action of insulin, thus raising gluconeogenesis and impairing the absorption of hepatic glucose.

**Subjects and Method**

This respective study was carried out at three main medical facilities in Baghdad; National Center For Teaching Laboratories, Poisoning Consultation Center/ Specialized Surgeries Hospital and the National Blood Transfusion center in Medical City, Iraq during the period from November 2019 to February 2020. It included 100 participants; divided into 2 groups(50 patient with type 2 diabetes and 50 healthy control) and 2 subgroups. The type 2 diabetic patient group were subdivided into(25 male, 25 female) with age (30-65) and healthy control group subgroup (25 male,25 female) with age (29-65). All the information about each individual in the above groups including data about their age, height, weight, cigarette smoking, family history, duration of disease, habit and medication were collected by filling a questionnaire case sheet for each patient. Statistical Analysis: Data was conducted by using SPSS program (Statistical Package For Social Science) version 24.

**Method**

Leptin and resistin was estimated by using ELISA (Enzyme linked immunosorbent assay) Kit from SHANGHAI YEHUA Biological Technology, HbA1c was estimated for each type 2 diabetic patient(T2DM) and healthy control by using Arkray Adam HA-8160 HbA1c is a fully automated analyser is used for estimation that uses high performance liquid chromatography (HPLC) cation exchange method.

**Results**

The study included 50 Males and 50 females were included in this study. The age range for patients and control groups was (30-65) and (29-65) years respectively as show in table(1-1). The Mean± Std. of glycatedhemoglobin (HbA1c %) for patients and control . The mean for patient was highly significantly higher than that of the control group (7.83±1.36% and 5.47±0.234 %respectively) as shown in table (1-2).

The result of serum leptin level summarized in the table (1-2) and figure (1-1) showed that there was highly significant difference when comparing the mean of total serum leptin of patient group (44.48±12.41ng/ml) with that of the control group(38.75±7.61ng/ml). While there was no significant difference between males and females of the control group in mean serum leptin level (36.982±6.705 and 40.522±8.169 respectively),
but there was significant difference among male and female patients (P<0.05). And the results in table (1-3) and figure (1-2) showed the mean of total circulating resistin in T2DM patient and healthy control (10.18±3.87 and 9.71±2.02 ng/ml respectively) with no significant difference between the two groups. Furthermore, there was no significant difference between male and female patients (9.208±3.632 and 11.1520±3.933 ng/ml respectively). Similarly, no significant difference in circulating resistin between male and female control (P>0.05).\textsuperscript{13}

Discussion

HbA1c analysis in the blood provides proof of the average blood glucose levels through the previous 2 to 3 months, which is estimated half-life of red blood cells (RBCs). HbA1c provides a most reliable measure of chronic glycemia and is well associated with the risk of long term complications of diabetes, so it is widely considered the test of choice for chronic diabetes management and monitoring\textsuperscript{14}.

The association between leptin and diabetes mellitus in humans was examined in few studies. But Leptin is an essential hormone derived from adipose tissue which has been shown to be involved in patho-physiological processes relating to diabetes. This study is consistent with Kumar, et al.,\textsuperscript{15} as the study found that the level of leptin is higher in diabetic patients compared to healthy subjects\textsuperscript{15}. The human laboratory studies indicate levels of leptin are closely linked to body fatness. Serum leptin is reportedly a good biomarker of obesity. Thus, body fat can mediate an association between serum leptin and diabetes mellitus\textsuperscript{16}.

Another study was agreement with these finding Gupta & Mukherjee., who was reported that the level of serum leptin were significantly increase in diabetic patient when compared to healthy control\textsuperscript{17}. In addition to that Osegbe, et al., found differences in the concentration of leptin levels, female with T2DM has higher serum leptin than healthy female and this compatible with our study\textsuperscript{18}. Females with diabetes have a higher concentration of leptin compared to males, and this is consistent with Diwan, et al., study in India reported that the serum leptin levels in females were higher than in males. In addition, the serum leptin levels in diabetics were significantly higher than in nondiabetics\textsuperscript{19}. On the other hand, we found that there was no difference in the level of leptin in males suffering from diabetes compared to healthy controls, and These result was compatible with Zamil.,2019 study in Iraq did not find any significant association in leptin concentration between male with T2DM and healthy control\textsuperscript{20}.

In present study there was no signficant difference between type 2 diabetic patient and control . This study is in agreement with Zamil .2019 a study in Baghdad that
concluded that there is no difference in the concentration of resistin in patients with type 2 diabetes and among healthy subjects. The main biological effects of resistin are associated with increased blood glucose levels and obesity in some animal models, explained in part as a result of increased production of hepatic glucose. Resistin is an adipokine that acts as a biomarker for inflammation and a mediator of insulin resistance linked to obesity. Resistin in humans reduce insulin-stimulated glucose in the isolated adipocytes. The fundamental mechanisms these effects remain unclear while data aim to suppress resistin AMPK activity, primarily in the liver, due to cytokine stimulation-3 suppressor activation. These results are also in agreement with Pfützner, et al., No significant association was found between serum resistin levels and obesity and insulin resistant clinical measures. Bu et al. also found resistin levels in both the T2DM and the normoglycemic group had no relationship to insulin resistance.

Abstract

Placentas from gestational diabetes mellitus (GDM) are Patterns of fetoplacental angiogenesis of GDM often hypervascularized. Placenta is a mirror that reflects the well-being of the fetus and continuously undergoes a change in weight, structure, shape and function in order to support the well-being of the fetus.

Aim of Study: In this work we attempted to identify villous vascular and morphological changes in a group of term placentae from mothers with GDM complicating pregnancy.

Objective: To analysis on the possible gross morphological changes and Patterns of fetoplacental angiogenesis of GDM.

Materials and Method: The study was observational, analytical and cross sectional. The patients under this study were selected from the Obstetric of AL-Emam AL-sadiq in the Babylon province. A total of eighty samples were collected from women completed weeks of gestation. Among them, 40 samples were from mothers having GDM, 40 belonged to normal pregnancy (control group). The placentas were examined to measure their weight, diameter, thickness, cotyledons number, Insertion of umbilical cord, Vascular pattern and Fasting blood glucose were determined by enzymatic method using Envoy® 500 reagents .Beta chorionic gonadotrophin, progesterone and estradiol were determined using chemilumiscence immunoassay technique on MAGLUMI 600 analyzer.

Results: In this study, the GDM group showed significantly higher values for the variables of the weight, thickness,diameter, number of cotyledons, Patterns of fetoplacental angiogenesis of GDM and placentas hypervascularized as compared to normal group. Consequences of GDM include increased risk of macrosomia and birth complications in the infant. Fasting plasma glucose FBG, β-HCG, P4, E2 were increased in the gestational diabetic women.

Conclusion: From the findings of this study, placental variations in diabetic and normal mothers during pregnancy. The variations in placental weight, thickness, diameter and fetoplacental angiogenesis found in gestational diabetic mother may be a long term compensatory mechanism, aiming to secure a sufficient nutrient supply to support the growth of the foetus. So, postnatal examination of the placenta can yield information that may be important for immediate and late management of the mother and neonate. Fasting plasma glucose FBG, β-HCG, P4, E2 were increased in GDM group was aimed at assessing placental peptides and maternal factors as potential predictors of the development of gestational diabetes among pregnant women. GDM appears to effect the microvascular remodeling at angiogenesis. So gestational diabetes mellitus (GDM) need to be identified early in pregnancy and managed to maintain a normal vasculature and prevent neonatal mortality and morbidity if rapid intervention is completed.

Keywords: Placenta, GDM, Gross morphology, vasculogenesis, angiogenesis.

Introduction

The placenta is a transient organ that forms during pregnancy to support the growth and development of the fetus. During placental development, trophoblast cells differentiate through two major pathways. In the villous pathway, cytotrophoblast cells fuse to form
multinucleated syncytiotrophoblast. In the extravillous pathway, cytotrophoblast cells acquire an invasive phenotype and differentiate into either (first) interstitial extravilloustrophoblasts, which invade the decidua and a portion of the myometrium, or (second) endovascular extravilloustrophoblasts, which remodel the maternal vasculature. These differentiation controlled by the interplay of oxygen tension, transcription factors, hormones, growth factors, and other signaling molecules. Abnormal placental development, the limited invasion of trophoblast cells into the uterus and the following failure of the remodeling of maternal spiral arteries.\(^1\)

The vascularity of placental tissue is dependent on various factors of which fetomaternal hypoxia plays a major role. Hypoxia can be of different types and each type influences the vascularity of the terminal villi. Chorangiosis was the most frequently identified lesion in the GDM group while normal group had normal villous vasculature. Maternal diseases have a major role in disrupting the placental vasculogenesis and angiogenesis by making a hypoxic that may distress the fetus harmfully. The trophoblasts is epithelial cells have functioning as a precursor for the syncytiotrophoblast and extravilloustrophoblasts (EVT). cytotrophoblasts fuse and undergo biochemical differentiation, giving rise to the multinucleated syncytiotrophoblast. Cytotrophoblasts may also acquire invasive properties, forming the EVT. These trophoblasts are able to invade and remodel maternal tissues (interstitial EVT) and uterine spiral artery (endovascular EVT), leading to the widening of artery lumen, reducing the resistance against blood flow that irrigates the fetus. EVT may also invade and remodel uterine glands (endoglandular EVT), which is important to provide nutrition to the embryo. Trophoblast interact with each other and with decidual cells, Hofbäüer cells, endothelial cells, vascular smooth muscle cells, providing a sole microenvironment that is vital for pregnancy outcome and fetal development.\(^2\)

Fetal growth requires remodelling of maternal spiral arteries to provide an adequate maternal blood supply to the placenta. This arterial transformation is achieved by placental trophoblast cells, which invade into the uterine wall. Fetal growth restriction is associated with reduced remodelling of maternal spiral arteries by trophoblast cells. In normal pregnancy, extravilloustrophoblast cells migrate as far as the myometrium and also infiltrate into the arterial media and endothelium of maternal spiral arteries. This results in dilatation and increased flow of maternal blood at low pressure into the intervillous space. In pregnancies affected by gestational complication, the depth of trophoblast invasion is reduced with less spiral artery remodelling. Blood flows at higher pressure and is more pulsatile, resulting in placental stress, reduced placental development and poor fetal growth. Under-invasion is associated with fetal growth restriction; but if invasion is excessive large babies can result. A growing body of evidence is controlled by interactions between killer-cell immunoglobulin-like receptors expressed on maternal uterine natural killer cells (uNK).\(^3\)

Fetal growth in utero depends on the development of a good maternal blood supply to the placenta that requires modification of the uterine spiral arteries. Trophoblast cells from the placenta invade deeply into the stroma to effect arterial conversion. The extravilloustrophoblast cells (EVT) encircle the arteries, and then cause direct destruction of the smooth muscle of the arterial wall with complete loss of vasoconstriction. Trophoblast cells only move down the inside of the arteries to replace the endothelium and functionally modify the media.\(^4\)

The angiogenic process is divided broadly into three major steps including the initiation of the angiogenic response, endothelial cell (EC) migration, proliferation and tube formation, and finally the maturation of the neovasculature. Angiogenesis is a complex, highly regulated process, involving the sprouting, splitting, and remodeling of the existing vessels.\(^5\)

### Material and Method

**Inclusion Criteria**

Pregnancy women with gestational diabetes mellitus.

**Exclusion Criteria:** Pregnant women with a complication, such as gestational hypertension and pregestational DM (Preeexisting type I and Type II diabetes mellitus), had a twin pregnancy, and hypertension or other chronic diseases were excluded.

A cross-sectional case-control study from January to March 2019. A total of 80 pregnant women 40 fore each group. The study procedure was approved by the ethics committee of the First Affiliated Hospital Department of AL-Emam AL-sadiq in the Babylon province. Informed agreement was obtained from each participant. Placentas and umbilical cords were collected after delivery from full-term within 36th to 40th week of gestation, were included in this study of normal and gestational diabetic groups. Patients and normal pregnant women, who were attended a pretested guided questionnaire.
The participant females were asked to undergo for Oral Glucose Tolerance Test (OGTT). The control women were within the accepted normal ranges of blood glucose level from 90 to 115 mg/dL throughout gestation while the GDM women initially showed levels ranging from 120 to 160 mg/dL. 6

**Macroscopic Examinations:** Morphological variables of each placenta groups were studied: Immediately after the delivery, within 20 minutes after delivery placentas and umbilical cord were collected after delivery from 40 full-term normal or 40 full-term gestational diabetic. The placental membranes were clipped and blood coagulants were removed. The placental weight, diameter and thickness were recorded. Diameter of the placenta. The membranes were trimmed from their edges. Blood was removed gently from both surfaces with cotton wool and the umbilical cord was cut about 2 cm proximal to its insertion. Then the maximum diameter of each placenta was measured with a metallic scale graduated in centimeters, the second maximum diameter was recorded. Then the mean of these two measurements was considered as the diameter of each placenta. Placental thickness measured by piercing a metallic scale through central part including the whole thickness of the placenta were taken from the center of the placenta beside the site of attachment of the umbilical cord. Then separation of the cotyledons to make them prominent in the maternal surface. Counting was started from left side of one end and going through rightward. In this way, counting was continued in spiral manner.

For histological studies, full depth tissue samples. The tissue was cut into ~0.5 cm3 pieces from placenta on the central and marginal areas. Normal saline was used to wash the pieces before they were dissected into small sections, were placed in 10% formal saline for 24-48 hours and were subsequently embedded in paraffin. The 4-µm thick sections were stained with Haematoxylin & Eosin. Numbers and diameter of blood vessels of TV were measured using stage, ocular and reticule micrometers.

Fasting blood glucose were determined by enzymatic method using Envoy® 500 reagents (Vital Diagnostics, USA). Beta chorionic gonadotrophin, progesterone and estradiol were determined using chemilumiscence immunoassay technique on MAGLUMI 600 analyzer. The sandwich chemilumiscence immunoassay technique was used, adhering to the manufacturers’ protocol. The statistical significance of difference between the two groups was evaluated using the Student’s paired t-test.

**Result**

The results in this work, table(I) shows that the weight of placenta is an significant and functionally important parameter as it is related to foetal metabolism and villous area. So placental weight, diameter, central thickness and number of cotyledons per placenta 658±36.5, 22.7±3.44, 167.1±12.22 and (20.55±5.06) respectively Increase in diabetic mothers comparison with the normal placenta. In recent study variation was found in umbilical cord insertion between the two groups. Site of umbilical cord insertion was eccentric (37 vs 25), centric (3 vs 10), marginal (0 vs 3) velamentous (0 vs 2) respectively. Vascular magistral pattern was one case in the GDM group while it was more frequently observed in the normal group. mean birth weight of babies were 3659±123. Ratio of newborn weight to placental weight was 5.8±0.5 reduced in GDM compared to controls. The result of recent study is sex male/female was 24/16 vs 19/21 . In this study the preterm birth only three was in GDM group. Apgar score the mean was 8.9±0.5 vs7.3±0.2, the mean of Apgar score was less than normal group. (Table 2) was revealed the number of BVs were increased in the GDM group compared to normal was 10.50±3.33 vs 19.87±4.62, while its mean diameter of blood vessels was 0.04±0.03 vs 0.03±0.02 found to be significantly decreased. (Table 3) Fasting plasma glucose FBG (mmol/l) 6.30±1.02, β-HCG Iu 5001.0±0.01, P4 (ng/ml) 72.74±10.53, E2 (pmol/L 4501.0±1334.33 were increased in the gestational diabetic women. Histological finding Fig. 1(left): The GDM placenta showed increased syncytial knots, thickening of vasculosyncytial membrane, massive fibrinoid necrosis and chorangiosis as fig(1) and Fig.2(right): placental villi showing the Hofbauer cells within the edema and fibrin deposition.
Fig. 1 (Left): The GDM placenta showed chorangiosis with Fetal vessel thrombosis, increased thickening of vasculosyncytial membrane (arrow).

Fig. 2 (Right): Placental villi showing the Hofbauer cells within the edema, fibrin deposition, and infarction villi.

Discussion

This study was started to determine the comparative between morphological observation of normal and GDM groups included variables as the following table (1).

Site of umbilical cord insertion eccentric and central in most of placentas except in three cases in which there was marginal insertion and two cases velamentous of placenta in GDM group. Vascular magistral pattern was one case in the GDM group while it was more frequently observed in the normal group. The dispersal pattern showed successive divisions of umbilical vessels with decreasing caliber from center to periphery while the magistral pattern showed fewer divisions of blood vessels.
with noticeably no decrease in diameter from center to periphery. Reduction of uteroplacental circulation results in foetal hypoxia & intrauterine growth restricted IUGR. Because macrosomia affects the fetal portion of the placenta, the placental weight, diameter, and central thickness in diabetic mothers increase. The basal lamina of the chorionic capillaries is part of the placentation barrier increase in its thickness. The result of recent study is sex male/female was 24/16 vs 19/21 this observation agreement with study. Macrosomic newborns are at an increased risk with preterm birth and hypoglycemia. GDM is associated with an increased risk of additional pregnancy complications, including preterm birth and surgical delivery of the baby is required. In this study Apgar score the mean was 8.9±0.5 vs7.3±0.2, the mean of Apgar score was less than normal group. A study of 94 patients with GDM showed lower Apgar scores and increased incidence of perinatal morbidity of neonates compared to neonates of mothers without impaired glycemic control. GDM appears to effect the microvascular remodeling at angiogenesis at 3rd trimester of pregnancy. insulin as a key factor playing a modulatory role in GDM-associated altered angiogenesis. The angiogenic response to VEGF not only depends on its total concentration, but also on the spatial Vascular magistral pattern was one case in the GDM group while it was more frequently observed in the normal group. The dispersal pattern showed successive divisions of umbilical vessels with decreasing caliber from center to periphery while the magistral pattern showed fewer divisions of blood vessels with noticeably no decrease in diameter from center to periphery. Reduction of uteroplacental circulation results in foetal hypoxia & intrauterine growth restricted IUGR. These factors lead to endothelial cell organization within vessels as tip and stalk cell phenotypes ultimately resulting in dynamic developing and branching angiogenesis.

Increased number of capillaries (Chorangiosis). Thickened vessel walls due to endothelial proliferation and thickening of the basement membrane were also identified. Infraction of the villi, fibrin depositions were found in the placenta on histological observations. The decreased elasticity of vessel wall leads to vascular hardening and increased susceptibility to arteriosclerosis, which can lead to a narrowing of the maternal blood vessel lumens, reducing the uteroplacental circulation and thickness of the placentation barrier. It has been seen that increased blood glucose levels induce oxidative stress (OS) and subsequent changes of the placentation architecture. essentially the vascular properties, which are apparent in GDM. Placental Hofbauer cells (HBCs) even in low-grade inflammatory states such as GDM. It is concerned in placental vasculogenesis and angiogenesis. This indicates a regulatory, tissue remodeling rather than an inflammatory macrophage phenotype. Also, it was shown that even inflammatory pathologies. HBC are thought to play a role in maternal immunological tolerance against the fetus. The basal lamina of the chorionic capillaries is part of the placentation barrier; therefore, the increase in its thickness will make the placentation barrier thicker overall, which can lead to a reduction in the oxygen transport and other nutrients through the barrier. In response to this reduction in pO2, the terminal villi exhibit a hyperplasia that may be partially responsible for the increased placental weight in the diabetic group. The distance between maternal and fetal circulation is increased because of an increase in the chorionic villi on the surface as well as greater thickness of the syncytiotrophoblast basal membrane due to an increased type IV collagen deposition. The stroma between the villi is edematous, the capillary surface is enlarged due to of vascular neoformation and a greater penetration of these vessels within the villi. Low oxygen partial pressure (pO2) was noticed, which would produce hyperplasia of terminal chorionic villi. In GDM the placenta suffers alterations are correlated to an oxygenation lack in the fetus and variations in the transplacental conveyance of nutrients and other alterations, causing fetal overgrowth by increasing their availability and adverse outcome. Chorangiosis was defined as the occurrence of 10 or more villi with 10 or more capillaries in 10 or more low power microscopic fields (×10). Hydropic villi were diagnosed when large terminal villi were present with edematous fluid and villous macrophages in placenta of GDM. Fetal vessel thrombosis was diagnosed when a large fetal stem villous vessel was partially or completely occluded by a thrombus. Avascular villi were diagnosed when a group of at least five fibrotic avascular villi without inflammation were seen. These trophoblasts are able to invade and remodel maternal tissues (interstitial EVT) and uterine spiral artery (endovascular EVT), leading to the widening of artery lumen by remodeling normally, reducing the resistance against blood flow that irrigates the fetus. They recommends that all women undergo a fasting plasma glucose (FPG) test at their first prenatal visit (where a reading ≥92 mg/dL is revealing of GDM), and that women with FPG <92 mg/dL undergo a 2-h 75 g oral glucose tolerance test (OGTT) between 24 and
28 weeks’ gestation.\textsuperscript{19} The hormones produced by EVT contribute to vascular and uterine tissue remodelling and to regulate EVT migration and invasion.\textsuperscript{1} They demonstrated that patients with HCG > 1.04 MoM (Multiple of the Median) and unconjugated E\textsubscript{3} (uE\textsubscript{3}) ≤ 0.88 MoM measured in a triple test were associated with GDM development.\textsuperscript{20} Human chorionic gonadotropin (hCG) is a pregnancy-specific hormone that regulates placental development. hCG concentrations vary widely throughout gestation and differ based on fetal sex. Abnormal hCG concentrations are associated with adverse pregnancy outcomes including fetal growth restriction. This was the case for both male and female fetuses. In contrast, high hCG concentrations during the late first trimester were associated with increased fetal growth amongst female, but not male fetuses. Low hCG in the late first trimester is associated with lower birth weight due to a decrease in fetal growth. Fetal sex differences exist in the association of hCG concentrations with fetal growth.\textsuperscript{21} It was reported that the concentrations of the steroids (progesterone and estrogen) are increased in women with GDM.\textsuperscript{22}

Coinfection of Enteric Viruses in Elderly Patients with and without Acute Gastroenteritis in Hilla City

Dalalabdulkareem¹, Ghanim Aboud Jaber Al-Mola²

¹ M.Sc. Student, University of Babylon, College of Science for Women, Dept. of Biology,
² Prof. Dr., University of Babylon, College of Science for Women, Dept. of Biology

Abstract

This study was conducted to find out the extent of the presence of mixed viral infections for elderly people with and without acute enteritis. 100 stool samples were collected, 50 samples of which were for people with acute enteritis and the other 50 samples were from non-infected people. These mixed infections were obtained within the group of infected patients, where the age group 45-49 was the most infected and then the sample was prepared by making several treatments For the purpose of performing the PCR molecular test. As the results of this test indicated that 15 samples contain Astrovirus from the total number of samples. And 7 samples containing norovirus from the total number of samples. while the test recorded 10 samples containing the sapovirus from the total number of samples. The study showed that the relationship between acute gastroenteritis and gender revealed that male infection is close to female infection, as there is no significant difference between them. In regard to mixed infection the study showed that the number of samples infected with Rota, Adeno, and Astro viruses was 4 positive samples, while the number of samples containing Rota adenonoro is only one positive sample is the same as the number of samples containing only Astro and Noro that were recorded as a result of acute enteritis. The results also indicated that three coinfection positive samples of rota, adeno and sapo. As tested by Rapid test and PCR technique.

Keywords: Coinfection, norovirus, sapovirus, elderly.

Introduction

Acute gastrointestinal is one of the most common diseases in humans, and continues to be a significant cause of mortality and morbidity worldwide. Recently the estimates of mortality associated with diarrhea declined, however the majority of deaths still occur in developing countries and thus urgent intervention is needed for the prevention of these diseases. The incidence of acute gastrointestinal infection rises in the aged group under five years and in those aged over 75. At all ages incidence in men was higher than in women in elderly patients¹. The common enteroviral infection rotavirus, adenovirus, astrovirus, norovirus and sapovirus the most common etiology of acute gastroenteritis (AGE) among infants and young children. Acute gastrointestinal symptomatology—including diarrhea and nausea/vomiting—in patients². Rotaviruses are non-enveloped double-stranded RNA (dsRNA) viruses that have a complex architecture of three concentric capsids that surround a genome of 11 segments of dsRNA³. Human adenoviruses (HAdVs) are nonenveloped, double-stranded DNA viruses in the family Adenoviridae; seven species (A–G) and >60 genotypes are known to cause human infection⁴. Astroviruses are nonenveloped, positive-sense single-stranded RNA viruses that cause gastrointestinal illness⁵. Human noroviruses have a non-segmented positive-strand RNA genome, of approximately 7.5 kb⁶. Sapovirus, a member of the Caliciviridae family, is a single-stranded positive sense RNA virus, with 4 genogroups, that infect humans ⁷.

Materials and Method

During a period (from September 2019 to January 2020) 100 stool sample from adults (equal to or more than 45 years) who were hospitalised with or without acute gastroenteritis (AGE) their primary diagnosis for in enteric virus from four hospitals in the Babil Governorate Region with a total population of 18000,000 people.
These samples were taken from (Imam Sadiq Hospital, Al-Kiif Hospital, Margan Hospital and Hashemia Hospital).

Stool samples were collected in clean sterile containers within 48 hours of admission. Each sample was labeled according to the date of collection and the sample number. The samples were kept at 4°C at the hospital before being transported to the College.

Rapid test of Rotavirus and Adenovirus (Zaragoza, Spain), stool samples and controls to reach room temperature (15-30) prior to testing. The test performed according to company instructions.

Viral RNA was extracted from stool samples by using AccuZol™ Total RNA extraction kit (Bioneer, usa) and done according to company instructions.

PCR test.

PCR was performed for molecular detection of virus based on core protein. This method was done according to\(^8\).

PCR master mix was prepared by using (AccuPower® PCR PreMix) and done according to the company instructions.

The PCR primers used for direct detection of Norovirus, Astrovirus and Sapovirus were designed by\(^9\) and PCR primers were designed in this study using NCBI Database and primer 3 plus and these primers were provided by (Macrogen. Company, Korea)

**Result and Discussion**

The total positively rate of combined viral infection in elderly patient with acute gastrointestinal infection in relation to age.

Among the 50 samples collected from elderly individuals patient with gastrointestinal symptoms the age distribution of positively rate of viral infection (rotavirus, adenovirus, astrovirus, norovirus and sapovirus) infections was detected in the age group 45-49 years were 12 at 24% for each rotavirus and adenovirus while astrovirus recorded 6 at 12% and norovirus recorded 2 at 4% followed by 9 at 18% for rotavirus and adenovirus while astrovirus has 5 at 10% The norovirus has 2 at 4% sapovirus has one infected at 2% at the age group 50-54. At The age groups 55-59, 60-64 and 65-69 years show 6, 2 and 1 for every rotavirus and adenovirus respectively at a percentage 12%, 4% and 2% while astrovirus has 1 at 2% At The age groups 55-59, sapovirus recorded one infected for each these group 55-59 65-69 and 70-74 at 2% (table 1).

**Table 1. The total of positively rate of poly- viral infection in elderly patient with acute gastrointestinal infection in relation to age.**

Viruses infect host cells releasing their genome (DNA or RNA) containing all information needed to replicate themselves. The viral genome takes control of the cells and helps the virus to evade the host immune syste10.

Infectious diarrhea is an important cause of morbidity and mortality among the elderly in the United States. The full scope of its impact has been recognized more in recent years11 can be life threatening in an elderly immunocompetent individual. The whole gastrointestinal tract can be affected by viral, however, small bowel was rarely the only site of disease, In elderly individuals, even though they are immunocompetent, may result in major complications such as bowel perforation, and it should be included in the differential diagnosis of diarrhea if it is resistant to conventional treatment21. Acute diarrheal illness is a global health problem that causes immense human misery. Military history is testament to the overwhelming power of acute diarrheal illness: Napoleon Bonaparte’s army, soldiers of the American Civil War, and German forces of World War II were pillaged by enteric infections. The French Expeditionary Force to Indochina was stricken with many enteric infections. These infections hampered military efforts and were deemed to have played a pivotal role in military defeats. The significance of enteric infection in military campaigns contributed to the US Army’s surgeon general’s decision to establish a team to assess the magnitude and to determine the cause of diarrheal outbreaks among American troops in Vietnam. With the exception of fevers of undetermined origin, diarrheal diseases were responsible for more hospital admissions than any other diseases13. The total positively rate of combined viral infection in heathy elderly individuals in relation to age. Among the 50 samples collected from elderly individuals without acute gastrointestinal infection the age distribution of positively rate of viral infection(rotavirus, adenovirus, astrovirus, norovirus and sapovirus) infections was detcated in the age group 45-49 years only astrovirusrecored 2 at 4% while astrovirus and norovirus have 1 at 2% at the age group 50-54. At The age groups 55-59 for aeah one astrovirus and sapovirus have only one infected at 2% while in this age group norovirusrecored tow infected at 4% when sapovirusrecored one infection at 2% at age group 70-74 (table 3).

Adults more than 65 years of age were the age group most commonly affected.

The mixed viral infection in elderly individuals with and without acute gastrointestinal infection

This figure showed the mixed viral infection in 100 sample collected from elderly individuals with and without symptoms. The mixed infection were found between rotavirus, adenovirus and astrovirus were more domine at 4% followed by rotavirus, adenovirus and sapovirus 3%. Then rotavirus, adenovirus and norovirus 1%, and the double infection were noticed between astrovirus and norovirus at 1% (Figure 4-1).

![Virus](image)

Figure (1) The distribution mixed viral infection in elderly individuals with and without acute gastrointestinal infection.
This could be explained by a close-knit family environment where the elderly frequently look after their grandchildren. Vomiting was, thus, associated with viral pathogens. Various factors influence symptoms and signs, including pathogen and host factors, infectious load, and mixed infections. The English re-examination study showed that about 40% of symptomatic patients harbored mixed infections the occurrence of mixed infections suggests that a wide test panel should be applied in some cases, such as for food handlers. Selective testing is necessary for cost efficiency and is widely practiced\textsuperscript{19}. Antibodies were found in 10% of serum samples from the aged. Of patients with acute gastroenteritis, showed a significant rise in antibody to adenovirus, and of the same serum samples had a significant rise in antibody to rotavirus by enzyme immunoassay \textsuperscript{20}. The PCR results of stool sample from acutgastrointestinal infection showed that the produce analysis Astrovirus form exacerbated RNA stool of patients with AGI positive for gives 15 sample with positive Astrovirus at 523bp PCR produce these results indicate the presence of Astrovirus during exacerbated of AGI while may indicated the chance of association with AGI.

![Figure (2): Agarose gel electrophoresis image that show the PCR product analysis of Astrovirus, where ladder (1500-100bp), some positive samples at (523bp) PCR product.](image1)

The PCR results of stool sample from acutgastrointestinal infection showed that the produce analysis Norovirus form exacerbated RNA stool of patients with AGI positive for gives 7 sample with positive Astrovirus at 560bp PCR produce these results indicate the presence of Norovirus during exacerbated of AGI while may indicated the chance of association with AGI.

![Figure (3): Agarose gel electrophoresis image that show the PCR product analysis of Norovirus, where ladder (1500-100bp), some positive samples at (560bp) PCR product.](image2)
The PCR results of stool sample from acute gastrointestinal infection showed that the produce analysis Sapovirus form exacerbated RNA stool of patients with AGI positive for gives 10 sample with positive Sapovirus at 401bp PCR produce these results indicate the presences of Sapovirus during exacerbated of AGI while may indicated the chance of association with AGI.

Figure (4): Agarose gel electrophoresis image that show the PCR product analysis of Saprovirus, where ladder (1500-100bp), some positive samples at (401bp) PCR product.

Sapovirus,astrovirus and Norovirus increasingly are recognized as cause of acute viral gastroenteritis (AGI). We evaluated the RT-PCR viral stool panel for detection of SaV, AstV and NoV in clinical stool samples.

A total of stools were tested using reverse transcription RT-PCR, PCR to detect and quantify SaV, AstV and NoV were detected in many age groups, especially in the elderly.

Financial Disclosure: There is no financial disclosure.

Conflict of Interest: None to declare.

Ethical Clearance: All experimental protocols were approved under the University of Babylon and all experiments were carried out in accordance with approved guidelines.

Oral Fordyce’s Granules and Serum Lipid Profile; any Relationship?

Ameena Ryhan Diajil

Assistant Prof., BDS, M.Sc., Ph.D. in Oral Medicine, University of Baghdad-Collage of Dentistry-Oral Diagnosis
Department-Oral Medicine

Abstract

Background: Sebaceous glands are normal structures of the skin, but may be ectopically found in the mouth, as oral Fordyce granules. They are located just beneath the overlying epithelium and are visible through the epithelium producing local elevations. It has been suggested that there is a relation between elevated lipid profile and the presence of these granules.

Method: A total of 130 individuals were included in this cross-sectional study, who were subjected to the oral examination for the presence & scoring of oral Fordyce granules, then blood samples were taken. Case sheet involved, demographic information and medical history. Using specialized kits, lipids profile analysis was done on a fully automated spectrophotometric analyzer.

Results: Fordyce granules were recorded in 25% of cases, with males formed the majority of them. In both gender, lip was the most commonly affected sites. Fordyce granules were observed in one-third of patients with systemic diseases.

The majority of cases with Fordyce granules, recoded normal triglyceride, HDL, LDL and VLDL levels, but one-fourth of patients with hyper cholesterol were seen with Fordyce granules. Chi-Square test showed no association between lipid profile & these granules.

A negative correlation was found between Fordyce granules number and cholesterol, HDL and LDL levels, although statistically non-significant.

Conclusion: Oral Fordyce granules were most frequently observed in the lips, with male gender and older age predilections. The current study did not support the association between oral Fordyce granules and serum lipid profile changes.

Keywords: Oral Fordyce granules, lipid profile.

Introduction

Sebaceous glands are normal structures of the skin but may also be found ectopically in the mouth, where they are referred to as oral Fordyce granules or ectopic sebaceous glands.1

Fordyce granules (FGs) are ectopic sebaceous glands located on the mucosal surface of the oral cavity which may be considered as a variation of normal anatomy2. These spots are typically present as small asymptomatic, multiple whitish, or yellowish 1-3-mm sized papules3-5. The glands are located just beneath the overlying epithelium and often produce a local elevation of the epithelium6.

Fordyce granules are often discovered during routine dental examinations which are mainly seen on the labial and buccal mucosa in adults7.

The common site for Fordyce’s granules is vermillion border and lips, with buccal mucosa particularly inside the commissures and retro molar region has also been suggested as common site8.

Studies reported that FGs are not usually visible in
children, and tend to appear at about age 3, then during puberty and become more obvious in later adulthood\textsuperscript{8}.

Some studies showed that they are more prominent in males while, other studies reported no significant difference in the prevalence between both genders\textsuperscript{9}.

Few patients were seen with hundreds of granules while the majorities were seen with only one or two.

Etiologically, it is not known what causes FGs, but some studies have linked their development to hormonal changes and genetic; and they are not known to be associated with any disease or illness and are of cosmetic concern only. While, some authorities believed that FGs are seen in some rheumatic disorders and in hereditary non-polyposis colorectal cancer syndrome\textsuperscript{10}.

Lipid is an important for normal cell function, with normal level of cholesterol is a vital component of cell membranes structure. It is also involved in many enzymatic processes and genetic stability\textsuperscript{11,12}.

Considering lipid profile, total cholesterol (TC) measures all the cholesterol in all the lipoprotein particles. High-density lipoprotein (HDL) measures the cholesterol in HDL particles takes up excess cholesterol and carries it to the liver for removal. Low-density lipoprotein (LDL) measures the cholesterol in LDL particles, it deposits excess cholesterol in walls of blood vessels, which can contribute to atherosclerosis. This can be calculated using the results of total cholesterol, HDL and triglycerides (TG). Triglycerides measure all the triglycerides in all the lipoprotein particles; most of it is in the very low-density lipoproteins (VLDL)\textsuperscript{13}.

A study showed that individuals with an elevated lipids profile tend to have oral FGs and may be with higher numbers compared to normal range of lipid profile\textsuperscript{14}.

A very few research in this topic, and to date, no study has been published to describe the clinical manifestation of FGs and lipids profile in Iraqi population. Thus, the present study was designed to investigate the prevalence and relationship between serum lipids profile with oral FGs in relation to demography and medical history of patients.

**Material and Method**

The protocol of this observational cross sectional study was reviewed and approved by the Ethical Committee of the Oral Diagnosis Department of the College of Dentistry- University of Baghdad. The written informed consents were obtained from all recruits, after clearly explained the protocol to the participants, and detailed information about the study and the blood samples collection.

From September 2019 to March 2020, a total of 130 participants attended Al-America primary health center in Al-America sector in Baghdad, who were sent for serum lipids profile tests, were enrolled in this study. During their follow up, those patients were already asked to fast overnight approximately 8-12 hours to test their lipids profile.

The subjects were excluded if they had a major illness in recent past or were taking or had previously taken any medications known to influence lipid levels metabolism in the past 6 months.

Case sheets were filled for the patients who gave their consent form to participate in this study. Case sheet includes demographic information such as age, gender, marital status, number of children. The individuals were also questioned about systemic diseases.

During the same visit of taking the blood samples, oral examination of each participant’s mouth, was performed by the oral medicine specialist (author) focusing on the presence of the FGs in the oral cavity. Recording their location and the number, using five scoring system: Group 1: 0 granules, Group 2: up to 10 granules, Group 3: up to 30 granules, Group 4: 30 to 100 granules and Group 5: more than 100 granules.

Under sterile conditions, 4-5 milliliters of venous blood was collected after an overnight fast, from antecubital vein in vacuumed blood collection tubes with gel and were labeled with an individual patient ID, then serum was extracted after centrifugation for 15 minutes (2000 rpm).

Estimation of serum lipids profile was done on a fully automated analyzer based on spectrophotometric principle using enzymatic colorimetric method kits. The serum lipid profile was analyzed on the same day of the withdrawal of blood samples.

Plasma levels of TC, TG, HDL were estimated using enzymatic colorimetric test (Linear Chemicals S.L.U, SPAIN). VLDL and LDL were calculated using the formula given below: 

\[
\text{VLDLC} = \frac{\text{TG}}{5} \\
\text{LDLC} = \text{TC} - \text{VLDLC} - \text{LDLC}
\]
Statistical Analysis: Data analysis was performed using Statistical Package of Social Sciences software version 20.

Descriptive statistics were obtained for all variables in the study with means, standard deviations and standard error of mean (SEM) were applied as appropriate.

Analysis of variance (ANOVA), student T-test, Chi-Square test, Fisher’s Exact and correlation coefficients tests were used. A p-value of less than 0.05 was considered to indicate statistical significance.

Results

1. Patients Demography: In this study, 130 participants were included, with an age range of 20-79 years and a mean age of 51.4 years. Patients were divided into three age groups; 20-39, 40-59 and 60-79 years, with the age group 40-59 years, formed the majority of patients, followed by the older age group 60-79 years.

The majority of patients were males 75 (57%) with males mean age was 52.9 years. Females were younger than males with a mean age of 49.6 years.

2. Fordyce’s granules distribution in the oral cavity: Thirty-two patients (25%) out of 130, were with FGs. Twenty-four (75%) were recorded in the lips and 12 were recorded in the cheek (4 cases were with both lips and cheek). Considering the number of FGs, the majority of patients were with ≈ 10 granules per location, with only one patient was with more than 100.

The majority of patients were males 75 (57%) with males mean age was 52.9 years. Females were younger than males with a mean age of 49.6 years.

3. Fordyce’s granules, Age, Gender, Medical history and Lipid profile tests: The mean age of males with FGs (54 years) which was higher than that of females with FGs (49.3 years).

Regarding gender, out of the 32 patients with FGs, 22 were males forming 69% and 10 (31%) were females. In both gender, lips showed the most common oral sites for these granules. Considering males, 14 were with lips FGs and 8 were with cheek granules. Similarly, in females lips recorded more FGs (6 out of 10).

In the current study, the majority of participants were with systemic diseases (90, 69%) while rest 40 (31%) were without any systemic diseases. The majority of patients (54, 42%) were previously diagnosed with hypertension, followed by both hypertension and diabetes mellitus (23, 18%) and only 13 (10%) were with a diabetes mellitus only.

Considering gender, those with systemic disease, 55 were males and 35 were females. While those without any systemic diseases, 19 were males and 21 were females.

The majority of patients (66%; 21/32) with systemic diseases were with FGs, and all of them were with lips involvement, but only 3 cases with FGs, were without any systemic diseases.

As shown in Table (1), hypertensive patients showed higher mean cholesterol, triglyceride, HDL and VLDL compared to patients with diabetes and those suffered from both hypertension and diabetes mellitus together. While patients with both hypertension and diabetes showed higher mean values for LDL. Students t-test showed no significant difference between different systemic diseases in mean lipids value.

As shown in Table (2), a higher mean lipid value was seen in females in cholesterol and LDL, while higher means were seen in males in triglyceride, HDL and VLDL. However, t-test showed no significant differences.

Fordyce’s granules, Cholesterol and Triglyceride

Both cholesterol and triglyceride levels were divided into 3 levels; normal range, border line and high range level, which subsequently scored as 0,1 and 2, respectively; Table (3).

One-fourth of cases with hyper cholesterol were seen with FGs; however, Chi-Square test showed no association between cholesterol level and oral FGs (1.214, df:2, p=0.545).

The majority of cases were with normal level, followed by high and then border line values.

The majority of FGs cases, were with normal triglyceride and ≈ 1/3 of cases with higher triglyceride. Chi-Square test showed no association between triglyceride level and FGs (1.556, df:2, p=0.459). Considering gender, the majority of males were seen with high level range of triglyceride compared to females.

Fordyce’s granules, HDL, LDL and VLDL

High density lipoprotein, LDL and VLDL levels were divided into 2 scores; Table (4). Cases with
FGs were commonly seen with normal HDL values, followed by the higher HDL levels; Chi-Square test showed no association between HDL and FGs (0.192, df:1, p=0.661), although half of cases with hyper LDL were seen with FGs.

Similarly, LDL showed no association with presence of FGs (0.002, df:1, p=0.966); an equal number of FGs were seen in normal and high level scores.

Regarding VLDL, the majority of cases were within normal range values followed by the high values.

Although, the majority of both gender recorded normal VLDL, males were seen with higher VLDL values compared to females. FGs cases were nearly equally in number in normal and high VLDL level. Chi square test showed no association between VLDL and FGs (0.761, df:1, p=0.383), although ≈ half of FGs cases were observed with high LDL levels.

4. **Hyperglycemia:** In this study, overlap records were seen in recording higher levels of lipids profile. Using just the higher lipid score values for the all 5 lipids, cases with higher levels of LDL and VLDL were commonly seen with positive FGs, followed by those with higher HDL, triglyceride and cholesterol.

However, Chi square test showed no association between the presence FGs and each type of lipid with its higher recorded levels (0.457, df=4, p=0.978); Table (5).

Using cases with different types of hyperlipidemia to study the association with FG, Fisher’s Exact Test showed no association between FGs and hyperlipidemia in only, one type of lipid, 2 types, 3 types, 4 types and all the 5 types of lipid profile (P=0.65).

5. **Correlations between study parameters:** Using Pearson correlation, although no significant correlation was found between FG count and the five lipid profile values; there is a negative relations between FG number and cholesterol, HDL and LDL; Table (6). Also, a negative but no significant correlation was recorded between HDL and oral FGs, using the scores for each type of lipids (r = -0.040, p=0.664).

Discussion

Oral Fordyce granules are often discovered during routine dental examinations. They are considered anatomic variations and are typically seen on the labial and buccal mucosa.14,7

The current study recorded FGs in 25% of the participants which is lower than what was recorded by Gaballah and Rahimi (2014)15, but it is higher than what was recorded (7.2%) by Tortorici et al., (2016)16 who studied the prevalence and distribution of oral mucosal non-malignant lesions.

Studies have investigated the relation of FGs with age, puberty and gender.17,18 According to Choudhry, the incidence increased with age, with 60-80% of patients were elderly.19 This agrees with this study which found that patients with FGs were older than those without FGs.

The current study showed that FGs were predominant in males and the majority of cases were with lips involvement, which agrees with Gorsky et al., (1986)20 who found that lips were the most common location for these granules (82.2%).

Also, Olivier (2006)9 found that FGs were mostly seen on the lips, followed by buccal mucosa, with no significant difference in the prevalence between males and females.

This completely agrees with the current study which reported that lips were the most common site, followed by cheek, but no significant difference between both gender.
Cardiovascular disease is the most common cause of death in industrialized countries and hyperlipidemia can lead to accelerated atherosclerosis and premature death from ischemic heart disease.\textsuperscript{21,22} The risk of developing atherosclerosis is directly related to the plasma LDL and inversely related to the HDL level.\textsuperscript{23,24}

Although, the majority of the previous studies did not find a relation between FGs and systemic diseases (Scully, et al., 2004). In the current study, one-third of patients with systemic diseases were with FGs.

Hypertensive patients showed higher mean values of cholesterol, triglyceride, HDL and VLDL compared to patients with diabetes and those suffered from both hypertension and diabetes mellitus together. This is supported by the findings of a recent study which found that diabetes mellitus, cardiovascular disease, liver and thyroid disease could also lead to changes in lipids profile.\textsuperscript{25}

In this study, no relation was found between FGs and cholesterol, triglyceride, HDL and VLDL levels, although between 1/4 and half of cases were with hyperlipidemia were observed with FGs. This may be due to the sample size or other confounder factors.

Cases with positive FGs recorded higher means cholesterol, triglyceride and VLDL values, but lower mean values of HDL and LDL, with males showed the highest VLDL levels.

This study reported a negative correlations between FGs number and cholesterol, HDL and LDL; however, non-significant. Further studies with larger number are required to be able to discuss these findings.

Because there are many factors affecting lipid metabolism and subsequent lipid profile levels. Recent progress in molecular biology may assist researchers in the near future to identify the genes and enzymes of lipid metabolic pathways and can understand the relation between each individual lipid and FGs in the oral cavity. Up to our knowledge, no study(s) considered these relations.

To conclude, the hyperlipidemia may contribute to the appearance of the oral FGs either by the increase fatty content of clinical undetectable glands making them easily visible during the oral examination or de novo differentiation of cells leading to more oral FGs. Both explanations require confirmation studies histochemically.

The findings of this study required larger population groups with wider age groups. Due to the fact that there are many factors affecting lipid metabolism, the inclusion criteria could lead to different conclusion.

Also, dentists as care providers for the oral cavity should be aware of the importance of referring patients with high density of FGs for lipid profile tests and then for an appropriate medical care especially those with risk factors for the cardiovascular system.

Molecular Detection and Quantification Gene Expression of Efflux Pump Antibiotic Resistance Genes in Extensive Drug Resistance Pseudomonas Aeruginosa Isolated from Clinical Infection Patients in Al Diwaniyah City of Iraq

Hassan Hachim Naser¹, Adnan H. Aubaid²

¹Lecturer, Department of Medical Microbiology, College of Medicine, University of Al-Qadisiyah, Iraq,
²Prof., Department of Medical Microbiology, College of Medicine, University of Al-Qadisiyah, Iraq

Abstract

The study was included investigated 16 extensive drug resistance pseudomonas aeruginosa isolates which previously isolated from sputum, burns, urine, and ear swab clinical patients samples. The reverse transcription Real Time PCR (RT-qPCR) was performed for molecular detection and quantification of gene expression levels for efflux pump antibiotic resistance gene (mexA, mexB, mexC, mexE, and mexY) and chromosomal lactamase (AmpC) gene, as well as outer membrane prion protein (OprD) gene in extensive drug pseudomonas aeruginosa isolates. The relative expression analysis was done by used the 2-ΔΔCT (Livak) method, this method was used for normalization of expression levels (mRNA transcript levels) in target genes with suitable housekeeping gene. In this study 30S ribosomal protein S12 (rpsL) housekeeping gene was used in normalization of antibiotic resistance genes expression levels in extensive drug pseudomonas aeruginosa isolates. The efflux pump resistance gene expression were by RT-qPCR technique. The relative gene expression analysis were showed highest frequency of overexpression at (100%, 100%, 87.5%, 81.25%, 56.25%) for (mexB, mexE, mexA, mexC, and mexY) with fold change ranged (2.16- 184.82) fold change compared to wild type PA control isolate. The relative gene expression analysis of chromosomal lactamase AmpC gene was showed highest frequency of overexpression (100%) in XDR isolates with expression levels ranged (6.77- 73.1) fold change compared to wild type PA control isolate. Whereas, the relative gene expression analysis of OprD gene was showed (68.75%) frequency of down expression in XDR Pseudomonas aeruginosa isolates with expression levels ranged (0.01-0.16) fold change compared to wild type PA control isolate. In conclusion, The XDR Pseudomonas aeruginosa isolates can ability to over expression production of inducible chromosomal lactamase AmpC gene, efflux pumps protein genes, and low expression outer membrane prion protein (OprD) gene as important antimicrobial mechanism against Cephalosporins and Carbapenems antibiotic classes.

Keywords: Pseudomonas aeruginosa, XDR, efflux pumps genes, gene expression.

Introduction

The development of XDR Pseudomonas aeruginosa has become a genuine overall clinical issue. The decrease of medication amassing in the cytoplasm is likewise a significant system to oppose anti-microbials. There are two different ways to accomplish the reason for lessening drug collection: one is through layer impermeability, and the other is by film related siphons. The overexpression of efflux siphons was accounted for to add to multi-drug opposition in P. aeruginosa. Most Gram-negative microorganisms have the characteristics for efflux siphons having a spot with the restriction nodulation division family and a couple of homologous hindrance nodulation cell division-type siphons are delegate in P.
**aeruginosa** with the ultimate objective that MexAB-OprM (coding quality: mexA, mexB and oprM), MexCD-OprJ (mexC, mexD and oprJ), MexEF-OprN (mexE, mexF and oprN), MexXY-OprA (mexX, mexY and oprA) and some P. aeruginosa strains lost oprA quality. MexAB-OprM adds to counter-agent poison assurance from β-lactams, for instance, cephalosporines or penicillins, macrolides, chloramphenicol, anti-infection prescription and fluoroquinolones MexCD-OprJ adds to antidote poison insurance from macrolides, anti-toxin drugs, fluoroquinolones and a couple β-lactams including cefepime. MexEF-OprN adds to hostile to microbial security from fluoroquinolones, chloramphenicol and trimethoprim. MexXY-(OprA) adds to hostile to contamination insurance from aminoglycosides, cefepime, ciprofloxacin and levofloxacin. Mutational changes can cause diminished counter-agent poison take-up, alterations of against microbial targets, and overexpression of efflux siphons and hostile to contamination inactivating synthetics; all of which license minuscule living beings to make due inside seeing antimicrobial particles. For instance, an investigation by showed that inactivation of the DNA oxidative fix framework expands change frequencies in P. aeruginosa prompting upgraded β-lactamase creation and overexpression of the MexCD-OprJ efflux siphon. Unconstrained changes can influence the articulation or capacity of a particular porin, consequently diminishing bacterial layer penetrability and expanding anti-toxin opposition. Our examination was meant to measurement quality articulation of efflux siphon anti-toxin opposition gene in extensive multidrug resistance Pseudomonas aeruginosa isolates was carried out according to method described by and include the following steps:

**Total RNA extraction:** The XDR Pseudomonas aeruginosa bacterial isolates were inoculated on Luria Bertani broth and incubated at 37°C into reach bacterial cells (OD600:0.8-1.0), the bacterial cells were harvested by centrifuge at 13000rpm for 1min then, supernatant removed. Total RNA was extracted by using (easy-BLUE™ Total RNA Extraction Kit) and done according to company instructions.

**Estimation of extracted total RNA:** The extracted total RNA was checked by using Nanodrop (Thermo Scientific Nano Drop Lite UV Visible Spectrophotometer. USA) that measured RNA concentration (ng/µL) and checked the RNA purity at absorbance (260/280 nm).

**DNase I treatment:** The extracted RNA were treated with DNase I enzyme to remove the trace amounts of genomic DNA from the eluted total RNA by using samples (DNase I enzyme kit) and done according to method described by Promega company, USA instructions as following table (1).

<table>

**Material and Method**

**Bacterial Isolates:** A 16 XDR Pseudomonas aeruginosa isolates were provided from Microbiology laboratory in college of Medicine. These XDR isolates were previously isolated from different official hospitals includes Al-Diwaniyah teaching hospital, Diwaniyah burn center hospital, Diwaniyah Chest center hospitals, as well as from many private medical laboratory in Al-Diwaniyah city.

**Quantitative Reverse Transcription Real-Time PCR:** The quantitative Real-Time PCR technique was performed for quantification detection and gene expression analysis of antibiotics resistance efflux pumps genes and normalized by housekeeping (rpsL)
After that, these RT mix components that mentioned in table above placed in AccuPower® RocketScript™ RT PreMix kit strip tubes that containing all other components which needed to cDNA synthesis such as (Reverse Transcriptase, 5 x Reaction Buffer, DTT, dNTP, and RNase Inhibitor). Then, all the strip tubes transferred into Exispin vortex centrifuge at 3000rpm for 3 minutes, and then incubated in Thermocycler (BioRad-USA) as following thermocycler conditions protocol as showed in table (3)

### Real-Time PCR (qPCR) master mix preparation:
qPCR master mix was prepared by using (RealMODTM Green SF 2X qPCR mix Kit) based on SYBER green dye amplification in Real-Time PCR system and the qPCR master mix was prepared as following:

### Real-Time PCR primers:
Real Time PCR primers were designed in this study using NCBI-Genbank database and primer3 plus online. These primers were provided by Macrogen company from Korea as following table (4).

Data analysis of qPCR: The data results of qPCR for target and housekeeping gene were used expression analysis (fold change) used (The ΔCT Method Using a reference gene) that described by\(^9\) as following equation:

\[
\text{Ratio (reference/target)} = 2^{\Delta CT(\text{reference}) - \Delta CT(\text{target})}
\]

Statistics Analysis: The statistical analysis was done by using LSD test, one way anova at P value < 0.05 were performed by using GraphPad Prism 7 Statistics software.

Results and Discussion

The converse record Continuous PCR (RT-qPCR) was performed for sub-atomic recognition and evaluation of quality articulation levels for efflux siphon anti-toxin obstruction quality (mexA, mexB, mexC, mexE, and mexY) and chromosomal lactamase (AmpC) quality, just as external layer prion protein (OprD) quality in broad medication pseudomonas aeruginosa separates. The relative articulation investigation was finished by utilized the 2-ΔΔCT (Livak) strategy, this technique was utilized for standardization of articulation levels (mRNA record levels) in target qualities with appropriate housekeeping quality. In this investigation 30S ribosomal protein S12 (rrpL) housekeeping quality was utilized in standardization of anti-toxin obstruction qualities articulation levels in broad medication pseudomonas aeruginosa detaches as appeared in figure (3). The constant PCR productively was dictated by utilizing genomic DNA standard bend and the qPCR intensification plot results for three 10 overlay weakened DNA (1x102, 1x104, 1x106, and 1x108/duplicate number) with RT-PCR effectiveness (100%) were appeared in figure (1) & (2).

The mean of overlap change quality articulation investigation in of efflux siphon anti-infection obstruction qualities in XDR Pseudomonas aeruginosa disengages as appeared in figure (4):

Figure (4): The mean of overlap change quality articulation investigation in of efflux siphon anti-toxin opposition qualities in XDR Pseudomonas aeruginosa detaches.
The present study was showed that all XDR Pseudomonas aeruginosa isolates has significantly increased overexpression production of inducible chromosomal lactamase AmpC gene expression at (100%) and their relative expression ratio ranged (6.77-73.1) fold change compared to wild type PA control. This finding explains that overexpression of chromosomal AmpC (ampC) is mainly responsible for upregulation to resistance mechanism to penicillin and cephalosporinase β-lactams class as showed in our results for antibiotic susceptible pattern that (XDR) Pseudomonas aeruginosa isolates are resistance to cephalosporins. Study by[10] who finding that mutation-dependent overproduction of intrinsic β-lactamase AmpC is considered the main cause of resistance of clinical strains of Pseudomonas aeruginosa to antipseudomonal penicillins and cephalosporins and these finding consistent with our results that exhibiting a greater resistance to ceftazidime and Cefepime as well as Piperacillin antibiotics. Another study in France showed increased resistance to ceftazidime among the clinical isolates of P. aeruginosa it primarily because of AmpC over-expression[11]. The present study was showed the relative gene expression analysis were showed highest frequency of overexpression at (100%, 100%, 87.5%, 81.25%, 56.25%) for (mexB, mexE, mexA, mexC, and mexY) with fold change ranged (2.16-184.82) fold change compared to wild type PA control isolate and all the XDR isolates were produced overexpression at relatively variable expression levels, it may be resulting from single mutation in efflux pump antibiotic resistance genes that effect on expression regulatory mechanisms. This suggestion consistence with previously observed results in the P. aeruginosa clinical isolates [12]. Who finding that overexpression of the two efflux systems may result from mutations affecting multiple regulatory genes. The expression of AmpC is significantly increased, P. aeruginosa is resistant to almost all classes of β-lactams, except the carbapenems[13]. Finally, our study was concluded that Pseudomonas aeruginosa is important causes of nosocomial diseases and has high ability to acquired multidrugs resistance capacity especially in burn infection patients, XDR Pseudomonas aeruginosa isolates can ability to overexpression production of inducible chromosomal lactamase AmpC gene, efflux pumps protein genes, and low expression outer membrane prion protein (OprD) gene as important antimicrobial mechanism against Cephalosporins and Carbapenems antibiotic classes.

Principles of Humanitarian Law in the War Biography of Imam Ali (Peace be upon Him) the Equestrian Principle and Proportionality as a Model

Amer Abdul Hussein Abbas¹, Thamer Mohamed¹

¹Lecturer, Republic of Iraq, University of Kufa, Faculty of Law

Abstract

The biography of Imam Ali included the most human principles and rules, and his war biography was a mixture of justice, fairness and mercy. This brief study reached several results, which we summarize as follows: The Imam hated war and pushed it as long as he found a way to do that. The basic principle for him is the state of peace, and war is an exceptional and urgent case, and all his wars were self-defence, a response to aggression and the payment of sedition and corruption. The Imam prevailed in his battles against humanism over the necessities and requirements of war, so love, peace, compassion and mercy were the basis of his personality, and his perseverance was forgiveness and tolerance, even if that led to the loss of victory, as happened in the incident of the law of water in the battle of ((Safin)). The principle of chivalry was evident in its most beautiful form in the personality of the Imam, with the qualities of honesty, courage and arrogance he carried.

Keywords: Humanitarian law, biography of Imam Ali, Proportionality as a Model.

Introduction

The personality of Imam Ali (peace be upon him) is distinguished by its many dimensions and its intellectual, scientific, spiritual and literary aspects... and each dimension has its great human value and value, and among those bright dimensions is its humanity in war and his unique horsemanship with the values of nobility, magnanimity, fairness and mercy of enemies. His military career included many humanitarian principles, what he calls - today - international humanitarian law. The importance of the research stems from the fact that it deals with a modern vital topic that has little experience, especially since the issues of humanitarian law are among the studies developed in our universities.

Research reasons and objectives:

1. The research aims to show the greatness of Islam and its human and moral civilization, by reviewing some of the positions of Imam Ali (PBUH) - in word and deed - in war and what is related to its affairs, as his war history represents in that the true approach of Islam.

2. On the occasion of the passage of one thousand four hundred Hijri years since the martyrdom of the Imam (PBUH), the University of Kufa decided to consider this year - 1440 AH - as its own and direct its professors to show some aspects of this great personality.

3. Many subjective reasons, including familiarity with and depth of most issues of humanitarian law and the diversification of our legal research.

The research problem: It is represented in knowing the extent to which Imam Ali’s war biography includes the most important principles of humanitarian law and their application before their appearance in Western civilization.

Methodology

We followed the descriptive historical method, the legal analysis method, as well as the comparative approach.

Search Plan:

For the sake of brevity, we will address the topic in two main points:
**First:** Humanism in the military biography of Imam Ali.

**Second:** The principles of chivalry and proportionality.

The conclusion comes with the summary, results and recommendations it contained, and then the approved sources.

**First: the humanism in the military biography of Imam Ali**

The military biography of Imam Ali consists of two stages:

1. **The First:** During the era of the Messenger (PBUH) -1-11 AH- in which the Imam was a military commander in what is used - today - in military terms ((Chief of Staff of War)), and at this stage, he participated in all the major wars of Islam led by the Messenger (p.) Himself, as the Messenger sent him during this period as commander of several companies - Khaybar - Fadak - Yemen, and others.

2. **The Second:** The days of his caliphate 35-40 AH - and in it, he was the political leader of the nation and the supreme commander-in-chief of the armies of the Islamic state, and in which he led the major internal wars himself - Al-Jamal-Siffin-Al-Nahrawan.

In both phases, his military practices manifested the humanism that is the model for noble warriors, bypassing the requirements and necessities of war. The war did not have a means of extending influence and control, nor did it aim to heal and retaliate or exterminate the opponent, and he only fought it in defence of freedom of belief and the security of the state and society.

The evidence for this in his war biography are many, including that he did not invite anyone to fight him, and if he was invited he answered, thus recommending his son Al-Hassan: ((Do not call for a duel, and if you are called, then he will answer, for the caller is absent and the perpetrator is killed))\(^1\). Bin Wad in the battle of the Trench is what confirms this. Before confronting him, Islam offered him or return and peace \(^2\), and if he met the two armies he would not authorize the fighting until he offered peace and return to the enemies and frightened them with the consequences of the war, and he invoked his words: ((Oh God, inject our blood and their blood and reform the self) Between us and them, and save them from their misguidance so that the truth is known from his ignorance, and he feeds on the treachery and treachery of his accusers))\(^3\).

This is what happened in the Battle of the Camel. After the leaders of the other side responded to his envoys and did not heed his advice, he remained until the last moment, appealing to them and inviting them to peace, and one of his companions sent them with the Qur’an in hand to offer them his arbitration and they killed him, and then they attacked his army, so he said: ((Oh God, bear witness ...)).\(^4\) He had no choice but to defend himself and repel aggression.

Thus he did with Muawiyah and the people of Levant before the battle of ((Safin)), as they were guided by the month of Muharram from the year -37 AH- so that they might respond to the call of reason and humanity. God Almighty, by calling you to him, you did not refrain from tyranny, and you did not answer to the truth, and I rejected you the same because God does not love the traitors))\(^5\), and he used to recommend his soldiers before meeting the enemy in two ranks by his famous saying: ((Do not fight them until they start you, for you Praise be to God for proof, and he left you until they start another argument for you on them)).\(^6\)

And this is how his position was with the internal opposition - the outside - where he dealt with them with unprecedented humanity, for after they broke with his rule and opposing him, he did not imprison them or restrict them, nor did he exclude them from participating in political life, and they would attend the mosque with him, discuss it and pray alone, and he protested them several times and obeyed He had many of them, and decided to deal with them by saying: ((You have three times with us, we do not prevent you from praying in this mosque, and we do not prevent you from your share in this category - what your hands were with ours - and we do not fight you until you fight us))\(^7\) And when they announce the disobedience and rebel Corruption on the ground and they killed the Muslims, who wrote them and warned them against the consequences of war and preached them, and when the battle took place on them he raised a flag of safety for them, as he allowed those who wanted to leave the war to leave, and healed their wounded \(^8\)

Upon studying his war behaviour, we see that his war was not an unrestrained war with no boundaries, but rather disciplined and moderate, in which he refrained from using harsh or hideous method and means under
any circumstance or name - such as the necessities of war or reciprocity, and his war behaviours stemmed from an innate and moral human capacity. Sublime, his actions and war stances were validation of what (Grosius) looked to him after ten centuries defending the controls of moderation in war.

Among these behaviours was the incident of the Sharia of water in the Battle of Siffin, where Muawiya’s army took control of it first, and they decided to put the Imam and his army to death by thirst. And his leaders were to prevent Muawiya’s army from it and exterminate them thirst, or they surrendered to a reciprocal treatment, so the imam refused that and left between them and the water and said to his commanders: (Indeed, God has given you victory over them by their injustice and their intent ... and all water is in it).

This is the core and essence of humanitarian law and its goal that it seeks to achieve.

Second: The principle of chivalry and proportionality of Imam Ali: Humanitarian law is based on a set of basic principles whose origins are traced back to humanitarian, religious and ethical sources. They existed before the emergence of the law and governed after its codification. The conventions may explicitly mention them in the preamble or the context with the expression ((laws of humanity)) or ((the prevailing custom)) or ((What is dictated by the general conscience)), and it applies to all times and places, and we will deal with it in this point two basic principles, as follows:

1. The Equestrian Principle: It is an ancient principle known to most nations, including the Arabs, and emerged in the Middle Ages among the Romans and Franks after they converted to Christianity, and the principle is the qualities of heroism and nobility in a knight or a fighter, which necessitate refraining from treachery, treachery, deception, or the use of excessive force and brutality or prohibited weapons, and all that it would avert honour, and the principle also requires not to finish off a wounded, unarmed or prisoner, or attack civilians and loot their property, and among the equestrian rules is reciprocity, and unfortunately, previously Christian countries did not apply them to non-Christians, especially in their Crusades against Muslims, which were committed. It contained the most heinous human crimes until it came to decorating some churches with the bones of Muslims.

The principle contributed to alleviating the pain of war and sparing non-combatants from its woes.

It is not an exaggeration to say: The most perfect validation of the principle is the person of the Imam, because of the qualities and morals of the knights he possessed, and in that he says - Carlyle -: ((As for that boy Ali you cannot help but love him, God has installed nobility in his character since modernity, In its shade, generosity was manifested throughout his life, and then it was imprinted on work, impassion and frankness of strength, and the mystery of chivalry and the boldness of the Layth came to him, and all of this was in the tenderness of the heart, sincerity of faith, and effective generosity worthy of Christian chivalry)).

It is not mentioned in its history that he betrayed a covenant or betrayed anyone, who said: ((Loyalty is the twin of sincerity, and I do not know a better paradise than it ... We have become in a time when most of his people have taken treachery and attributed them to the people of ignorance in it to good resourcefulness ..., he may see the change. The heart is the face of the trick, and without it is an objection to the command of God and forbids it, so it allows it to see the eye after being able to it, and it takes its opportunity for the one who does not need religion)).

And he confirmed this in his covenant to the owner of Ashtar - when the ruler of Egypt - saying: ((If you made a knot between you and your enemy or clothe him from you, then make your pledge to honour your commitment and make yourself a paradise as you were given ... so do not betray your responsibility and do not betray your pledge ...)).

He also did not mention in his fights and wars - despite their many - that he killed someone from behind or killed a wounded person. Rather, in his wars, he used to repeat his commandment to his commanders and companions that: ((... do not kill a mastermind, and do not prepare against a wounded ...)) Historians have mentioned His duel in ((Battle of Uhud)) for one of the leaders of the great polytheists - Talha bin Othman - where he called for the duel, so the imam went out to him, cut his leg and left it. The imam was told:

((Could I be ready for him, so he said: God and the Womb have appealed to me, and I have stopped him)), and this is the core of the equestrian principle.

2. The principle of proportionality: It is an ancient principle that emerged under the principle of
chivalry and was established after the spread of Christianity, and it is a compromise principle that seeks to establish a balance between two opposing interests, the first being the war imperatives, which allows the use of violent method and means of combat to defeat the enemy and achieve victory - even if that leads to excruciating pain. And heavy losses among combatants, and even civilians, who are covered by special protection, while the other interest is represented by humanitarian requirements and considerations, which prohibit the use of unfamiliar or brutal method and means of combat and prevent excessive injuries, and call for civilians and those covered by special protection, such as the wounded and sick, to be spared the scourge and pain of war.

**Conclusion**

The biography of Imam Ali included the most human principles and rules, and his war biography was a mixture of justice, fairness and mercy. This brief study reached several results, which we summarize as follows: The Imam hated war and pushed it as long as he found a way to do that. The basic principle for him is the state of peace, and war is an exceptional and urgent case, and all his wars were self-defence, a response to aggression and the payment of sedition and corruption. The Imam prevailed in his battles against humanism over the necessities and requirements of war, so love, peace, compassion and mercy were the basis of his personality, and his perseverance was forgiveness and tolerance, even if that led to the loss of victory, as happened in the incident of the law of water in the battle of ((Safin)). The principle of chivalry was evident in its most beautiful form in the personality of the Imam, with the qualities of honesty, courage and arrogance he carried. The Imam applied the principle of proportionality in his wars, so he did not use unfamiliar and despicable method of brutal weapons, such as killing the enemy at night or using poisonous weapons, and he did not go too far in killing or eradicating enemies, and he was content with achieving victory on the battlefield, and this is the essence of proportionality. The significance of what was stated in the proclamation of Saint Peter Burg - 1168.

**Financial Disclosure:** There is no financial disclosure.

**Conflict of Interest:** None to declare.

**Ethical Clearance:** All experimental protocols were approved under the University of Kufaan and all experiments were carried out in accordance with approved guidelines.

Assessment of Mothers’ Knowledge toward Cesarean Section Complications at the Hospitals in Baghdad City Hospitals

Buthainah Basheer Saleh¹, Wissam I. Wardia²

¹Lecturer, Collage of Nursing-Al-Bayan University,
²Assistant Lecturer, Collage of Nursing-Al-Bayan University

Abstract

Background: Cesarean section is one of the most frequently performed major abdominal surgeries and carries the risk of infection, including local wounds, pelvic, respiratory tract, and urinary tract infections, as well as lung emboli, venous thrombosis, and complications of anesthesia.

Objective: The study aimed to assess mothers’ knowledge toward complications of cesarean section and to find out the relationship between mothers’ knowledge and their demographic characteristics such as (age, level of education, and multipara cesarean section).

Methodology: A descriptive (cross-section) study design was conducted on (100) mothers with cesarean section in the maternal ward. (The data were collected by the investigator, fill the questionnaire formats by interview technique and fill it by the investigator). Questionnaire form was constructed for the purpose of the study. It consists of two parts which were dealing with the demographic characteristics of mothers and the mothers’ knowledge towards cesarean section complications. The data collection reliability of the questionnaire was determined through internal consistency. Content validity of the questionnaire was determined through panel of experts. Data were analyzed through descriptive and statistical approach (frequency and percentage, and chi-square) by Socioeconomic Package for Social Science approach Version 16.

Results: The finding of the study demonstrated one result about the knowledge of mothers there was accepted statistical percentage between mothers’ knowledge and their demographic characteristics such as (age, level of education, and multipara cesarean section).

Keywords: Assessment, Cesarean Section, Complications, Hospitals.

Introduction

Cesarean section (CS) is one of the most frequently performed major abdominal surgeries. Despite a lack of upsurge in obstetric emergencies, the rate of CS has increased in many parts of the world, reaching higher than 50% in some countries.¹⁻³ Most of these CS surgeries are performed without any medical indication and some are cesarean delivery on mother’s request (CDMR).⁴ The world incidence of CDMR is estimated to be 8–14% of all cesarean deliveries.⁵ In order to prevent the dangers of vaginal delivery, the idea of elective CS in full-term pregnancy attracted the media’s attention about 20 years ago.⁶ Since then, there have been serious discussions about performing CDMR in full-term pregnancies.⁷ Although recent studies have shown that the risk of planned CS and planned vaginal delivery in the short term are low and similar, in subsequent pregnancies, the risk will be higher in a mother who has had a previous CS.⁸⁻¹⁰ Like other surgical operations, CS carries the risk of infection, including local wounds, pelvic, respiratory tract, and urinary tract infections, as well as lung emboli, venous thrombosis, and complications of anesthesia. Thus morbidity and mortality rates are higher in CS compared to normal vaginal delivery (NVD) in both mother and child.¹¹ In addition, studies show that financial burden of repeated CS, including duration of hospitalization, drugs used, and their complications, are significantly greater as...
compared to NVD. Other complications of CS are the increased risk of placental adherence and uterine rupture in subsequent pregnancies, intensive care admission, hysterectomy, problems with subsequent fertility (e.g., reduced fertility, ectopic pregnancy, miscarriage), and increased risks of fetal and neonatal mortality.

**Methodology**

Descriptive study design was conducted on (100) mothers having multipara delivery, data collection started from 20\(^{th}\) February 2016 to 20\(^{th}\) April 2016 achieve the objectives of the study. The study was carried out by Baghdad Teaching Hospital at medical city and Mohammed Bakeer Al- Hakeem Teaching Hospital. Non-probability (purposive) sample of (100) mothers multipara cesarean section. The questionnaire was designed and constructed by the investigator to measure the variable underlying the study. A questionnaire was consisted of two parts : (1) demographical information includes items such as (mothers’ age, mothers’ multipara cesarean deliveries) and the complications effects on the mothers. The second part it comprised of structured (16) items concerning mothers’ knowledge toward complications of cesarean section on her health. Items related to the knowledge of sample under study rated according to 3 points rating scale (I know, uncertain and don’t know) data were collected through the use of questionnaire format and, means of an interview with mothers who have multipara cesarean section in maternity ward. A pilot studies was conducted on (10) mothers who have mulipara cesarean section selected from Nurse Home Hospital at 15 February 2016, and the result by Split Half : (r = 0.80). Data analyzed through the application of statistical procedure which may assist for the determination of the study finding.

*F. = Frequency, ***% = Percent

This table shows that most of the mothers were knowledgeable (89%) about delayed healing wound after operation, more than half of them (53%) knowing about bleeding after the operation, more than one third (48%) weakness of bowel movement after delivery, more than one half (61%, and 63%) about obesity and bulge their abdomen, and about urinary tract infection. While in regard to other items mother have no information about them.

This table shown that the association between mothers’ knowledge and their level of education have significant for the items: bladder puncture during operation, respiratory tract infection as a result of anesthesia, placenta permeation in the next pregnant, and hysterectomy related to placenta permeation, while the other items and total of it have no significant association.
This table shown that the association between mothers’ knowledge and their multipara cesarean section has significant with Inflammation of the uterus lining, while the other items and the total have no significant association.

**Discussion of the Results**

In figure (1) twenty seven percent (27%) (2-3 times) of multipara cesarean section mothers were at age (20-29) years old and twenty three percent (23%) of them also have (4 and above) multipara cesarean section at age (30-39) years old this results agreed with the study by Ahmad study(14) reported that thirty seven percent (37%) of multipara was within age group of (21-25) years with a mean of 27.6.0, while nearly one third (32%) of grandmultipara was within age group 36-40 years with a mean of 33.2. Also(15) reported that the average age of the study group was 25.1 years, which was a suitable age for reproduction. Simonsin study(16) reported that numerous obstetrics complications have been independently associated with progressive maternal age. In addition, older women with 5 or more babies known as risk group. (17) Daniel and Seidman(18) considered the age factors that increase the hazards of high parity, so the grandmultipara is an older woman and suffers those disabilities which accompany age; especially her cardiovascular system is less resilient so that hypertensive disease is more manifest. The risks of teenage pregnancy are well known, but these account for a relatively small proportion of pregnancies in most countries. In contrast, the proportion of pregnancies in women aged 35 and older are higher and are rising in many countries. The proportions of older mother are rising in many countries ranged from a low of 7.5 in Slovakia to a high of 24.3 in Ireland.(19) Older mothers have a higher prevalence of pregnancy complications, including some congenital anomalies, hypertension, and diabetes. Older maternal ages is significant risk factor for maternal mortality and morbidity, are more delivered by C/S. and have more low birth weights, which will thus cause higher rates of fetal and infant death.(20)

*Educational level* concerning poor educational status of women largely contributes to multipara cesarean section (MCS) and its complications, and prevents
them to take benefit from available facilities. That is why MCS is more common in lower socioeconomic group.(21) The educational level for most mothers in both groups (2-3, and 4-and above) times (MCS) was limited (secondary and primary educational level graduate) as shown in figure (2). This result agrees with Ahmed and Roman et al.14 and 22 studies who stated in their study that concerning obstetric and neonatal outcomes in grand multiparity that grand multipara was in lower level of education, and consistent with Begum study(23) who reported that the level of education status almost poor in grand multiparous women. Mothers of poor level of education often face the following consequences: social isolation, poor life habits, low education level, maltreatment, stress, and depression, in addition young mothers are at greater risk of leaving school or attaining a lower level of education.(24) Educational level is well correlated with perinatal outcome.(20)

The results indicated that more than two third of mothers (89%) have information about delayed healing wound after operation and more than half (53%) knowing about bleeding after the operation, more than one third (48%) weakness of bowel movement after delivery, more than one half (61%, and 63%) about obesity and bulge their abdomen, and knowing about urinary tract infection after cesarean section and this results agree with Ghasvari, et al. study(25) indicate mothers have good and moderate knowledge about maternally complication for elective and emergency cesarean section.

In table (3) shows that no significant association between maternal knowledge and their age groups, and its agree with Ghasvari and et al. study(25).

In regard to their Educational Level study by Ghasvari and et al.25 reported that have (35.5% and 41.8%) good and moderate knowledge level about cesarean section at under diploma mothers educational level and its agree with the present study in tables (4), while the association between mothers’ knowledge and their level of education have significant for the items: bladder puncture during operation, respiratory tract infection as a result of anesthesia, placenta accreta in the next pregnant, and hysterectomy related to placenta accreta only.

Related to their multipara cesarean section the present study table (5) shown that the association between mothers’ knowledge and their multipara cesarean section has significant with Inflammation of the uterus lining item only and the other items and totally knowledge items has no significant and it’s agree with Ghasvariand et al.25 reported that have (33.9% and 43.5%) good and moderate level of knowledge.

### Conclusion

Most of the study samples have multipara cesarean section at age above thirty years old; means the previous twenty years increase number of cesarean section instead of normal vaginal delivery. Most of them have low educational level lead to poor information about the risk of cesarean section and chose easily kind of delivery with no difficulty pain.

Value of the Perineal Ultrasound in the Diagnosis of Anterior Urethral Stricture in Male Patient

Firas Abdullah Noori¹, Ali Abdu Baqi Ali², Riyadh Adel Abdulazeez³

¹Assist. Prof., FICMS, Department of Radiology, College of Medicine, University of Thj-Qar, Iraq. ²Assist. Prof., FICMS, Department of Urology, College of Medicine, University of Thj-Qar, Iraq. ³Assist. Prof., FICMS, Department of Radiology, College of Medicine, University of Thj-Qar, Iraq

Abstract

Objectives: Determine the role of perineal ultrasound in the diagnosis of anterior urethral strictures and assessment of peristenotic fibrosis.

Material and Method: Thirty healthy adult male and thirty patients with suspected urethral stricture have had urethral ultrasound after distension of urethra with a normal saline. The thirty patients also underwent retrograde urethrogram (RUG).

Results: Average diameters healthy urethra were 11.6 +/- 3.1 mm at penile level, 11.2 +/- 2.7 mm at the bulbous level, and 9.7 +/- 2.8 mm at the bulbomembranous level. The periurethral tissue thickness averaged 2.7 +/- 0.5 mm at penile level, from 3.5 +/- 0.65 mm to bulbous level and 3.8±0.6 mm at the bulbomembranous level. Ultrasound made the diagnosis of 31 stenosis or 96.87%. On ultrasound, the length of the stenosis was significantly longer than that seen on retrograde urethrogram with a significant difference between the two techniques (P = 0.045). There is also a significant difference in diameter of urethral strictures between the two techniques. The thickness of the periurethral tissue at the level urethral stenosis was more than that measured in a healthy zone in all cases, whatever the urethral portion concerned. There was not no correlation between periurethral tissue thickness and degree of stenosis.

Conclusion: Urethral ultrasound is a method that allows us to make the diagnosis of urethral stricture and to assess periurethral fibrosis. It could validly replace retrograde urethrogram in diagnosing anterior urethral stricture.

Keywords: Perineal ultrasonography. Urethral stricture. Retrograde urethrogram.

Introduction

Urethral stenosis is the decrease of the caliber of the urethra, causing a resistance to the antigrade flow of urine¹. Stricture of male anterior urethra is a common pathology and may be congenital or acquired in origin². It has a therapeutic problem which is the risk of recurrence related to the development of a peristenotic fibrosis in the spongy tissue³. A precise therapeutic preassessment taking into account the characters of the urethral stenosis and peristenotic tissue appears so indispensable³. The usual investigation of diagnosing urethral stricture were based on retrograde urethrogram which have limits in evaluation of the exact length of the urethral stricture and they cannot appreciate the associated spongy fibrosis³⁻⁴. Ultrasound could be a good alternative to them due to the possibility of evaluation both the urethral stenosis and the peristenotic tissue (3-4). Our purpose is determining the value of ultrasound in the diagnosis of urethral stricture and in the appreciation of peristenotic fibrosis.

Patients and Method

We conducted a prospective study over one-year period that has consisted of comparing the ultrasound of the anterior urethra to the retrograde urethrogram (RUG) in adults. Sixty adult men were recruited from the urology department and have been divided into two groups. Thirty men were considered healthy without trouble in micturition or antecedent of urine pathology.
have undergone Urethral ultrasound. The ultrasound study of the normal urethra made us familiar with normal ultrasound anatomy before studying the stenotic urethra. Thirty patients suspected of having a urethral stenosis have undergone RUG and urethral ultrasound performed on same day.

**Technical:** At retrograde urethrogram: number, degree of stenosis, length and gauge stenosis were appreciated each time on the view that unfolded it best. The length and gauge were evaluated by direct measurements on radiographic images. The degree of stenosis was obtained by dividing the diameter of the residual lumen in narrowed area on the diameter of the healthy zone downstream. Urethral Ultrasound were performed using an ultrasound General Electries Logiq E9 machine with an ML 6-15 probe. A specialized radiologist who did not know the results of RUG.

![Moderate 1/3-1/2 Lumen occluded](image)

![Severe > ½ Lumen occluded](image)

**Fig (1): McAninch Ultrasound classification of the degree of urethral stricture**

The patient was lying supine; the urethra was distended by a retrograde perfusion of normal saline. The penile urethra has been visualized by a ventral approach, the bulbar urethra was visualized by transscrotal, and bulbo-membranous urethra was visualized transperineally. The urethral strictures were evaluated by direct measurements on the screen in their following aspects: topography, number, degree of stenosis, length, caliber. The echostructure and the corpus spongiosus peristenotic thickness were compared to those of the adjacent normal area, to appreciate peristenotic fibrosis. We adopted the classification by MacAninch of the degrees of stenosis. According to this, a mild stenosis is less than 33%, moderate between 33 and 50% and severe stenosis is greater than 50%. Examination ended with suprapubic route ultrasound of the bladder, prostate and seminal vesicles. Analysis was performed using IBM SPSS v 23.0 software. The paired t-test and correlation coefficients were calculated. In all tests, p values of ≤0.05 were considered significant.

**Results**

The average age of the 30 healthy subjects was 39.77 +/- 9.5 years old. Average diameters healthy urethra were 11.6 +/- 3.1 mm at penile level, 11.2 +/- 2.7 mm at the bulbar level and 9.7 +/- 2.88 mm at the bulbo-membranous level. The periurethral tissue thickness averaged 2.7 +/- 0.5 mm at penile level, from 3.5 +/- 0.65 mm to bulbar level and 3.8±0.6 mm at the bulbo-membranous level. The average age of 30 patients suspected to have urethral stricture was 44.8 +/- 7.71 years old.

On RUG, we observed 32 urethral strictures including 28 single and two double strictures. At the ultrasound radiologist reported 31 urethral strictures, 96.87% of which 29 single and one double strictures. Because in one patient who had two strictures (bulbar and penile), ultrasound had detected only the penile one.

At RUG, the types of urethral strictures were the following: 5 penile (15.63%), 21 bulbar (65.62%), 6 bulbo-membranous (18.75%). Locations on ultrasound were identical but one bulbar stricture less (figure 2). Urethral stricture causes were traumatic in 6 cases, 20% and post-infectious in 24 cases, 80%.

The length of the strictures was compared in an accurate way between the two techniques RUG and ultrasound. Of 26 strictures, the length of urethral stenosis measured on ultrasound is greater than that seen
on RUG. Of 6 strictures, the length is the same between the two techniques. At RUG, strictures ranged from 2 to 14 mm with an average of 5.96 +/- 3.05 mm. On ultrasound the length of the strictures varied from 3 to 25 mm with an average of 9.25 +/- 5.9 mm, there was a significant difference between the two techniques (P = 0.045). As for the caliber, it varied from 1 to 7 mm at the RUG, while from 1 to 12 mm at ultrasound with averages of 3.1 +/- 2.2 mm and 4.6 +/- 1.9 mm respectively with a significant difference (P = 0.05). The comparison of the degree of stenosis with RUG and ultrasound did not show significant difference (P = 0.66). The minimum values were 12% and 15% at RUG and ultrasound and the maximum 70% and 80% respectively (table 1). The thickness of the periurethral tissue (TPU) at the level of urethral strictures was greater to that measured in a healthy zone in all cases, whatever the portion urethral concerned. This thickness averaged 6.9 +/- 2.05 mm at the level of penis, 6.3 +/- 1.67 mm at the level bulbar urethra and 6 +/- 1.8 mm at the bulbomembranous level. The peristenotic fibrosis had more echogenicity than healthy periurethral tissue but there was no correlation between periurethral tissue thickness and degree stenosis.

Discussion

The average age of patients with urethral stricture was 44.8 +/- 7.71 years has been in line with the data from the Quirassy study. Preponderance of the infectious etiology was observed by many authors. Ultrasound diagnosed with urethral stenosis in 96.87%, these results are comparable those of Gluck’s study in which two bulbar urethral strictures were undetected without having a precise reason. In our study undiagnosed stenosis could be explained in that the patient presented a double stenosis and only the stenosis the tighter was individualized. This would be overridden with more experience of examining urethral strictures. We found that the lengths of urethral strictures were significantly greater in ultrasound than RUG, our results are consistent with those in Das [9] while differs from the results of Pierredon-Fulongna in which the lengths on ultrasound and UCAM were substantially equal. Our ultrasound measurements were not compared to the surgical results. But studies which have compared the length of the urethral stenosis determined by ultrasound and by RUG to the urethroplasty results showed better ultrasound reliability. Ultrasound measurements seemed more reliable because they have been carried out directly on the exact stenotic area without radiological magnification or distortion of the image. In our study there was a concordance of the topography of urethral strictures between RUG and ultrasound except for one bulbar stenosis. The predominance of the bulbar seat (65.62%) in our work was observed by other authors. This predominance could be due to stagnation of urethral gland secretions at this level according to Thoumas. We did not have observed a significant difference between degree of stenosis measured on RUG and ultrasound as in Pierredon-Foulongne study. On ultrasound, a periurethral tissue thickening in the portions where there were stenosis has been demonstrated in all our patients. However, we could not distinguish perstenotic tissue from the fibrosis properly. The prognostic value of the echogenicity of the perstenotic tissue could not be specified in the absence of comparison with the follow-up imaging of the patients. Several authors noted in their studies that the visualization of the fibrosis was inconstant with its ultrasound appearance, because it was hyper or isoechoic for some and hypoechoic for others. The use of a higher frequency probe would provide a better definition of perstenotic structures according to the study of Garcia. Magnetic resonance imaging can highlight any evidence of an inflammation of the urethra in the form of a diffuse thickening of the TPU which appears as an intermediate signal intensity in T2 weighed imaging.

CONCLUSION

Urethral ultrasound is an easy accessible method of diagnosing urethral stricture with a greater safety than retrograde urethrography and voiding cystourethrogram. Ultrasound can reliably replace them especially in post-infectious etiologies after proper training of the operator. Ultrasonography has more value than RUG in assessment of length and caliber of the anterior urethral stricture. Also has advantage in assessing the periurethral tissue thickness (TPU).

Judicial Jurisdiction According to the United Nations Convention Against Corruption and its Application to the Iraqi Medical Sector

Sarmad Amer Abbas

Assist. Prof., University of Babylon/Faculty of Law/Iraq

Abstract

There is no doubt that corruption is a growing scourge in all countries due to its direct negative impact on the development of societies and limiting their development. It has also become a phenomenon with social, economic and political aspects. Combating it does not require the concerted efforts of one state institutions only, but rather the necessity for states to cooperate with each other to curb administrative and financial corruption. Since 1996, international anti-corruption conventions have served to raise political commitments to fight corruption and have defined basic international standards and practices to tackle corruption. The medical sector in Iraq suffers from corruption in its various health and administrative sectors.

Keywords: Judicial jurisdiction, Corruption, application, medical sector.

Introduction

Notwithstanding a surge in awareness and a plethora of international initiatives, many hurdles remain on the road towards a corruption-free world. To start with, there is no agreement as to what exactly constitutes corruption. Different countries and actors apply differing definitions. Even where agreement exists as to a corrupt act, jurisdictional problems may impede the prosecution of such acts. Moreover, even after a successful legal challenge of corrupt acts, the recovery of assets needs to overcome several legal and logistical hurdles in order to be successful. In addition, the link between corruption and good governance, and between corruption and human rights, remains the subject of intense debate. Iraq has continued the constitutional embrace of international law over the past 15 years by making new international commitments, including joining the United Nations Convention against Corruption. As the United Nations Secretary-General recently noted, the agreement promotes “the shared goals of good governance, stability and prosperity for the international community” and disrupts money laundering, organized crime, and theft of public funds. Iraq took a number of steps in accordance with these goals that led to, and shortly after, accession to the Anti-Corruption Convention. They included, for example, developing and maintaining “coordinated anti-corruption policies”, such as issuing an anti-money laundering law, issuing public procurement and investment laws, issuing a law mandating disclosure of assets by senior government officials, reinforcing the responsibilities of Article 5 of United Nations Convention against Corruption. In addition, the state has established and maintained “bodies, as appropriate, that prevent corruption,” such as the Integrity Commission, which has investigated thousands of corruption cases since 2004. The health sector in Iraq lives in the midst of an intractable crisis that has worsened in recent years in a country that does not know stability for several reasons that vary but are closely related to the political will of the country’s rulers. The health care system in Iraq suffers from several diseases that have decayed its body, such as the permanent shortage of medicines and the unavailability of medical staff.

The Connection between Corruption and Human Rights: When several global and regional treaties to combat corruption were adopted in rapid succession. Regarding the emergence of anti - corruption international legal standards, the Chief of Crime Conventions Section of the United Nations Office on Drug and Crimes (UNODC) maintains that: “the gradual understanding of both the scope and seriousness of the problem of corruption can be seen in the evolution of
international action against it, which has progressed from general consideration and declarative statements, to the formulation of practical advice, and then to the development of binding legal obligations and the emergence of numerous cases in which countries have sought assistance from other countries in investigating and prosecuting corruption and in tracing, freezing, confiscating and recovering proceeds of corruption offences."Bribery and embezzlement involving public officials diminishes the enjoyment of a human right. Any specific corrupt act is considered a violation or diminution of human rights.

Accordingly, “Corruption” and “bribery” Corruption and bribery are two terms often mistaken for one another or used interchangeably as they have very similar meanings. However, it is important to understand the differences between the two so that businesses can effectively manage, mitigate or hopefully prevent the problems they cause. And the Corruption, is not a technical term; it is not considered a criminal offence in most criminal codes around the world and it also does not have a legal definition in most international treaties. The most common definition is that used by the NGO Transparency International, according to which corruption is the abuse of entrusted power for private gain. Such abuse may happen on the level of day-to-day administration and public service (“petty corruption”), or on the high level of political office (“grand corruption”). These terms do not mark a legal distinction but merely describe variations of the same theme. Often, a particular scheme of corruption permeates the various levels of public administration, and thus links both forms of corruption. Because of the growing power of large corporations and non State actors such as FIFA, the abuse of obligations arising from private law—in a “private” principal-agent relationship—is also increasingly qualified as corruption. The relevant criminal offences are active and passive bribery, criminal breach of trust, graft, illicit enrichment, and so on. In the private sector, offences include anti-competitive practices and regulatory offences. This is not about any (new) human right to a corruption-free society. Such a right is neither recognized by legal practice nor is there a need for it. Rather, corruption affects the recognized human rights as they have been codified by the UN human rights covenants. In practice, what is most often affected are social rights, especially by petty corruption. For example, corruption in the health sector affects the right of everyone to the highest attainable standard of health (Article 12 ICESCR); in the education sector, the right to education (Article 13 ICESCR) is at issue. But also the classical liberal human rights may be undermined by corruption: If a prisoner has to give the guard something in return for a blanket or better food, then the prisoner’s basic right to humane conditions of detention (Article 10 ICCPR) is affected. If – as most observers tend to think – the current surge in human trafficking is made possible and facilitated primarily by corruption that induces police and border guards to look the other way, then this affects the human right to protection from slavery and servitude (Article 18 ICCPR). Obviously, corruption in the administration of justice endangers the basic rights to judicial protection, including the right to a fair trial without undue delay (Article 14 ICCPR). In the case of grand corruption and foreign bribery, however, the implications for human rights—such as the effect of nepotism on the right to equal access to public offices (Article 25(a) ICCPR)—are less clear.

The most important principles related to the implementation of the United Nations Convention are as follows:

1. The agreement is a binding legal instrument for the states parties, and the failure of the state to implement it entails its international responsibility. Article 66 of the agreement allows for the settlement of disputes between the states parties regarding the interpretation of the agreement and its application through arbitration. If the states parties are unable to agree to arbitration, the dispute may be referred to a court. International justice.

2. The implementation of the agreement shall be through the adoption of a set of legislative and administrative procedures to put the state’s commitment into practice.

3. The implementation of the convention by the national judge shall be through the frameworks laid down by national legislation that explain how to implement the convention and clarify the implementation procedures.

4. The obligation to implement the agreement does not undermine the respect for the national sovereignty of the states parties, including the exclusive exercise of the jurisdiction over their territory in all prosecution and punishment procedures, unless the mechanisms of international judicial cooperation allow for some kind of joint investigation.
Preventive Measures: It is a set of public policies aimed at preventing corruption and states must implement or activate them. Among the most important policies mentioned in the agreement are:

1. Establishing independent bodies responsible for combating corruption and cooperating with states parties to the convention,
2. Spread anti-corruption awareness
3. Establish codes of conduct for public employees and private sector employees with the aim of enhancing integrity and responsibility.
4. These measures also include the establishment of systems and regulations requiring public officials to disclose their earnings from work and any other external activities.
5. Regulating public procurement in addition to enhancing cooperation between law enforcement agencies and private sector entities,
6. It should be noted in this regard that the agreement also emphasized the role that civil society and civil organizations play in the field of prevention and preventive measures.

Criminalization and enforcement: Chapter Three of the Convention consists of twenty-eight comprehensive articles. The importance of this chapter is due to its relevance to the acts criminalized according to the convention. Accordingly, all states parties must adopt “all the legislative and other measures that may be necessary to criminalize these acts,” when they are committed intentionally. This chapter also deals with law enforcement procedures. The convention lists legislative measures to criminalize a number of acts, including but not limited to; A public official promised an undue advantage in return for performing an act or abstaining from it, or seeking or accepting a public official for an unworthy advantage, and the bribery is considered one of the most criminal and most dangerous acts, and the matter is equal in the case of bribing a public official affiliated to the state party, or bribing a foreign public official, or An employee of an international public institution as long as the purpose behind granting him such advantage is to obtain an undue benefit or advantage related to the work of that employee concerned.

The convention also criminalizes the exploitation of the actual influence of the public office, and obligates states to take the necessary legislative and other measures to criminalize the public official’s intention to abuse and exploit the public office.

Trial procedures and protection of witnesses, informants and experts: It is legally established that the procedures for any trial must be conducted in accordance with the fair trial standards established by international human rights covenants, which are affirmed by almost all state constitutions, and that conviction is only made with sufficient evidence that reaches a stage beyond reasonable doubt, and that such a trial Its existence is only conceivable if there is sufficient evidence that is legally acceptable, and that this evidence needs procedural protection, otherwise it will lose justice.

* On the other hand, the necessary measures must be taken to protect witnesses, and here comes the issue of witness protection to take on growing importance, especially when it comes to crimes related to money, and Article (32) of the Convention dealt with the issue of protecting witnesses and experts, while Article (33) dealt with Of the United Nations Convention against Corruption, protection of whistleblowers and those in a more dangerous situation than witnesses; This is because the amount is the source of the first information about the alleged crime, and this puts the amount in a situation where it needs legal protection during and after the litigation procedures. In order to achieve the goals aimed at by the convention, articles (37-38-39) deal with aspects of cooperation with law enforcement authorities on the one hand, and the cooperation of these authorities with each other on the other hand. Among the forms of corruption is the employee’s interference in the safety of more or more government tenders or the abuse of office influence in obtaining rights for others at a low price and deliberately damaging state funds, which is one of the crimes of gross negligence. General No. 19 of 2008 due to its attachment to public money and its preservation, and in accordance with Article 341 of the Iraqi Penal Code No. 111 of 1969, as amended, every employee or person assigned to a public service who causes a serious error to inflict serious damage on the funds and interests of the entity in which he works or is related to it by virtue of his position or With the money or interests of the people entrusted to him if this resulted from gross negligence in performing his job or from abuse of authority or from a serious breach of his job duties, and other laws that deal with cases of administrative and

an arrested, detained or arrested person, accompanying
him or moving him and causing one of them to escape.
The Integrity Commission Law considered the crime
of forgery stipulated in Article 290 of the Penal Code
No. 111 of 1969, as amended, which stipulates that
(Whoever carries an employee and is assigned to a
public service while recording a report is within the
competence of his job, either by impersonating another
person’s name) Or by acting in a capacity that he does
not have, or by reporting false facts, or by other means
to record or prove an incorrect fact regarding a matter
that the document would prove to be proven by the legislator
as the legislator considered as one of the corruption
cases that the employee or the person charged with a
public service issued one of the aforementioned papers
with the knowledge that the one for whom it was issued
He has assumed a false name or a false personality, as
well as Article (296) of the Penal Code considered a
crime of corruption that punishes with imprisonment
whoever is legally mandated to keep books or papers
subject to the control of the public authorities, and he
writes in them things that are not true. It is possible or
omitted to record true matters in it, and that would have
deceived the aforementioned authorities and made them
into a mistake and any other crime in which one of the
aggravating circumstances provided for in paragraphs 5,
6 and 7 of Article 135 of the Penal Code in force.

More than 50% of the money allocated to building
hospitals in Iraq has been wasted, indicating that huge
sums of money were spent to build 15 to 20 large
hospitals, of which only 4 hospitals entered service. And
the reality in Iraqi hospitals in light of the Corona virus
crisis is that Iraqi hospitals are a hotbed of transmission
of infection and the spread of the epidemic between sick
people and health personnel.

International Cooperation: Under Chapter Four
of the Convention, states parties must assist each other
in combating corruption, and this chapter provides
standards for mutual legal assistance, and cooperation
comes in the form of extradition, mutual legal assistance,
transfer of judgments of persons, criminal procedures
and law enforcement cooperation, which encourages
Also, cooperation in civil and administrative matters.
Likewise, member states must, in accordance with this
chapter, take the necessary measures that would support
tracking, freezing, seizing and confiscating proceeds of
corruption.
Asset Recovery: Chapter five is one of the basic principles of the agreement, as the recovery of assets obtained from incidents of corruption is a very important issue, especially for developing countries where corruption rates are increasing.

The agreement includes the essential provisions that establish specific measures and mechanisms for cooperation with the purpose of recovering assets while preserving flexibility in recovery procedures that may be justified under special circumstances, and those provisions would support countries’ efforts to address the effects of corruption by sending a message to those responsible for committing Acts of corruption that there will be no place to hide illegal assets in the presence of international cooperation based on the recovery of the proceeds of corruption.

Jurisdiction: The United Nations Convention against Corruption requires both the requesting state party and the requested state to have jurisdiction according to the role entrusted to it in the issue of asset recovery, i.e. the state submitting the recovery request must have jurisdiction over the crime from which the money the subject of the recovery request was obtained from. The acceptance of the requested State Party shall depend on this request. She referred to this agreement condition in paragraph (1) of Article (55), which affirmed that the state party receives a request from another state party for the purpose of confiscating proceeds or property obtained from a crime of corruption that has jurisdiction over it or the tools used to commit this crime if it takes The necessary procedures, that is, the state party receiving the request for confiscation does not accept the request and does not take the necessary measures unless the state party submitting the confiscation request has jurisdiction over the crime from which the money or property to be confiscated was obtained.

Not only that, but also the preparations for the draft United Nations Convention against Corruption confirmed this condition, as it mentioned an explanatory note regarding Paragraph (1/a) of Article (54) of the Convention that the state party does not take the necessary measures to enforce a confiscation order issued by the courts of a state party. Others, by referring it to its competent authority for implementation in the event that this order is issued by a court that does not have jurisdiction over the crime of corruption and the money obtained from it.

Regarding the state party receiving the request for recovery, the agreement requires this state to also have jurisdiction in relation to the legal actions that it takes in relation to the proceeds of crime, property, money or equipment that are the subject of the recovery request. Article (52) devoted to measures to prevent and uncover the transfer of proceeds derived from a crime of corruption stipulated in this agreement, as it required the State Party that received the request to have jurisdiction to take the necessary measures regarding obligating existing financial institutions to take a set of measures in relation to opening Accounts in them, verify the identity of customers, and take reasonable steps to determine the identity of the beneficial owners of the funds deposited in high-value accounts, and to carefully examine the accounts to be opened. The state party can also inform the financial institutions that have jurisdiction over them and upon a request from another state party or on its own initiative, with the identity of natural or legal persons, by carefully examining their accounts. The request cannot undertake these measures if it does not have jurisdiction over the financial institutions that wish to undertake the aforementioned procedures.

Asset recovery through confiscation: The agreement specified three cases of freezing or seizure in paragraph (2) of Article (54), where it stipulated that the State Party, in order to be able to provide mutual legal assistance, upon a request submitted pursuant to Paragraph (2) of Article (55) of the Agreement, must: It shall, according to its national law, the following:

1. The State Party shall take the necessary measures to enable its authorities concerned with the freezing and seizure of property, in accordance with a freezing or seizure order issued by a court or other concerned authority present in the requesting State Party that constitutes a reasonable basis for the requested State Party to believe that there are sufficient reasons to take such measures and that in the end, the mentioned property will be forfeited.
2. The State Party shall take the necessary measures to enable its competent authorities to freeze or seize property and in accordance with a request issued by another State Party that constitutes a reasonable basis for the requested State Party to believe that there are sufficient reasons to take such measures and that these properties will eventually be confiscated.
3. The State party should consider taking additional measures to enable its competent authorities to
preserve property for the purpose of confiscation based on an arrest or a criminal accusation related to the possession of such property.

An explanatory note regarding Paragraph (2/a) of Article (54) (first case) indicated that the State party can choose between instituting the procedures either for recognition and enforcement of the foreign seizure or freezing order or for the use of this foreign order as a basis for obtaining a seizure or freezing order. The reference to the freezing or seizure order stipulated in Paragraph (2/a) of Article (54) should not be interpreted as requiring the enforcement of this order upon its issuance by an authority that does not have jurisdiction or recognition.

It can be said that the invitation is necessary for the drafters of the agreement to amend paragraph (2) of Article (54) to remove the ambiguity or confusion arising in it by clarifying when the request for freezing or seizure should be based on an order issued by a court or other competent authority and when the mere request is sufficient to complete this process. It is also necessary to clarify when the request is based on sufficient reasons and what are these reasons, and it is also necessary for them to indicate what the additional measures are, whether for example or exclusively.

The authority governing the confiscation: Confiscation is a complementary punishment, and since it is a punishment, it must be issued by a court ruling, meaning that a person’s money cannot be confiscated except by the court hearing a case related to a felony or misdemeanor, and by referring to the United Nations Convention against Corruption, we find that it has violated this rule and deviated from it as it came with a ruling. The meaning of the permissibility of a confiscation order issued by a non-judicial authority when defining confiscation in Paragraph (g) of Article (2) as it defined “the term confiscation, which includes forfeiture, where applicable, means the permanent deprivation of property by an order issued by a court or other competent authority.” The agreement did not indicate what this authority is, is it the public prosecutor or an administrative body.

Conclusions

1. Encouraging the states parties to the convention to adopt the mechanisms of international cooperation contained in the convention, and to include them in their domestic laws and bilateral or multilateral agreements that they conclude; Because this cooperation has a great role in reducing corruption.
2. The necessity to develop anti-corruption mechanisms in international agreements to suit the specificity of the country in which they will be applied, with an emphasis on the common goals of all these countries to achieve a high level of good governance and transparency, and not to hinder efforts made for all these countries to join global and regional conventions against corruption.
3. The necessity to establish a special body to combat corruption in every country of the world consisting of persons of credibility and integrity, to give it complete independence and to grant it full powers and immunity in conducting investigations and decision-making and to develop carefully studied strategies that apply the true concept of financial, administrative and judicial control for those who attack public money and those who commit Corruption crimes and for the United Nations Convention against Corruption to be more meaningful and effective.
4. The researcher calls on the Iraqi legislator to enact a law concerned with combating corruption and to allocate part of its articles to the international cooperation mechanisms mentioned in the agreement.
5. Cooperation internationally and regionally to combat corruption in all its forms, and other phenomena related to corruption, such as organized crime and money laundering, and to join and ratify international treaties and charters that achieve combating corruption.
6. Establishing an international court similar to the International Criminal Court, with jurisdiction over corruption crimes and the trial of the most corrupt and theft of public money, including money laundering crimes in third world countries whose people are unable to bring them to justice.

Abstract

The terrorist financing activities are considered one of the most important threats that facing the security and safety of people of society in all its forms, as their danger increases by adopting a pattern of transnational organized crime. There is no longer planning, managing and implementing them is done within the territory of one country, but its lines are woven across multiple countries to conduct them in the targeted country with the crime. Iraq comes in the forefront of countries that suffered from terrorism and the violent crimes, in order to strike stability in it, also to sow discord and sectarian fighting for this, the Iraqi state must confront the terrorism in general, as well as the terrorist financing activities in particular, reducing its seriousness and punish the perpetrators, so, the Anti-Terrorism Law No. 13 of 2005, and the Anti-Money Laundering and Terrorist Financing Law No. 39 of 2015, was issued, as it was issued in implementation of Article 22 of the Money Laundering Law that was mentioned previously, this leads to the question about the adequacy of these legal texts to address the crime of financing terrorism, whether the Iraqi legislator succeeded in putting in place the necessary mechanisms with the appropriate part to prevent these funds for reaching to the hands of terrorist organizations.

Keywords: Terrorism, penalties, Anti-Terrorism.

Introduction

Criminal legislation did not agree on a unified concept of terrorism, as this is normal in light of the variation in their perception of terrorism (¹) because it is in what is considered a terrorist act in the eyes of a specific country or a specific community may not be considered so in the view of another country or society (²) then by referring to the Iraqi Penal Code No. 111 of 1969, it did not include a definition of terrorism, but it indicated in item (a) of Article (21) of it that the terrorist crime is not considered a political crime without specifying its concept, as this is a legislative deficiency in it, where it referred to a term without defining its concept. As for the Iraqi Anti-Terrorism Law No. 13 of 2005, terrorism was defined in its first article as: (Every criminal act by an individual or an organized group that has targeted an official or unofficial individual or groups or institutions or has caused damage to public or private property in order to disturb the security situation, stability and national unity or introduce terror or fear among people, creating chaos to achieve terrorist goals) in this way, the Iraqi legislator has followed the direction that was limited to defining terrorism without mentioning terrorist crimes, as some may see that what distinguished the definition that the legislator which he mentioned in the anti-terrorism law is that he limited terrorism to the acts that were criminalized by the law as the description was not detailed, that this is one of the advantages of the text that prevents the authority from arbitrarily using its authority in the fight against terrorism (³), while we can find others criticizing this definition in several ways, on the one hand, it was limited to the terror of individuals and groups, that the state terrorism has not been shown despite the gravity of the threat which is posed by terrorism of the state, on the other hand, others see that what the Iraqi legislator did not represent a definition of terrorism, but a description of the act of terrorism that it is counting and formulating a group of criminal acts, that which must be give a direct definition of the term terrorism, in addition, its formulation according to which the definition was established was weak, as the definition came vague, as the legislator did not show what these goals were, nor did he explain the criteria for determining them (⁴).
term terrorism financing, it has been dealt with by economists more than that dealt with by legislators, as the economists have defined it as (searching for sources through which money can be spent to spend it on implementing or conducting a plan) \( ^{(5)} \), also others define it as (taking the necessary measures to obtain funds from their appropriate sources at the appropriate time and on satisfactory terms) \( ^{(6)} \), as for the jurists of the law, they have defined the financing of terrorism as (providing or collecting, under any name, money or related services for the purpose of using it, or that he knows you will use all or part in a work that provides benefit to any individual or collective terrorist project and whether or not the result is achieved) \( ^{(7)} \). It is also it was defined as (financial support in various forms which is provided to individuals and organizations that support terrorism or who are planning terrorist operations, as the transfer may come from legitimate sources such as charities, for example, with or without intent or other illegal sources, for example, the trade of damaged goods and drugs) \( ^{(8)} \), while others went on to define it as (financial support or presenting financial support in any form for terrorism, or for those who encourage or develop its plans, or participate in or assist in it, or those who personally undertake terrorist operations) \( ^{(9)} \). In light of these definitions that are provided for the financing of terrorism, it can be said that the financing of terrorism is every act through which, whether directly or indirectly, collecting, or providing money or whatever is equivalent to it to a terrorist group or terrorist person, or the intention of the perpetrator is to use it for terrorist purposes. The sources of financing terrorism have developed in Iraq after the terrorists which occupied several cities in the northern and the western of Iraq from traditional sources of financing, which are represented by rented murder, kidnapping, robbery, armed robbery and other terrorist acts to the more organized and more self-financing sources of influence and larger, traditional internal funding sources no longer meet the aspirations of terrorist groups in Iraq, this is because these groups seek to expand their areas of influence to include new regions to disperse the international efforts to combat it on one hand, establishing terrorist bases of influence in areas that are allowed to move across international borders to facilitate the movement of their trade, whether from smuggling crude oil, antiquities or other, in addition for expanding its revenues from customs duties, whether through transit fees for foreign trade between Iraq and a number of neighboring countries, or by paying the fees to their terrorist groups to facilitate the transportation of crude oil to the sources of maritime transport through pipelines that pass in the controlled by the territories. Among the most important sources of self-financing for the terrorist groups in Iraq are the revenues from oil exports which derived from the sale of crude oil, smuggling it from dominated fields and trafficking in evil, as well as smuggling Iraqi antiquities \( ^{(10)} \). The sources of financing terrorist operations in Iraq have varied in various forms and in various styles, with the aim of continuing the sources of financing to the maximum extent possible. So the terrorists are already developing new measures and plans to finance it, that the method that succeed in combating it become, as soon as they are successful, outdated method, as terrorism like malaria is changing continually and constantly, among the most important sources of its financing are money laundering, international financing, foreign aid, external financial support, external financial transfer, and others in the absence of financial control from and to Iraq, as most terrorist operations are funded from abroad which is from suspicious sources, however, a statement issued by the White House stated that 29 of the largest groups that deal in drugs that were classified by the US Department of Justice in 2010, as its number was 63, it had an association with terrorist organizations, which indicates that administrative corruption with the loss of citizenship for the motherland will cause harm not only to the country itself, but will also harm other countries, so how it could be going on if terrorism, administrative corruption, loss of citizenship, national identity and political sectarian tension in the same country as in Iraq? Also government agencies may participate, with or without intent, in financing terrorist operations. Often times, commercial deals are conducted to finance goods such as foodstuffs, equipment, devices, etc. from outside Iraq without external financial transfer for some Iraqi merchants, then those commercial deals are disposed of and sold on the local market, therefore the financing of terrorist operations is carried out from those suspicious deals \( ^{(11)} \). When the legislator actually criminalizes something, he sets a penalty commensurate with the gravity of this act, so the punishment is a penalty determined by the law which is signed by the judge for an act that is considered a crime in the law, so the punishment, then, must be prescribed by a text in the law and must be signed within the limits of what the law says according to the principle (no crime or punishment except by text), accordingly, we will deal in this pillar with the penalties or punishments which are prescribed for the crime of financing the original, dependent and
complementary terrorism. The original penalties for the crime of financing terrorism are life imprisonment, as this is stipulated in Article (37) of the Money Laundering and Terrorist Financing Law which is conducted, while the Anti-Terrorism Law went to criminalize the financing of terrorism as a form of criminal behavior in the crime of inciting of a sectarian strife in the fourth item of the second article, whereas the financier’s punishment was specified in the second item of the fourth article as it came in it: (... the financier and anyone who enabled the terrorists to carry out the crimes that were mentioned in this law shall be punished with the punishment of the original perpetrator), meaning that this article considers him a partner in the terrorist crime, as the financier shall be punished with the punishment stated in the Anti-Money Laundering Law, as the funded terrorist crime did not take place, as it is an original actor in the crime of financing terrorism, that is, the text of Article (1) item (10) of the Anti-Money Laundering Law applies to it. But if the result is achieved, that is, if the funded terrorist crime occurred, the financier shall be punished with the punishment stipulated in the second paragraph of Article 4 of the Anti-Terrorism Law as a partner in the terrorist crime, therefore, we can sum up the financier’s penalty in general with the following penalties:

1. The death penalty: The legislator considered the death penalty to be the appropriate punishment against the terrorists, since the gravity of the danger and the gravity of the damage that results from these crimes are what prompted the legislator to decide that punishment, as it is the best deterrent for such criminals, so the legislator has done well when he stipulated that punishment despite the voices of those opposing it.

2. As we see if the Iraqi legislator added to the death penalty the maximum by taking measures to resolve terrorist cases and counting them as urgent cases, provided that there are different courts to consider their cases and fast in issuing rulings on them, so as not to delay the resolution of their cases and be subject to external and internal interference from them, then the innocent right is lost because justice has not been achieved, as there was no deterrent and decisive later on for the criminals who did not apply on them the death penalty.

The subordinate penalties, according to Article (25) of the Iraqi Penal Code are (that inflicts on the convicted by the rule of law without the need to stipulate it in the ruling) Article (20) of the Iraqi Penal Code stipulates that: (Every judgement of the death penalty entails the rule of law from the day it was issued until the time of the execution of the judgement, depriving the convict of the rights and benefits that were stipulated)

In the two preceding articles, there is invalidity of every act of management and administration that is issued during the aforementioned period, except of the will and cessation, the Personal Status Court or the Personal Material Court is appointed according to the cases which are based on the request of the public prosecution or any person of valuable interest to the convict), as the deprivation that which mentioned in this article includes the rights which were mentioned in Article (21) penalties and they are as follows:

1. Jobs and services he undertakes
2. To be a voter or elected in the representative councils
3. To be a member of the administrative or municipal councils or one of the companies or was a director
4. To be a trustee or agent
5. He must be the owner, publisher or president of a newspaper

As for the material precautionary measures in the crime of financing terrorism, the Iraqi legislator did not define the material precautionary measures, but rather he explained their types and provided for material precautionary measures that could be applied to the convict by committing the crime of financing terrorism, the measures that are confiscation with the removal or dissolution of the legal entity.

Recommendations: After we have completed our humble study, we can recommend a number of points, as it would be desirable if the competent authorities and the legislative bodies took them, as the most important of them are: The necessity of activating the national supervisory to monitor the sources of financing terrorism, especially in relation to money laundering, human smuggling and sale in the slave market. Issuing deterrent penalties for media promoters of terrorist groups and refraining from granting them legitimate descriptions. Respecting human rights and rejecting violence in all of its forms. Prosecuting cross-border crimes through cooperation and agreement with other countries in the judicial areas and facilitating, extraditing and transferring the accused to bring them to trial. The necessity for national laws in their formulation to combat terrorism and the financing of its sources to take into account all possible aspects of
them with the existence of prior studies on the nature of societies and their national also ethnic configurations, so that they do not lead to provoking counteractions from the purpose of their legislation, so that they are far from applying them to human rights violations.

Assessing Knowledge and Perceptions of Health Care Workers toward Novel Coronavirus (COVID-19)

Hashim Jebur Abed AL-Kaabi¹, Hussein Ali Mohammed ², AbidSalih Kumait³

¹Ph.D. Adult Nursing, Ministry of Health, ²Lecturer Department of Adult Nursing, College of Nursing, University of Kirkuk, ³Ph.D. Assistant Professor, Department of Adult Nursing, College of Nursing, University of Kirkuk

Abstract

Objective: To assess the knowledge and perceptions of health care workers towards coronavirus (COVID-19) in most of the governorates of Iraq.

Method: A cross-sectional survey, web-based study was conducted among HCWs about COVID-19 during the last two weeks of April 2020. Knowledge and Perception were assessed by five components adapted from the Ebola knowledge scale, and A 7-item instrument this part was developed using WHO course materials on Emerging respiratory for viruses COVID-19 and distributed randomly to HCWs using social media. Descriptive statistics were used to express participants’ demographic information, mean knowledge score and mean Perception score of HCWs. Chi squares tests were used to assess the association between study variables and Perception questions was used to identify the level of association among variables at the significance level of p<0.05.

Result: (184) participated of HCWs complete the survey (64.1%) are males, aged 20-29 years (54.3%), and most of them are Nurse (64.7%) and Lab-technicians (20.1%). Regarding COVID-19, most of them used social media to obtain the information (68%), About less than half of the respondents (41.30%) opined that COVID-19 was — a severe illness transmitted to people from wild animals. Approximately 87% of respondents identified “contact by airborne droplets through breathing, sneezing or coughing” as the most common mode of transportation; Most of the participants associated COVID-19 with fever (90.80%), shortness of breath (89.10%) and coughing (76.66%). Handwashing and social distraction were chosen by most respondents (95.70%) as a method of preventing infection while 9.80% reported consuming gin, garlic, ginger, herbal mixtures and foods/soups as precautions against COVID-19. The majority of participants (81%) believed that COVID-19 is fatal; It was also noted that the social media (Whatsapp, Facebook, Instagram, Twitter etc.) are the most common source of health information about COVID-19 (65.20%). demonstrated a positive perception of prevention and control towards COVID-19. Most elements of Perception were significantly associated with gender and age at (P <0.05).

Conclusions: The results of this study showed that healthcare workers have a good knowledge and positive Perception towards COVID-19. As the global threat of COVID-19 continues to emerge, it is critical to additional education interventions and campaigns are required for healthcare workers.

Keywords: Coronavirus, outbreak, COVID-19, Media, knowledge, perceptions, healthcare.

Introduction

Covids are a huge gathering of infections regular all through society. Truly, proof has demonstrated that the infection is sent by feathered creatures and warm blooded animals, with people especially defenseless against disease and transmission of the infection⁴. Past episodes of Covids, for example, SARS-CoV and Middle East Respiratory Syndrome-(MERS-CoV) in 2003 and 2015 show similitudes with the new Covid, which was first detailed in December 2019, which is the momentum sickness in questions Which Caused Coronavirus Outbreak Worldwide, COVID-19.² It was first revealed
by the Chinese experts in Wuhan, capital of Hubei Province in China toward the finish of December 2019(3). The progressing COVID-19 pandemic was affirmed without precedent for Iraq in February 2020. Cases were affirmed in each of the nineteen Iraqi governorates until March 27, with the Kurdistan Region of Iraq representing 309 (26%) of these cases until April 8. (4) During the pandemic, Iraq announced its initially affirmed instances of SARS CoV-2 contamination on February 22, 2020 in Najaf. (5) By April, the quantity of affirmed cases surpassed 100 in Baghdad, Basra, Sulaymaniyah, Erbil, and Najaf. (6) Coronavirus fundamentally spreads from individual to individual through close contact (around 6 feet) with contaminated individuals through the respiratory framework (hacking or wheezing) or is sent by contacting a surface or something in which the infection is discovered (7). As far as manifestations, the World Health Organization revealed that over 80% of the COVID-19 patients demonstrated gentle indications and recouped with no clinical intercession, and about 20% of the influenced cases experienced serious sicknesses, for example, dyspnea, septic stun and various organ disappointments. It has been accounted for that 2% of cases can be deadly (8). Furthermore, it is analyzed through a research facility test. Contamination can prompt intense respiratory issues or demise, particularly among the older and individuals with fundamental ceaseless ailments. Notwithstanding, some tainted individuals are transporters of the infection without side effects, while just others may experience the ill effects of a mellow disease and recuperate effectively (9). As of now, there is no particular antiviral therapy and preventive antibody; Medical therapies are restricted to steady measures pointed toward mitigating side effects and the utilization of examination medications and corrective meds. Along these lines, applying a preventive measure to control COVID-19 contamination is a significant intercession. This is finished by washing hands with cleanser and water, by face covers, and confining affirmed and suspected cases (10,11). Furthermore, medical services laborers (HCWs) are at a high danger of contamination and the wellspring of transmission in the network. Some past investigations have demonstrated that HCW laborers need information and Perception about MERS CoV(12), and SARS (13). Before the finish of January, WHO and CDC (Centers for Disease Control and Prevention) proposals for the avoidance and control of COVID-19 for medical services specialist (14,15). Indeed, WHO has likewise left on various internet instructional classes and articles on COVID-19 unique dialects to advance preventive systems, including mindfulness raising, and preparing arrangement exercises in HCWs (16). This investigation planned to survey information and ideas towards COVID-19 among medical services laborers during this worldwide wellbeing emergency. Additionally, we likewise investigated the function of various data sources in molding the information and impression of COVID-19 HCWs during this pinnacle period.

Method

1. Setting and Participants: This cross-sectional survey has been carried out to assessing knowledge and perceptions of health care workers toward Novel Coronavirus (COVID-19). They were used an online questionnaire to collect data from participants. Health care workers were purposively sent the link through Social media (Whatsapp, Facebook, Telegram, and Fiber) they were asked to participate in an online survey. A snowball sampling technique was conducted using a survey instrument to obtain responses from HCWs from the provinces of Iraq during the last two weeks of April 2020.

2. Procedure: Because of social distance rules and curfews/closures, physical interaction was not possible, so online surveys were promoted and current study participants were urged to send the survey link to potential responders.

3. Instruments (the questionnaire was divided into 3 parts): The first part comprised of Social and demographic data were obtained from respondents about variables such as gender, age, marital status, Occupation, and awareness which including heard about Novel coronavirus, and attended lectures/discussions related to COVID-19.

The second part identified of respondents’ Knowledge about Novel Coronavirus COVID-19 was assessed by five components adapted from the Ebola knowledge scale developed by Rolison and Hanoch(17).

Respondents’ knowledge about Coronavirus COVID-19 is assessed by summarizing the correct
responses via Element 1, method of preventing and curbing the infection, (correct = (b) and (d), (f) or (h)), Element 2, symptoms, (correct = (a), (b) and (g)), Element 3, source of Coronavirus COVID-19, (correct = (d)), Element 4, transmission of COVID-19, (correct = (a), and (b), (c) or (d)), and Element 5, awareness of Coronavirus COVID-19 fatality, (correct = (a)), the maximum degree possible the generation of five elements. The rule is set to 3 which indicates a moderate level of knowledge about COVID-19. Scores greater than 3 indicated a high level of knowledge about COVID-19 while Scores less than 3 indicated a low level of knowledge about COVID-19. The mean score and the standard deviation for the sample population were calculated to indicate the level of knowledge of the sample. Similarly, scores above the base indicate high knowledge and score lower the base indicated low knowledge of Coronavirus COVID-19 for the sample.

The third part Which consists of Source of Knowledge about Novel coronavirus (4 element/4-point Likert scale), and perceptions toward COVID-19 (7 items/Yes or No option), This part was developed using WHO course materials on Emerging respiratory for viruses COVID-19 (World Health Organization. 18).

4. Statistical Analysis: Descriptive statistics were applied to calculate frequencies and percentages of sociodemographic data and knowledge about COVID-19, the Chi-square test was used to explore the level of correlation between variables, Considered the p-value less than 0.05 statistically significant and performed using SPSS Statistic version 19.

Results

We received responses from 184 HCWs participated, as at 2th May, 2020, which was the data cutoff collection date for this study who had completed the online questionnaires, including the respondents were aged between 20 to 60 ≥ years old (Mean 26.85, SD = 9.17), and almost all respondents (n=118, 64.1 %) are male, Regarding to marital status (58.7 %) were married. Majority of respondents are Nurse (n=119, 64.7%), and Lab-technicians (n=37, 20.1%), and almost all respondents agreed that they heard about Novel Coronavirus (COVID-19) (n=183, 99.5 %), but only (n=124, 67.4 %), of them got the chance to attend lectures/discussions about Novel Coronavirus (COVID-19) Table (1).

N = number of samples, F = frequency, % = percentage, \( \bar{X} \) = Mean, SD = standard deviation.

When we requested about sources of information about COVID-19, it was the main source of information obtained through social media (Facebook, Twitter, Whatsapp, YouTube, Instagram, Snapchat) and official government websites. 36% of the respondents reported they use news media (TV/video, magazines, newspapers, and radio) to obtain information about COVID-19. Furthermore, over 80% of respondents sometimes discussed COVID-19 related topics with family and friends (Figure 1).
The results (Figure 2) showed that about less than half of the respondents (41.30%) opined that COVID-19 is — a severe illness transmitted to people from wild animals while 29.90% identified it as — a biological weapon designed by the government of China.

Concerning knowledge about the most common mode of transportation, approximately all (87%) were chosen to “contact drops from an infected person/object by breathing, sneezing or coughing” while slightly more than the average (76.60%) chose “touching contaminated objects” or surfaces. As a means of transmitting and communicating with the virus (Figure 3).
The high majority of the HCWs knew that washing hands with soap and water could help to prevent COVID-19 transmission (99.5%), and sick patients must share their last travel history (98.9%), and symptoms will appear in 2-14 days (97.3%). Besides, (96.2%) agreed that all equipment used in wet markets should be cleaned every day. Feeling unclear eating well-cooked meat during an outbreak of 88.6% and flu vaccination is not enough to prevent (88.6%). However, about 66.8% of the HCWs knew that were not fatal regarding COVID-19 (Table 2).

N = number of samples, F = frequency, % = percentage, *correct answers.

The elements of perception COVID-19 among HCWs in the study were analyzed using a test $\chi^2$ to evaluate the correlation with age, sex. (Table 4).

**Discussion**

Presently, COVID-19 is the subject of worldwide discussion in the media and among people in general, particularly among HCWs and patients. With the current increment in COVID-19 transmission that has raised pressures for everybody, including wellbeing and wellbeing framework authorities, this is an issue of how data is figured out how to help forefront laborers in general wellbeing emergency circumstances. Thus, this information and view of medical care experts can help contain the plague by forestalling and controlling COVID-19 during a worldwide scourge, which will
improve the physical and psychological well-being of people.

The aftereffects of this investigation demonstrated that a huge level of study members knew about and proficient about COVID-19. The outcomes were related with information on COVID-19 as far as respondents’ information on the wellspring of COVID-19, transmission of COVID-19, manifestations of COVID-19, preventive conduct towards COVID-19, mortality from COVID-19 and the primary wellsprings of data about COVID-19 for medical services laborers, the outcomes were altogether high.

The a large portion of HCWs (68%) utilized web-based media as a significant wellspring of data, additionally around 43% that pertinent COVID-19 updates posted online by legitimate government wellbeing specialists have indicated that they effectively affect improving the information levels of HCWs. Furthermore, hence, rely upon solid sources is a primary factor in accepting that straightforward data about a COVID-19 disease is essential for react to HCWs. These days, an assortment of data accessible on the web and this unsubstantiated data can spread rapidly and can misdirect medical care laborers. Wellbeing specialists and specialists specifically have cautioned against the inescapable falsehood of COVID-19 (19,20-12). In this regard, medical care laborers should practice cautious assessment of the data identified with COVID-19, and the first and logical substance of the data sources ought to be utilized. The aftereffects of the current investigation likewise firmly uphold comparable outcomes in which the fundamental wellspring of MERS was accounted for as the web and web-based media(22,23) (Figure 1).

The outcomes (Figure 2) indicated that about not exactly 50% of the respondents (41.30%) thought that COVID-19 is — an extreme sickness communicated to individuals from wild creatures. This is apparent of the different wellsprings of data concerning the COVID-19 that is accessible (24).

Most of respondents (87%) were about the transmission of COVID-19 through airborne drops by means of breathing, wheezing, or hacking which is like an examination by Li, Weic, et al. (25). (Figure 3).

The outcomes appeared, true to form, that medical services experts have a generally high information on COVID-19, and a decent extent concur that a lot of practices endorsed and affirmed by the World Health Organization, for example, hand washing, physical separating, surface sanitization Contaminated, school closings and public occasions, and vaporization of spots the public was important to forestall the spread of the infection. Just a couple of consented to depend on blessing oil, supplication, blistering climate and the utilization of qualities, spices and nourishments, just as chloroquine and anti-infection agents as precautionary measures for the spread of the pandemic. These outcomes are predictable with the past examination Bhagavathula et al.(26). In one examination, it was discovered that medical services laborers washing hands were higher among attendants than different specialists (27). Likewise, the most ideal approach to forestall transmission is by washing hands and utilizing social removing, sterilization of tainted surfaces. Our outcomes are like those of the Khan concentrate on Middle East respiratory disorder(28).

When all is said in done, contrasts were distinguished across various classes of HCWs in their recognitions. About 87.9% of wellbeing laborers somewhere in the range of 20 and 29 years of age understood that flu antibody was deficient to forestall COVID-19 at (p esteem 0.009) and More than 90% of a similar age gathering (20-29) understood that eating meat during an episode is sheltered at (p esteem 0.02). (99%) of HCWs decidedly accept that announcing the ongoing travel history when people are wiped out at (p esteem 0.004), and they understand that indications of COVID-19 show up between 2 to 14 days. At last, most of medical services laborers unequivocally consent to keep up handwashing with cleanser that can help forestall COVID-19 transmission (at p esteem 0.045) and tidy up hardware utilized in wet business sectors.

Conclusions

The current examination is a study to survey information and discernments about COVID-19 among medical care laborers. This examination was significant in light of the fact that it considered information about COVID-19 in the majority of the governorates of Iraq, spaces of information incorporate source, transmission, side effects, wellsprings of data, and defensive conduct toward COVID-19. The outcomes affirm that medical care laborers are completely mindful of COVID-19 and their fundamental wellsprings of data about the pandemic are customary media. As the worldwide danger of COVID-19 keeps on developing, there is a pressing need to convey wellbeing instruction crusades generally.
to medical care laborers to expand the knowledge of healthcare workers that will positively influence their perceptions towards COVID-19.

Assessment of Mother’s Knowledge and Attitude Regarding Newborn Care at Public Hospitals in Kirkuk City

Hewa Shareef Azeez¹, Bahar Nasradeen Majeed²

¹M.Sc. Student, Department of Pediatric Nursing/College of Nursing, University of Sulaimani,
²Lecturer, Dr., Department of Pediatric Nursing/College of Nursing, University of Sulaimani

Abstract

Objectives: To assess mother’s knowledge and attitude regarding newborn care and find out the relationship between socio-demographic characteristics with the mother’s knowledge and attitudes in Kirkuk city.

Methodology: Quantitative approach, cross sectional study design has been carried out in Kirkuk public hospitals from period of 9 August 2016 to 26 May 2018. A non –probability/convenient sampling technique was applied in the present study. Taken those mothers whose babies age are less than one month in three public hospitals of Kirkuk city.

The questionnaire was designed and constructed by the researcher to measure the variables underlying the present study, which consists of three sections, with reliability (0.830) was measured by using Cronbach’s alpha formula.

Results: The findings demonstrate that overall knowledge mean were 1.49, which mean fair level of knowledge. Regarding to the attitudes result indicates that 88% of the sample had positive attitude. The findings indicate significant relationship between knowledge of mother with both variables type of family at p value and educational level and attendance to antenatal care while the relationship highly significant relationship received any information on newborn care during this pregnancy, mother age, occupation and rank of neonate in family. Concerning mother’s attitudes there is a significant relationship between attitude of mother and received anti tetanus vaccine, rank of neonate in family and occupation.

Keywords: Mother’s Knowledge, Newborn Care, Public Hospitals, Kirkuk City.

Introduction

Newborn is considered to be tiny and powerless, completely dependent on others for life within one minute of birth the normal newborn adapts from a dependent fetal existence to an independent one; capable of breathing and carrying on life process. The first hours are crucial because multiple organ systems are making the transition from intrauterine to extrauterine functions¹. There are many causes of neonatal deaths. Complications during pregnancy, the poor health condition of the mother, lack of proper care during pregnancy, filthy conditions during delivery, critical conditions after birth and improper newborn care are some of the major causes of neonatal mortality. Children also die due to premature birth, severe malformation, obstetric complications, or because of infections caused by harmful practices at home. It is estimated that around one percent of infants being born with major congenital anomalies around the world and it is found more common in developing and poor developed countries than in developed countries¹. Globally 4 million newborns die every year before they reach the age of one month. Out of the 1.5 million newborn die in four countries of South Asia. Approximately 3.4 million newborns die within the first week of life. Of these deaths, 66% occur during the 1st 24 hours. Late death i.e.; after 24 hours, still occur 34% and may be prevented if mothers have knowledge about newborn care including dangers sign of newborn. The care the newborn depends a lot on the knowledge, skills, and attitude of the mother. The prim gravida mothers are supposed to be lacking in knowledge and attitude of newborn care ². The majority of newborn deaths take
place in developing countries where access to health care is low. Most of these newborns die at home, without skilled care that could greatly increase their chances for survival. Skilled health care during pregnancy, child and in the postnatal (immediately following birth) period prevents complications for mother and newborn and allows for early detection and management of problems.

**Methodology**

**Design of the Study:** Quantitative approach, descriptive study design has been carried out in Kirkuk public hospitals from period of 9 August 2016 to 26 April 2018. To assess the mother’s knowledge and attitude regarding newborn care at public hospitals in Kirkuk city.

**Setting of Study:** The study was carried out in pediatric wards of three governmental hospitals in Kirkuk city (Azadi Teaching Hospital, Kirkuk General Hospital and Pediatric Hospital).

1. **Azadi Teaching Hospital:** Azadi teaching hospital is considered as one of the major hospital which is established in 1983 and located to the north of the city. The building consists of (6) floors with (400) beds, pediatric wards consist of (64) beds.

2. **Kirkuk General Hospital:** Kirkuk general hospital is one of the oldest hospitals in Kirkuk city. The building is constructed in 1945 and located in the center of the city. It consists of many departments and has (350) beds, pediatric department is one of them which includes (20) beds.

3. **Pediatric Hospital:** Pediatric hospital which is located at the center of Kirkuk city, established in 1972, it is a special hospital for pediatric that includes 120 beds, which offers the services exclusively to children.

**Sampling of the Study:** A non-probability/convenient sampling technique was applied in the present study. Taken those mothers who is their baby’s age with less than one month in governmental hospitals of Kirkuk city. Two hundred forty mothers were constituted the study sample that they were recruited from (Azadi Teaching Hospital 80 mothers, Kirkuk General Hospital 80 mothers, Pediatric Hospital 80 mothers).

**Inclusion Criteria:**
- Mother’s of neonates age (0-28) days.
- Mother’s agree to participate in the study.

**Exclusion Criteria:**
- Mother’s of neonates died at the birth.
- Mother’s of babies with congenital anomalies.
- Mother’s are unconscious or mentally retarded.

**Tools of Data Collection:** In order to collect the proper information study, the questionnaire was designed and constructed by the researcher to measure the variables underlying the present study.

**Patterns of Means of Scores Calculation:** The total mean scoring for section two (knowledge questions) in each domain regarding to the following patterns:

1. The mean of each item if equal to (1.00-1.333) indicate poor level of knowledge.
2. The mean of each item if equal to (1.334-1.666) indicate fair level of knowledge.
3. The mean of each item if equal to (1.667-2.00) indicate good level of knowledge.

The total mean scoring for section three (attitude questions) regarding to the following patterns:

1. The mean of each item if equal to (1.00-2.00) indicate negative attitude.
2. The mean of each item if equal to (2.01-3.00) indicate positive attitude.

**Pilot Study:** A pilot study was conducted on (20) mothers in Azadi teaching hospital, Kirkuk general hospital and Pediatric hospital. It was carried out from 6-10 June in 2016. The pilot study sample were excluded from the study sample. Objectives of the pilot study include the following:

1. To identify the barriers that may face the researcher during data collection.
2. To examine the cooperation of study sample
3. To estimate the time required for each mother interview
4. To determine the stability and clarity of questionnaire or study tool

Before data collection began, pilot test was conducted to assess the general of administering the instrument, and conciseness of the questions.
Reliability and Validity:

Validity: Once the questionnaire for the study is prepared it must be validated. This validation aims at assessing questionnaire according comprehension, relevance to their intended topics, effectiveness in providing useful information and the degree to which the questions are interpreted and understood by different individuals. Content validity of the instrument was determined through the use of panels (15) experts (Appendix A) to investigate the clarity of the questionnaire, the mean of expertise years of experience were 11 years. Relevancy and adequacy of the questionnaire are required in order to achieve the present study objectives. Their responses indicated that all of them had agreed upon the questionnaire content clarity, relevancy, and adequacy. Then the questionnaire was considered valid after taking into consideration their suggestions and recommendations for modification.

Reliability: To test the questioner reliability, internal consistency was measured using Cronbach’s alpha formula on twenty nurses who is excluded from the original study sample. The result of pilot study was (0.830), that indicate reliable of the questionnaire and it is acceptable and adequately to measure and assessment of these mother’s knowledge. The following formula was used for reliability estimate of stability of a measure (polite and hungler, 1999).

$$r = \frac{n \sum xy - (\sum x)(\sum y)/\sqrt{(n \sum x^2 - (\sum x)^2)(n \sum y^2 - (\sum y)^2)}}$$

$r = \text{the correlation coefficient for variable } x \text{ and } y$

$n = \text{number of sample}$

$x = \text{an individual score for variable } x$

$Y = \text{an individual score for variable } y$

$\sum = \text{the summation of.}$

Method of Data Collection: The interviews technique was done by the researcher with each selected mothers those stayed at public hospital mentioned above to get their responses and to clarify the items mentioned in the questionnaire form of the study.

Each interview took approximately (10-20) minutes with each mother. All participants were informed that the information will be kept confidential and used just for a scientific purpose. The data collected for the period between 9 August to 5 November 2016.

Statistical Analysis: All the data were coded and entered to the computer using SPSS software version 23.

Results

Table (1) raveled that more than half of samples which accounts 51.3% their babies age between (1-7) days, it means they are newborn baby and they need special newborn care, followed by both age groups (8-14) days and (15-21) days which accounts 20.0% for each group, the fewest percentages of samples 8.8% their babies age between (22-28) days. Regarding the neonate’s birth order or rank of neonate in family majority of sample their babies were first birth order or/first ranking in the family which accounts 39.6%, third and second birth order records, 25.4% and 23.8% respectively. Only few percentage of sample 11.3% their babies are fourth or more birth order, recently family size become small, although majority of samples their babies was first birth order, it means they have no experience about how to take care of newborn baby. It is worth to mention that more than half of samples 57.9% visits primary health care center four or more time, and very small percentages which accounts 5.8% have no visits (PHCC), this is good indicator for that our samples have commitment to attending (PHCC) for receiving information about newborn care and this important issue related to pre, post, and antenatal care, vast majority of samples 97.9% were received anti tetanus vaccine, and the rest of sample not received anti tetanus vaccine.

D 1-Mother’s knowledge on newborn care for Breastfeeding.
D 2-Mother’s knowledge on newborn care for Immunization.
D 3-Mother’s knowledge on newborn care for Umbilical Cord care.
D 4-Mother’s knowledge on newborn care for Thermoregulation.
D 5-Mother’s knowledge on newborn care for Danger signs.
f-Frequency.
% -Percentage.

The findings in the above Table (3) explore that fair level of knowledge of the sample records the highest percentages in all domains one, two, three, and five which accounts 54.2%, 63.3%, 51.7%, and 49.2% respectively, while only in domain number four which deals with knowledge about thermoregulation the good level of knowledge records the highest percentages which accounts 46.7%. Regarding the total mean of score, in all
five domains total mean scores were in fair levels which accounts 1.59, 1.53, 1.51, 1.56, and 1.45 and total mean score in general were 1.49 which is also fair level of knowledge. It is worth mentioning that domain number one which deals with knowledge about breastfeeding records’ the highest mean score 1.59 followed by domain number four 1.56 which deals with knowledge about thermoregulation, then domains two, and three records 1.53, 1.51 respectively. While the lowest mean score was record in domain five. This indicated to that mother’s level of knowledge in general was not bad and it was in fair level, and they need more knowledge about newborn care. In the study conducted among mother’s knowledge on newborn care for breastfeeding. And they found more than three quarter have a good knowledge this study incompatible with our present study. Related to the second domain, the present study is supported by a study carried out in Ethiopiaby Birhanu et al., (2016), who found that average knowledge level regarding immunization.

ANOVA (Analysis of Variance), Comparative Significance CS: Highly significant (HS) at <0.01, Significant (S) at p ≤0.05, Not significant (NS) at p ≥0.05.

Table (4) The findings in this table shows that high significant relationship were found between each of mother age, occupation and rank of neonate in family at p <0.001 respectively, as explore in Table (4-1) majority of the samples their age ranged between (16-30) years old, so they are between late adolescent and young adults stage of life which is a suitable period for receiving knowledge and learning, in the same Table (4-1) more than half of sample were housewife and this is a good indicator for that the mothers in our sample have enough time for taking care of their newborn babies.

Although one quarter of sample was graduated from institute and college, most of the sample were housewife and not employed, this is a good indicator to that the mothers in this study had enough time for taking care for their babies and receiving knowledge and information about newborn care, regarding neonate’s birth order, most of neonates in the present study were first order, so the mothers have more interested to learning what is important regarded baby care.

Significant relations were found between mother’s level of educational and level of knowledge p value 0.005, it is indicated to that high level of education means good level of knowledge. Also, significant relationship was found between of mother’s level of knowledge and mothers whom visiting to PHCC during this pregnancy, at p value 0.010, one objective to PHCC is to raise mothers or caregivers level of knowledge and attitude about newborn care.

It is worth mentioning that no significant relationship were found between samples residency, religion, economic states, and age of neonate with mother’s level of knowledge.

The finding in the present study agrees with the results of previous study done by that there is significant relationship between knowledge of mother and educational level and non-significant with residence, while it disagrees with our study which found that there is non-significant relationship between knowledge of mother and their (mother age, occupation).

The result in the present study agrees with the results in the previous study done by Vinod and Anuchithra, 2014 which found that there is non-significant relationship between newborn care among prime mother and (Religion, Economic, Age of neonate).

(*) Highly significant (HS) at < 0.01, Significant (S) at p ≤ 0.05, Not significant (NS) at p ≥ 0.05.

The above table demonstrates that high significant relationships were found between respondents’ knowledge and who receiving information on newborn care during this pregnancy p value <0.01 without doubt receiving information specialty at time of pregnancy affect the level of knowledge of mothers regarding newborn care.

Significant relationships were between the mother level of knowledge and the type of family, more than half of samples have nuclear family which indicated the caregiver dependent on her-self for caring of babies. In addition to that, no significant relationships were found between the type of delivery, received ATS, received any newborn care information since delivery/at hospital, p value ≥ 0.05 which records 0.209, 0.129, and 0.699 respectively.

Bofarraj, M. (2011), did a study entitled “Knowledge, attitude and practices of mothers regarding immunization of infants and preschool children at Al-Beida City, Libya“. This study agrees with our results that found there is a significant relationship between the knowledge of mother and the type of family while disagrees with our results among the relationship between the knowledge of mother and the type of delivery that found a significant relationship between them, also that agrees with our result that found non-significant relationships between the knowledge of mother and the (Received antitetanus vaccine). A study was done by Timilsina and Dhakal, 2015 to examine the knowledge on postnatal care among postnatal mothers this study disagrees with our present study results which found non-significant relationship between the knowledge of mother and received any information on newborn care during this pregnancy, while it agrees with our results among relationship between knowledge of mother and received any newborn care information since delivery/at hospital. According to the researcher point of view, children are the future of any nation. It is well established that the welfare of a child and his future are totally dependent upon the care and attention bestowed upon him before and after birth. The care of children had always traditionally been the forte of mothers irrespective of education.

Conclusions

The main conclusions in this study are:-More than half of the sample mother age ranged between (16-20) years and (21-25) years old, and proportion of urban record higher percentage. More than half of the sample were housewives and highest percentage of the sample gain institute or college degree. According to economic status most of them have a sufficient. More than half of the sample were nuclear family. Majority of the sample their age of neonate ranged between (1-7) days. Significant relationship was found between knowledge of mother and the type of family, educational level and previous attendance to antenatal care or primary health
care center during this pregnancy. Non-significant relationship was found between knowledge of mother and the type of delivery, received anti tetanus vaccine, received any newborn care information since delivery/ at hospital, residence, religion, economic and age of neonate. Significant relationship was found between attitudes of mother and their received anti tetanus vaccine, occupation and rank of neonate in family, while remaining variable were non-significant.

**Financial Disclosure:** There is no financial disclosure.

Determination of Premature Birth Causes at Bint Al Huda Teaching Hospital

Adil Ali Hussein¹, Asala Riyadh Mohammed², Amer Muhasin Naser³

¹Lecturer, College of Nursing, University of Basrah, ²Assistant Lecturer, College of Nursing, National University for Science and Technology, ³Lecturer, Community Health Department, Nasiriyah Technical Institute, Southern Technical University

Abstract

Objectives: The study aims to: To Determination Causes of Premature Birth at Bent-Al-Huda Teaching Hospital in Al Nasiriya City.

Methodology: Descriptive study design was conducted throughout the present study for period from 6th February 2020 to 1st September 2020. A purposive (non-probability) sample of 100 patients at Bent-Al-Huda Teaching Hospital in Al Nasiriya City. Data were collected through the questionnaire constructed and the self-administrative reporting process. The questionnaire consisted of two parts: parents’ socio-demographic variables (age, educational level, occupation, monthly income and residence). The second part consists of questions related to causes of premature birth. The validity of the content of the instrument was determined by a panel of experts, and the internal consistency of the instrument was determined through a pilot study and the calculation of the alpha correlation coefficient (r = 0.870). Analyzing Data by descriptive and inferential statistical approaches using (SPSS) version 20.0.

Results: The findings shown that most of sample were fall in the age group 19-24 years old. The majority of premature birth gender are male, Level of education, the greater number of study sample do not read and write and they are accounted for (30%) of the sample, the occupation status, the results showed that the highest percentages in the studied sample are (have no work), and are considered (70%). Most of the monthly income of the study sample studied are insufficient and are considered (60%). They majority of study sample were lives in rural area. The results of study show the highest percent of prevalence of these causes of premature birth among women which are (Malnutrition, Diseases in pregnancy, Early rupture of membranes, Repeated abortion and premature birth, early cervix Dilation and different blood type), there is statistically significant differences between causes of premature birth and (mother age, educational level and occupation) and there is non-statistically significant differences between causes of premature birth and (gender of premature birth, income and residence) at (p value > 0.05), when analyzed by Chi-Square Tests.

Recommendations: The study recommended to do Provide instructional heath education to pregnant women to increase their knowledge about causes of premature birth.

Keywords: Causes of Premature Birth, Pregnant women.

Introduction

If the baby is born before the 37th week of pregnancy, it is called premature birth. Some preterm births happen on their own: the mother has contractions and the baby is born premature¹. In other cases, pregnancy problems encourage doctors to give birth earlier than expected. About three-quarters of preterm births are spontaneous and about a quarter are due to medical complications. Overall, approximately one in eight pregnant women gives birth prematurely². Preterm delivery is associated with 5–18% of pregnancies and is the leading cause of infant morbidity and mortality. Spontaneous premature birth, a syndrome caused by multiple pathological processes, leads to 70% of premature births. Prevention
and treatment of premature birth are long-standing problems. Summarize current understanding of disease mechanisms associated with this condition and review developments related to intraamniotic infection, decidual aging, and impaired maternal and fetal tolerance.

The success of progesterone therapy in preventing preterm birth in a high-risk group of patients is cause for optimism. Unraveling the mystery of premature birth, which endangers the health of future generations, is a difficult and valuable scientific task.

**Objectives of the study:**

1. To Determination Causes of premature birth at Bint Al Huda Teaching Hospital.
2. To find out association between causes of premature birth and socio-demographic variables of the study sample.

**Methodology**

In this chapter present the following:

**Design of study:** Descriptive study design was conducted throughout the present study for period from 6th February 2020 to 1st September 2020.

**The setting of the study:** Study was conducted at Bint Al Huda Teaching Hospital in Al Nasiriya City.

**Sample of the study:** Randomize sampling of (100) patients that come and admitted to at Bint Al Huda Teaching Hospital in Al Nasiriya City.

**Criteria:**

A. Pregnant women at second and third trimester.
B. Patients accepted to cooperate in in study.

**Tool of study:** In order to determine the causes of premature birth the researchers constructed questionnaire consists of:

**Part 1: Socio demographic characteristics** includes (mother age, gender of child, educational level, occupation, monthly income, and residency).

**Part 2: Questionnaire consist of questions related to causes of Premature Birth:** includes (causes related mother, causes related uterus and placenta, and causes related fetus).

**Ethical Considerations:** Official permission was obtained from the administrative of Thi-Qar health office and from patients at Bint Al Huda teaching hospital before their inclusion in the study. The nature and aims of the study were explained to each of the participants.

**Data collection:** The data when collected with constructed questionnaire though an application direct interviewing and indirect answers as mean of data collection.

**Statistical analysis:** Data was analyzed using IBM SPSS (version 20) to data was presented as number and percent data analyzed through an application of frequency and percent.

**Results**

This table shows there is statistically significant association between causes of premature birth and (mother age, educational level of mother and occupation) and there is non-statistically significant differences between causes of premature birth and (gender of premature birth, income and residence) at (p value > 0.05), when analyzed by Chi-Square Tests.

### Discussion

**Part-I: Discussion Association between Causes of Premature Birth and Socio-Demographic Variables of the Study Sample:** Related to determination causes of premature birth in Bint Al Huda Teaching hospital in Al Nasiriya city. The results of the study show that most of the study sample occurrence of these causes which is (Malnutrition, Diseases in pregnancy, Early rupture of membranes, Repeated abortion and premature birth, early cervix Dilation and different blood type), this results agree with study done by Goldenberg et al\(^7\) that group of factors that contribute to causes premature birth such as nutrition, some diseases during pregnancy, premature rupture of membrane, and previous cases of preterm baby. These finding support and agree present study.

**Part-II: Association of Causes of Premature Birth and Socio-demographic Variables of Study Sample:** The present study findings shows statistically significant association between causes of premature birth and mother age these results supported by Schleußner\(^8\), that said the maternal age is the ones of causes of premature birth. Regarding the gender of premature birth Di Renzo et al\(^9\) that concluded male gender is an independent risk factor for negative pregnancy outcomes. Evidence suggests that female have an advantage over male with better perinatal outcomes, especially after preterm labor, these finding result not compatible with present finding that funded there is no association between gender of premature birth with labor. Regarding mother level of education with premature birth, result of the present study accompanied with result funded by Shah et al\(^10\) significant association between mother education and incidence of premature birth. Klerman et al\(^11\) disagree...
with present study findings due to who funded there is relationships between residence and family income with premature birth.

**Conclusion**

1. A highest percent of the study sample were male gender premature more than females, they women with low level of education were read and write, and primary school and married. They were no have work, having insufficient monthly income.

2. The determination causes of premature birth are (Malnutrition, Diseases in pregnancy, Early rupture of membranes, Repeated abortion and premature birth, early cervix Dilation and different blood type).

**Recommendations:**

1. Extensive and comprehensive population-level (national) studies can be carried out to determine the causes of preterm birth.

2. Provide instructional health education to pregnant women to increase their knowledge about causes of premature birth.

**Financial Disclosure:** There is no financial disclosure.

Comparison of Average Inhibition Zones of Methanolic Extracts of *Chaetomium globosum* on the Growth of Different Groups of Pathogenic Micro-Organisms

Haider Mashkoor Hussein¹, Sanaa Hasan Abdalakhwa², Ragha A. Razaq³

¹Assist. Prof., Department of Environment, College of Science, University of Al-Qadisiyah, Iraq, ²Lecturer, College of Basic Education, University of Babylon, Hillah City, Iraq, ³Bachelor, Department of Biology, College of Science for Women, University of Babylon, Iraq

Abstract

The objectives of this study were analysis of the secondary metabolite products and evaluation of antibacterial activity. The FTIR analysis of *Chaetomium globosum* proved the presence of functional group assignment Alkyl halides, Amide, and Alkane with Peak (Wave number cm⁻¹) 1018.41 (Strong), 1238.30 (Strong), 1317.38 (Strong), 1379.10 (Strong), 1614.42 (Bending), 2850.79 (Strong), 2920.23 (Strong). Zone of inhibition (mm) of test bacterial strains to *Chaetomium globosum* bioactive compounds and standard antibiotics were (4.00±0.31), (4.77±0.13), (5.00±0.16), (3.22±0.41), and (4.29±0.11) uses *Chaetomium globosum* bioactive compounds, and (2.01±0.10), (1.77±0.41), (1.98±0.11), (2.00±0.30), and (1.05±0.42) uses Rifambin, and (2.42±0.18), (2.12±0.46), (1.40±0.12), (1.00±0.10), and (2.90±0.47) uses Kanamycin for *Staphylococcus aureus*, *Escherichia coli*, *Proteus mirabilis*, *Klebsiella pneumonia*, *Pseudomonas eurigenosa* respectively. *Chaetomium globosum* was very highly active against *Escherichia coli* (4.77±0.13).

Keywords: *Chaetomium globosum*, FT-IR, Secondary metabolites.

Introduction

Chaetomium species are widespread worldwide in soil and plant debris. *Chaetomium globosum* is a well-known mesophilic member of the mold family Chaetomiaceae. It is a saprophytic fungus that primarily resides on plants¹, soil, straw, and dung. Both the C. globosum hyphae and the spores contain antigens such as Chg45, to induce IgE and IgG antibody production in allergic individuals. Although the IgE upsurge is transient, increased IgG levels persist in the serum. This can lead to non-atopic asthma, sinusitis, and respiratory illnesses in the residents of contaminated buildings.² Such allergic onsets can be prevented with the use of potassium chlorate in building materials. Chlorate, toxic to many fungal strains, disrupts nitrate reduction in fungi by using fungal nitrate reductase to produce the toxic chlorite. Although it is unclear as to whether C. globosum contains nitrate reductase, chlorate is still a well known C. globosum toxin. However, even though chlorate suppresses perithecia formation, it does not affect hyphal growth nor sporulation. Secondary metabolites often play an important role in plant defense against herbivory and other interspecies defenses. Humans use secondary metabolites as medicines, flavourings, pigments, and recreational drugs.⁴ Secondary metabolites aid a host in important functions such as protection, competition, and species interactions, but are not necessary for survival. One important defining quality of secondary metabolites is their specificity. Usually, secondary metabolites are specific to an individual species, though there is considerable evidence that horizontal transfer across species or genera of entire pathways plays an important role in bacterial (and, likely, fungal) evolution. Research also shows that secondary metabolism can affect different species in varying ways. In the same forest, four separate species of arboreal marsupial folivores reacted differently to a secondary metabolite in eucalypts.⁶

Materials and Method

After growing on potato dextrose agar (PDA) medium at 25°C for 4 days, the fresh mycelium of strain *C. globosum* No. 04 was inoculated in liquid medium
containing: Oat flour 80 g, maltose 10 g, yeast extracts 2 g dissolved in 1,000 mL dH2O. The pH was adjusted to 6.0 before autoclaving. Fermentation was carried out in 2 L flasks each containing 1 L medium on a rotary shaker at 180 r/min, 25 °C for 8 days, and the cultures were used for the extraction and isolation.

Fourier transform infrared spectrophotometer (FTIR): The powdered sample of Chaetomium globosum products was treated for FTIR spectroscopy (Shimadzu, IR Affinity, Japan). The sample was run at infrared region between 400 nm and 4000 nm.

Antibacterial activity: Determination of antibacterial activities of pure extract of C. globosum cultures performed using streak-plate method. Mueller Hinton agar plates were prepared and inoculated with C. globosum cultures by a single streak of inoculum in the center of the petri dish and incubated at 27°C for 4 days. Antagonism was measured by the determination of the size of the inhibition zone in millimeters.

Results and Discussion

The FTIR analysis of Chaetomium globosum proved the presence of functional group assignment Alkyl halides, Amide, and Alkane with Peak (Wave number cm⁻¹) 1018.41 (Strong), 1238.30 (Strong), 1317.38 (Strong), 1379.10 (Strong), 1614.42 (Bending), 2850.79 (Strong), 2920.23 (Strong). Zone of inhibition (mm) of test bacterial strains to Chaetomium globosum bioactive compounds and standard antibiotics were (4.00±0.31), (4.77±0.13), (5.00±0.16), (3.22±0.41), and (4.29±0.11) uses Chaetomium globosum bioactive compounds, and (2.01±0.10), (1.77±0.41), (1.98±0.11), (2.00±0.30), and (1.05±0.42) uses Rifambin, and (2.42±0.18), (2.12±0.46), (1.40±0.12), (1.00±0.10), and (2.90±0.47) uses Kanamycin for Staphylococcus aureus, Escherichia coli, Proteus mirabilis, Klebsiella pneumonia, Pseudomonas aeruginosa respectively. Chaetomium globosum was very highly active against Escherichia coli (4.77±0.13). Infrared spectroscopy provides a useful method for herbal analysis and elucidate the compounds structures as well as for quantitative analysis of drugs. Recently, a number of plants have been reported for antibacterial properties across the world. It is hoped that this study would direct to the establishment of some compounds that could be used to invent new and more potent antibacterial drugs of natural origin. Further work will emphasize the isolation and characterization of active principles responsible for bio-efficacy and bioactivity. The differences in the susceptibilities of Gram positive and Gram negative bacteria to Streptomyces extracts have been observed by previous workers. Gram negative bacteria are inherently more resistant to antimicrobials than Gram positive organisms and this has been ascribed to the combined exclusion of antimicrobial compounds by double membrane barrier and transmembrane efflux present in this group of organisms. The three main classes of fungal secondary metabolites are: polyketides, nonribosomal peptides and terpenes. Although fungal SMs are not required for growth they play an essential role in survival of fungi in their ecological niche.

The goal of absorption spectroscopy techniques (FTIR, ultraviolet-visible (“UV-Vis”) spectroscopy, etc.) is to measure how much light a sample absorbs at each wavelength. The most straightforward way to do this, the “dispersive spectroscopy” technique, is to shine a monochromatic light beam at a sample, measure how much of the light is absorbed, and repeat for each different wavelength. (This is how some UV–vis spectrometers work, for example).

Bacteriological and Molecular Study of *Klebsiella Pneumoniae* Isolated from Patients with Urinary Tract Infections from Several Hospitals in Baghdad

Rasha Zaid Tariq Ahmed¹, Teeba Fares Hadi², Rana Mujahid Abdullah³

¹Assist. Lecturer, Second Al-Karkh Education Directorate, Ministry of Education, Baghdad, Iraq, ²Assist. Lecturer, AL-Rasheed University College Department of Biology, ³Prof., Department of Biology, College of Education Ibn-Al Haitham, University of Baghdad, Baghdad, Iraq

Abstract

This study obtained 20 isolates of *Klebsiella pneumoniae* from out of 50 isolates collected from patients with urinary tract infection; all isolates were diagnosed and then the sensitivity test for isolates was performed using the discs method (Kirby-Bauer) to determine the resistance of *K. pneumoniae* to 10 antibiotics. The results detected that the highest resistance was against Ampicillin, Cefotaxim, and Piperacillin by 100% for each of them, while the rest of the antibiotics had a resistance percentage of 80% for Trimethoprim, 54% for Gentamicin and 65% for Azithromicin, however the lowest resistance was found against Imipenem, Chloramphenicol and Ofloxacin by 4%, 12. % and 35% respectively. The genomic bacterial DNA of studied isolates was extracted and the genotyped was performed identify the genetic relationships between the bacterial isolates using ERIC-PCR method. The results of the study showed the presence of 12 genotypes and also the results revealed the presence of two clones, each of which contains similar genotypes, while the rest of the isolates contain different genotypes.

Keywords: *Klebsiella pneumoniae*, antibiotic resistance, ERIC-PCR.

Introduction

*Klebsiella pneumoniae* is one of the most important genera of the Enterobacteraceae family. It is characterized by being Gram-negative bacilli, non-motile, and lactose fermented, non spore forming, appear under the microscope are made up of thick edges, as the edges are curved outward and have rounded ends and have a capsule that increases its pathogenicity (Braun et al., 2004; Bensen 2001; Sambrook et al., 2001). It was called by this name in the nineteenth century in relative to its discoverer Edwin Klebs, a German-born scientist, in 1834 (Brise et al. 2005).

*K. pneumoniae* is one of the causative agents of opportunistic diseases in humans, including respiratory tract infection, Burns inflammation, wounds inflammation, septicemia, diarrhea, and liver abscesses (Zhang et al., 2018).

Urinary tract infection is one of the most common diseases caused by *K. pneumoniae* after *Escherichia coli*. Moreover, it is become more dangerous for people who suffer from Diabetics, alcoholics, pulmonary deficiency, immune suppressive, and hospitalized patients especially in intensive care units, thus the accurate and rapid diagnosis is required to prevent the infection in hospitals (Li et al., 2012; Chiu et al., 2013; Guo et al. 2016).

*K. pneumoniae* bacteria possess many virulence factors including production of polysaccharide, capsule, serum resistance, production of iron siderophore, production of enterotoxin and urea and thus this bacteria with high virulent in addition to developing its resistance to many antibiotics (Navan-venzia et al., 2017; Dubey et al., 2013).

The major reasons for *K. pneumoniae* resistance to antibiotics including beta-lactam antibiotics is due to producing the broad-spectrum of beta-lactamase (ESBL) which is one of the most important problems of increased infection in hospitals, or through the changing of the permeability barrier or in the target site.
represented by penicillin binding protein, or alteration of outer membrane protein (Aghamohammad et al., 2018). Additionally, K. pneumoniae have many Efflux Pumps that expel the antibiotic to the outside. Beta-lactam antibiotics include a group of antibiotics including penicillins, cephalosporins, carbenems and monobactam (Livermore, 2012; Sachse et al., 2012, Levinson., 2016).

Trimethoprim inhibits dihydro pterotese Synthetase (DHPS) and dihydro folate reductase (DHFR), which are involved in the synthesis of bacterial DNA, and K. pneumoniae showed high resistance to Trimethoprim. The reason for this resistance is via modulating the target site that bind with the enzymes, and also having encoded genes carrying on conjugate plasmids that may be acquired or given to other bacteria present in the same culture medium, as well as containing a flow mechanism that changes the membrane permeability (Shin et al., 2015).

Moreover, K. pneumoniae possesses multiple mechanisms to resist aminoglycoside; these mechanisms including its production of the three modulating enzymes: Acetyl transferase, Phospho transferase and Adenal transferase (Serio et al., 2017). Additionally, K. pneumoniae have several mechanisms of resistance to antibiotics including Quinolones antibiotics such as Ciprofloxacins, Norofloxacins, Levofloxacin and Ofloxacins. These mechanisms involved the modulation of the target site that bind with the antibiotics by triggering chromosomal genetic mutations in the genes encoding for DNA grease or Topoisase resulting in producton of different enzyme that is resistant to these antibiotics. K. pneumoniae also have OqxAB and QepA efflux Pumps on the outer membrane of the bacteria that serve to expel the antibiotic to the outside and prevent the permeability of it (Jacoby, 2017).

Genotyping method are important in finding the genetic affinity between bacterila isolates and also in the classification of bacteria, identification the sources of infection and characterization of the most pathogenic strain. There are several method of genotyping including Enterobacterial Repetitive Intergenic consensus method which is easy and rapid method that does not need long time and less expensive in comparison with other method (Goudarzi et al., 2011).

Aims of the study:
1. Isolation and diagnosis of Klebsiella pneumoniae from patients with urinary tract infections.
2. Determination the resistance and sensitivity of Klebsiella pneumonia to antibiotics.
3. Detection the genotyping and genetic relationships of Klebsiella pneumonia using ERIC-PCR method.

Materials and Method
1. Bacteria isolation: 50 samples were collected from patients with urinary tract infections, male and female, from several hospitals in Baghdad (Central Child Hospital, Medical City, Al-Yarmouk Hospital, Child Protection Hospital) for the period from 1/10/2019 to 6/12/2019.
2. Diagnosis of Isolates: Samples were diagnosed using blood agar and MacConkey agar culture media. For final diagnosis of isolates, Vitek 2 system was used.
3. The sensitivity of the bacterial isolates was performed using the discs diffusion method (Kirby-Bauer) to determine the resistance of K. pneumoniae for 10 antibiotics included Ampicilin, Cefotaxime, Piperacilin, Gentamycin Sulfamethoxazole + Trimethoprine, Imipenem, Ciprofloxacin, Azithromycin, Ofloxacin and Chloramphenicol. The measurement of the inhibition zone diameter with around the antibiotic discs was performed and compared with the tables of international measurements (CLSI, 2017).
4. DNA Extraction: Genomic DNA extraction and Purification Kit was used to extract the bacterial DNA according to manufacturer instructions (Promega,USA).
5. The genotyping of K.pneumoniae: it was performed using PCR technique to detect the genotype of ERIC gene using the following primers:

   ERIC (F): 5’ - ATG TAA GCT CCT GGG GAT TCA C-3

   ERIC (R): 5’ - AAG TAA GTG ACT GGG GTG AGC G-3

The results of this test included the production of bands with variable size. The reaction mixture included 20 μL of GO Taq Green Master Mix10, 2 μL of DNA template, 2 μL of each primer and 6 μL of deionized (molecular) distilled water. The reaction conditions was programed according to the manufacturer instructions (Promga, USA) with some modifications as following (Mehr et al., 2017):
1. The initial denaturation with the single cycle at 94°C for 3-minute.

2. DNA amplification using one cycle at 94°C. In order to attach the primer with DNA template, 35 cycles was used and each cycle included the following steps:

   A- Anneling stage: one cycle at 48°C for 1 minute.

   B- Extension stage: at 72°C for 2 minutes.

   C- Final Extension stage: one cycle at 72°C for 5 minutes.

6. The reaction products were separated using agarose gel (Bio Basic Inc, Canada) (2%) containing 5 μl of Ethidium bromide (Promega USA), and using DNA ladder (100-1500) base pair with a voltage difference of 100 volts for 80 minutes and imaged using UV light (Optima, Japan).

   Results and Discussion

After performing the laboratory tests, 20 isolates of Klibsiella pneumoniae were obtained from a total of 50 samples collected from patients with urinary tract infections from several hospitals in Baghdad.

   K.pneumoniae are among the most important causes of urinary tract infections, fees, burn, respiratory tract infections and bacteremia (Le et al., 2012).

   The results of this study revealed that the highest resistance and sensitivity of K. pneumoniae to the studied antibiotics was against Ampicillin by 100%, Cefotaxime by 100%, Piperacillin by 100% and for Trimethoprim by 80%, while the rest of the antibiotics, the resistance percentage was 54% for Gentamicin and 65% for Azithromycin. Furthermore, the lowest resistance was against Imipenem 4%, 12% for Chloramphenicol and 35% for Ofloxacin as shown in Figure (1).

   Intereastingly, our results are consistent with the findings of Mehr et al. (2017) study where it showed resistance to Chloramphenicol by 14%. The results of the current study also in agreement with the results of the Algarawy (2016) study that found the resistance to Piperacillin was 91.1%; however it is inconsistent with the results of Vasaikar et al. (2017) study that reported the resistance to Piperacillin was 79%. The results of this study also were consistent with the findings of Chasemian et al. (2018) study that isolated K. pneumonia which isolated from several hospitals in Tahran and found that the resistance to Cefotaxime was 94.6%; although our results not consistent with the results of Babakhani et al., 2015 study where the resistance to Ofloxacin was 86%.

Moreover, the current results were also in agreement with the results of Mustafa (2018) study which showed that the resistance of K. pneumonia isolated from different clinical cases and from several hospitals in Baghdad were 32% and 84 against Ofloxacin Cefotaxime respectively. It is also consistent with Zedan-ALobadi study whose studied the resistance of K. pneumonia, isolated from several hospitals in Baghdad, against various antibiotics; it was revealed that the resistance rate was 2.5% for Imipenem, 95% for Piperacillin, 97% for Ampicillin, and 7.5 for Trimethoprim.

   The genetic relationship was determined by genotyping of the studied bacteria using the Enterobacterial Repetitive Intergenic Consensus (ERIC) method. The results of the current study showed the presence of a genetic relationship between K pneumoniaea isolates and also the presence of 12 genotype; the molecular weight of these bundles ranged between (100-1000) base pair as shown in Table (1). Furthermore, the results as shown in Figure (3) found the presence of two clones, each of which contains similar genotypes and found between them a genetic affinity, while the rest of the isolates contain different genotypes. The first clone contained three isolates (3, 5, 8) isolated from hospitalized patients in Al-Yarmouk Teaching Hospital in Baghdad, and from the patients with urinary tract infection. Additionally, these isolates also showed high resistance to antibiotics including Ampicillin, Cefotaxime, and Piperacilli. While the second clone contained four isolates (8, 9, 5 and 6) and these isolates were with a genetic affinity.

Moreover, these isolated showed high resistance to antibiotics and showed sensitivity to Imipenem. Thus, the genotyping method is important in the field of finding...
the genetic relationship, determining its resistance and sensitivity to antibiotics, and determining the most pathogenic strain. The results of this study is in agreement with the findings of Mehr et al. (2017) which found that there are 12 genotype of *K. pneumoniae* isolates using ERIC-PCR method. While it is inconsistent with the findings of Wasfi et al. (2016) study which detected 21 genotype of *K. pneumoniae* using ERIC-PCR method.

Psychological Burden of Caregivers of Children with Cancer at AL-Amal Hospital in Baghdad City

Ahmad Shihab Ahmad

Ph.D. of Community Health Nursing Science/ALZahrawi College University

Abstract

Objectives: To assess psychological burden of caregivers of child with cancer at Al-Amal Hospital in Baghdad City.

Method: Descriptive study conducted among 50 caregivers, they are using self-administration method to answer the psychological burden items. The data collection started from October 7th 2019 to March 9th 2020 at Al-Amal Hospital in Baghdad city.

Results: 50% of caregivers had moderate level of psychological burden and 44% had severe level of psychological burden. The grand mean was (2.21) at moderate level of assessment. There is no significant relationship between the caregivers psychological burden and their general information at P-value 0.05.

Conclusion: the caregiver had moderate to severe psychological burden due to caring child with cancer. They are need for psychological support.

Keywords: Psychological Burden, Caregivers, Children, Cancer.

Introduction

Cancer is expected to rank as the leading cause of death and the single most important barrier to increasing life expectancy in every country of the world in the 21st century. According to estimates from the World Health Organization (WHO) in 2015, cancer is the first or second leading cause of death before age 70 years in 91 of 172 countries, and it ranks third or fourth in an additional 22 countries.‘Burden’ may be defined as a multidimensional concept with objective and subjective components. ‘Objective burden’ is defined as specific happenings and activities related to caregiving, for instance, financial problems or personal activity limitations. ‘Subjective burden’, on the other hand, encompasses affective responses to the caregiver experience, such as feelings and emotions related to fear, strain and guilt. Family caregivers (FCs) are a pivotal source for quality of life, well-being and quality of care in terminally ill patients. However, they are also affected by caring for the patient and may thus be affected by significant physical and psychosocial burden. Psychosocial burden and anxiety are associated with the number of unmet needs in FCs of advanced cancer patients. Frequently unmet needs of FCs relate to information on caregiving and care planning, support in managing fear as the patient’s physical or psychological status declines, and preparing for the patient’s death and their own bereavement. Supportive needs can be summarized in four main categories: needs concerning the patient’s well-being, transfer of information, practical problems of caregiving, and emotional support. Some studies suggest that FCs’ needs might be better addressed if specialized palliative care is included during home or hospital care. In addition, FCs’ quality of life has been shown to be higher in patients receiving care in palliative care facilities rather than in acute care hospitals. Cancer is a family experience, and often family members have as many problems coping with it as does the diagnosed patient. The family goes through different stages of adjusting to the disease. The emotional reactions may include anger, resentment, guilt and adjustment pain, and may or may not lead to the acceptance of the disease. The cancer’s diagnosis, as well as the subsequent phases of the disease and its treatment, may be a source of intense stress both for the patient and for the family. Patients and their relatives need to
face the challenge of a life defined with uncertainty; treatment routines, the threat of recurrence or the failure of the treatment.\(^{(4)}\)

Caring for a child with cancer can be profoundly distressing to parents and in turn, parental psychological distress (PD) can affect child and sibling wellbeing. Caring for a child with advanced cancer is likely to be even more distressing, yet very few prospective studies have evaluated parent PD among these families. Understanding the degree of PD and contributing factors among parents with children with advanced cancer has the potential to better enable clinicians to identify higher risk families and optimize outcomes.\(^{(5)}\)

Family caregivers often feel overloaded with the additional obligations and roles they have to pick up. They find it increasingly burdening to care full-time for the household and provide emotional support for the patient. The family’s problems and the way family members regard the disease may be also a result of the family system they are in.\(^{(6)}\)

The role of a family in the course of cancer changes according to the needs of the patient and the cancer’s phase. In the diagnosis phase, depending on the type of family, a big mobilization, with readiness to give support to the patient, is observed. Family members try to get information about the diagnosis, treatment and chances of survival. Other family types may avoid talking about the cancer to avoid creating an additional stress for the patient. Also, very often both the patient and family members try to search for the reasons for the sickness. Looking to find some sense in the universe is a very common tendency, which results from the conviction that everything in the world has its place and reason. Depending on the family’s coping style, if it is a task concentrated family, attitude towards the sickness may promote healthy behavior or strengthen the will of the patient to fight.\(^{(7)}\)

Taking care of a sick patient, most caregivers share some common needs which unfortunately are not always possible to be fulfilled. All of them have a need for information, for feeling close to and needed by the patient, and to have a chance to get external support whereby they can speak about their own problems – to ‘ventilate’ their emotions.\(^{(8)}\)

**Method**

Descriptive study design was conducted to assess psychological burden of care givers of child with cancer at Al-Amal Hospital. The data collection started from October 7th 2019 to March, 9th 2020 at Al-Amal Hospital in Baghdad city. The study carried among 50 caregivers selected by a non-probability (purposive sample). The study tool was used constructed questionnaire tool psychological burden of care givers of child with cancer. The questionnaire consists of two parts:- Demographic data of sample composed of (5) items that represent the sample demographic data such Age, gender, level of Education, relative to the child and socio economic status and the psychological burden consisted from 14 items constructed to measure the phenomena, rating and scoring according to 3 likert scale answered by 3 key answer always (3), sometimes (2) and never (1), which assessed by cutoff point (0.66) due to scores (1, 2 and 3) respectively. level of assessment: (1-1.66) = low = L, (1.67-2.33) = moderate = M, (2.34-3.00) = severe = S. The data collected after taken the sample agreement to participate in the study and using self-administration method to gathering data. The data analysis by using descriptive and inferential data analysis (SPSS version 20).

There is no significant relationship between the caregivers psychological burden and their general information at P-value 0.05.

**Conclusion**

Parenting a child with advanced cancer is strongly associated with moderate to severe levels of psychological burden. Interventions aimed at aligning prognostic understanding with concrete care goals, and easing child suffering and financial hardship may mitigate parental psychological burden. Suggestions for further research are presented to support efficient psychosocial interventions and minimize the psychosocial problem experienced by pediatric caregivers over the course of onco-hematological treatments.

Abstract

Gestational diabetes mellitus (GDM) constitutes carbohydrate metabolism disorders that lead to severe and sometimes life-threatening complications of pregnancy.

Materials and Method: 40 placenta biopsies with blood samples were taken from gestational diabetic pregnant women and 20 placenta biopsies with blood samples were taken from healthy pregnant women, the tissues were fixed, processed, embedded and cutting separately depending on procedure for enzyme histochemical and routine histological technique and the blood was centrifuged.

Results: The histological changes in the GDM group represented by villous oedema in approximately (30%) of the GDM group, an excessive amount of collagen fibres in the villous stroma (57.5%). Syncytial knots were formed (70 %) in addition to an excessive number of cytotrophoblast cells in about (65 %). The stromal fibrinoid deposition was noticed in (52.5 %). Hypo-vascular villi are seen in (32.5%) also, atherosis of the uteroplacental arteries in (40%) of biopsies. In enzyme histochemistry, the villous stroma of the GDM group has a strong reaction to the G-6-P enzyme. There is a significant increase (p<0.05) in serum blood sugar, cholesterol, blood urea in the GDM group when compared with the normoglycemic group.

Conclusions: The increment of serum blood sugar caused histological and enzyme histochemical alteration during pregnancies.

Keywords: Gestational Diabetes Mellitus, placenta, Histopathological, Enzyme histochemical.

Introduction

Gestational diabetes mellitus (GDM) is defined as a condition of glucose intolerance that appears during pregnancy1. This type of diabetes accompanies the pregnancy period and disappears after birth. It is a medical complication that affects about 3-10% of pregnant women, and it appears more in women with a family history of the disease.2

Diabetes occurs during the second trimester of pregnancy 3, but most of it occurs in the third trimester of pregnancy, as the mother is likely to develop diabetes after childbirth, especially type-2 diabetes mellitus 4. The causes of GDM in some women are not known in a specific way, but there are contributing factors in the occurrence of the disease, including the interference of the hormones required by the fetus’s growth that is an obstacle to the work of insulin 5, and that weight gain may lead to increased insulin resistance and insulin resistance will deprive the fetus of the benefit of the effect of insulin product 6. The placenta during pregnancy produces...
additional amounts of the hormone (Cortisol) and other hormones that are anti-insulin, such as progesterone and human chorionic gonadotrophin and the human placental lactogen. All of these hormones increase the level of glucose in beta cells. Beta-cells in the pancreas is unable to produce sufficient amounts of insulin to offset this increase in the level of glucose or there was insulin resistance by the mother (Maternal insulin resistance) as this increases the possibility of a case of excess glucose in the pregnant mother (Hyperglycemia) or what it is called GDM. The incidence of complications of GDM in Iraq has increased dramatically in recent years and the health importance of pregnant women and the complications that occur during pregnancy.

The current study aimed to identify some of the histopathological, enzyme histochemical and biochemical changes accompanying these complications.

**Materials and Method**

**Study Samples:** The 60 placenta tissue and blood samples were obtained for pregnant women from Baghdad Teaching Hospital and based on the medical diagnosis by the gynaecologist. A questionnaire was completed containing much information about the pregnant woman, the diseases she had during pregnancy and the laboratory tests that were performed. The women under study were divided into two groups: The first group of 40 pregnant women with GDM, age ranging from 20-43 years. The second group 20 normoglycemic pregnant women, age ranging from 18-40 years.

**Tissues Collection:** Placental tissue biopsies were collected and dissected from the central part of the placental bed after normal vaginal deliveries or caesarian section and prepared for histopathological and enzyme histochemical analysis as follows:

The fragments for the histopathological study were then immediately fixed in formalin 10%, dehydrated in a graded ethanol sequence and embedded in paraffin according to a standard protocol, sectioned at 5 μm and installed for the staining with Hematoxylin-Eosin (H & E) on glass slides and examined under the microscope. The fragments for enzyme histochemical study were then immediately fixed and dehydrated in a mixture of equal volumes of cold acetone and absolute alcohol for 24 hours for demonstration of Glucose-6-Phosphatase (G-6-Pase) were based on the modified procedure described by 11.

**Blood Samples Collection:** The 5 ml of venous blood was drawn for each of the women from the study groups, the blood was placed in a test tube and left at laboratory temperature 15-25 ° C until the thrombus was formed, then the thrombus was separated by the centrifuge at 3000 rpm for five minutes, a serum was withdrawn and preserved - 20 ° C until laboratory tests.

**Biochemical test:** Serum Glucose, Cholesterol and Urea were determined by an enzymatic method with the commercially available kit (Randox).

**Statistical Analysis:** All results are expressed as Mean values ± Standard Deviation or as N (%). For computation, we used the SPSS program version 25 for Windows (SPSS Inc., Chicago, IL, USA) software package. Differences were considered as significant if p< 0.05.

**Results and Discussion**

**A-Placental tissues:** Placental tissue from normoglycemic, chorionic villi test appeared as vascular villous stroma surrounded by multinucleated syncytiotrophoblastic layer with indistinct cell borders and darkly stained nuclei. Very rarely we have been able to distinguish villous cytotrophoblastic cells that behave as ovoid, greatly variable in thickness, with well-defined cell borders and light cytoplasm staining. The villous stroma consisted of a core of connective tissue that had several bundles of collagen fibres and flattened fibroblasts. There were 2-5 dilated capillaries lined with fetal blood in the villous stroma (Fig. 1A & B).
All the placenta obtained from the two groups were stained with H & E histological stain. On examination of these sections with a light microscope, our result recognized several histological changes with different proportions. These changes are listed in (Table -1) as following:

Villous oedema was easily seen in the placenta stained, it was seen in 12 placentae (30%) of the GDM group. However, we couldn’t find placentae with villous oedema in the normoglycemic group, (Fig. 2A). Other studies found that one of the pathological features of placentae in hyperglycemic pregnant women is villous oedema\(^1\). The intervillous distance was of various extent, but some of the distance was vast when compared with normal placentae resulting from intervillous oedema with the increased amount of fibrinoid\(^6\)

On the other hand, an excessive amount of collagen fibres in the stroma of the villi was easily demonstrated, stromal fibrosis was observed in 2 placentae (10%) of the normoglycemic group, but increased up to 23 placentae (57.5%) from GDM group, (Fig. 2B). This results matched with other studies that observed a histological change in GDM placenta represented by stromal fibrosis\(^6\)

Syncytial knots were formed in more than one-third of the examined villi, in 28 placentae (70%) from the GDM group. However, this deviation from the normoglycemic group was noticed only in 4 placentae (20%) (Fig. 2C). More than previous paper observed Syncytial knots in placenta of GDM pregnant women \(^6,13\). Immoderate forming Syncytial knots is a relationship with placental pathology, and a knotting indicator is employed to estimate riskiness\(^14\).

In GDM group cases an excessive number of cytotrophoblast cells have been frequently observed. This change was observed in the normoglycemic group in only 2 placentae (10%), in the GDM group in 26 placentae (65%). El Sawy et al \(^6\) and other study\(^15\) confirm that one of indicator of placenta tissue of GDM pregnant is cytotrophoblast cells proliferation\(^6\).

Stromal fibrinoid deposition affecting of the villi was observed in the normoglycemic group 4 placenta (20%). Although it was found in 21 placentae (52.5%) in placentae obtained from the GDM group, (Fig. 2D). Another study confirms that the morphological feature of villous tissue in GDM of women is fibrin deposit\(^13\). Hypo-vascular villi are seen in 3 placentae (15%) of the normoglycemic group and 13 placentae (32.5%) of the GDM group, (Fig. 2E). A study on placenta tissue in hyperglycemic pregnancy noticed alterations in vascularity repeating by surprisingly hypovascular and these had a smaller diameter and show a wavy course compared with normal villi.\(^16\) Also, atherosis of the uteroplacental arteries appears as multiple foamy cells within the walls of the vessels. It was seen only in one placenta from the normoglycemic group (5%), and in 16 placenta (40%) from the GDM group, (Fig. 2F). A study found that placental atherosclerosis occurred in 28.94% of the group with GDM compared to 10.52% of the group with normoglycemic pregnancy\(^17\).

Figure (1): Light microscopical appearance of normoglycemic pregnant women placenta showing microvilli (V) with narrow intervillous spaces (IS) and syncytial knots (head arrows). The villous stroma (VS) shows blood vessels (arrows) containing blood cells, (A & B: H & E staining, X10).

Figure (2): Light microscopical appearance of GDM placenta showing, (A): Villous oedema (B): stromal fibrosis (red arrows), (C): Syncytial knots (red arrows), (D): Fibrinoid deposition (black arrows), (E): Hypo-vascular villi (red arrows), (F): Atherosis of uteroplacental vessels (A & B: H & E X10).
B-Enzyme histochemical of Glucose–6-phosphatase: The placental tissues acquired from normoglycemic women or other maternal disorders exhibiting a weak reaction to the enzyme G-6-Pase (Fig. 3A & B). The villous stroma showed more dense activity to the G-6-Pase (Fig. 3C & D), while the trophoblastic showed moderate activity to G-6-Pase in the placental tissue of GDM pregnancy (Fig. 3E & F). The G-6-Pase plays the important role of supporting glucose during starvation, an enzyme product mainly in the kidney and the18. The moderate reactive with normoglycemic proof that it presents in the placenta and this was in a match with other studies that detect the G-6-Pase histochemically in the syncytiotrophoblasts of the placent19. In our study we found that there is a strong activity of the enzyme in hyperglycemic tissue, the previous result confirms that by documentation 2-3 fold increasing the activity of G-6-Pase in the liver of diabetic20. G-6-Pase is an enzyme that analysis Glucose 6-phosphate, lead to the formation of a free glucose and phosphate group.21 When the activity of G-6-Pase increases, free glucose also increases and our results from the increased blood sugar in hyperglycemic pregnancy supporting these results.

Figure (3): The light microscopical appearance of placental tissue: A & B obtained from normoglycemic showing a weak reaction to the G-6-Pase (arrows), C & D: strong reaction to the G-6-Pase in syncytiotrophoblast (red arrows) and cytotrophoblast cells, E & F: moderate reaction to the G-6-Pase, in placenta GDM(G-6-Pase, X10).

C-Biochemical study: The serum level of glucose for both healthy pregnant women and GDM pregnancy is shown in (Table -2). A significant (p<0.05) increase is found in the mean value of the glucose in GDM pregnancy (173.82±2.47 mg/dl) compared with that of the healthy pregnancy (84.04±2.3 mg/dl).

High glucose or diabetes during pregnancy may be caused by a decrease or resistance to the hormone insulin by placenta hormones such as progesterone or human placental lactogen, or as a result of the increase in the secretion of the hormone cortisol that occurs during pregnancy(22,23). Jansson et al24 showed that the high level of glucose from its normal level leads to an increase in its transmission to the placenta. Also, the imbalances in carbohydrate metabolism during pregnancy lead to many complications for the mother25.
While the serum cholesterol level is found to be significantly ($p<0.05$) increased in the mean of GDM pregnancy when compared with that of a healthy pregnancy. Table (2) showed the mean of GDM pregnancy to be (224.50±7.68 mg/dl), while in a healthy pregnancy is (184.80±4.34 mg/dl). The increase of total cholesterol level in the serum of women with GDM in the current study supports the results study of Quinlivan and Lam, and its rise can be attributed to the occurrence of a disorder of fat metabolism (Dyslipidemia) as a result of the disease. Several studies have shown approaches during the and beyond the pregnancy, adverse metabolic consequences of diabetes.

Recently, the high levels of cholesterol can cause atherosclerosis, research has shown that low density lipoprotein cholestrol LDL-C is not the only type of cholesterol that increases the risk of atherosclerosis, and that any non-HDL-C cholesterol, such as very-low-density lipoprotein cholesterol (VLDL-C) and apolipoprotein B, that increase that risk. Study of Ryckman et al. found that women with previous GDM Insulin resistance elevate the VLDL-C abnormalities contained in non-high-density lipoprotein cholesterol (HDL-C) along with (LDL-C) and lipoprotein of intermediate density.

Recently, blood urea has been documented to be associated with diabetes mellitus(DM), commonly regarded as one of the markers of kidney functions. On the one hand, (DM) cause kidney disease, and on the other hand, kidney disease may increase the risk of (DM), including urea or other uraemic elements. Our result showed the level of serum urea shows an increase in GDM pregnancy as compared with a healthy pregnancy, (Table 2). The mean value of serum urea in GDM pregnancy is found to be (28.12±1.06 mg/dl), and in a healthy pregnancy is (21.5±1.2 mg/dl). Statistically, there is a significant ($p<0.05$) difference between the two groups.

This result is consistent with many researchers who indicated that the GDM condition leads to a rise in the level of urea in the blood serum, and this rise is due to the physiological change as a result of the pathological condition which leads to a decrease in the rate of glomerular filtration rate (GFR). This causes a rise in the level of urea in the blood serum.

### Conclusions

The hyperglycemia during pregnancy leads to the serious histological changes in placentae representing by oedema in stromal villi, fibrinoid deposition, hypovascular, atherosis of uteroplacental arteries. The villous stroma showed more dense activity to the G-6-P enzyme that indicates to increase the sugar content in it and the study found a strong relationship between hyperglycemia during pregnancy and the rise of serum cholesterol and urea in blood serum.

The Characteristics of Abortion Liability by Doctor in Indonesia after Enactment of Health Law 2009

Sutarno

Lecturer, Faculty of Law, Hang Tuah University, Surabaya, Indonesia

Abstract

This study analyzed the characteristics of abortion liability by doctor after the promulgation of health law year 2009 in Indonesia. The result found that the pregnancies that are legal to be aborted are: those dangers for the mother concerned (for life saving), womb that's the foetus is heavy handicap and the pregnancy because of rape (until 6 weeks of pregnancy), but for the doctor who performed abortion to help the mother who has failed in her family planning method or the idiot women who pregnanted by unknown man and pregnancies because rape but more than 6 weeks of old must be held accountable for his action. The liability is including criminal liability, civil liability, administrative liability, professional discipline liability and ethical liability. For the criminal liability, can be use criminal code as a “ius generals” or the article 194 of health law as a “ius spesialis” This characteristics of abortion liability for the doctor will prohibit the doctor who help someone who need performing of abortion because of: failing of family planning method, idiot woman that pregnanted by unknown man and pregnant woman because of rape more than 6 weeks. This reason is not for pregnancy that caused by promiscuity and immoral habits.

Keywords: Abortion liability, doctor in Indonesia, Health Law of 2009.

Introduction

Data from the World Health Organization in 2018, there are 21.6 million women worldwide undergoing illegal abortions every year. Of these, 18.5 million of them occur in developing countries. In Southeast Asia, deaths caused by unsafe abortion account for 14-16% of all maternal deaths. Indonesia which is around 2.3 million per year, is sufficient to prove that abortion is not a problem that can be underestimated, because abortion is one of the causes of the high mortality rate for pregnant women in addition to other factors. Abortion that is fatal, especially if it is worst because of complications, which are caused by bleeding or infection. Maternal mortality due to illegal abortion contributed 5.6% of total maternal mortality cases. Don Marquest in Bonnie Steinbock says that abortion is considered immoral, because the fetus in womb is the same as a living human. However, there are some views that say that it is okay to have an abortion because the fetus is not yet considered a human. Therefore, abortion that is illegal and not in accordance with medical method is still ongoing and remains a major problem that threatens women during their reproductive years. In addition, because abortion is considered illegal and prohibited by religion, people hide the incidence of abortion and handle it with non-medical assistance/traditional healers, who use improper method. In Mexico, change that is occurring is the increased use of misoprostol as a method of abortion. Misoprostol was originally developed to prevent gastric ulcers but its off-label use as an abortifacient drug has become known worldwide as an effective way to end a pregnancy. The other situation, where people can easily get drugs or herbs that are sold freely and promise to have an abortion, at affordable prices. Conclusion of Latt et All study demonstrates that maternal mortality is lower when abortion laws are less restrictive.

Many events in society need the attention, because health concerns affect all aspects of life and have a broad and complex scope. Where does a mother who has failed in family planning program ang become pregnant, have to complain? Actually, due to economic reasons, she was unable to increase the burden on the family with her pregnancy. Another problem that has been encountered, where a young woman with a retardation mental experiences rape and becomes pregnant without knowing who is the biologic husband. They are
victims of a system, as v. Boven stated that victims are individuals who or have suffered loss, including physical or mental injury, emotional suffering, economic loss or actual deprivation of their basic rights, either by action or by negligence. This tendency to have an abortion cannot be separated from the view of the nature of when the life of a human child begins. Abortion is a complex problem, covering religious, ethical, moral and scientific values, as well as specifically as a biological problem. In a debate about termination of early pregnancy, there are words that are considered important, namely: life, potential life and alive. From this each word, we can think, must we accept the liability when we do it.

Liability: Legal liability is a concept of legal responsibility. A person who is legally responsible for a certain act can be subject to a sanction in the case of his actions which are contrary/contrary to the law. Sanctions imposed for one’s own actions that hold the person responsible. the subject of responsibility and the subject of legal obligation are the same. According to Titik Triwulan, accountability must have a basis, namely things that cause legal rights for someone to sue others, as well as things that give birth to other people’s legal obligations to give their accountability.

The basic principle of responsibility on the basis of mistakes means that a person must be responsible because he or she has done something wrong that harms others. Legal accountability is always required for all persons in a country of law for their actions, including a doctor who performs his actions, including abortion. Accountability here means that the doctor must be ready in case of a lawsuit against him, whether criminal, civil or administrative, beside from ethical and professional problems.

Why should you be responsible if you don’t harm other people and society can accept it? Maybe ethics is still argued and evidence base medicine is violated, including religion rejects or approves it. Considering the needs of the community, it is necessary to conduct separate sociological research. Not all religions refuse it, of course, by considering special circumstances. According to John J. Donohue III And Steven D. Levitt in their study, teenagers, unmarried women, and poor women are most likely to deem a pregnancy to be either mistimed or unwanted, and that a large proportion of these unintended pregnancies will be terminated through abortion.

Criminal Liability: In criminal liability, it must meet 3 (three) requirements: a. There must be criminal action, which is included in the legal delic formula; b. The act that can be sentenced should be contrary to the law, and c. There must be an offence from the perpetrator. It is obvious that a person can be held accountable if there are elements: an act that is against the law, able to be responsible, the existence of errors (schuld) in the form of intentional (dolus) or because of forgetfulness (culpa), as well as the absence of justification reason or excuse reason.

Accountability or known as the concept of “liability” in terms of legal philosophy, it is as stated by a great 20th-century philosopher, Roscoe Pound which stated that the accountability does not only concern the legal matter. However, there is also a problem of moral values or morality in the life of people. Criminal liability According to Roscoe Pond, is as an obligation to pay the retaliation that the perpetrator will receive from someone who is harmed. The responsibility is not only about the legal matter, but the problem of moral values or morality in a society. S.R. Sianturi says the criminal liability is intended to determine whether or not the person can be asked to take responsibility for his or her own actions.

Doctor’s accountability to the Illegal Abortion, if analyzed by the accountability theory of Roscoe Pound is very relevant, because the doctor in taking the abortion action should be responsible to the person who is harmed in this case is the patient who is experiencing the act of abortion, which concerns moral, and morality in the community. In the Sianturi theory of abortion, the abortion itself is a criminal offence. The Doctor who does the abortion means committing a criminal offence. Abortion is a meaningful source of controversy, but some do not cause a killer stigma for the culprit. So, this abortion is a view of life that must be fought from human life.

According to Sianturi, it’s not everyone who performs actions belonging to the category of criminal acts is to be convicted. So, the Doctor who does the abortion clearly commit a criminal offence can be sentenced to or cannot be convicted. The doctor will be convicted if the criminal act of abortion is fulfilled by the criminal act, against the law and making offence. For doctors who have an abortion in pregnant women who are experiencing medical emergency and are aiming to save his life, there is no element against the law, so after the enactment of health law Year 2009, the doctor...
cannot be punished because of his abortion performed. Likewise, in the act of abortion committed to pregnancy, where the fetus suffers from severe genetic defects that will not be able to live independently after birth, also in pregnancy due to rape cannot be sentenced because there is no element against the law.

The criminal threat in the health law of 2009 for abortion is contained in section 194, which states a criminal threat to those who perform abortion acts, that any person who intentionally commits an abortion does not conform to the provisions referred to in article 75 clause (2) will be sentenced to imprisonment of 10 years and the most fines of Rp. 1 billion, -(1 billion). So, the criminal liability of doctors who do abortion is not in accordance with the allowable in article 75 and 76 the health law will be threatened with article 194. This is if the judge uses lex specialist that is this health law. A pregnant woman who will be aborted, is required to obtain her husband’s approval (according to law number 36-year 2009 on health, section 76). Problems arise when the husband does not give consent in this situation! In the case of abortion in the criminal code, the criminal liability of the physician who did the abortion is in accordance with article 349, which will get the threat of a third more severe than the layman who did. In the case of abortion by everyone, it should also be remembered Article 299 of the criminal code. Although the intention will not disbelieve, but with the administration of the drug followed by the provision of hope for the occurrence of abortion, then if there is actually a miscarriage, this drug provider can be sentenced.

In Indonesia, criminal code is “lex generalis” and health law year 2009 is “lex specialis”, so that the judge will certainly choose health Law year 2009 in accordance with the principle of “lex specialis derigate Lexi generali”, but may be considered also the chapters in this psnsl code because it is more detailed. It was the authority of the judge to decide. Criminal liability for doctors who have abortions in women with the failure of the family planning program or in women with a mental retardation that is pregnant due to rape, the doctor has not been protected, so it is still considered illegal so that it can be ensnared with the criminal code or health law.

Legal enforcement of doctors who have illegal abortion can be performed in accordance with the criminal proceedings in general. First of all, will be conducted investigations by police, whether the event reported is correct. If this is true, then it can be upgraded to an investigation and then prosecuting by prosecutors and subsequent proceedings in court. Once there is a decision of the judge, the judgment will be executed by the prosecutor.

**Civil Liability:** The Abortion performing generally is an action of agreement between 2 persons/parties, it is unlikely that the patient will sue because of the things done mutually beneficial. But if there are complications that harm the patient, certainly does not close the possibility of the patient or his family will sue the doctor. The legal relationship between a physician and a patient in performing the abortion may be an alliance born due to a treaty, but it is generally a treaty under the hands, either written or orally. The reason why it usually an under-hand agreement is: a. On illegal abortions are unlikely to carry out authentic agreements, b. Usually until abortion, many of these cases of abortion are considered disgraceful of the family.

Although this agreement is a treaty under the hands, if the patient is harmed, he or she can sue his doctor for compensation. This can happen to a legally occurring abortion. The agreement between the doctor and the patient on an illegal abortion is actually invalid, because according to article 1320 Civil Law, the agreement must be fulfilled 4 conditions, where the 4th condition is the agreed condition must be something “halal” (that does not break the law), when the abortion is illegal, so it is not lawful or violate existing laws and regulations. In the act of legal abortion, doctors are also allowed to be sued for tort, for example if complications resulting from unfulfilled implementation of the standards of service, professional standards and standards of operating procedures, as well as medical discipline and medical ethics. It is based on article 1339 Civil Code.

Under the provisions of article 1339 of the Civil Code, then all liabilities and prohibitions that constitute the compliance and customs in the medical world become part of the therapeutic agreement. Thus, if a civil dispute arises between a physician and a patient, that is, because the Doctor is deemed by the patient to have not carried out its obligations as determined by the unawareness and/or customs prevailing in the medical world, in the relationship of doctors with the patient, then the one that is referenced is customs prevailing in the medical world.

Civil litigation can originate from both the patient and the family. This lawsuit is threaded “materii” and “immaterial”, it can be proposed if the patient
or his family feel harmed. In Materiil claims, it can be estimated and calculated the number of claims in advance, albeit only in an outline. While a lawsuit that is Imateriil is usually very large in number, because it is often associated with things that are not very related directly with the abortion itself.

The civil liability for this abortion can be resolved both litigation and non-litigation. For settlement by way of litigation means completion by court. This can take a long time and require great expense. While non-litigation settlements can be mediation. Settlement of disputes with mediation can be done in court or out of court. According to Regulation of Supreme Court Number 1 of 2008 updated with Regulation of Supreme Court Number 1 of 2016, civil matters are expected to be resolved by means of ADR (alternative Dispute Resolution), especially mediation. By mediation the dispute resolution becomes cheaper and faster to complete, the outcome is expected to achieve a win-win solution. For a physician who commits the dispute resolution of the case with patients in a mediation, facilitated by a mediator, it is actually profitable in terms of problem resolution speed. But there are constraints, because the results of mediation that is considered strong is the deed of peace, whereas with the deed of peace from the court considered as a public domain, so it is open to the public. For a doctor who is experiencing this incident certainly does not want the problem spread widely known by the public, because it will harm his reputation as a doctor.

Administrative Liability: Doctors accountability in the field of administrative law, became clearer since the enactment of the Medical Practice Act of 2004. With the enactment of health law year 2009, there is relatively little change pertaining to the accountability of administration for doctors. Because it has been contained in the Medical Practice Act of year 2004. In conducting an abortion, a physician must fulfill administrative requirements such as the Letter of the Registry Sign (STR) and the Practice Permit (SIP), in addition to the competency of performing abortion must be obtained from the training that has been followed in accordance with Regulation of Health Minister Number 3 of 2016 on the training and management of the abortion for indications of medical emergency and pregnancy due to rape. If any requirements are not met then the doctor will face a problem that leads to a violation of administration with the sanction of its practice licenses.

Even the threat of administrative action pursuant to article 188 of this health legislation through the Minister to health workers (in this case still include the doctors) and health facilities. Article 188 paragraph (1) states the Minister may take administrative action on health workers and health care facilities in violation of the provisions as provided for in this law. Similarly, in verse (2) that reads that; The Minister may delegate the authority as referred to in paragraph (1) to a non-ministerial government institution, head of provincial service, or district/municipality whose principal duties and functions in the field of health.

In article 76c and d of Health law year 2009 mentions performing of abortion as mentioned in article 75 can only be done c. With the consent of the pregnant mother concerned; d. With the consent of the husband, except rape victims. In this case the consent in question is the presence of informed consent first before the action, either from the patient himself or the permission of the husband or his family.

In article 349 of the criminal code, in addition to the doctor can be sentenced to heavier than the general person if doing illegal abortion, can also be revoked practice permit. It is written as follows; If a doctor, midwife or physician assists in committing the crime in article 346, or doing or assisting, committing any of the crimes described in article 347 and 348 of the criminal code, then the criminality prescribed in those chapters can be augmented by a third and can be revoked the right to carry out its work in which the crime is committed.

We know that physician who performed illegal abortion, the responsibility should be in ethical and legal domain. Similarly, when the abortion is both legal and illegal not in accordance with the discipline of the knowledge, there can be consequences that will end with a complaint of the patient or his family to the MKDKI. The process at MKDKI itself can end with the complaint was rejected, the complaint is not acceptable or the pen received and the complaint that the process is terminated. If received and processed further, then the decision may be that the doctor is guilty or innocent. Sanctions if the doctor is guilty, is a disciplinary sanction in the form of written warning, obligation to participate in training and revocation recommendation of STR and or SIP. There are two kinds of sanctions following education and training: formal re-education and non-formal re-education. Recommendations for revocation of STR or SIP can be temporary (at least 1 year), remain or forever, or there are also restrictions on certain medical care measures.
The parties that can be held accountable in the hospital are juridically in the group in: a. The Management of the hospital represented by the head of the hospital/director/CEO; b. Doctors, dentists who work in hospitals; c. The nurses and other health workers and non-health personnel (administration, security, hygiene, etc.).

With the strong predicate as a public servant, the hospital should be prosecuted to be able to conduct services in the field of health with the best to the community. In addition to some hospital responsibilities as a medical service, the hospital is also legally responsible for all losses incurred by the negligence made by the medical personnel, other health workers, as well as the negligence made by any officer who is under the hospital.

It also applies responsibility if there is an illegal abortion. A practising doctor in the hospital can be an employee or a guest physician. Some argue that the hospital as an institution that provides care and treatment services, is responsible for all the events that occur in it. On the basis of the Corporate Liability doctrine, hospitals are responsible for the overall quality control of the services to the patients they care about. The working relationship between doctors and hospitals needs to be redefined with the rules that the hospital has made in which doctors work, so that the purpose of hospital service is more quality and provides safe protection for patients.

Ethics and Professional Discipline: The ethical liability is severely perceived by the doctor, precisely by the formal ethical basis in this case through MKEK, the accountability of doctors who perform illegal abortion is very severe. But if it is thought deeper, then the goal of doing ethical actions is for the benefit of being helped. Teleological ethics will certainly consider the correct purpose of the action. For abortion, these adherents could have thought of what it would be if people who wanted this abortion were not followed. But from the moral side, it must also be used to consider it. For doctors in violation of the ethics, implementing an illegal abortion, will be sanctioned by the Indonesian Ulema Council of Medicine, pursuant to law number 29 of 2004 on medical practice.

Religion: Almost all religions and the flow generally defy abortion.

a. Islamic Views: According to Abdulrahman in Maryati mention, abortion that be done after blowing the spirit by Allah, which is after 4 (four) months of pregnancy is “haram” (forbidden), and all of the scholars of the Fiqh agree to this. But the view is different with the performing an abortion done before this event (blowing of the spirit by Allah), some scholars have allowed and others disagreed. The fatwa of the Indonesian Ulema Council (MUI) said that it has issued a fatwa abortion exemption since the government removed the health Law in 2009. “So, it’s not new anymore. We have issued a fatwa supporting abortion with the exception since the government still boil law and then the rule of government, “said deputy general chairman of the Ma’ruf Amin Center to CNN Indonesia, Monday, 17 November 2014, responded to the exit of PBNU decision on the exclusion of prohibition of abortion, while MUI allowed abortion.

Abortion against rape content can be done before the content reaches the age of 40 days. Fatwa MUI No. 4 year 2005 about abortion, explaining the action of abortion is allowed if pregnant women suffer from severe physical pain such as advanced stage cancer, tuberculosis with Caverna and other physical diseases that must be prescribed by the Doctor team. Then, in a situation where the pregnancy threatens the life of the mother. The Fatwa also describes a state that related to pregnancy that can allow abortion, namely the fetus that was detected is a genetic defect that if born later is difficult to heal.
b. **Christian Views:** From the Christian view, abortion is an unjustified act. In the Bible it says clearly, that God is not pleased with the murder as it does in the act of abortion. Human life has begun when conception occurs. If we do miscarriage consciously, it means that we are doing immoral and asocial deeds. We should not let the cessation of the lives of anyone.

c. **Catholic Views:** The Catholic Church ceases to condemn abortion, which is directly and well-planned to revoke the life of an unborn infant. The Catholic people believe that all life is holy. The church invites to respect human life from the beginning. Therefore, it can be said firmly, the church denies any abortion in any way and reason. Abortion is a deed against the law of God and nature. This action will lead to adverse consequences, especially to the fetus’s mother and father, perhaps to abortion executants and the general public.

d. **Hindu’s Views:** Abortion in Theology Hinduism, belongs to the deed called Himsa Karma, which is one of the deeds of sin that is aligned with killing, hurting and torture. Killing in a deeper sense as “removing life”, underlying the philosophy of the Atma or spirit that has been and attached to the baby, although still a blood clot that is not perfect like the human body.

e. **Buddhism Views:** The Buddha teaches a variety of teachings that can be entirely classified into three core teachings, namely: Sila, Samadhi and Panna. The essence of Sila is not committing wickedness and always doing good and virtue. The hallmark of Sila is Order and serenity. This states the inner state of living rules encompasses all good behaviors and traits including moral and ethics. Samadi is to purify the mind. The ultimate goal of the Buddhist teaching is to bring its implementation to liberation (Panna). In Buddhist views, abortion is an act of miscarriage or killing a living creature already in the womb of a woman. From a Buddhist standpoint, abortion can be tolerated to do when it carries a dangerous impact to the mother and not the other.

Thus the Doctor who will do an illegal abortion, will also be affected by the religion he has. adopted, and think according to his knowledge.

**Conclusions**

The high number of abortion cases in Indonesia proves that abortion is not a problem that can be underestimated, because abortion is one of the causes of the high mortality rate for pregnant women in addition to other factors. Many of these abortions are carried out in secret, possibly carried out by incompetent people and in an unsafe way. This occurs because many pregnancies require abortion (according to the mother concerned), but are not covered by legal indications. In this case the doctor also cannot help her, and if he tries to help, he will have an illegal abortion.

The liability of illegal abortion done by the doctor in Indonesia are include criminal liability, civil liability and administrative liability. Besides that, professional discipline liability and ethical liability also must be borne to the doctor concerned. Criminal liability can be borne heavier to the doctor, midwives or medicine man compared to the common man, if criminal code is be used, but just the same if the health law that being used.

According to the health law of 2009, legal abortion is including performing abortion to save the life of woman concerned, to the womb of the woman that the foetus is severe handicap (and cannot life by self after being born) and pregnancy due to rape (not more than 6 weeks). But not for pregnancy due to the fail of family planning method and to the pregnancy of idiot woman that pregnant without knowing who is the biological husband.

These characteristics of abortion liability for the doctor will prohibit the doctor who help someone who need performing of abortion because of: failing of family planning method, mental retarded woman that pregnant by unknown man and pregnant woman because of rape more than 6 weeks. This reason not for pregnancy that caused by promiscuity and immoral habits.

Abstract

We report here an autosomal STR DNA database of Population of Madhya Pradesh and evaluation of autosomal STR diversity in the context of population genetics and forensic efficiency parameters. In this study, Allele frequencies of 15 autosomal STR loci were investigated in 123 unrelated individuals (57 Female & 66 Male) from the various geographical regions of Madhya Pradesh using PowerPlex® 16 HS System. All the studied loci appeared the high degree of genetic polymorphism with observed heterozygosity (Ho= observed heterozygosity) ranged from 0.911 (D21S11) to 0.659 (TPOX). Locus PENTA E showed the highest power of discrimination (0.978) and the highest polymorphism (PIC = 0.90). The combined probability of match (CPM) and combined paternity Index (CPI) for all the 15 STR loci was found to be 2.8 x 10^-18 and 1.2 x10^6, respectively. The combined discrimination power (CPD) and combined exclusion power (CPE) for all the tested 15 Loci was observed 1 and 0.99999989 respectively, assign that all the loci are highly polymorphic and have the potential for forensic application.

Keywords: Autosomal, Madhya Pradesh, Forensic DNA Typing, Population study, Short tandem repeats (STRs).

Introduction

Madhya Pradesh is geographically located in the centre of India. It is rich in cultural and linguistic diversity and the second largest state by area in the country. In history, it was the primary route of human migration, which is the major factor behind the rich human genetic diversity. As per census 2011, the population of Madhya Pradesh is 7.27 Crore, which is 6% of the total population of the country4(1). In this study, we evaluated the population genetic parameters in population of Madhya Pradesh. The data reported here will contribute toward the DNA database that can be used as a reference for forensic studies for human identity as well as for population genetic and anthropological purposes.

Materials and Method

Sampling: In this study 123 (57 Female & 66 Male) autosomal short tandem repeat (STR) data generated from blood samples were taken from routine casework analysis performed by the authors who work at the DNA Fingerprinting Unit, State Forensic Science Laboratory, Sagar, MP, India. The samples for this study were taken only from unrelated individuals belonging to all regions of Madhya Pradesh. For all the samples prior informed written consent was also obtained from the individuals as per the routine DNA examination procedure of the laboratory and following the Code of Ethics of the World Medical Association (i.e., Declaration of Helsinki)(2). No minor was involved in the study.

DNA Extraction and Quantification: Genomic DNA extracted from the blood samples using 12 GC automated DNA extraction system (PSS, Japan). Extracted DNA was quantified using Qubit Fluorometric Quantitation (Applied Biosystems, Foster City, CA, USA- Thermo) with Qubit ds DNA BR Assay Quantification Kit (Thermo) as per the protocol recommended by the manufacturer.

PCR amplification and STR typing: 15 STR loci and a sex determination marker (Amelogenin) were amplified simultaneously using PCR multiplex PowerPlex® 16 HS (Promega) as per procedure recommended by the manufacturer using ABI 9700 thermal cycler (Thermo). The amplified DNA fragments were separated on capillary electrophoresis following the manufacturer’s recommendations using a 3100Genetic Analyzer (Thermo) and sized withGeneScan500-LIZ internal lane size standard (Thermo) following manufacturer’s recommended protocol. After amplification and separation, DNA fragments were genotyped using GeneMapper Software v3.5 (Thermo). The complete procedure and steps were followed as per standardized internal laboratory and kit controls. The authors also have qualified international proficiency test organized by GITAD, Spain (http://gitad.ugr.es/principal.htm).

Statistical and phylogenetic analysis: Allele frequencies were computed using GenAlEx version 6.5(3). The Hardy–Weinberg P-values, observed heterozygosity (Ho) and expected heterozygosity (He), population differentiation test were calculated using Arlequin Version3.5(4). Genetic parameters of forensic interest viz. Power of Discrimination (PD), Matching Probability (PM), Polymorphic Information Content (PIC), Power of Exclusion (PE), and Typical Paternity Index (TPI) were calculated using the PowerStatsv1.2(5). Allele frequencies obtained from the studied population were compared with data of other published populations on the basis of p-value of the exact test for Hardy–Weinberg equilibrium (calculated using the Arlequin software version 3.5(4)). Also, population differentiation tests Fst genetic distances for comparison with other published populations was carried out using Arlequin version 3.5(4). A phylogenetic tree of the studied population with previously reported 15 populations was constructed with the Neighbour-joining method by software package Poptree2(6) comparing 13 common STR loci showing the inter-population relationship.

Findings: Distribution of allele frequencies and statistical evaluations of the 15 autosomal STR loci in the studied population are reported in Supplementary data. All loci demonstrated the high level of genetic polymorphism with observed Heterozygosity (Ho) ranged from 0.911 (D21S11) to 0.659 (TPOX), the Expected Heterozygosity (HE) ranged from 0.904 (PENTA E) to 0.701 (TPOX). PENTA E demonstrated the greatest power of discrimination (0.978) in the studied population, while TPOX showed the lowest (0.863). The power of exclusion (PE) varies between 0.367 (TPOX) and 0.817 (D21S11). Among all the studied 15 loci, PENTA E had the highest polymorphism (PIC = 0.90), whereas TPOX had the lowest (PIC = 0.65). The most polymorphic and discriminatory STR locus of the studied population is PENTA E with the value of 0.978 (power of discrimination)and 0.90 (polymorphic information content), respectively. The combined power of discrimination (CPD) and the combined power of Exclusion (CPE) were observed with a value of 1 and 0.99999989, respectively. The combined probability of match (CPM) and combined paternity Index (CPI) for all the 15 STR loci was found to be 2.8 x 10^{-18} and 1.2x10^{6}, respectively.

Values in bold represent lowest and highest values of forensic parameters.
Population differentiation test was carried out through Arlequin software. In this test, allelic frequencies of studied population (Madhya Pradesh) was compared with geographically neighbouring regions for which published data is available, namely Balmiki (Punjab), Sakaldwipi-Brahmin (Jharkhand), Mahadev-Koli (Maharashtra), Iyengar (Tamilnadu), Kurumans (Tamilnadu), Lambadi (Andhra Pradesh), Yerukula (Andhra Pradesh), Santal (Chota Nagpur), Bhil (Madhya Pradesh), Balmiki (Jharkhand), Bhil (Gujarat), Central Indian population, Gond (Madhya Pradesh), Kahar population (Uttar Pradesh), population of Jharkhand, population of Uttar Pradesh. After applying the Bonferroni correction (at the significant level of 95% p<0.003), the population differentiation tests showed that studied population had significant differences with Balmiki (Punjab) in 2 out of 13 loci, with Sakaldwipi_Brahmin (Jharkhand) in 4 out of 13 loci, with Mahadev_Koli (Maharashtra) in 5 out of 13 loci, with Iyengar (Tamilnadu) in 1 out of 13 loci, with Kurumans (Tamilnadu) in 1 out of 13 loci, with Lambadi (Andhra Pradesh) 3 out of 13 loci, with Yerukula (Andhra Pradesh) 9 out of 13 loci, with Santal (Chotanagpur) 6 out of 13 loci, with Bhil (Madhya Pradesh) 3 out of 13 loci, with Bhil (Gujarat) 2 out of 13 loci, with central Indian population 1 out of 13 loci, Gond (Madhya Pradesh) 6 out of 13 loci, with population of Jharkhand 1 out of 13 loci and there is no significant difference with UP population and Kahar population (Uttar Pradesh).

To confirm the results of the population differentiation test (Fst-P), Neighbour Joining (NJ) Tree (Fig.1), and Principal Component Analysis (PCA) (Fig.2) were performed for the studied population along with previously reported populations. NJ tree revealed the genetic relatedness with the previously reported population of Madhya Pradesh, central Indian population, and clustered with Population of Uttar Pradesh along with some outlier population (Fig.1). In Principal Component Analysis (PCA), component 1 and component 2 explained 67.918% variance in the studied population. In the PCA plot, geographically close population pooled in one cluster (Fig.2). Neighbour Joining Tree and PCA plot showed consistency with each other.

![Fig. 1: NJ tree of the studied population showing the genetic relatedness with the previously reported populations.](image-url)
Fig. 2: Principal component analysis (PCA) plot based on Nei’s Da distance matrix showing the distance pattern of studied population with previously reported populations.

Conclusion

The data set generated from this study will enrich the DNA data bank. The studied 15 STR markers are polymorphic, informative and can be used in forensic application as well as anthropological studies for Indian population. The studied population has significant genetic diversity.

Conflict of Interest: Authors declared that they have no conflict of interest.

Abstract

Introduction: Optimal growth and development in children under two years is usually supported by good nutritional status. In addition, there is also a need for developmental stimulation from the mother, family and closest people to support children’s intelligence. The government has long launched the Maternal and Child Health (MCH) Handbook as an attempt to assist mothers in meeting the needs of their children. However, the implementation of the program is still not optimal. This can be proven by the number of nutritional status and development of children which does not match their age that is still quite high.

Method: This study was a quasi-experimental study, with a pre-test and post-test nonequivalent control group design. The number of samples used was 60 children under two years, which was taken from a population of 131 children under two years in Gunung Kapur. The sampling technique used was non-probability sampling with consecutive sampling method. The instrument used was a questionnaire adapted from the MCH Handbook. Data were then analyzed using univariate and bivariate analyses with independent t-test.

Results: The results of hypothesis testing with Paired T-Test showed that there was an effect of education on the utilization of the MCH Handbook using the brainstorming method on the fulfillment of nutritional intake (p value = 0.001) and developmental stimulation (p value = 0.001). Analysis of the difference on the two groups showed that the treatment group with the educational intervention using the MCH Handbook using the brainstorming method had a greater effect on the fulfillment of nutritional intake and developmental stimulation with the Independent T-Test (p value = 0.001) compared to the control group.

Conclusion: There is an effect of education on the utilization of the MCH Handbook using the brainstorming method on the fulfillment of nutritional intake and developmental stimulation of children under two years (aged 6-24 months) in Gunung Kapur, Lempake Village.

Keywords: Education, nutritional intake, developmental stimulation.

Introduction

Children are important human resources as the successor of a future nation. As adults, children who have healthy and optimal growth and development are able to develop the nation properly and wisely. The quality of the nation in the future is determined by the quality of today’s children. It is supported by Sofyan Djilal as Head of the National Development Planning Board (Bappenas) together with UNICEF stating that 30% of the total population of Indonesia is children. They are 100% of the future of the nation and deserve attention in terms of growth and development from various circles¹.

e-mail: sukritanatoa72@gmail.com
Unfortunately, growth and developmental delay in children is still a serious problem in both developed and developing countries in the world\textsuperscript{2-5}. This is also an urban health problem\textsuperscript{1}. Based on Indonesia’s health profile in 2011, 13-18\% of children experienced developmental delay\textsuperscript{6}.

Furthermore, the Profile of Indonesian Children in 2015 shows that 16.17\% or 13,396,485 of Indonesia’s population are children under two years. The prevalence of children under two years with malnutrition shows that 17.9\% and 4.9\% suffer from malnutrition. Besides, in East Kalimantan Province, there were 19.4\% children under two years with malnutrition in 2010. This condition has almost reached the national standard of 20\%, which so far still needs to get much concern\textsuperscript{7}.

In fact, mother is primary care or who has direct involvement in process of providing care and feeding for children under two years\textsuperscript{8-10}. Thus, mothers have a very important role in meeting children’s needs. Those who have children under two years should know or have read the contents of the Maternal and Child Health (MCH) Handbook. This book contains information about instructions, guidelines and ways to achieve maternal and child health as a government effort to increase knowledge and behavior in healthy living. A correct and consistent perception or view of the MCH Handbook as a tool to monitor children’s health and growth and development is needed\textsuperscript{11}. Perceptions of an object, whether right or wrong, good or bad, positive or negative, cause a response to a person, so that it can be the basis for determining positive or negative attitudes.

Considering the aforementioned phenomenon, researchers are interested in conducting a study entitled “The Effect of the Education on the Utilization of the MCH Handbook Using the Brainstorming Method on the Fulfillment of Nutritional Intake and Developmental Stimulation of Children Under Two Years (aged 6-24 Months) in Gunung Kapur, Lempake Village”.

Materials and Method

Research Location: The research was carried out in 5 Integrated Services Post (Posyandu) spread out in Gunung Kapur, Lempake Village.

Research Design: This study was a quasi-experimental study, with a pre-test and post-test nonequivalent control group design.

Data Collection Method: The data were collected by conducting a pre-test using a questionnaire for the fulfillment of nutritional intake and developmental stimulation in the treatment and control groups. It was then continued by providing education regarding the utilization of the MCH Handbook with the brainstorming method in the treatment group. After one month, a post test was carried out using a questionnaire on the fulfillment of nutritional intake and developmental stimulation in the treatment and control groups as evaluation materials.

Data Analysis: The data that had been collected were analyzed, including univariate and bivariate analyses, using independent t-test to determine the effect of education on the utilization of the MCH Handbook with the brainstorming method on the fulfillment of nutritional intake and developmental stimulation of children under two years (aged 6-24 months) in Gunung Kapur, Lempake Village.

Results

Univariate Analysis:

Respondent Characteristics:

Based on Table 1, it can be seen that the characteristics of mothers based on age indicate that most of them are in the 20-29 years category as much as 53.3%. The characteristics of mothers based on the last education indicate that most of them are junior high school/equivalent graduates as much as 53.3%. Moreover, the characteristics of mothers based on occupation indicate that almost all of them are housewives as much as 86.7%. In addition, the characteristics of mothers based on family income show that some are in the 2,000,000-4,000,000 category as much as 50.0%.

**Fulfillment of Nutritional Intake before and after Education Given to Control and Treatment groups:**

**Table 2: Fulfillment of Nutritional Intake Before and After Education Given to Control and Treatment Groups**

<table>
<thead>
<tr>
<th>Variables</th>
<th>N</th>

<td>0.001</td>
</tr>
<tr>
<td>Control</td>
<td>30</td>
<td>60.00±17.794</td>
<td></td>
</tr>
</tbody>
</table>

Based on Table 5, the mean and standard deviation values of the fulfillment of nutritional intake variable before treatment were 48.91 ±23.932, while the values of the control group were 43.44 ±24.169 with p = 0.374 > 0.05. It means that there was no significant difference in the difference value between the two groups.
Additionally, the mean and standard deviation values of the fulfillment of nutritional intake variable after the treatment were 83.30 ± 11.490, while the values of the control group were 44.97 ± 24.169 with p = 0.001 < 0.05. It means that there was significant difference in the difference value between the two groups.

More importantly, the mean and standard deviation values of the treatment group before the treatment were 58.03 ± 22.021, the values of the control group were 59.30 ± 18.107 with p = 0.809 > 0.05. It means that there was no significant difference in the difference value between the two groups. Besides, the mean and standard deviation values of the treatment group after treatment were 83.30 ± 11.490, while the values of the control group were 60.00 ± 17.794 with p = 0.001 < 0.05. It means that there was significant difference in the difference value between the two groups.

Therefore, it can be said that there was no significant difference between the fulfillment of nutritional intake in treatment and control groups before using the MCH Handbook. However, there was a significant difference between the fulfillment of nutritional intake in the treatment and control groups after the treatment in the form of education on the utilization of the MCH Handbook.

**Discussion**

**a. The Effect of the Education on the Utilization of the MCH Handbook Using the Brainstorming Method on the Fulfillment of Nutritional Intake of Children Under Two Years (aged 6-24 Months) in Gunung Kapur, Lempake Village**

In this research, the mean of the fulfillment of nutritional intake variable in the treatment group before the education on the utilization of the MCH Handbook was 48.91. Mothers, as research respondents, then received the education on the utilization of MCH Handbook with the brainstorming method.

Besides, the mean of the fulfillment of nutritional intake variable in the treatment group after the education on the utilization of the MCH Handbook was 83.30. This shows an increase in the mean of fulfillment of nutritional intake variable before and after the education on the utilization of the MCH Handbook, which is 34.39 with p = 0.001 < 0.05.

Moreover, mothers in the treatment and control groups affirmed that they had read the MCH Handbook. However, they only read without applying how to fulfill proper nutritional intake for children under two years (aged 6-24 months). In fact, knowledge is closely related to the amount of information a person has. The more information a person has, the higher their knowledge. Brainstorming method was deliberately chosen with the aim of increasing the active role of the mother, generating creative roles, stimulating participation, and creating a pleasant atmosphere.

**b. The Effect of the Education on the Utilization of the MCH Handbook Using the Brainstorming Method on the Developmental Stimulation of Children Under Two Years (aged 6-24 Months) in Gunung Kapur, Lempake Village**

In this research, the mean of the developmental stimulation variable in the treatment group before the education on the utilization of the MCH Handbook was 58.03.

More importantly, the mean of developmental stimulation after education on the utilization of the MCH Handbook was 83.30. It indicates an increase in the mean of developmental stimulation before and after the education on the utilization of the MCH Handbook, which was 25.27 with p 0.001 <0.05.

Here, the mothers admitted that they had read the MCH Handbook, but they did not know the developmental stimulation that should be given to children based on age.

In this study, it was found that there was an increase in the mean value in the treatment group after the education. These results are in line with the research conducted by Muflihah (2017) which claimed that mother’s knowledge and skills in providing developmental stimulation to toddlers have increased after receiving education.

**c. The Differences in the Fulfillment of Nutritional Intake and Developmental Stimulation in the Control and Treatment Groups**

The results of the research analysis obtained independent t-test on the fulfillment of nutritional intake and developmental stimulation in the control and treatment groups, that is p = 0.001 <0.05.
Education with the brainstorming method has a significant effect on the results obtained. It is in accordance with the research conducted by \(^{15}\) (Syafi’udin, Wantiyah dan Kushariyadi, 2018) which proved that health education using the brainstorming method is more effective than the lecture method. One of the advantages of the brainstorming method is that it is able to provide stimulation for all participants to actively take part in it, besides that it uses little equipment.

**Conclusion and Recommendations**

There is an effect of education on the utilization of the MCH Handbook using the brainstorming method on the fulfillment of nutritional intake and developmental stimulation in Gunung Kapur, Lempake Village. Last but not least, this research recommends the Health Office to further motivate community health center officers in socializing and educating mothers with toddlers regarding the utilization of the MCH Handbook. The community health center is expected to be able to hold regular meetings with Integrated Services Post cadres in providing education on the utilization of the MCH Handbook to mothers.

Abstract

Forensic DNA fingerprinting is the most believed method of the criminal investigation. With the advancement in technology, the method has become more and more sensitive and the technology now uses advanced method and new generation faster multiplex amplification systems. Most of these improvements in the technique are after the extraction of DNA. Despite automation in DNA extraction, still, the basic process of lysis of cells is an integral part of the analysis. We present here the comparison of DNA extraction results with and without using the proteinase k enzyme.

Keywords: DNA Extraction, Proteinase k, Forensic, DNA Fingerprinting.

Introduction

Deoxyribonucleic acid (DNA) based human identification is now accepted as the gold standard in forensics(1). It is recognized as the most convincing and practiced method in the criminal investigation since last two decades or more(2). Forensic evidence collected from various crime scenes areanalyzed by the present-day forensic DNA technology using capillary electrophoresis (CE) technique(3). The present-day DNA technology has faced many transformations to achieve the present state. With the advent of polymerase chain reaction (PCR), now it is possible to amplify even very minute quantities of DNA recovered from the crime scene in the detectable range(4). The results of DNA testing on evidence samples are compared with the results of DNA analysis of reference samples collected from known individuals. This power in the DNA technology was achieved with the development of the PCR based short tandem repeats (STRs) testing(1) coupled with CE. DNA profiling is done using pre-formulated and pre-validated multiplex amplification kits(5),(6) incorporating 15 to 27 markers. With the advancements in the technology, the multiplex kits used in forensic science are also improved not only in the number of markers in a single multiplex but also in the master mix, making the PCR faster(6). Such analyses can link victims with suspects, other evidence items, or with a crime scene.

The forensic DNA technology is well developed, and now since the last decade, attempts are being made to make the technology faster and cheaper. There have been many attempts towards the direct amplification of forensic evidence(7)(8)(9) including the launch of direct amplification kits for selected forensic samples by various manufacturers of multiplex kits. But still today, the standard method of DNA extraction using lysis buffer, sodium dodecyl sulfate (SDS) and proteinase k enzyme (PK) is widely accepted and most commonly used the technique in forensic DNA analysis because this technique is standardized with the whole variety of forensic samples.

Normal forensic lysis buffer contains Tris (pH is maintained by HCL), EDTA (pH is maintained by NaOH) and NaCl. Besides lysis buffer SDS (Sodium dodecyl sulfate) is the most commonly used strong anionic detergent, which has the capability, to disrupt the cell membrane by solubilizing proteins and lipids along with denaturing histones and other DNA binding proteins. Proteinase k is the second most important chemical used in DNA extraction, which helps in digesting proteins. This enzyme also deactivates nuclease enzymes, which degrades DNA in the process of DNA extraction. Proteinase k is a costly chemical, in comparison with the other chemicals used in the process of DNA extraction. With the advancement of present DNA technology, the requirement of input DNA is less than 500 picograms with all the new generation multiplex amplification systems (Table 1). We tested the routine DNA extraction protocol of lysis with and without using the proteinase k enzyme.

**Material and Method**

Twenty-five liquid blood samples received as a case exhibit at the DNA Fingerprinting unit of State Forensic Science Laboratory, Sagar, MP, India, were used for the study. All the samples were collected with written informed consent and as per the declaration of Helsinki\(^{10}\) for the DNA fingerprinting examination. The samples were transported to the laboratory under the ice and were preserved at 4°C till further processing. 600µl of each liquid blood sample was processed with the lysis buffer (namely forensic buffer) routinely used in forensic DNA examination of the laboratory.

To each sample, 600 µl of forensic buffer (1 M Tris pH 8 with HCL, 0.5 M EDTA pH 8 with NaOH, and 5 MNaCl), 50 µl of 20 % SDS, and 10 µl of PK (20mg/ml) was added. All the samples were also processed simultaneously without using PK. A forensic paternity examination was also processed using both approaches.

Extracted DNA was quantified using the PowerQuant\textsuperscript{TM}human DNA quantification kit (Promega, Madison, WI, USA/Promega) on Real-Time PCR 7500 machine (Thermo). Quantified DNA was subjected to amplification for 15 autosomal Short Tandem repeats (as STRs) along with sex-determining Amelogenin marker using AmpFISTR®Identifiler\textsuperscript{®} Plus PCR Amplification kit (Thermo) on ABI 9700thermal cycler (Thermo) as per the recommendation of the manufacturer except 10µl reaction volume was used. 1 µl of amplified DNA was diluted in the solution of 10 µl HiDiFormamide and 0.2 µl Liz 500. DNA fragments were separated using POP-4 and 36 cm capillary array on ABI 3100 Genetic analyzer (Thermo) as per the recommended protocol of the manufacturer. Allelic Ladder provided along with the multiplex kit was used for the designation of the allele and obtained data was analyzed using Genemapper\textsuperscript{®} software v3.5 (Thermo).

**Findings:** The results of DNA extraction from blood samples with and without using the proteinase k enzyme are presented in Figure 1. All the 25 samples processed with and without proteinase k enzyme yielded a good quantity of DNA. The yield of DNA without PK ranged 30 to 46 ng/µl and the yield of DNA with PK ranged 35 to 61 ng/µl (Figure 1).

</table>

The mean value of DNA extracted using with proteinase k approach was 49.87 (Standard deviation=6.33) however the mean value of DNA extracted without using proteinase k approach was 36.33 (Standard deviation=3.48). The obtained results showed difference in the yield of DNA in both the approaches. However, as the need of DNA required for amplification using new generation multiplex kits are less than 500 picogram, hence the achieved quantity of extracted DNA sounds good enough for use in forensic DNA typing of samples which is expected to have a good amount of DNA.

We also present a case of sexual assault in which a lady was sexually assaulted and gave birth to a male child. The blood samples of suspect along with the samples of the victim and the newborn male child were received for establishment of paternity at State Forensic Science Laboratory, Sagar, MP, and India. DNA is extracted using both the approaches in this case of paternity establishment involving blood samples of the trio. The obtained results in the case using both the approaches are shown in Table 2.

Figure 3: DNA profile quality parameters in the same case of paternity
The child showed a perfect trio match with both the parents using both the approaches and same results were obtained. The DNA profile observed using both the approaches showed the concordance. DNA profile quality measures, namely peak height ratio, total peak height and mean locus balance were also compared (Figure 4). The compared profile quality parameters also showed the suitability of both the approaches for forensic DNA typing work using blood samples.

The compared profile quality parameters also showed the suitability of both the approaches for forensic DNA typing work using blood samples. As blood contains comparatively higher amount of DNA, hence we recommend this approach to be used for all the samples which has good amount of DNA. However with other range of forensic samples which has comparatively lower amount of DNA, this approach needs to be further evaluated.

**Conclusion**

The yield of DNA varied with and without the use of proteinase k, but a good quantity of DNA was extracted using both the approaches. The yield of obtained DNA without proteinase k was sufficient enough to be used in today’s forensic DNA testing, as the requirement of DNA in present-day DNA testing is less than 1ng. This study is useful for forensic DNA typing as well as human genetics and anthropological studies concerning high-quality DNA extraction.

Abstract

This paper aims to analyze the factors which cause the violation of the Governmental Decree No. 6 of 2012 on Cattle Control at Palu City by cattle owners. This research was conducted at South Palu, especially at the North Birobuli District using the qualitative-naturalistic method. The results of this research show that the society has not yet obeyed the Regional Decree No. 6 of 2012 on Cattle Control at Palu City area due to some factors: (1) the new values of the Regional Decree No. 6 of 2012 is against the old values of the cattle owners; (2) the cattle owners do not have an understanding of the stipulations which apply nor do they understand the social change which is currently happening; (3) The attitudes and behaviors of the police officers and the changemakers were inconsistent and rather discriminative; and (4) the disobedience may cause health problems which are anthrax, nail and mouth disease, or other diseases to the cattle.

Keywords: Law, Sociology, Obedience, Cattle, Control, Health Issues.

Introduction

Cattle owners have not yet shown attitudes and behaviors which support the development of a safe and a comfortable city. They do not act according to the legal stipulations which apply. On the contrary, they let their cattle free to roam public areas, including roads. Even, some cattle were not brought in to their sheds at night.

Such manner of animal husbandry causes problems in the societies’ lives. There are usually problems between the people caused by some loss experienced by one of the parties, as their plantations, gates, or vehicles were wrecked by the roaming cattle. At night, there are some cattle which are not put in their sheds, but they rest at places such as roads, people’s lawns, or public facilities. At such places, the cattle leave their feces, which disturb the cleanliness and the aesthetics of the roads, the people’s lawns, and the public facilities.

These phenomena cause continual loss, not including the environmental destruction and the increase of the rate of road accidents. Another impact is that the cattle are not hygienic; they bring diseases which may spread to people, such as causing diarrhea when the cattle secrete their feces at water springs which are consumed by the people. They may cause other diseases also. Thus, it is important to carry out a research on the effectivity of this Regional Decree, with the title, “Legal Obedience, Social Change, and Health Issues: Analysis of the Governmental Decree No. 6 of 2012 on Cattle Control at Palu City.”

Method

This research used sociology juridical methods and library research approach. This research is also a prescriptive study, which aims to offer solution towards the problems in the Palu cattle control². This research is qualitative research that’s Denzin and Lincoln stated that qualitative research is the research which uses natural settings, aimed to interpret phenomena which occur and carried out by involving various existing methods.

1. The Cattle Owners Who Let Their Cattle Roam Free in the Morning and at Night: Generally, the cattle roam surrounding or proximate to the residences of their owners. This is carried out continually and is maintained due to the physical and the behavioral natures of the cattle, which make it possible for them to be proximate to human beings. The physical and the natural characteristics
of the cattle which enjoy resting in muds and leave feces may cause health problems, especially when discussing about sanitation and water sources. But the reason of why the cattle owners try to place their cattle in the shed is so that they are not caught, fined, nor imprisoned by the law-enforcing apparatus.

The research results show that there are still people who let their cattle roam free both in the morning and at night. Among them, there are those who have tried to cage their cattle but fail to do so. Yet, there are also those who leave their cattle be since the issuing of the Regional Decree No. 6 of 2012. The cattle owners who have posed an ignorant attitude since the initial issuing of the decree generally have some cattle which are rather wild and difficult to approach. Because of that, they are forced to only secure the cattle in the mornings and in the afternoons. Then, they let their cattle free at night. They feel rather relieved as they law-enforcement operation is carried out in the mornings and in the afternoons from 09.00 to 17.00 o’clock at the local time. Then, the cattle owners also let their cattle roam freely due to lack of energy and time, even though some realize that there are strengths and weaknesses in putting their cattle in the shed.4

2. The Cattle Owners Who Cage Their Cattle Solely at Night: The aim of the cattle owners in caging their cattle is to maintain their safety from unwanted issues such as getting them lost or stolen, having them hurt or injured due to traffic accidents, or having them catch some diseases. Even so, they realize that even though the cattle have been caged, the same unwanted issues may still happen, such as cattle theft.

Regarding their compliance with the implication of the Regional Decree No. 6 of 2012, they have the same reason as the cattle owners who let their cattle roam free in the morning and at night – which is solely to avoid being arrested or detained by the law-enforcing apparatus. These people try to save their cattle from the chance to go or to roam at city roads or other public places. In the morning, some of those cattle owners keep their cattle in the sheds and feed them grass or bran until around 10.00-11.00 o’clock. After that, the cattle are let out and brought to the field. The aim of keeping the cattle in the shed is so that they feel comfortable there, and to minimize the time that they roam at the forbidden places.

Whilst monitoring the cattle, there are times when the alertness of the owners decreases. Thus, the officials who were at that time carrying out the law-enforcement operation may detain the roaming cattle. Seeing such event, most of the cattle owners choose to surrender. But there are also those who oppose this action, such as RBI, a cattle-owner. Some of those cattle unexpectedly roamed to the city roads, where there were some officials in operation at that area. Then, RBI’s cattle were caught. Seeing this, RBI demanded the officials to release his cattle. Due to RBI’s strong and stern manner, the law-enforcing officials chose to let those cattle go.

3. The Cattle Owners Who Feed and Cage Their Cattle at Night: The cattle owners feed and cage their cattle at night because of their understanding on the cattle’s safety and their understanding on the areal development of the cattle which is limited by plantations and people’s residences. But, this type of cattle owner is at a low rate compared to the total population of 384 families of cattle owners, which is only 14 families, or 3,65%

On the issuing of the Regional Decree No. 6 of 2012, they took it seriously. This is because they opined that they were afraid of being caught by the police, in a conversation with BHR, WK, MRD, SNR, RBI, MSR, and KRL (September 2019). In effect, same as the two aforementioned types of cattle owners, they had to spare their time to take care of the cattle’s safety.

These are the descriptions of the cattle owner’s compliance to the Regional Decree No. 6 of 2012 on Cattle Control at North Birombi, South Palu District, Palu City, Central Sulawesi. According to Kelman, such compliance is caused by the attention which is focused solely on the impacts of law violation, which are punishments or negative sanctions. The law compliance is not based on the belief on the essence of the law, but it is based on the control from the authorities. Due to this principle in law-obedience, such compliance may only be carried out if there is a tight supervision.5 This is proven by the short effectivity in implementing the Regional Decree No. 6 of 2012.

After that period, the cattle owners return to their former habits, even though the Regional Decree No. 6 of 2012 had not been revoked. Habits which are present in the society can neither give contribution, nor can it be developed to the stage in forming higher rules or values.6 If compared to the development of material or physical cultures, as proven by the short description on the people and the area of research, the immaterial or the
non-physical cultures (especially regarding the manner in animal husbandry) of the people are still behind. According to Ogburn, such phenomenon is called the cultural lag.\(^7\)

4. The Factors Which Cause the Cattle Owners to Violate the Regional Decree No. 6 of 2012: There are some factors which cause the cattle owners to violate the Regional Decree No. 6 of 2012. A value is a guide and a stimulus of human behavior in the social interaction process, thus concretely, it functions as a system of manners.\(^8\) Raising livestock by letting them loose and roam free everywhere around the villages of the South Palu District has become the local people’s system of manner. Based on the field observation, all cattle owners do so in raising their livestock, in a conversation with SDM, HF and SF (September 2019).

Apart from that, in the educational aspect, such manner in raising livestock is not only limited to those who are of low education, but even those who had underwent middle or even high education, such as those who have obtained the bachelor’s degree. Thus, what is opined by Soedjito that education may change the cultural values in a society is not proven in this study.\(^7\) thus it is a tradition which is difficult to change.

The change programmed by the government does not bring welfare. On the contrary, some problems emerged in the social system of the cattle owners.\(^9\) As what has been explained in the previous part, most of the South Palu people farm for a living. Their farms, rice fields and plantations are a type of subsistent farming, which means that they use them to fulfill their own needs. Farming is their main jobs. Their time is mostly used to work in the rice fields or the plantations.

Such condition forces the South Palu people to not have much time to take care of their livestock intensively. Taking care of the livestock is only a part-time job which is not their priority. They do not depend on their cattle for life. Even though the cattle may bring forth much income if they are sold, such condition cannot be depended on, unlike the farm produces. Taking care of the cattle needs much time compared to that of farming. Thus, the livestock only functions as a source of reserve income, in a conversation with YSW, MSR. HF and KUI (September 2019).

Thus, the application of the Regional Decree No. 6 of 2012 results to the shift in the roles, jobs, time utilization which had been designed for years in the life system of the cattle owners in the South Palu District. They cannot yet accept such regulation. Lauer states that the shift in special social roles of individuals in a society regarding traditions, birth, and gender roles will shake the familial system.\(^10\)

The ignorance and the incomprehension of the cattle owners is caused by the lack of the regional decree socialization efforts by the government. The government has only informed of the prohibition from letting the cattle loose and free to roam through a megaphone from a vehicle along the roads. Such information was only announced trice. Then, the next week, there were arrests and detachments of the cattle which are caught roaming free. Such action of arrests and detachments were only carried out for three weeks. After that, no more of them had been done, in a conversation with KS, SDM and, MSR (September 2019). In this case the researcher agrees with Kurniaisih’s argument that the more intensive a socialization of a law is, the higher the understanding will be, and the more compliant someone is in abiding to that law.\(^11\)

Then, Alfian states that the manners of the law-enforcing officials have a great impact on the plans of development, especially because it is through them that the people will or will not be interested in participating in the development.\(^11\) Ironically, some of their actions even widen the gap between the people and the programs created. There are even those who feel antipathy or even hate to those programs, as known from an interview with EFR, REI, MSR and BLR (October 2019).

6. Health Problems and Social Change: The factor of facilities also has a role in the implementation of the program of social change through the issuing of the Regional Decree No. 6 of 2012. These facilities are not a principal thing, but it is a supporting factor in the program’s implementation. But their fulfillment must absolutely be carried out.

The facility meant is the location which becomes the shelter for the cattle which are arrested and detained, including the guarantee of their food, drink, and safety. The provision of this facility is crucial to anticipate the long detainment of some cattle, as they had not been picked up by the owners. Thus, the death and anything related to the cattle’s safety is the responsibility of the officers.\(^12\)

The real risk due to the handling of cattle carcasses
which experienced sudden death or due to sicknesses whilst they roam is usually ignored by the cattle owners in the village, even though they realize that there is a law against it. The unhygienic manner in animal husbandry is difficult to erase. Such situation cannot be separated from the socio-economic condition of the villagers who mostly live in poverty. The behaviors of the cattle owners are encouraged by the need to maintain the economic value which may be obtained by raising livestock whilst violating the law.

The stakeholders must give support to the Governmental Service which takes care of the animal health to plan a response towards the urgency in saving the lives of the animals and the people. There must also be the animal health risk assessment.

Conclusion

The results of this research show that the social change in the aspect of material culture is not simultaneous with the social change in the aspect of immaterial culture, which causes a cultural lag in the society. A cultural product may easily and quickly be accepted in a society if they directly sense the benefits.

The socialization of a developmental program, such as the Regional Decree No. 6 of 2012 regarding the Cattle Control in the area of Paly City is not intensive. It also lacks integration. It is incidental by the government, which makes the government lack understanding of that regulation’s essence. Thus, the short-term and the long-term goals which are to be achieved through the legal institutions cannot be realized as expected.

Apart from that, the planning which is underdone, like the problems of the provision of developmental operational facilities are neither complete nor adequate. This causes inefficiency. Thus, it causes the implementation of the development to stop. Another impact which is the emergence of issues and problems in the health issue, due to the in compliance of the cattle owners in implementing the constitution. The health issue which arise is due to the unhygienic animal husbandry system carried out by the people in Palu.

Prevalence and Molecular Detection of Rotavirus in Children in Ramadi City-Iraq

Suha Ali Abd-Al Fattah¹, Mohamed Abdullah Hamad², Muhammad Qais AL-Ani³

¹Assistant Professor, Department of Biology Science, AL-Anbar University, ²Director of the Center of Biotechnology and Environmental Technology/University of Fallujah, ³Professor, Department of Ophthalmology

Abstract

Matter: This is the first study in Al-Anbar governorate with this design aim to the detection of rotavirus group A (ROV A).

Method: A total of (150) stool samples obtained from children <5 years with acute gastroenteritis were randomly collected from Maternity and Children at al-Anbar governorate from (1-9-2019 to 1-2-2020); Rotavirus was detected by rapid test for stool samples and real-time polymerase chain reaction for blood and serum.

Results: Out of total 150 stool sample there were 101(67.3%), 49(32.6%) Negative and positive result respectively, from rapid test. The result of RT-PCR from serum & blood were Thirty-one (31)81.57% of (38) samples positive for rotavirus & eight samples were no ct there was Significant value (0.0016)(0.0075) between PCR (blood, serum) test and Rapid test under p<0.05. Based on that RT-PCR was more sensitive & specific than rapid test.

Keyword: Molecular detection, RT-PCR, Rotavirus, children patients.

Introduction

Rotavirus is transmitted as a result of contamination of the hand with the stool of infected people, and then it reaches the mouth or respiratory system¹²,³,⁴ Rotavirus (RV) infects small intestinal epithelial cells, inducing severe diarrhea in children, resulting in over 500,000 deaths annually.⁵ The virus replicates in the intestinal villi cells⁶ this replication decreases the ability of the intestine to absorb salts and water.⁷ The symptoms often start with fever, nausea, and vomiting, followed by abdominal cramps and frequent watery diarrhea, which may last for 3-8 days. Infected children may also have a cough and runny nose.⁸,⁹,¹⁰,¹¹,¹²,¹³ Generally, reinfections are common in Rotavirus disease.¹⁴ Immunity develops with each infection, so subsequent infections are less severe; adults are rarely affected.¹⁵ Because of the frequency of the virus in the winter season, it was called winter diarrhea before the virus was discovered.¹⁶,¹,⁹,¹⁷,¹⁸,¹⁹

Rotavirus is the second cause of death in newborns and the cause of more than half of cases of acute diarrhea according to the WHO report²⁰ because no specific antiviral therapy is available, effective RV vaccines are crucial to prevent morbidity and mortality. Treatment of RV infection is only possible through fluid and electrolyte replacement, as no specific antiviral therapy is available.²¹

In 2009, WHO recommended the introduction of RVA vaccines into the routine immunization programs, and despite evidence that these vaccines provide good protection against hospitalizations, the acute gastroenteritis morbidity associated to RVA Internationally, oral rotavirus vaccines available (RotaTeq and Rotarix) ²² Rotarix (RV1 product from one strain G1P [8] strain is used as a human vaccine in two doses, RotaTeq (RV5) resulting from combining five strains (G1, G2, G3, G4, and G1P[8])., is used as a vaccine in three doses.²³ Early diagnosis of Rotavirus gastroenteritis in hospitalized patients will decline the morbidity and mortality impressively and avoids keeps away from improper utilization of anti-toxins in pediatric patients.¹⁴ Rotavirus infection is not routinely
diagnosed in Al-Ramadi hospitals probably due to the cost of its diagnosis and because the clinical spectrum of signs and symptoms are similar to other gastroenteritis infections\textsuperscript{24,25}. There is a need for regular detection of RV strains because this information is needed to interpret the results of vaccine studies and epidemiologic surveillance \textsuperscript{9}.

This is the first study in Al-Anbar governorate with this design aim to the detection of rotavirus group A (ROVA) & evaluation methods of detection, initially with a rapid test (immunochromatography) for rotavirus in stool specimen, secondly, by molecular methods RT-PCR. In the other side, we were finding out the epidemiology of rotavirus in AL- Ramadi city in Al-Anbar governorate.

**Method**

Stool samples were collected from children aged less than 5 years, admitted with acute gastroenteritis to hospitals or outpatient wards, a total of (150) stool samples obtained From (1- 9-2019 to 1-2-2020), from children<5 years with acute gastroenteritis were randomly collected from Maternity and Children at al-Anbar governorate.

Detection of Rota Virus by Rapid Chromatographic Immunoassay, The chromatographic immunoassay performed to the first method that we used to detect the rotavirus in stool samples according to (Qingdao High top Biotech Co.Ltd, China).

We were extracted RNA of 38 samples (serum & blood) according to manufactured company (VIASURE RNA –DNA Extraction Kit) protocol Spain.

Samples were stored in clean Eppendorf tub at deep freeze; kit of extraction was stored at room temperature RT (15-30°C) until the day of the experiment, any lyophilized or dissolved substance must be stored at -20°C (like carrier RNA, Proteinase K) and wash buffer at RT.

After preparing our samples, kits and devices; there were initial steps before isolation RNA according (manufactured company (VIASURE RNA –DNA Extraction Kit) protocol Spain.):

Isolation genomic RNA of rotavirus from serum blood samples according (manufactured company VIASURE RNA –DNA Extraction Kit) protocol Spain.:

- **Real-time PCR detection of Rotavirus according** (The protocol of DNA & RNA RT-PCR kit by VIASURE Company – Spin)

**Statistical Analysis:** All results were conducting statistically on SPSS Ver.22. Frequency distribution and percentage for selected variables were done first. \textsuperscript{26} For all statistical analyses, sig. represent P (Probability) value in every table, a P value of less than 0.05 was considered statistically significant. For comparison between variables, we used the Pearson Correlation Coefficient, which ranges (-1 to +1); a positive value means direct correlation & negative value means reverse correlation. & we used Chi-square to compare between the variable. Sensitivity & Specificity were done by MedCalc® v19.5.2.

**Results and Discussion**

**Description of the study sample:** Rotavirus is still the main cause of diarrhea in children. The World Health Organization has indicated that more than half a million children under the age of five face death as a result of contracting rotavirus, and most of them are from poor countries. \textsuperscript{27}

The study included 150 samples from children less than 5 years which suffering from diarrhea, the results were 101(67.3%), 49(32.6%) Negative and positive result respectively, in the rapid test in the stool. The study samples- amounting (150) samples suffering from diarrhea-were collected in the laboratories of the Maternity and Children Hospital in the city of Ramadi, in Anbar governorate, for the period from 1- 9-2019 to 1-2-2020. Samples were rapid test & RT-PCR.

The present study aims to evaluate detection methods of rotavirus; to contribute as much as possible to the use of the fastest and most accurate method for early detection of the virus, and to provide the necessary treatment to save the lives of children in Iraq, specifically in Anbar Governorate.

**Rapid test Results:**

**Prevalence & Influence of Age:** The study showed that out of 150 fecal samples, 49 of them infected children (ROV+ positive) with ratio of 32.6% and the other 101 samples were healthy (ROV- negative) with a ratio of 67.3%. The table 1 also shows that there was no significant statistical difference when comparing the means of age between positive and negative sample
Table 1: The percentage of the number of children infected with rotavirus compared to the age Mean.

This result corresponds to a study conducted in 2018 Ramadi (32%) study in Baghdad showed that thirty-three per cent of all collected samples have positive Rotavirus, and prevalence of 32.2% in Kaduna State, Nigeria. with a median of 30% in Saudi Arabia. And 30.3% in Baghdad (2018). In Jordan, Rotavirus was detected in 35% of children hospitalized with acute gastroenteritis 39% in 2012 in Anbar. 33% in Baghdad(2016). But not corresponds to a study in Al-Diwaniyah, 2019 there results recorded the incidence of 40%.42 In the region of Mid Iraq.43 In Thi-Qar 2019 45%.44 In Babylon city is 48%.33 The reason for the presence of Rotavirus infection in Iraq and neighboring countries despite the use of the vaccine is the emergence of new genotypes and new strains not included in the vaccine, and this is due to the nature of the genome virus of re-assortment while in Ethiopia 20.4% for rotavirus infection RV-associated diarrhea of 25.6%, Brazil.41

**Influence of Age group:** Table 2 shows that the number of infected children within the age group 1-12 months is 35 children, at a rate of 71.4%; the table also shows 12 infected children in age group of 13-24 months by 24.4 % percent and 2 children at rate of 4 in the 25-60 months out of a total of 49 children. We were found that the stag less than a year was the highest average of infection.

*: Month

This results agreement with Another study, in Ramadi City, Iraq, Babylon City study and with the study. Group of 7-12 months. Others disagree with the study showed that half of the children were below 6 months of age, 37% in the age group of 7-12 months. Another study. The occurrence of rotavirus diarrhea in this age group is probably due to the absence of breastfeeding.

**RT-PCR results:** The limitation of antibody-based tests for the detection of enteric pathogens is the requirement of high concentration of free antigen to generate a positive reaction; the free antigen is decreased significantly during disease. Therefore, these tests have lower sensitivity and could miss positive samples collected late in the course of clinical disease, when compared to RT-PCR.

Thirty-eight (38) samples (21) serum samples & (17) blood samples were detection for RT-PCR after extraction their RNA in the Biotechnology and Environmental Centre University of Fallujah. Thirty-one (31) of (38) samples were positive for rotavirus & eight samples were no ct. As in Table 3

Table 3: The result of RT-PCR from serum & blood.

Our study showed that (81.57%) positive for RV which consistent with study showed that 80.6% among children < 5 years in Diyala province, and with (93.8%) of positive for RV antigen detected by conventional RT-PCR in Diyala, Iraq, with the study And with study which detects rotavirus from NSP3 gene.
In addition to positive control which it was reading (26.01) in the FAM filter & (24.9) in HEX (JOE) filter. The results of samples were reading in the same two filters (according to the protocol of manufactured company).

In the present study we counted on Ct value <40 according protocol of manufactured company of kit to detection positive results corresponding with 39.

In Figure 1: Carves of amplification were explaining the number of the cycle in (X-axes) vs. intensity in (Y-axes). Fluorescence data (FAM) collection during 60°C extension for rotavirus, their curves higher the threshold line were positive results and the negative result the curves under threshold line in RT-PCR for rotavirus detection 47.

**Sensitivity & Specificity:** Our study showed (Table 4) that from 14 stool samples, there were 12 true positive (TP) samples and 2 false negative (FN) samples as a result of rapid test while for same 14 samples, all their serum in the RT-PCR test were positive and there is no result of false positive (FP), nor a true negative (TN).

</table>

The sensitivity of PCR blood test = TP/TP+FN *100 → 15/17*100 =88.2%
Specificity of rapid test =TN/FP+TN *100 → 0/0*100 =0% no Specificity

Result of Chi-squared was (9.941) at DF (1) and there was Significant value (0.0016) between PCR blood test and Rapid test under p<0.05.

In our study showed that sensitivity and specificity of PCR serum samples were 85.7% and no specificity, respectively than Rapid test, sensitivity and specificity of PCR blood samples were 88.2% and no specificity, respectively than Rapid test, based on that RT-PCR was more sensitive & specific than rapid test.

RT-PCR has replaced the conventional methods since; they are rapid, accurate and also having good sensitivity and specificity 14.

Conclusion:

- Rotavirus continues to threaten the lives of nearly one third of children in Ramadi city.
- Children under one year of age are more likely to be infected with rotavirus, especially males.
- There was correlation between RT-PCR test and rapid test.
- RT-PCR more sensitive than Rapid test.

Conflict of Interests: The authors of this paper declare that he has no financial or personal relationships with individuals or organizations that would unacceptably bias the content of this paper and therefore declare that there is no conflict of interests.

The Psychological Health and Social Impacts of Constitutional Court’s Verdict No. 97/PUU-XIV/2016

Nanik Prasetyoningsih¹, Muchammad Ichsan¹

¹Lecturer, Faculty of Law, Universitas Muhammadiyah Yogyakarta

Abstract

After the Constitutional Court’s Verdict No. 97/PUU-XIV/2016, acolytes of beliefs have electronic identification cards and family cards which say, “Belief towards the Almighty God” in the “religion” column. In this case, the status of the acolyte of beliefs’ existence is more acknowledged administratively in Indonesia. The research method used in this study is the normative-empirical research method. The data is collected using the literature study and interview methods. The aim of this research is to know how the psychological and social impacts of the Constitutional Court’s verdict are. This research finds that the acknowledgement of this status gives psychological and social impacts towards the life of the acolytes. The psychological and social impacts of the Constitutional Court’s Verdict happened to the uncertainty and doubt of the acolytes. If they change their statuses, they will face many problems and they must leave the comfort zone they have stayed at for so long. This research has value as the “religion column” is sensitive and results to impacts in Indonesia.

Keywords: Constitutional court, acolyte of beliefs, juridical, social, impacts.

Introduction

The Constitutional Court’s Verdict No. 97/PUU-XIV/2016 regarding the examination of the Constitution No. 23 of 2006 regarding the Citizenship Administration, as what is changed with the Constitution No. 24 of 2013 regarding the change of the Constitution No. 23 of 2996 regarding the Citizenship Administration regarding the Republic of Indonesia’s 1945 Constitution states that the stipulations of Article 61 clause (1) and clause (2), also Article 64 clause (1) and clause (5) regarding the void of the “religion” column in Family Card and the electronic Identification Card which is against the constitution.(1)

The consequence of the Constitutional Court’s Verdict is that the acolytes of traditional beliefs can now publish their beliefs in the “religion” column both in the Family Card and the electronic Identification Card. The basis of the Constitutional Court’s Verdict is that the rights to become a follower of a religion or a belief towards the Almighty God is a constitutional right of the citizens. The basis of the state’s responsibility to protect all streams of beliefs in Indonesia is the stipulations of Article 28I clause (4) which states that, “The protection, development, enforcement, and fulfillment of the human rights is the responsibility of the state, especially the government.”(2)

With the understanding which is constructed using lexical interpretations, the Constitutional Court uses it as the initial basis in understanding the position and the relations between “religion” and “belief” as stated in Article 28E clause (1) and clause (2) and Article 29 of the Republic of Indonesia’s 1945 Constitution. Then, to affirm the interpretation above, the Constitutional Court reviewed those articles’ formulation history. The Constitutional Court then concludes that based on the formation process of Article 29, Article 28E clause (1) and clause (2) of the Republic of Indonesia’s 1945 Constitution, “religion” and “belief” are regarded as separate things, as the two are regulated in two different clauses. It’s just that, by regulating “religion” and “belief” in two different norms, it can be said that the
Republic of Indonesia’s 1945 Constitution basically regards “belief” as different from “religion”. Because of this, on one side, “religion” and “belief” are regarded as separate things, as they are regulated in Article 28E clause (1) and Article 28E clause (2). But, on the other side, “belief” is also understood as part of the religion as stated in Article 29 of the Republic of Indonesia’s 1945 Constitution. Further, the term “religion” in Article 61 clause (1) and Article 64 clause (1) should be defined as part of “belief” so that it is according to the norms in Article 1 clause (3) of the Republic of Indonesia’s 1945 Constitution. Legally, it is very reasonable, so that the two articles do not contradict one another with the principles of law certainty and non-discrimination (same treatment in the face of law) as guaranteed in Article 28D clause (1) in the Republic of Indonesia’s 1945 Constitution. It also violates the citizens’ guarantee of equality in the face of law as stipulated in Article 27 clause (1) of the Republic of Indonesia’s 1945 Constitution.

Method

The research method used in this study is the normative-empirical legal research method. The data is collected using the literature study and interview methods. This is a qualitative research. The analysis is carried out towards the data from the introductory study results or secondary data. The analysis of the qualitative data in the field was carried out using the Miles and Huberman analysis models(4), which include data reduction, data model, verification or conclusion. In this qualitative research, the data analysis was carried out simultaneously with the data collection process.

The data analysis used is the descriptive-qualitative and explanatory analyses. The research results are described in narratively, which explains and describes the objects analyzed.

Discussion

Psychological Impact: Interpretation of the streams of belief outside of the government-acknowledged official religions which are Hinduism, Buddhism, Islam, Christianity, Catholic, and Kong Hu Chu; or the formal legality of the various belief streams which exist in Indonesia, is an Indonesian cultural heritage which are spiritual and mystical(5). The law which regulates the survival rights of the belief streams are defined as the freedom which is still in the boundaries of tolerance. It is so that there is harmony in the life of people in practicing their religions and beliefs. Plus, in carrying out their activities, the followers must comply with the constitutional regulations which apply, so that there is no emergence of social and legal issues.

There is the impression of ambiguity and contradiction between the regulative conceptions regarding the protection, respect, and fulfillment of the rights of religious and belief freedom in Indonesia; remembering that on one side, the state formulates a regulation which gives an affirmation that the rights for the freedom of beliefs and religion are non-derogable rights which cannot be decreased in any condition. There must not be discrimination, and the state has the responsibility in respecting, fulfilling, and protecting it. But, on the other side, the state also stipulates regulations which limit, decrease, and revoke the rights for the freedom of religion and beliefs. The dimension of the human rights legal regulations is on one hand universal and non-discriminatory. But, on the other hand, the dimension of the human rights law conception is particular and discriminative.(6)

The existence of the stream of belief acolytes in Indonesia has been legally and formally regulated in some constitutional regulations. Some of these regulations actually indicate two things, which are: (1) the formal existence, as mentioned in Pancasila, the Republic of Indonesia’s 1945 Constitution Articles 28E, 29, and 32, the Constitution No. 23 of 2006 regarding Citizenship Administration, and the Governmental Decree No. 37 of 2007 regarding the Implementation of the Constitution No. 23 of 2006 regarding Administration, and (2) the existence of the belief acolytes, especially regarding the history and the individual awareness of each acolyte.

According to the Director of the Belief to the Almighty God and Tradition, General Director of Culture, the Ministry of Education and Culture, Sri Hartini, in Indonesia there are around 12 million acolytes and followers of beliefs which are spread in 26 provinces, with 187 central-level organizations and 1.034 branches. The coaching for the belief acolytes were carried out based on the Presidential Decree No. 27 of 1999. On the New Order Era, based on the Outline of the State’s Direction (GBHN), the beliefs of the local religions are categorized into the stream of beliefs. At that time, the coaching of the stream of beliefs were directed so that they come back to the origin of each religion. At the New Era governmental period, a policy was issued which directs the local religions to join in the religion in which its teachings are similar to the mothering
religion (the majority’s religion). Some local religions such as Kaharingan (Dayak tribe, Borneo) and Aluk To Dolo (Tana Toraja tribe, Sulawesi) were merged into Hinduism. The Kong Hu Chu religion was merged into Buddhism. With the repressive governmental policies at that time, thus, to save the followers of the local religions which were approved by the government thus the feels psychological oppressed.\(^7\)

The formal existence of the belief stream followers towards the Almighty God has been formulated in the 1945 Constitution and the 1998 Outline of the State’s Direction, even though there are still some fundamental deficiencies. The Constitution’s mandate, as stated in Articles 28E and 29 has affirmed that the legal basis and the survival rights of the streams of beliefs in Indonesia gives a social reality aside from the existing religious institutions. Thus, the streams of belief obtain the human rights protection with the freedom to embrace a belief which is according to their conscience. They also have the freedom to create organizations.\(^5\)

**Social Impacts:** Still questions whether or not the Belief towards the Almighty God is a religion. This doubt must be given clarity, so that there are no conflicts between the belief acolytes and other members of the society. According to Endang, a belief is a manner of believing in God. The belief acolytes are administratively acknowledged, as it is allowed for the acolytes to publish their beliefs in the “belief” column in the electronic Identification Card or Family Card.\(^8\) Yet, in its development, not all belief acolytes have changed the status in their electronic Identification Cards or Family Cards into the belief they have. This may be caused by the family, work, social environments, or others. There are some belief acolytes who are in a family environment which embraces a certain religion. Thus, to maintain the peace in the family, that acolyte have not proposed for the electronic Identification Card or Family Card status change. This is because from the start, that person had a religion.\(^9\)

There are also some people who are raised in a family which acknowledges and embraces both religion and belief. The parents and the children both have two beliefs, which are as embracers of a religion and as acolytes of a belief. Usually, those people have electronic identification cards which state one of the valid and acknowledged religions in Indonesia. Thus, this type of people doesn’t feel the need to propose to have their belief stated in the electronic Identification Card or Family Card as they are comfortable with the status quo. From the start, they already have both a belief and a religion.

The work environment factor may also become the obstacle of the belief acolytes to change their status, considering that the change of status may change the employment administration data. Usually, the acolytes who have the status as Civil State Employees have written one of the valid religions in the electronic Identification Card or Family Card.

In the case of citizenship administration, MLKI returns this to each individual. They may or may not change the status in the electronic Identification Card or Family Card.

According to Endang, even though the belief acolytes write one of the religions in the electronic Identification Card and Family Card, they are actually belief acolytes who are true followers. Usually, the faith of the belief acolytes is very strong. This means that the belief acolytes do not want to carry out the rituals or worshipping methods of other religions or beliefs. The case where an acolyte of an “A” belief converts to become the acolyte of a “B” belief very seldom happens. This is what actually makes the bond between the belief acolytes in a faith very strong. Thus, the belief acolytes are also reluctant to preach to acolytes of other beliefs to join their belief. The belief acolytes use the Javanese principle which is popular in Javanese language, which is, “timbo sing marani sumur duduk sumur marani timbo”. It means that the belief acolytes do not preach. They only give examples from their actions. They are welcome to those who believe or those who want to follow. But the belief acolytes do not carry out a particular missionary endeavor.\(^10\)

So, basically, the Belief towards the Almighty God is mostly as described. There is the principle that when someone is a follower of a particular belief, he/she should not show it nor should he/she act proud about it. But, if someone asks about it, they will answer the questions. In the Yogyakarta Special Province, there are Belief Associations which are open to public, such as SaptoDarmo.

Most beliefs in Indonesia do not have a Book of Teachings which are documented in the form of books, because there are some prohibitions from writing down or documenting the teachings. The teachings from the
ancestors may only be memorized. It is not allowed to be written down. The MLKI of Yogyakarta Special Province has suggested the Belief Associations to write down their teachings. But there are still associations which do not want to write them down, as they believe that the teachings cannot or may not be written down. This makes it difficult for the MLKI in the Yogyakarta Special Province to create the belief profiles.

Socially, the issuing of the electronic identification cards and family cards which include the belief has some advantages and disadvantages, according to Endang. The advantage is that the belief acolytes whose spirits are strongly attached to the belief will change their statuses. The minus is that there are those who doubt the need to. They worry that they may face problems if they change the status. This worry is usually caused by the social environment factor.

Actually, all governmental institutions are already very opened. They accept the participation of the belief acolytes in the government, and there are no more discriminations, so there’s nothing to worry about. The acolytes are also accepted as members of the People’s Representative Council of the Region, legislative candidates in the 2019 general election, and the Head of the Region candidate, like one of the Surabaya Mayor candidates who embraces SaptoDarmo. Thus, the General Election Commission has treated all candidates equally and without discrimination.

**Conclusion**

The Constitutional Court has pushed the government to issue some constitutional regulation instruments with the aim to give equal services and protection to the Belief Acolytes. The Belief Acolytes experience psychological and impacts in the aspects of citizenship, education, marriage, and institution of the Belief Acolytes. The inclusion of the belief in the electronic identification cards and family cards makes the Belief Acolytes more opened and accepted by the society. They admit their belief in the society. The society also starts to believe that the Belief towards the Almighty God is a belief which must be respected. The impact in the psychological of acolytes is excellent.

Psychological Obstacles of the PTUN Judges and Regulatory Reconstruction of the DKPP Verdict in Enforcing the General Election Organization Code of Ethics

Rudhi Achsoni¹, Istislam², Herman Suryokumoro², Aan Eko Widiarto²

¹Doctorate Student Universitas Brawijaya Malang, ²Associate Professor, Universitas Brawijaya Malang

Abstract

Verdict of the DKPP in Article 458 clause (13) in the Law No. 7 of 2017 on the General Election is final and binding. Yet, the implementation stage of the “final and binding” phrase causes multi-interpretation. Thus, there are some verdicts of the General Election Honorary Organizing Council (DKPP) which underwent legal efforts to the State Administration Court (PTUN). As a form of ius constituendum, the writer suggests that there should be a regulatory reconstruction on the verdicts of the DKPP in upholding the code of ethics in organizing the general election, by classifying that the verdicts of the DKPP is an ethical verdict; thus it is not proper to be corrected by the legal verdict in the PTUN. The room for correction will be opened by mandating it to the Court of Ethics. The ethical verdict corrected in the PTUN will risk the judges’ independence. It is highly possible that they will experience psychological pressure in making a verdict on the general election ethic violation in their capacity as Civil servant (PNS) who are institutionally under the Ministry of State Apparature Empowerment (Menpan), which specifically the minister is a political official which is chosen by the president.

Keywords: Reconstruction, DKPP Verdict, Code of Ethics in establishing the General Election, and Psychology of Judges.

Introduction

This research is entitled the regulatory reconstruction of the DKPP verdict in upholding the code of ethics in establishing the general election and also the psychological obstacles of the State Administration Court. The legal problem starts from the blanked norm in Article 458 clause (13) of the Law No. 7 on 2017 on the General Election. This article states that, “The verdict as aforementioned in clause (10) is final and binding.” In the explanation of that Article, it has been clearly stated that from the phrase “final and binding”, the DKPP verdict must be implemented by the president, the General Election Commission (KPU), the Provincial General Election Commission (KPUD), the External Monitoring Body (Bawaslu), and the Provincial External Monitoring Body (Bawaslu Provinsi).

Based on the writers’ observation, the parties which carry out legal efforts to the PTUN uses the basis of the Constitutional Court Decree No. 31/PUU-XI/2013¹. The Constitutional Court Decree basically explains that the DKPP verdict is binding to the president, the General Election Commission, KPUD, the City/Regency General Election Commission, and the External Monitoring Body, but not final to the justice-seekers².

On one side, in the perspective of the state administrative law, the Constitutional Court’s Decree may be understood. But, from the aspect of the State Administrative Law, the writer believes that it is improper to position the DKPP the same as other State Administration organs.³ and also the independence in ethical decisions. The DKPP verdict which cancels the general election organizer, from the KPU or Bawaslu due to the ethical codes, cannot directly be applied.

If the legal effort to the PTUN is deemed as correct, thus the PTUN Verdict will in the end be measured and evaluated based on the truth according to the legal perspective. It will be decided upon with the risk of the PTUN judges’ lack of independence as PNS who
are under the Menpan. There is a high chance for psychological pressure. Apart from that, this is because the DKPP ethical code assembly is psychologically more independent than the PTUN trial judges. This is because the former is not under the government, which is different from the latter, who has the capacity as PNS.

The problem which arises regarding the DKPP verdict is that if this is allowed, it will cause an uncertainty of law. The number of KPU which carry out legal efforts to the PTUN will also increase, as every DKPP verdict is issued with the order to lay off a general election organizer. Then, the laid off general election organizer will directly carry out legal efforts to the PTUN. This precedent becomes improper when the government (which is affiliated with the parties in power) have a great potential to pressure the PTUN judges who are PNS with the excuse of loyalty.

**Research Method**

This is a legal-normative research. The function of a legal research is to obtain coherent truth, which is seeking suitability between the analyzed object and the referral regulations and principles. The approaches used in this research are the statute approach, the case approach, the historical approach, and the conceptual approach.

**Discussion**

Due to the complexity of issues in organizing a general election, it is not enough to only depend on legal principles to achieve a good organization of the general election. Yet, it must be completed with ethical codes. This is necessary to create a demand to the public officials so as to have a high moral standard, so that they may maintain the trust of the people.

The main source of this conflict is the unclear regulations on the DKPP final verdict’s character in Article 458 clause (13) of the Constitution No. 7 of 2017. The phrase “final and binding” in the implementation stage has issues. Based on the results of the research, until February 2020, there are twenty-two cases of DKPP verdicts brought to the PTUN for legal efforts, as obtained from a personal communication with the Head of the Court Section, DKPP, Republic of Indonesia (February 2020).

In the processing stage in the PTUN, there were eighteen verdicts related to the DKPP verdicts. From that number, fourteen were granted, four were rejected. In the cassation stage in the Supreme Court, there were sixteen verdicts regarding the DKPP verdict execution. From that number there were ten KPU laid off by the DKPP who then won in the Supreme Court stage. Then, six cases were rejected.

The writer suggests that the DKPP existence with the final character of its ethical verdict is a form of innovation on some of the general election issue complexities. Meanwhile, regarding the perspective which positions the DKPP verdict correctable by the PTUN, it is sourced from the inextensive thought on the judicial power, where the judicial poers is only based on Article 24 clause (2) of the 1945 Constitution.

If it is only based on Article 24 clause (2) of the 1945 Constitution, thus there is a perspective that the DKPP only has a position as an organ of the State Administration. Thus, their products are included as part of the State Administration verdicts. Yet, it must be observed that in Article 24 clause (2) of the 1945 Constitution, it also states, “Other bodies whose function is related to the judicial power is regulated in the constitution.” The idea to give a room for the DKPP verdict correction to the Court of Ethics may be deemed as legally correct. This is because apart from the fact that the formation of the DKPP is strengthened by the Law No. 7 of 2017 on the General Election, according to the writer, this Council also has a constitutional basis, which is Article 24 clause (3) of the Constitution of 1945.

The DKPP verdicts on the general election ethical violation is related to the political interests of the general election participants. Meanwhile, the status of the DKPP assembly is not a governmental organ, thus it is psychologically possible to be independent. The contrary happens if the DKPP verdicts are then corrected by the PTUN judges who tend to have their position intervened as PNS. They are psychologically under the influence of the government in political issues by the parties in power of the affiliated power. Judges who are psychologically under pressure will not be able to decide clearly and objectively.

This is because a good verdict of the judges must contain three main considerations, which are the philosophical justice, the sociological justice, and the judicial justice, which cannot be obtained if the judge is psychologically pressured in their capacity as a PNS.

The improper DKPP verdicts are brought to the
PTUN for legal effort, as this Court is part or an organ of the government. Thus, hierarchically, the position of the PTUN judges is under the Menpan. Then, psychologically, the independence of this court’s judges will be disturbed in deciding upon the ethical issues in establishing the general election. There are some aspects which are currently related to the judicial position, such as the judge recruitment, financial rights, career path/stratification according to the rank, and facilities, which still follow the regulatory standard of civil servants (PNS), as state by Marzuki. Such position will psychologically cant maintain themselves from the intervention of authority. Giving a room to correct the DKPP verdict to the PTUN is the same as opening a room for intervention.

The writer suggests that the formation of the DKPP is part of a legal innovation on the general election. According to Oemar Seno Adji, “A court which is independent and uninfluenced are indispensable requirements for a state of law”. Independent means that there is no intervention from the executive and legislative powers in carrying out the judiciary functions. According to Bagir Manan, the judicial assembly which is deemed as unneutral or taking sides may be due to the influence of power, where the judicial assembly is psychologically powerless in facing the wills of those in higher power. The judges of the PTUN also face a psychological dilemma in facing the governmental influences when deciding upon the ethical code verdicts of the KPU in their status as PNS who are bound with their obligation to be loyal to the government (in this case the parties in power of the coalisions in the government).

Based on the description above, it can be concluded that justice will be better enforced if supported by a system of law and a system of ethics where both synergize to uphold justice. In the rule of law system exists the code of law, which is equipped with the court of law or a law-enforcing institution (the legal court). Also, in the rule of ethics, there is the code of ethics which surely needs the court of ethics, which is an institution which upholds the ethics.

Then, regarding the interpretation of the DKPP verdict which is final and binding in Article 458 clause (13) of the Law No. 7 of 2017 and also impact of the Constitutional Court decree No. 31/PUU-XI/2013 which has caused some problems, the general election legal frameworks should be formulated as comprehensively as possible, so as to avoid multi-interpretation. It is so that it may easily be understood. It must answer issues regarding the general election to create and to make sure that the general election runs democratically.

The writer suggests that the DKPP verdict has an important relation to the quality of the organization and the result of the general election. So, apart from the urgency of the regulation on the DKPP verdict’s final character, there should also be a room for appeal on this verdict. According to the writer, this thought is in line with the ratio decidendi or the legal consideration in the Constitutional Court Decree No. 31/PUU-XI/2013, because in this decree, the Constitutional Court principally states that the the DKPP verdict is binding to the president, the General Election Commission (KPU), KPUD, the City/Regency General Election Commission, and the External Monitoring Body.

Departing from the thoughts above, it should be noted that the room for appeal is not the room for legal appeal by the PTUN. But it is the ethical appeal room by the ethical court, which in this case is the Court of Ethics. The writer believes that the room for appeal or correction is important to be opened to make sure that the DKPP is more careful and accurate in issuing a product of verdict.

The influence of governmental power in the PTUN opens the chance for misuse of power by the government regarding the handling of the general election code of ethics violation for the sake of power. The PTUN judicial power is constitutionally predicted to not be able to give a verdict without psychological pressure, considering that their status as PNSs are subordinantes of the government. The judges’ status as the PNS makes it possible for intervention of the judicial freedom, because the structural psychological, corporal, and bureaucratic characteristics bring or demand certain bindings.

In the context of the DKPP verdict regulations, the writer agrees that appeal may only be carried out on one stage, and it must be carried out by the ethical institutions instead of the legal ones. Based on that, the DKPP verdict regulatory reconstruction in upholding the ethical codes of the general election organization becomes urgent.

1. **Reconstruction of the Law No. 7 of 2017 on the General Election:** There should be a revision on Article 458 clause (13) on the Constitution No. 7 of 2017, which states that the DKPP verdicts are final
and binding. The writer suggests that the “final and binding” phrase should be changed into, “The DKPP verdict must be implemented by the president, the General Election Commission, KPUD, Bawaslu and the Provincial External Monitoring Body.”

After there is an addition to that article, there should be two new clauses, which are clause (14) and clause (15). On clause (14) it should state that if there are parties who object the verdict as aforementioned in clause (10), an effort of ethics may be brought to the Court of Ethics. Then, on clause (15), it should state that the Court of Ethics’s verdict on the code of ethic alleged violation as meant in clause (11) is final and binding, and cannot be a case object in the courtly environment of the Supreme Court.

2. Reconstruction of the Law No. 9 of 2004 on the Change of the Law No. 5 on 1986 on the DKPP:
The writer suggests that in the reconstruction, there is an additional criterion that the verdict regarding the DKPP verdict is not included as an object which may be proposed to the PTUN. The regulation regarding the object which cannot be proposed to the PTUN is written in Article 2 of the Law No. 9 of 2004 regarding the change of the Law No. 5 of 1986 regarding the PTUN, which states that, “Those not included in the definition of the PTUN verdict according to this Constitution are as follows:”

First is the PTUN verdict which is an action of the civil code. Second is the PTUN verdict which is a common regulation. Third is the PTUN verdict which is a final regulation. Fourth is the PTUN verdict which still needs approval. Fifth is the PTUN verdict which is issued based on the stipulations of the criminal code and the code of criminal law procedure or other laws which have the character as criminal codes. Sixth is the PTUN verdict regarding the administration of the Indonesian National Army. Seventh is the verdict of the General Election Commission. Based on the seven exceptional verdicts above, the writer suggests that an additional criterion is added, where that criterion should be placed in Article 2 letter h number eight.

**Conclusion**

An ethical verdict is different from a legal one. This is because the institutions which issue them and the references which become their bases are also different. Thus, it is not proper to investigate the validity of an ethical verdict – which is sourced from ethical principles – at the PTUN, in which the basis is the legal principles.

The revision of the General Election law is necessary to state that the DKPP verdict must be implemented by the President, the General Election Commission, KPUD, the External Monitoring Body, and the Provincial External Monitoring Body. The room for correction or the cassation of the DKPP verdict will be carried out by the Court of Ethics instead of the PTUN, as the latter has a psychological obstacle in handling the cases on the general election code of ethics violation as a PNS. These judges will psychologically have trouble if the government then intervenes or pressures them to make decisions regarding the general election code of ethics violation which menguntungkan the parties in power or the coalitions in the government.

The Eradication of Women and Children Trafficking in Jember Regency in Relations to the Legal Protection for Victims in the Health Perspective

Yanny Tuharyati1, Muhammad Rusydianta2, Muhammad Rizal3, Tri Siswanto4, Achmad Muchsin5, Zainur Wula6

Abstract

The development of human trafficking has changed to happen to the kinds of people who are disadvantaged, such as woman and children. The trafficking of woman and children is one of the bad forms treatment from the exploitation activity which is faced by woman and children. Trafficking is included as a crime and a human rights violation. Indonesia itself is a region where woman and children trafficking happens, either as country of the victims’ origin or as a transit country. Some regions in Indonesia are estimated as targets of border countries’ crime syndicate activities which organize woman and children trafficking. This research analyzes the women and children trafficking in Jember Regency in the perspectives of law and health.

Introduction

There is an interesting data which is released by the Center for Protection of Women and Children (Pusat Perlindungan Perempuan dan Anak/P3A) Jember. From a quick study conducted by ILO/IPEC on 2003 in East Java, it is shown that 4.081 people under 18 years old are estimated to become victims of children and woman trafficking. This study also stated Jember and eight other areas as places which are signaled to become the original areas of women and children trafficking victims who were to be sold for sex. The eight areas are Banyuwangi, Sampang, Malang, Blitar, Ponorogo, Pacitan, Gresik, and Nganjuk Regencies. Meanwhile, the areas in Jember Regency which are signaled to be the original areas of where the trafficking victims are sent from are Ambulu, Tempurejo, Puger, Arjasa, Patrang and Sumberbaru1.

These days, there are more and more news on human trafficking in Indonesia, both in the domestic and transnational scales. There is only recent attention from the society through the mass media these last years towards the human trafficking of women and children in the sexual industry activity. Surely, it cannot be concluded that before this, the phenomenon did not happen. There is a chance of it happening in a small scale or in a well-organized trafficking activity. This is part of the reason of why the trafficking news did not attract the attention of the mass media in the past2.

Indonesia becomes the state of origin, transit, and destination of human trafficking especially woman and children who are forced to become sexual workers or forced workers. The victims from Indonesia are brought to Malaysia, Singapore, Taiwan, Hongkong, Brunei, countries of the Persian Gulf, and Australia. The trafficking has also happened extensively in the Indonesian territory for sex and labor exploitation. Indonesia becomes one of the destination countries for the trafficking victims who are sold to be sexually exploited3.
Based on the background above, it can be formulated that the research problem is: How is the eradication of the women and children trafficking in relations to the legal protection for the victims?

Result and Discussion

1. The Definition of Women and Children Protection:

   Based on the Constitution No. 21 of 2007 regarding the eradication of Human Trafficking, trafficking is the action of recruiting, transporting, sheltering, sending, moving, or bringing in someone with the threat of violence, the use of violence, kidnapping, captivating, fraud, deception, misuse of power to someone in a disadvantaged position, debt bondage, or giving payment or benefits so that there is the agreement from the person who has power over the stated person, both carried out within the country or between countries, with the aim of exploitation or to make someone become exploited.

   The rampant case of human trafficking in Indonesia causes concerns to its people. There are various cases of human trafficking which happen nowadays based on the news of electronic or non-electronic media. Some of the research results which had been carried out show that the cases of human trafficking, especially those which happen to women and children, require serious attention.

   The women and children trafficking which happen in Indonesia is usually with the aim of bringing them into prostitution. It also regards pornography, begging, or labor as household assistants. The women and children trafficking is a real violation of the basic human rights. It is complex as well as multidimensional and is carried out both blatantly and implicitly. These informations are obtained from the results of reports and data displays from various sources. As stated by Sumaryoto as the Minister of Women Empowerment⁴, to prevent the problem of women and children trafficking, the Indonesian government has carried out some efforts both which are practical and strategic.

2. The Forms of Women and Children Trafficking:

   There are various forms of women and children trafficking. In reality, it is the same as the women and children trafficking which happen in European countries. Yet, to ease the identification, there are some forms or actions which may be categorized as the forms of women and children trafficking based on the research carried out by Syafaat. According to him, the forms of women and children trafficking which happen in Indonesia are as follows:

   1. The adoption of children with the procedures or which are sold to citizens of Indonesia or to foreign citizens.
   2. Involving children in the sales of drugs.
   3. Pornography of women and children.
   4. The trafficking of women and children to work by force.
   5. Forcing women and children to work as beggars or to scrounge in the streets.
   6. Forcing women and children to carry out sexual work or to become prostitutes⁵.

   Then, according to a research carried out by Solidaritas Perempuan (The Solidarity of Women), the forms of women and children trafficking based on the cases found are not limited to forced prostitution or sex trade. Yet, they also include the forms stated by Syafaat.

3. The Factors which Cause Women and Children Trafficking to Happen in Jember:

   The main cause of the rampant trafficking cases towards the women and children in Jember Regency is poverty. People try to fix or to improve their economic condition by looking for work. But, obtaining work is not as easy as what they imagined. Some had to suffer in the process. As stated in the research carried out by Syafaat in East Java, the factors which cause women and children trafficking are as follows:

   1. Difficult economic condition.
   2. Disharmonious family.
   3. Early-age marriage and divorce.
   4. Early-age victim of sexual harassment.
   5. Victim of rape.
   6. Limited work opportunities.
   7. Influence from other people who have successfully worked in various filed. This happens as follows:

   The victims of women and children trafficking are victims who experienced physical and psychological suffering. After the crime is over, they will still experience trauma and long suffering. From the cases of women and children trafficking found, most regard forced prostitution or sex trade. Apart from that, they also regard forms of work prostitution and practices like slavery in some areas in informal sectors including
domestic work and wife-by-order. The victims stated that before they are trafficked, they have already experienced terrible conditions in the shelters. In those places, they are not equipped with skills. Instead, some have already been exploited to work without wage in living conditions which are not feasible, as stated by Fida, a companion of women and children trafficking victims in Jember Regency (personal communication, March 12, 2020).

Jember is divided into 28 districts. They holistically have a great potential for women and children trafficking, through the mediation of agents which come to villages. Usually, the agents as the recruiters directly enter the villages to find and to take women and children to be distributed to other agents as receptors. The victims will then become prostitutes. They may be trafficked to other areas or to other countries.

The modus operandi or the method of running the crime of women and children trafficking is usually through deception. This happens when the victims are influenced by the agents. They want to obtain a high wage, but then they are forced to become prostitutes. Most of the cases which happen in Jember Regency is prostitution.

From the cases of women and children trafficking which happen in Jember regency, the rights obtained by the victims are quite maximum. The victims are brought home if the case is uncovered. Also, if the victims ask for further investigation, this case may be filed to court. Yet, most victims do not want the case to be known extensively by the society as they regard the case as a disgrace. But, the gateway for the entrance of the criminal court process is the involvement of the victims in the criminal court, which is through reports and complaints.

Considering the complexity and the difficulty to detect the criminal act of human trafficking, thus there needs to be a regulation which is more suitable to the current condition. The regulations on human trafficking in the Indonesian constitution, as explained in the background, are not non-existant. Yet, they are deemed as inadequate.

Seeing the extensive definitions of human trafficking, there are no legal articles which can be used to cover all actions which are categorized as human trafficking in the limitations which currently apply according to the international society. If seen from the cases of women and children trafficking which happen in Jember Regency, there are some obstacles related to the legal protection for the victims, which are:

a. The Law or the Regulations: There are some articles which are specifically used to bind the perpetrators of women and children, which are Article 297 of the Criminal Code, Article 324 of the Criminal Code, and Article 329 of the Criminal Code. As explained in the previous part, there are some weaknesses of these articles. Then, the women and children trafficking are more specifically regulated in the Constitution No. 21 of 2007 regarding the Eradication of the Crime of Human Trafficking. With the Constitution No. 21 of 2007, the two articles in the Criminal Code which regulate the trafficking of women and children do not apply anymore. Yet, the existence of these regulations causes new problems for the law-enforcing apparatus, especially in the application of the articles.

The problem which may arise with the application of the new article in the constitution lies in the unclear words used in the formulation of some articles. As stated by Soekanto, this is because the definition of the words used may be interpreted extensively, or because the words used are translated from foreign languages. Thus, one of the obstacles in the law enforcement which comes from the regulations is the unclear words used in the regulations which cause uncertainty in the interpretation and in the application.

b. The Law-Enforcing Apparatus: The law-enforcing apparatus highly require help from many parties, such as reports from the society as an information to uncover a case. Because of that, there are some factors which influence the uncovering of the trafficking case. The lack of the number of personnel, the lack of facilities and infrastructure, and the lack of funds become the police force’s classical excuses in uncovering the cases of trafficking. These limitations are further added with the lack of the investigating personnel’s abilities in uncovering the cases filed by the society. In the investigation process, the police force must have special abilities in handling the trafficking cases.

Based on the results of a questionnaire given by the researcher to 50 police force personnel in the investigation and in the inquiry sections, 11 public prosecutors, 24 technical administrators in the Jember District Court which consists of the judges and the
clerks, it can be concluded that the law-enforcing apparatus generally know about the existence of the women and children trafficking as they have not yet reached an understanding. This is proven by the results of the questionnaires given, considering that there must be special skills in handling the cases of trafficking.

c. The Trafficker: As mentioned before, the traffickers have an extensive network in this crime. Even though accurate evidences had not been found, yet it may be estimated that the perpetrator is a group of people within a certain organization, thus often called an organized crime. Such crimes involve many people and they have a rather extensive network. Thus, it is not impossible that the perpetrators of this crime are very difficult to be caught, even more so to bring them to the legal process.

Usually, their activities are difficult to be mapped out. It is also difficult to find who the real perpetrators are. Even, it is not impossible that they have known the police force’s efforts in catching them. This results to them taking preventive actions, thus they may get away safely. The apparatus must be aware that the perpetrators who are caught are usually small-scale perpetrators or powerless “messengers”. Meanwhile, the intellectual actors in the organized crime will never be caught. And there is an even less chance for them to be processed by the law.

d. The People’s Perception on Human Trafficking:
The problem of human trafficking, especially that which happens to women and children is an example of the women’s disadvantaged condition towards the sexual interests of men. The women’s sexual image which places women as men’s sexual object actually has a high impact towards women’s lives. Thus, they must always face physical and mental violence, coercion, and torture. Because of that, the women and children trafficking is not only a reflection of the women’s image as a sexual object, but it also reflects women as men’s object of power. The weak position of women and children is actually a consequence of human’s sexual differences. It is widely known that Indonesians are a patriarchal society which as a structure which derogates women. This happens both from the governmental policies and in the people’s behavior.

4. The Protection for Women and Children Trafficking Victims from the Health Perspective:
The trafficking victims generally face both physical and mental torture. Thus, they need special treatment. To achieve this, there needs to be a cooperation between the legal, psychological, and medical fields. This is so, because the victims experience torture in the shelters, which will influence their mental and physical health condition. The rights which must be obtained by the victims regarding the compensation for the loss they suffered are as follows:

1. Freedom from torture or harassment from the parties in control.
2. Adequate physical and psychological health services, which are confidential and affordable, which are provided by the state or private sectors which are funded by the government.
3. The protection of the victims’ personal identities and information. Their names, addresses, and photos are prohibited from being published to the general public.
4. The victims have the right to obtain information regarding the results of the investigation. The victims and the families have the right to know if the traffickers are freed.
5. The victims have the right to be helped and to be assisted in the whole legal process.

All of these rights must be upheld for the enforcement of justice and welfare for the people. The rights obtained by the victims must also specially be handled by institutions which treat victims of women and children trafficking. As commonly known, the rights of the victims of these cases have not yet been maximally obtained by the victims. Most victims are only brought home. Worse, even if the case is handled by the law-enforcing apparatus, it is not completely uncovered.

Conclusion

Based on the explanation above, it can be concluded that the form of women and children trafficking which happen in Jember Regency is prostitution. The eradication of the women and children trafficking regards the protection towards the trafficking victims who experience both physical and mental sufferings. There needs to be a special treatment for the victims, thus, there needs to be a cooperation between the aspects of law, especially the three things which regard the law enforcement, like the constitution, the law-enforcing apparatus, and the society (culture). There also needs to be a cooperation with the fields of psychology and medicine.

Determinant Factors of Interprofessional Collaboration in Labuang Baji General Hospital

Patima Patima¹, Ridwan Amiruddin R.², Syahrir A. Pasinring², A. Ummu Salmah², Ariyanti Saleh², Fridawaty Rivai², Anwar Mallongi²

¹Doctoral Program Science of Public Health, Universitas Hasanuddin, Indonesia, ¹Faculty of Nursing, UIN Alauddin Makassar, Indonesia, ²Faculty of Public Health, Universitas Hasanuddin, Indonesia

Abstract

Background: Health services provided to the community were often overlapped among health care professionals. Poor communication may affect the quality of patient care and potentially increase the number of medical errors.

Objective: The study aims to analyze the most determinant factors associated with the implementation of Interprofessional Collaboration (IPC) at Labuang Baji General Hospital.

Method: The study used a cross-sectional design for data collection method. A questionnaire was administered to 291 respondents. The data analysis was performed using a computer program and statistical analysis, namely Univariate analysis distribution (of frequency) and logistic regression.

Results: The results reveal that the determinant factors affecting the implementation of IPC are Communication (P = 0.000), Trust and Respect (P = 0.017), Administrative Support (P = 0.000), Culture (P = 0.000), Law and Regulations (P = 0.001), and Finance (P = 0.000).

Conclusion: An effective communication with other healthcare teams in the implementation of IPC leads to effective and safe healthcare services at Labuang Baji General Hospital, Makassar. Based on this reason, a policy is needed to improve the implementation of IPC in Labuang Baji General Hospital.

Keywords: health care services, Interpersonal Collaboration, individual competence.

Introduction

An efficient Interprofessional Collaboration (IPC) provides holistic services to patients in increasing the quality of healthcare and patient satisfaction as well as cost-efficient healthcare. Morley and Cashell¹ state that nurses-physician relationships improve patient care quality. WHO² and Schadewaldt et al. argue that IPC improves the quality of patient care, shortens hospital stays, reduces healthcare costs, and reduces health worker’s workloads and stress²-³. Besides, a study conducted by Hughes and Fitzpatrick and Gausvik et al demonstrates that IPC leads to a reduction of mortality, increased job satisfaction, and a reduction of healthcare costs 4, 5.

WHO describes the importance of IPC in decreasing total patient complications, length of hospital stay, tension and conflict among caregivers, mortality rates, cost of care, duration of treatment, and increasing patient and career satisfaction². Meanwhile, communication is an essential thing in implementing IPC to provide health services to patients and the community. Caring without effective communication leads to guesswork and is based on stereotypes⁶. Communication in IPC is also a substantial effort to improve the quality of caring and patient safety⁷,⁸.
Materials and Method

Location and Design: The researcher conducted this study at Labuang Baji General Hospital, Makassar. This study was non-experimental research with quantitative approaches, descriptive statistics and correlation, and cross-sectional study design. Population and Sample: The population in this study were all healthcare providers who provide health services to patients in the Labuang Baji Hospital treatment rooms, Makassar. The sample was 291 health workers consisting of doctors, nurses, pharmacies, and nutritionists. The sampling was performed employing proportional stratified random sampling.

Data Collection: The primary data were sparse through questionnaires and observations. The secondary data was obtained from relevant parties such as Labuang Baji General Hospital, Makassar. Data Analysis and Presentation: Data were analyzed by using computer programs and statistical tests of Univariate analysis distribution (of frequency) and logistic regression

Table 2 describes that the determinants factors associated with the implementation of IPC are Competencies with P-value 0.000, Trust and Respect with P-value 0.017, Administrative Support with P-value 0.000, Culture with P-value 0.000, Law and Regulations with P-value of 0.001, and Finance with P-value 0.000.

Discussion

Interprofessional collaboration is when health professionals from various professions work together to provide patient-centered care. Poor communication can be the main root cause of service errors in patients. In order for collaboration between professionals to be carried out all health professionals need to know the contribution made by each profession; maintain mutual respect for each other’s expertise; communicate effectively and look for continuing education training opportunities to enhance collaboration between professionals.

The effective communication relationships for interprofessional teamwork results in positive outcomes for effective and safe healthcare services. This is consistent with the theory that communication supports high-quality, safe, effective and efficient interprofessional care in a complex health care system. Various attempts were made as an effort to improve IPC, among other things, by implementing an integrated patient record system. IPC can optimize patient safety.
Likewise, the efforts made by Labuang Baji General Hospital, among others, by initiating training for health workers for IPC.

Nurses and other healthcare teams are required to build an effective communication and leadership skills to work productively within interprofessional teams, establish open communication, use mutually respectful communication, and assist in decision making to promote quality patient care. One of the core competencies for interprofessional collaborative practice is effective communication. All health workers must be able to communicate effectively with other healthcare teams to integrate safe and effective care for patients and other health workers.

IPC within professional work environments has been recognized by nursing staff, other healthcare teams and health care professional associations as an essential determinant in improving patient safety with high quality and providing patient-centered care. In its implementation there will be a general challenge that can be found, namely the cultural complexity of the arrangements which are socio-cultural aspects of each health profession.

Collaboration among health professionals and effective interprofessional collaborative practices are the theme developed in hospitals for healthcare settings. Collaboration between healthcare professionals providing services to patients is an effective way to stabilize care, reduce the excessive use of the health care system, increase the delivery of health services, and reduce the cost of care. Interprofessional teamwork is a very effective factor that can contribute to positive interprofessional collaboration practices.

Conclusion

Based on the findings, determinant factors of the implementation of IPC are Communication (P= 0.000), Trust and Respect (P= 0.017), Administrative Support (P= 0.000), Culture (P= 0.000), Law and Regulations (P= 0.001), and Finance (P= 0.000).

Implication: IPC is an effective and efficient strategy to improve healthcare quality and patient health outcomes at Labuang Baji General Hospital, Makassar. IPC should, therefore, be continuously improved and developed. Further studies exploring challenges that become obstacles of physicians-nurses IPC with more accurate research instruments are needed.

Abstract

Female adolescents who have experienced menstruation are at high risk of anemia, especially iron nutritional anemia. Efforts made by the Government in overcoming anemia in adolescent girls are by providing Blood Plus Tablets, but based on data from the Ministry of Health in 2017, the percentage of Fe (iron) tablets obtained by adolescent girls is still very low, namely 13.8%, so it is not yet fulfilling. the national target is 30%, so there needs to be another strategy to overcome anemia in adolescent girls. Reproductive health exercise is one of the physical activities that can be an alternative for adolescent girls who experience anemia because it can increase hemoglobin production. This study analyzed the hemoglobin levels of adolescent girls after being given reproductive health exercises. The results showed that Kespro exercise had an effect on hemoglobin levels in adolescent girls with a p value <α (0.05) where the hemoglobin level before being given treatment in the intervention group was the average hemoglobin level of 10.1 gr/dL and the hemoglobin level after treatment. That is, the average hemoglobin level is 13 gr/dL. The hemoglobin level before being given the treatment in the control group was an average hemoglobin level of 9.8 gr/dL and the hemoglobin level after being given the treatment was an average hemoglobin level of 12.2 g/dL.

Keywords: Female Adolescents, Hemoglobin Levels, Anemia, Reproductive Health Gymnastics.

Introduction

Adolescence is a period of change that occurs during childhood into adulthood which is marked by changes in growth and development. One of the developments that occur during adolescence is that it begins with the maturation of reproductive organs such as menstruation in young women. Menstruation or menstruation is periodic bleeding through the vagina with endometrial discharge that occurs for 3-7 days with blood output of about 50-150 milliliters1.

Physiologically, girls who experience menstruation will bleed every month. Excessive bleeding and irregular menstrual cycles can affect the condition of young women2. Teenage girls who have experienced menstruation are at high risk of anemia, especially iron nutritional anemia.

Anemia is a hemoglobin (Hb) level or the number of red blood cells that is less than normal (12.0 gram/100ml). Signs and symptoms of adolescents who have anemia such as pale, weak, tired, dizzy, which causes the ability to concentrate on learning to decline, inhibits physical growth and development of brain intelligence, and decreases in immune system due to increased infectious diseases3-8.

Based on data from the WHO (World Health Organization) in the SEARO (South East Asian Region Office) in 20149, young women suffering from mild to severe anemia in Southeast Asia range from 25-40%, while in developing countries women suffer from substance deficiency anemia as much as 370 million with 41% of non-pregnant women and girls in India the prevalence of anemia reaches 45%. In addition, the prevalence of anemia in Indonesia is still quite high. Based on the results of the 2018 Riskesdas data, the...
prevalence of anemia that occurs in women is 27.2% with the proportion aged 15-24 years of 32%^10.

Efforts made by the government in overcoming anemia in adolescent girls are by providing Blood Plus Tablets in schools such as Junior High Schools (SMP) and Senior High Schools (SMA) or the equivalent given the dosage of 1 tablet/week and 1 tablet/day during menstruation^11. Based on data from the Ministry of Health in 2017, the percentage of Fe (iron) tablets obtained by adolescent girls is still very low, namely 13.8%, so that it has not met the national target of 30%, for this we need another strategy to overcome anemia in adolescents.11-14

One of the strategies that can be done to overcome the problem of anemia is by providing therapy in the form of physical activity. Doing physical activity can increase blood volume caused by cardiovascular changes (Nurafandi, 2017). Individuals who exercise regularly will experience a slight increase in hemoglobin, this is because cells or tissues need more O2 (oxygen) when doing activities 15-17.

Increased oxygen consumption during physical activity allows hemoglobin which carries protein in erythrocytes to reach cells. An important function of hemoglobin is as a medium for transporting oxygen from the lungs (respiratory organs) throughout the body. Physical activity is an activity that can improve health status if it is done regularly, routinely and repeatedly. Physical activity that is in great demand by young women is gymnastics18,19. One of the exercises that teenagers can do to increase their hb level is by doing reproductive health exercises. Reproductive health exercise is a physical exercise adopted from aerobics and SKJ (Physical Fitness Exercises) in 2012 which requires sufficient oxygen to get a source of energy (Sarah et al., 2019). Based on research conducted by Sarah in the intervention group which was carried out for 4 weeks by being given Fe tablets and reproductive health exercises with a duration of 15-20 minutes 3 times a week. There was an increase in hemoglobin levels from an average of 10.43 gr/dL to 13.98 gr/dL, thus the effect of reproductive health exercise on adolescent hemoglobin levels at SMP 26 Semarang in 2019

Materials and Method

This research is a type of experimental Quasy research with a pre-post test control group design. This research was conducted in the Work Area of the Sowi Manokwari Health Center, Indonesia. This study used 2 groups where the control group was given reproductive health exercise without intervention and the intervention group was given reproductive health exercise.

The population in this study were girls aged 13-15 years in the work area of the Sowi Manokwari Health Center in 2020. The sample of this study was anemic girls aged 13-15 years who met the inclusion criteria. The sampling method in this study is nonprobability sampling with purposive sampling technique, namely sampling with the determination of researchers based on inclusion criteria. The number of samples in this study were 20 people.

Reproductive health exercise that is implemented is a development of reproductive health exercise products that have been validated by experts through small-scale validity and reliability tests, product testing and product revisions after small-scale trials to produce products. The product for the development of reproductive health exercise was carried out by Sarah in 2019. The reproductive health exercise movement will be observed using a reproductive health exercise guide.

In this study, data sources were obtained from secondary and primary data. Secondary data were used for a preliminary study to determine the prevalence of anemia in junior high schools in Manokwari Regency. Primary data is by collecting data directly to respondents. The research flow, namely: carrying out the research permit procedure, the research will be assisted by the enumerator, namely by selecting the enumerator. Prepare research instruments and equipment needs for research.

Young women who have agreed to be sampled need to fill out an informed consent form. In examining hemoglobin levels with the cyanmethemoglobin method by taking 20 ul capillary blood to find anemic adolescent girls who meet the inclusion and exclusion criteria that have been determined previously. After finding the young women who had mild dysmenorrhea and anemia who met the criteria to be sampled. Provide an explanation of the objectives, benefits, risks and research procedures to anemic adolescent girls.

Researchers provide education about anemia in young women and alternative treatments by doing reproductive health exercises. Hemoglobin levels were checked before intervention, during menstruation and after intervention with the cyanmethemoglobin method.
The intervention group was female adolescents with anemia aged 13-15 who received reproductive health exercises, where the first week of menstruation was carried out 5 times a week and in the following week after menstruation was carried out 3 times a week with a duration of 15-20 minutes and administration of Fe 60 tablets mg as much as 30 tablets.

The control group was anemic adolescent girls aged 13-15 years who only received 30 tablets of Fe 60 mg for 4 weeks. After being given the intervention for 4 weeks, a re-assessment will be carried out by taking 20 ul of blood for the hemoglobin level which will be checked by the cyanmethemoglobin method using a photometer. Assessment of planned hemoglobin levels will be carried out by the researcher himself and assisted by the enumerator. After each treatment got the final result of the measurement, the researchers made a comparison, namely which intervention group experienced changes in hemoglobin levels. Furthermore, data processing and analysis are carried out.

### Results and Analysis

The results of the univariate data analysis illustrate the mean and standard deviation of the research variables, while the bivariate test analysis was carried out to analyze the effect of reproductive health exercise on hemoglobin levels using a parametric test. Bivariate and correlation tests were carried out if the data were normally distributed and homogeneous with values (p value> 0.05).

**a. Univariate Analysis:** The data normality test used the Shapiro Wilk method because the sample size was less than 50 respondents, in this study the number of respondents was 20 people or 10 people in each group. The data is said to be normally distributed if the p-value is> 0.05.

1. **Test for normality of hemoglobin levels:** The results of the normality test of hemoglobin levels before the intervention, during menstruation and after the intervention were given reproductive health exercise and Fe tablets in the intervention and control groups can be shown in Table 1.

Shapiro Wilk: Significant > 0.05

Table 1 shows that all significant values are> 0.05, which means that the data of hemoglobin levels before and after treatment and hemoglobin levels before and after menstruation in the intervention and control groups were normally distributed.

2. **Homogeneity test:** The results of the homogeneity test of hemoglobin levels before the intervention, during menstruation and after the intervention were given reproductive health exercise and Fe tablets in the intervention group can be shown in Table 2.

Test Homogeneity of Variances : significant>0.05

Table 2 shows that the significant value of hemoglobin levels in the intervention group before treatment is 0.05 and when menstruation is 0.73, which
means that the data is homogeneous, while the significant value after treatment is 0.014 which means that it is not homogeneous because it is smaller than the value 0.05.

b. Bivariate Analysis:

1. Differences in hemoglobin levels before and during menstruation in the intervention group and the control group: The difference in hemoglobin levels before and during menstruation in the intervention group (giving reproductive health exercises and Fe tablets) and the control group (giving Fe tablets) can be shown in table 3.

*P value: significant<0.05

Table 4 shows the results that in the intervention group the hemoglobin level before treatment was 10.1 gr/dL and after treatment 13 g/dL there was an increase of 2.9 g/dL, while in the control group the average before treatment was 9.8 gr/dL and after treatment 12.2 g/dL and an increase of 2.4 g/dL with a p-value of 0.000, which means that there were differences in hemoglobin levels in the intervention and control groups before and after treatment.

3. Differences in hemoglobin levels before treatment between the intervention and control groups: The difference in hemoglobin levels before treatment in the intervention group (giving reproductive health exercise and Fe tablets) and the control group (giving Fe tablets) can be shown in table 5.
Table 5 Differences in pre-treatment hemoglobin levels between the intervention and control groups.

Table 7 shows the results that the average hemoglobin level after being given treatment in the intervention group was 13 g/dL and in the control group an average of 12.2 g/dL with an average difference of 0.8 gr/dL and a p-value of 0.014., meaning that there is a difference in mean hemoglobin levels between the intervention and control groups.

Discussion

This study was conducted on 20 anemia adolescents who were divided into 2 groups, 10 anemia adolescents in the intervention group who were given reproductive health exercise with Fe tablets and 10 anemia adolescents in the control group who were given Fe tablets alone for 4 weeks to see their hemoglobin levels. In the intervention
and control groups, hemoglobin levels were checked before being given reproductive health exercise and Fe tablets for the intervention group and Fe tablets for the control group for 4 weeks. After 4 weeks of treatment, re-examination was carried out in the intervention and control groups.

Based on the results of the t-test dependent statistical test, it shows that there is a difference between the hemoglobin levels before and after treatment in the intervention and control groups. After being given treatment to the intervention group (giving reproductive health exercises and Fe tablets), the respondents experienced an average increase in hemoglobin levels by 2.9 g/dL and the control group (giving Fe tablets) the respondents experienced an average increase in hemoglobin levels by 2.4 g/dL. The difference in the change in the mean difference in hemoglobin levels between the intervention and control groups which has a p-value of 0.000 means that there are differences in the mean difference in hemoglobin levels in the intervention group and the control group.

This research is in line with the results of research conducted by Sarah et al., (2019) concerning the effect of reproductive health exercise on adolescent hemoglobin levels at SMP 26 Semarang in 2019 which were divided into 2 groups, namely the intervention group and the control group. Results in the intervention group that was carried out for 4 weeks with iron tablets and reproductive health exercises with a duration of 15-20 minutes for 3 times a week. There was an increase in hemoglobin levels from an average of 10.43 gr/dL to 13.98 gr/dL, thus the effect of reproductive health exercise on adolescent hemoglobin levels at SMP 26 Semarang in 2019.

In addition to reproductive health training, this is in line with research conducted by Setyaningrum et al., namely aerobic exercise in the morning and evening to increase blood hemoglobin levels at SMK Muhammadiyah and SMP Kradenan Blora. Based on the results of research that did aerobic exercise in the morning before being given treatment, the hemoglobin level was 11.90 gr% (early adolescents) then increased to 13.2 gr% and 12.20 gr% (late adolescents) increased to 12.70 gr%. Exercises carried out at night before being given treatment had a hemoglobin level of 12.20 gr% (early adolescents) increased to 13.60 gr% and 12.30 gr% (late adolescents) increased to 13.10 gr%, it can be concluded that there was a difference in hemoglobin levels before and after giving gymnastics to adolescents.

According to Kumalasari, teenage girls who have experienced menstruation are at high risk of anemia, especially iron nutritional anemia, this is because young women bleed every month and consume less iron intake which causes an increase in iron expenditure so that iron levels in the blood decrease and can trigger anemia. During menstruation, women lose ≤ 1.0 mg or lose 28 mg. The iron that women need when they are not menstruating is 1000 calories of food containing 6 grams of iron, while during menstruation women need iron consumption of 18mg/day. Efforts that can be made to overcome anemia in adolescent girls are by giving Blood Supplement Tablets with a given dose of 1 tablet/week and 1 tablet/day during menstruation (KEMENKES). Blood added tablets are iron tablets that contain 200 mg of ferrous sulfate or 60 mg of elemental iron and 0.25 mg of folic acid in each tablet.

Apart from giving blood supplement tablets to adolescents. According to Nurafandi, one strategy that can be done to overcome the problem of anemia in adolescents is by providing therapy in the form of physical activity. Doing physical activity can increase blood volume caused by cardiovascular changes. Individuals who exercise regularly will experience a slight increase in hemoglobin, this is because cells or tissues need more O2 (oxygen) when doing activities.

Increased oxygen consumption during physical activity allows hemoglobin which carries protein in erythrocytes to reach cells. An important function of hemoglobin is as a medium for transporting oxygen from the lungs (respiratory organs) throughout the body. Physical activity is an activity that can improve health status if it is done regularly, routinely and repeatedly. Physical activity that is in great demand by young women is gymnastics.

Reproductive health exercises that are carried out regularly can stretch muscles so that an increase in metabolic activity increases blood circulation and activates the parasympathetic nerves which causes blood vasodilation, resulting in large oxygen concentrations, in the presence of large oxygen in the body, changes in intramuscular osmotic pressure can occur which encourages vascular compartment to the interstitial space which causes plasma volume to decrease so that red blood cells recompile and increase the transfer of iron from the bone marrow to red blood. So that these cells produce an increase in hemoglobin production.
Conclusion and Recommendation

Based on the results of the research and the discussion that has been described, the conclusions in this study are that reproductive health exercise affects the hemoglobin levels of adolescent girls. Provision of reproductive health exercise can increase hemoglobin levels for adolescents who have anemia and can be an effort to overcome anemia in addition to giving blood added tablets, physical activity for reproductive health exercises can be used as an alternative in the treatment of anemia in adolescent girls, because exercise is one of them. Physical activity that many adolescents like.

Abstract

Leprosy (Morbus Hansen) is a chronic infection disease caused by Mycobacterium leprae that firstly attack peripheral nervous then the skin, mucosamembrane, upper respiratory track, eyes and others body tissue except central nervous system. The province of West Papua have the largest number of leprosy in Indonesia. This number is shocking and make people worried. Data from public health office of West Papua province discovered as much as 607 cases of leprosy was found in West Papua distributed in many areas. From that data, West Papua province in 2015 was selected as endemic categories. The purpose of this research was to know the affect of information education using pocket book and audio visual to knowledge increase on leprosy and prevention behavior on leprosy patient at Malanu public health center working area sorong city.

Research design used was “Quasi experimental pre-post test design” with audio visual and pocket book intervention. This design used to learnt about “caused-effect correlation” framework phenomenon with giving intervention or manipulation on research subject, and then learn the effect of the intervention. Population in this research was all patient with leprosy at Malanu Public Health Center working area. Total sample in this research was 20 people for each group using purposive sampling technique, purposive sampling technique is a choosing a group of subject based on certain characteristic that has a strong bond with population characteristic that have been known before. The affect analysis of information education to knowledge increase on leprosy after intervention was meaningfully increase than before intervention as much as 0,000 (p value <0.05). Conclusion, there was a significance affect to respondent’s knowledge increase after intervention.

Keywords: Leprosy, Pocket Book Information Education, Knowledge.

Introduction

Leprosy (Morbus Hansen) is a chronic infection disease caused by Mycobacterium leprae that first attack peripheral nervous, then skin, mucosamembrane, upper respiratory track, eyes and others body tissue except central nervous system. Data from World Health Organization (WHO)¹ showed 224.717 of leprosy cases and 259.017 cases in 2015. In 2013, Indonesia was the third in the world after India and Brazil, with 16.856 new leprosy case and the amount of grade two disability among new case was 9.86 ²

The province of west papua have the largest number of leprosy case in Indonesia. The number was large enough to makes people worried. Data from west papuaprovince, showed that 607 cases found in many areas in west papua. From that data, in 2015 west papua was selected as high endemic categories. Based on preface survey on June 11 2018 at Sorong Public Health Office obtained as much as 122 cases found in the last quarter, and leprosy case in Malanu Public Health Center in 2018 was 20.
Leprosy is a chronic infection disease caused by Mycobacterium leprous (M lepra) that its intracellular obligate attack peripheral nervous system first, then skin, mucosa membrane, upper respiratory track and other organs except central nervous system. Leprosy caused by M leprous that found by G.H Armauer Hansen in 1873 in Norwegia. This basil is acid resistant, pleomorflurus shape, slim stick and the rest has paralel shape with both ends, round with 1-8 um length and 0,25-0,3 um diameter.

Epidemiologi: The infection source is patient with so many multibasiler (MB) basil type. How its infected people is still unsure yet, just based on classic opinion that stated long and tight direct contact between skin. Other opinion stated trough inhalation,because M leprosystill could live for days in droplet.

Patophysiology: The exact leprosy infection mechanism is still unsure yet. Some hypothesis stated such as skin contact and airborne. Proved that not all people infected by M. Leprous experienced leprosy. Weather, diet, nutrition status, social economy status and genetic also play a role found after some research and observation was done on leprosy group on certain family.

Materials and Method

Design: This research using “Quasi experimental pre-post test design” with audio visual and pocket book intervention. This design can be use to learn the phenomenon on framework of “cause-effect correlation” with giving intervention or manipulated on research subject, then learn about its intervention effect.

Population: Population is all individual who become the references of research result that have certain characteristic. Population in this research is all patient with leprosy on Malanu Public Health Center working area.

Sample: Sample is a part of population that chosen with certain way to represent the population also sample is a part or vice from target population. Sample used in this research contain with so many benefits, such as cheaper, easier, faster, specific and representing the population.

The amount of sample use in this research is 20 respondent for each group, using purposive sampling as the sample technique, a technique that choose a group of subject based on certain characteristic that considered having strong relation with population characteristic that have been known before.

Location: The research was done with home visited method to the family with leprosy member on Malanu Public Health Center working area.

Data Analysis:

Univariat: Univariat analysis done to describe every variable that measure on the research. Respondent characteristic including age, gender, education level and job are categorical data analyzed for measuring frequency and variable percentage.

Bivariat: Bivariat analysis done to prove the research hypothesis, is to see the affect of information education using audio visual and pocket book to knowledge increase about prevention of leprosy disability before and after intervention at Malanu Public Health Center working area using Mann Whitney T-Test.

Analysis of the affect of information education to knowledge increase on disability leprosy prevention after intervention increase significantly and meaningfully than before intervention was given with p value 0.000 (p value < 0.05).

Discussion

This research purpose is to describe the affect of information education using pocket book and audio visual to knowledge increase of disability leprosy prevention. Ability of patient before intervention was mostly under 12 respondent from all (60%). This mean education and knowledge about leprosy is still below. This research was in line with research about the correlation of knowledge and infection prevention behavior of leprosy at TanjungAnom Public Health Center stated that knowledge is result from know and this happen after somebody using their senses on certain subject.

Respondent ability after intervention, increase into good rank as much as 10 respondent (50%). This mean there is showed an effect to their knowledge after intervention was given. Antari also stated the similar thing in her research that there is a significance correlation between knowledge and leprosy disability prevention9-16. The affect of education using pocket book and audio visual to behavior increase to leprosy disability prevention. Analysis about respondent behavior on Wilcoxon test resulted with 0,014 (p value <0,005), it means there is no significance affect to respondent behavior and attitude on leprosy disability prevention at Malanu Public Health Center working area.

Different with research done by AgustiNala at all stated that good behavior and attitude, surely will prevent the disability on leprosy which means respondent with bad attitude and behavior are 7 times more risk on disability of leprosy. So that, the higher the respondent knowledge about leprosy, the better their action to prevent disability caused by leprosy. All factor environmental and nutrition potential to affect the health status leprosy patients17-26.

Conclusion

There is a significance affect to respondent knowledge after intervention 2 days in row at Malanu Public Health Center working area.

Suggestion:

For leprosy patient: Expected to increase their knowledge with actively seeking for information as much as possible about leprosy and how its spreading.
For health staff: Giving information about leprosy as optimal as possible, in hope to increase patient knowledge, as beginning step to prevent the disease and its spreading.

For researcher: For the next researcher, hope this research will help you to find any data or references.

Effects of Vitamin E Administration on Menstrual Disorders among Adolescents who have Smoking Family Members

Cory Situmorang¹, Anwar Mallongi², Zaenab Ismail¹

¹Lecturers of Poltekkes Kemenkes Sorong, ²Professor of Environmental Health Department, Faculty of Public Health, Hasanuddin University, Makassar

Abstract
Smoking habit can cause health problems and disease in the community. One of the effects is related to reproductive health and fertility problems among women who are second hand smokers. Vitamin E is a supplement to treat fertility problems. The purpose of this study was to determine the effect of giving Vitamin E to menstrual disorders among adolescents who have smoking family members in Senior High School 2 Sorong Regency. Design of the study was quasi-experimental study using 30 samples who are chosen by purposive sampling techniques. The sample was divided into 2 groups. The experiment group was given vitamin E 100 IU/day for 3 months and the control group was not given anything. The result of the data analysis used Mann Whitney Statistical Test obtained p value 0.031<0.05. Conclusion there is a significant effect of giving vitamin E to menstrual disorders among passive smoker adolescents or those who have smoking family members in Senior High School 2 Sorong Regency. It is highly recommended that vitamin E be given as an antioxidant for both active and passive smokers.

Keywords: Cigarette, vitamin E, menstrual disorders.

Introduction
Adolescence is a period of transition from children to adulthood where adolescents are experiencing physical and psychological changes. The number of teenagers in Indonesia continues to increase annually. In Indonesia according to the Central Bureau of Statistics, the 10-19 years age group is around 22% of the population, consisting of 50.9% of male and 49.1% of female adolescents. Female adolescents are experiencing various changes marked by secondary sex growth such as enlargement of the breasts, growth of pubic hair and menarche.

Smoking causes health problems for the community and cause several diseases such as heart disease, chronic lung disease, infectious diseases, cancer by Bayoumi et al., ¹, and risk factors for asthma, respiratory infections, coughing, sneezing, middle ear infections, and sudden infant death syndrome and can affect reproductive health and fertility in women². Various studies have shown, passive smokers have the same risk as active smokers for coronary heart disease, stroke, emphysema, lung cancer, and chronic lung disease³. Cigarette smoke components that affect the female reproductive system, for example, nicotine, cotinin, the main metabolites of nicotine, carbon monooxides, cadmium, and some mutagenic polycyclic aromatic hydrocarbons⁴-¹⁰

In developing countries, the number of smoking men is higher than smoking women. Smoking men are usually surrounded by children and women including female adolescents. This makes adolescents become passive smokers or second-hand smokers which causes reproductive health issues such as problem during menstrual cycle². Components of cigarettes also cause oxidative stress and DNA damage to follicles in the ovary and affect folliculogenesis by inhibiting follicular growth¹¹,¹². An important component that is able to save human body cells from the danger of free radicals is antioxidants. Alfa-tocopherol or Vitamin E functions as the main antioxidant in the lipid compartment and has
the ability to protect from lipid peroxidation\textsuperscript{13}. Research conducted by Neunteufl\textsuperscript{14} that oral alfa-tocopherol supplementation can reduce transient endothelial function disorders among heavy smokers.

Preliminary study conducted in June 2019 at Senior High School 2 Sorong Regency by the interviews with 69 female adolescents about the existence of smoking family members and consumption of antioxidants. Result shows that 79\% of them have family members who smoke either father, mother or other siblings. Further, those female adolescents also have never consumed any antioxidants or supplements.

\textbf{Material and Method}

The design of the study is a quasi-experimental study using one-shot case study with control group design techniques. The sample in this study was 30 respondents, which were divided into 2 groups, the experiment group consisted of 15 respondents and the control group consisted of 15 respondents. Both groups were interviewed about their menstrual problems. The experiment given to experiment group was administration of vitamin E or alfa-tocopherol for 3 months with dosage 100 IU per day. After 3 months of treatment, interviews were then conducted about menstrual problems experienced during the 3-month of intervention.

\textbf{Results}

1. \textbf{Overview of Research Locations:} This study was carried out at Senior High School 2 Sorong Regency, located on Nangka Malawili Street, Aimas, Sorong Regency. The school had 48 teachers and 682 students consisting of 312 male and 370 female.

2. \textbf{Characteristics of Respondents:} The table below shows the characteristics of respondents by age and Body Mass Index (BMI).

\begin{table}[h]
\centering
\begin{tabular}{|c|c|c|c|c|}
\hline
Characteristic & Control group & Experimental group & Total & \% \\
\hline
Age (Years old) & & & & \\
16 & 2 & 0 & 2 & 6,7 \\
17 & 11 & 11 & 22 & 73,3 \\
18 & 2 & 4 & 6 & 20 \\
BMI & & & & \\
Thin & 0 & 2 & 2 & 6,7 \\
Normal & 15 & 13 & 28 & 93,3 \\
\hline
\end{tabular}
\caption{Characteristics of Respondents by Age and BMI in SMA Negeri 2 Sorong Regency}
\end{table}

As seen on table 1, it can be seen that the most respondents were 17 years old (73.3\%) and most had normal BMI (93.3\%).

3. \textbf{Effects of Vitamin E Administration on Menstrual Disorders among Passive Smoker Adolescents SMA Negeri 2 Sorong Regency:}

This study was conducted for 3 months with \textbf{stages}: 1) data collection before treatment to identify the presence of family smoking and menstrual disorders, 2) providing intervention by giving 100 IU/day of vitamin E for 90 days (three menstrual cycles) and 3) data collection menstrual disorders for three months. Data can be seen in the following table:

\begin{table}[h]
\centering
\begin{tabular}{|c|c|c|c|}
\hline
Menstrual Disorder & Control group & Experimental group & Total \\
\hline
Dysmenorrhea & 13 & 13 & 26 \\
Prolonged (> 4 days) & 5 & 7 & 12 \\
Too much bleeding (> 4 pads) & 10 & 11 & 21 \\
\hline
\end{tabular}
\caption{Menstrual Disorder among Passive Smoker Adolescents}
\end{table}
Based on table 2, it can be seen that the most respondents experienced menstrual pain or dysmenorrhea disorders with 26 respondents, too much bleeding with 21 respondents and prolonged menstrual period with 12 respondents. This shows that almost all respondents experienced menstrual pain and a few had long periods.

Table 3. Distribution of Menstrual Disorders After Treatment among Adolescents Who Have Family Members Smoking

Based on table 3, it shows that after treatment most control groups experienced menstrual disorders (66.7%) than those who did not (33.3%) while in the experiment group, most respondents did not experience most menstrual disorders (73.3%) as compared to those experienced disorders (26.7%). Furthermore, the hypothesis test using the Mann Whitney test obtained p value 0.031<0.05, which means that there is significant effect of giving vitamin E to menstrual disorders in adolescents who have smoking family members in SMA Negeri 2, Sorong Regency. The Vitamin E Administration reduced the occurrence of menstrual disorders.

Discussion

This study shows that the presence of smoking families has an impact on teenage menstrual disorders and most teenagers experience menstrual pain, more than four days of menstrual phase and more than four menstrual pads per day. Exposure to cigarette smoke can be either active or passive, and the type of cigarette smoke that is inhaled has a different origin. Active smokers inhaled smoker directly from the cigarette, while passive smokers will inhale from other people’s tobacco smoke. Various studies have shown that passive smoking has the same risk as active smokers for coronary heart disease, stroke, emphysema, lung cancer, and chronic lung disease.15-17

Cigarette smoke contains a number of ROS that can stimulate cell growth and proliferation, showing physiological functions in normal tissue. An excessive increase in Reactive Oxygen Species (ROS) will cause damage to DNA, lipid membranes, and proteins. Cigarette smoke also contains chemicals including oxidants, free radicals, and carcinogens.18 Research conducted by Khorram, et al.19 who used human endometrial epithelial cell culture reported that cigarette smoke can reduce endometrial proliferation via the nitric oxide pathway. Cigarette smoke has been linked to infertility, abnormal uterine bleeding, increased risk of endometrial cancer in premenopausal women and stimulates the production of nitric oxide in endometrial cells.19

Research conducted on mice given cigarette smoke for 8 weeks resulted in a reduction in the number of primordial follicles and loss of volume from the ovaries. Destruction of primordial follicles in mice is known from three types of PAHs: DMBA, 3-methylcholanthrene (3-MC), and BAP by destroying primordial follicles in laboratory animals and contributing to the onset of menopause in women who smoke.20,21 The results showed there was an effect of vitamin E administration to menstrual disorders (dysmenorrhea, menstrual disruption and the number of menstrual disorders) among adolescents who had family members smoking in SMA Negeri 2 Sorong Regency.

According to Kontush, et al.22 alfa-tocopherol in high concentrations will be a prooxidant which will increase the concentration of plasma and LDL peroxidation if the body is oxidized. The prooxidant effect of alfa-tocopherol on LDL is related to the production of α-tocopheroxyl radicals, can replace other soluble antioxidants, disrupt the balance of the natural antioxidant system and increase susceptibility to oxidative damage.23 This study uses vitamin E at a dose of 100 IU/day.

Prooxidant activity is derived from chain propagation by α-tocopheroxyl radicals (Toc.) which directly oxidize lipids (PUFA) to form lipid radicals (L.). The antioxidant activity of α-tocopherol can be prevented by eliminating α-tocopheroxyl radicals (Toc.) Through direct recycling into α-tocopherol mediated by co-antioxidants such as ascorbic acid (vitamin C) because physiologically vitamin C is present in high concentrations of plasma. Thus, α-tocopherol will always function as an antioxidant if the concentration of co-antioxidants is high enough.22

Furthermore, a study conducted by Chatterjee, et al.24 Vit-E supplementation at a dose of 400 mg per day for 7 days significantly inhibits platelet clumping.
and increases endurance capacity at each stage of the menstrual cycle in female athletes. Wardani in her study showed that vitamin E can increase levels of the hormone estrogen and alveolar bone structure in female mice that do maximum physical exercise.

Another study supporting the this study conducted by Bataille, et al. stated that the combination of pentoxifylline and alfatoropherol can increase pregnancy rates in patients with thin endometrium which is related to the function of the ovaries and endometrial thickness. This is supported by research conducted by Acharya, et al. that the combination of administration of pentoxifylline and tocopherol can increase endometrial thickness in women with thin endometrium undergoing pregnancy therapy.

According to Kelly smoker’s body exposed to cigarette smoke will result in lipid peroxidation so it needs to increase the need for antioxidants such as alfatoopherol to reduce oxidative stress that occurs. The administration of alfatoopherol supplementation to smokers increases alfatoopherol in serum and LDL concentrations by two to three times (dose dependent) and concentrations in lung tissue by 20 percent.

Alfatokoperol as an antioxidant in cell membranes plays a role in preventing lipid peroxidation because it can capture peroxil lipid radicals (scavenging) in cells and cell organelles and the speed of alfatoopherol in capturing free radicals exceeds the speed of radicals themselves in reacting with adjacent fatty acid chains. According to Nagama, et al. Vitamin E is a fat-soluble antioxidant by breaking the chain of oxidative reactions so that it helps to maintain and can protect cell membranes from damage caused by ROS and reactive products from lipid peroxidation as well as to reduce oxidative stress.

This is consistent with research conducted by Armiyanti proved the administration of red fruit oil to endothelial cells exposed to serum with severe malaria and normal neutrophils can inhibit the production of ROI (reactive oxygen intermediates) in endothelial cells thereby reducing oxidative stress. Oxidative stress that occurs due to ROS production by host phagocyte cells and endothelial cells as an immune response to infected erythrocytes and ROS formation through unstable hemoglobin. Red fruit oil is a potential source of antioxidants (α-tocopherol and β-carotene) and the highest antioxidant content is α-tocopherol. α-tocopherol is found in cell membranes and is hydrophobic so that it can inhibit the formation of superoxid radicals and change NADPH (nicotinamide adenine dinucleotide phosphate) oxidase in the membrane by inhibiting the formation of complex NADPH oxidase subunits thereby preventing oxidative stress and apoptosis in endothelial cells.

**Conclusion**

There is an effect of giving vitamin E to menstrual disorders among adolescents who have smoking family members in Senior High School 2 Sorong Regency. The Vitamin E administration reduce the occurrence of menstrual disorder among female adolescents in Senior High School 2 Sorong Regency.

Abstract

Local, general, and regional anesthesia is complex actions or events that cannot be separated from elective or emergency surgery. Anesthesia affects the three thermoregulatory elements consisting of afferent input elements, signal regulation in the central region, and also the efferent response which can lead to hypothermia. This study aims to determine the effect of the use of aluminum foil blankets on increasing body temperature in hypothermia patients after spinal anesthesia. This study uses a Pre-Experimental study design with a Pre-Post Test Only Design approach. Sampling in this study used a purposive sampling technique. 12 samples were given the intervention to use aluminum foil blankets. Analysis of data using the Shapiro-Wilk test, Homogeneity of Lavene Test, and Paired sample T-Test. The results of statistical tests using the Paired Sample T-Test obtained a p-value of less than 0.05 (<0.05), namely p = 0.000. There is an influence of the use of aluminum foil blankets to increase body temperature in hypothermia patients after spinal anesthesia.

Keywords: Hypothermia, Aluminum Foil Blanket, Post Spinal Anesthesia.

Introduction

Local, general, and regional anesthesia is complex actions or events that cannot be separated from elective or emergency surgery. Anesthesia affects all three thermoregulation elements consisting of Aferen inputs, signal settings in the central area, and also the efferent response otherwise, it can also eliminate the adaptation process as well as interfere with the mechanism of lipid or skin physiology in thermoregulation function. This resulted in the patient having hypothermia. The Post-operative hypothermia incidence rate can be said quite highly. The year 2015 at the Brazilian Hospital Hypothermia event number post operations as much as 98 (93.3%) Patients from 105 patients experienced Hypothermia postoperative. The year 2019 54 (69.2%) From 78 experienced hypothermia in the post-anesthesia recovery chamber. In the year 2017 at the RSUD Wates the hypothermia incidence rate as much as 36 (65.5%) Of the 55 patients who post operations. At the Sele Be Solu Hospital the hypothermia incidence is 8 out of 10 patients with an average temperature of 35.8°C. Preliminary study interviews were 38 patients with postoperatively in the Sele Be Solu Hospital.
operating room with several post-operative patients with anesthesia indicates that they often experience cold (hypothermia) while being in the operating room and recovery room.

Hypothermia is classified as induction hypothermia or an accident and secondary hypothermia. An induction or accident hypothermic is caused by low environmental temperature management, dose medications, and certain diseases such as myxedema and hypopituitarism. While secondary hypothermia can occur in surgical patients and cause by several factors such as, due to low temperature in the operating room, infusion with cold liquids, use of inhaled anesthetic techniques with cold gas, cavities or open wounds, muscle activity that decreases during anesthesia, advanced age or the type of medication used during anesthesia.

The occurrence of hypothermia will activate shivering mechanisms as to increase metabolism, muscle activity above normal levels to produce heat, also increases two to three times the consumption of oxygen and CO$_2$ production. Complications in the form of shivering in this case, occur due to skeletal muscle contractions or tremors in the face, chin, and extremities for ±15 minutes accompanied by a process of hypothermia and vasodilation. This condition can make things worse than pain, and disrupt the observation of the patient’s condition and physical comfort$^7$.

The treatment of hypothermia that can be undertaken involves non-pharmacological and pharmacological action. Non-pharmacological therapy techniques can be performed by providing warm blankets, regulating adequate ambient temperatures, as well as using fluid warmers for transfusion and other liquids$^8$-$^{12}$. Interventions to lower the state of postoperative chills can be with active or externally active internal heating. Ambient temperature in the room is recovered, wet dresses and blankets are removed and replaced with a dry because it can enlarge heat loss, intravenous fluid, and irrigation are heated to 37°C.

Regardless of the method used to warm the patient, the reforesting must be carried out gradually and not quickly$^7$. The use of an aluminum foil blanket is a method to stabilize body temperature. Clarissa’s research results, proved that the treatment of hypothermia can be solved by passive warming intervention. The results of the research Marlinda, et al.,$^{13}$ proved that the use of warm blankets that are coated in an aluminum foil is more effective than ordinary warm blanket use in the return speed of post-operation body temperature.

Based on the explanation above, the authors are interested to research on the effect of the use of aluminum foil blanket against an increase in body temperature in patients after spinal anesthesia in Sele Be Solu Hospital.

**Materials and Method**

This type of research uses a Pre-experimental study design with a Pre-PostTest Only Design approach. Pre experiments are experiments that have treatment, impact measurement, union experiment but don’t use assignments randomly to create comparisons to conclude changes that are caused by treatment. Sampling in this study used purposive sampling techniques. The total sample in this study amounted to 12 people. The data collected includes the characteristics of respondents based on age, gender, and body temperature pre and post-intervention using an observation sheet. Data retrieval is carried out at the Sele Be Solu Hospital Sorong for one day while observing the principles of beneficence ethics, respect for human dignity, and justice. Analysis of data using the Shapiro-Wilk test, Homogeneity of Lavene Test, and Paired sample T-Test.

**Results**

The collection of data on this research has been conducted at the Sele Be Solu Hospital in Sorong for 8 days on 18-25 March 2020. Characteristic data includes age and gender. The average age of respondents was 42.92 (± 9700). Male-gender respondents numbered four (33.3%) Female gender amounted to 8 (66.7%). Variable temperature data using the Paired test sample T-Test indicates there is a significant influence on the increase in body temperature after the intervention (P = 0.000).

DISCUSSION

Based on the results of the study showed the age characteristics of the most respondents were at vulnerable age 46-55 which amounted to six respondents with a presentation of 50% and the lowest was at the age of 16-25 which amounted to one respondent with a presentation of 8.3%. It is shown that the elderly are one of the factors affecting hypothermia post-anesthesia. This can occur because when a person enters the age of the elderly, the state of cells in the body will change. The thermoregulation system will be disrupted so the elderly are more likely to experience loss of body temperature. Anesthesia that is done in elderly patients can lead to a shift in the thermoregulation threshold with greater degrees compared to young patients.14

This research is in line with the research conducted by Amila Hanifa,6 which suggests that patients who often experience hypothermia are at the age range of 46-60 years with a total of 21 (38.2%) of 55 patients. Another research in line is the research conducted by Harahap, indicating that the incidence of hypothermia in the elderly reached 113 (87.6%) of 129 patients. While the research is not in line with this study, the research conducted by Clarissa,15 showed that elderly patients who experienced hypothermia only 20 (19%) of 105 patients.

The results showed that most respondents were female genders of 8 respondents with a 66.7% presentation. This suggests that gender is one of the factors affecting hypothermia post-anesthesia. Men and women have a difference in body temperature consistency. In general, women have a larger body temperature fluctuations than men. This happens because of the effect of the hormonal production of progesterone hormones. If the hormone progesterone decreases, then the body temperature decreases a few degrees below the normal limit.14

This research is in line with research conducted by Mendone,16 which shows the number of hypothermia in female gender reaches 62 (79.48%) of 78 patients. The results of this research is also in line with the research conducted by Harahap,14 explained that more hypothermia number in women is 51.2%. The results of other studies in line with this study were research conducted by Clarissa,17 explaining that female patients experiencing hypothermia reached 73 (69.5%) of 105 patients.

The characteristic of an aluminum foil is strong, lightweight, heat resistant, and almost airtight, which doesn’t contain magnets.18 An aluminum foil blanket is a method used to increase body temperature in preterm hypothermia due to an air resistant aluminum foil. Aluminum foil blankets can also be used to cope with and increase body temperature in patients with hypothermia due to the environment. Patients who experience hypothermia are caused by too cold room temperature, infusion with cold liquids, cold inhalation, decreased muscle activity, or the influence of drugs used such as vasodilators, spinal and generalized anesthesia.19-22

In the first hour after spinal anesthesia administration will occur decreased shivering threshold of about 1°C up to 2°C. Anesthesia affects all three thermoregulation elements consisting of afferent input elements, signal settings in the central area as well as the effusive response otherwise, it can also eliminate the adaptation process as well as disrupt the mechanism of fat or skin physiology in thermoregulation function. At the time of administration of anesthesia spinal body undergo vasodilation. This is what makes the body’s metabolism increased so that the body experiences a decrease in temperature.3

The use of heat-resistant aluminum foil covers and air can make the body vasoconstriction because the blanket of aluminum foil minimizes the body or skin to interact with air or the stimulus resulting in hypothermia. When the body does not get the stimulus, the body will undergo vasoconstriction due to heat restrained with an aluminum foil blanket. So slowly the body temperature will begin to increase to normal body temperature.3

Research conducted by Marlinda, Ramdani, and Mariana,19 concluded that there is an influence on the blanket of warm coated aluminum foil blanket to increase the body temperature of the patient’s hypothermia post-SC. Another research result that can support this research is research conducted by Jessica Watson3 concluded that the blanket of aluminum foil or warm blanket can also handle the problem of postoperative hypothermia.

This research is in line with previous related studies where there is an influence on the use of aluminum foil blankets against increased body temperature in patients with hypothermia after spinal anesthesia. The use of aluminum blankets within 10 minutes can make the blood vessels that have been vasodilation transformed into vasoconstriction. So that the blanket aluminum foil can be used to overcome the problem of post-anesthesia hypothermia.
Conclusion

Aluminum foil blankets are effective in increasing the body temperature post-spinal anesthesia. For nursing services, researchers recommend the blanket aluminum foil intervention can be used as standard operational procedures against hypothermia after spinal anesthesia. For further researchers to examine the factors affecting hypothermia post-anesthesia such as old surgery, body mass index, and anesthesia type. Further researchers can also add samples and compare blankets of aluminum foil to the increase in the body temperature of post-spinal anesthesia.

Abstract

The problem of STIs in Indonesia is believed to be like an iceberg phenomenon because the official report on the number of cases does not reflect the real problem. There is a high number of asymptomatic cases that the sufferer does not feel sick but can transmit the infection to other people. This study aims to analyze risky behavior towards STI incidents in the work area of the Community Health Center (Puskesmas) of Bintuni. This is analytic observation research, with a case-control design. A case-control study is carried out by identifying the case group and the control group, then retrospectively, the risk factors for STIs in the work area of the Community Health Center of Bintuni were examined with a total of 102 respondents, each group of cases and a control group of 51 respondents. Data were analyzed using SPSS to test the Odd Ratio. Results: The analysis of knowledge resulted in the OR value of 2.771, the analysis of attitude resulted in the OR value of 1.4644. Knowledge and attitude are risk factors for the incidence of STIs. This study suggests improving health education, especially about STIs, and the health office and health agencies should be more proactive in early detection of STI cases in the community.

Keywords: Knowledge, attitude, action, sexually transmitted infections.

Introduction

Sexually transmitted infections (STIs) are infections caused by bacteria, viruses, parasites, or fungi, which are transmitted primarily through sexual contact from an infected person to their sexual partners¹. STIs are one of the top ten causes of unpleasant disease in young adult men and the second most common in young adult women in developing countries².

According to the CDC in Upik et.al, the incidence of STIs out of 340 million new curable cases (syphilis, gonorrhea, chlamydial infections, and trichomonas infections) occurs annually in men and women aged 15-49 years. Epidemiologically, the disease is spread throughout the world, with the highest incidence rates recorded in South and Southeast Asia, followed by Saharan Africa, Latin America, and the Caribbean. In America, the number of women who suffer from chlamydial infections is 3 times higher than men. Of all women who suffer from chlamydial infections, the age group that makes the biggest contribution is those aged 15-24 years³.

The prevalence of STIs in developing countries is much higher than in developed countries. In pregnant women globally, the incidence of gonorrhea is 10-15 times higher, chlamydia infection is 2-3 times higher, and syphilis is 10-100 times higher than the incidence of pregnant women in industrialized countries. Adolescents (15-24 years) are 25% of all sexually active populations but account for nearly 50% of all new STI cases acquired. The detected STI cases represent only 50%-80% of all STI cases in America. This reflects the limitations of screening and the lack of news coverage of IMS².

In Indonesia, based on the Integrated Biological and Behavioral Survey Report (IBBS) by the Indonesian
Ministry of Health, the prevalence of STIs in 2013 showed that gonorrhea infection was 99.2%, chlamydia was 125.1% and syphilis was 36.6%. While the prevalence of HIV was 68.9%.

Everyone who is sexually active can contract an STI. But, there are several groups of people that have to be watched out for because they have a high risk of spreading the IMS, such as the people who like to keep changing their sexual partners and those who had only one sexual partner, but their sexual partners like to keep changing their sexual partners.

The problem of STIs - HIV in Indonesia is believed to be like an iceberg phenomenon because the official report on the number of cases does not reflect the real problem. The number of asymptomatic cases so that the sufferer does not feel sick, but can transmit the disease to other people. The first step in overcoming this problem is that we must have supporting and accurate data. Many data on STIs - HIV has been found and various prevention efforts have been made. However, the trend of increasing the number of STI cases and finding new HIV cases continues to increase.

Based on the description of the background above, the researchers interested in conducting a study with the title “Analysis of Risky Behavior Towards Sexual Transmitted Infections (STIs) In The Community Health Center of Bintuni, West Papua”.

**Method**

This is analytic observational research, with a case-control design. Case-control is a study conducted by comparing two groups, namely the case group and the control group.

The case population in this study were clients who had medical treatment and doctor diagnoses infected with sexually transmitted diseases (STIs) in the work area of the Bintuni Community Health Center as many as 82 clients and the control population in this study were clients who came to the health center for STIs test through laboratory examinations and were declared not infected by STIs. The sample size was 102 with a ratio between cases and controls 1: 1 = 51 cases and 51 controls. The research was conducted in outpatient services and STI service units at the Bintuni Community Health Center.

The number of STIs cases as the number of cases of Urethral Body Duh (DTU) from January to December 2016, was reposted as many as 10,672 cases and cases of genital ulcers/genital ulcers were reported as many as 1,628 cases. Cases of Sexually Transmitted Infection (STI) based on the syndrome and laboratory approach per risk group in 2016 for national Female Sex Workers/FSW (89,792), Male Sex Workers/MSW (506), Trans-women (6,951), Gay men (39,681), Injected Drug Users/IDU (4,425), High Risk Couples/HRC (93,520), Sex Worker Customers/SWC (14,043), and Others (192,786). For West Papua Province, the risk groups in 2016 were FSW (1,301), MSW (-), trans-women (7), gay men (7), HRC (32), SWC (543) and others (6,182) (SIHA MOH, 2016).

The number of pregnant women who visited the ANC for the first time and tested for syphilis at the national level was 43,873 people and 4,169 pregnant women who tested positive for syphilis and 1,254 pregnant women who were treated for syphilis were in West Papua. The number of pregnant women who first visited the ANC and were tested for syphilis was 1902, 120 people, and pregnant women who tested positive for syphilis and 60 people who were treated for syphilis. In one of the districts in West, Papua is TelukBintuni Regency, the number of STI cases in 2016 for the Bintuni Community Health Center was 94 cases and in 2017 from January to October there were 82 cases. Data on the latest HIV transmission pathways reported by the Directorate General of Disease Control and Environmental Health, Indonesian Ministry of Health, in the SIHA report per December 2016 according to risk factors is through heterosexual 17,754 cases, gay men 13,063 cases, others 5,479 cases and 12,479 unknown cases. The percentage of HIV infection reported by sex was male 63.3% and female 63.7%, while the percentage of HIV infection reported by age was ≤ 4 years 2.2%, 5-14 years 1.0%, 15 -19 years 3.7%, 20-24 years 17.3%, 25-49 years 69.3%, ≥ 50 years 6.5%.

Based on table 1 above, it shows that most case groups were respondents aged 25-49 years, which was 66.7%, while in the control group the most were respondents aged 25-49 years, which was 56.9%. In the respondents’ gender cases and the control group had the same number of respondents, most respondents were females at 96.1%. At the education level of the respondents, the case group at the junior and senior high school education level had the same high proportion, which was 43.1%, while the control group had the highest proportion of respondents with high school education, which was 47.1%. Based on marital status in the case group and the control group, the highest proportions were respondents with widow status, 58.8%, and 49% respectively. Most respondents in the case and control groups were female sex workers, 92% and 76.4%, respectively.

Based on Table 2, it shows that the comparison of proportions between cases and controls, respondents with less knowledge, higher in case group (37.3%) compared with the control group (17.6%). The results of the odds ratio test show the value of OR = 2.771; 95% CI = 1.108-6.931, which means that knowledge is a risk factor for the incidence of STIs.

b. Attitude

<table>
<thead>
<tr>

</table>

Based on Table 3, it shows that 13.7% of respondents in the case group had less attitude, higher compared to the control group by 9.8%. Based on the results of the analysis, the OR = 1.464; CI 95% = 0.432-4.957, which means that attitude is a risk factor for the incidence of sexually transmitted infections.

Discussion

Knowledge risk of the incidence of sexually transmitted infections: Based on the results, it shows that the largest proportion of respondents in the control group good knowledge i.e., 82.4% compared to the case group that was 62.7%. While the largest proportion of respondents that has a lack of knowledge in the case group is 37.3% and 17.6% in the control group. The results of the analysis of odds ratio OR = 2.771; 95% CI = 1.108-6.931, which means that knowledge is a risk factor for the incidence of sexually transmitted infections (STIs). One of the factors affecting knowledge is the level of education. The higher a person’s education, the better the knowledge about the risk of sexually transmitted infections, and vice versa. Table 1, shows that only 3.9% of respondents were highly educated so that knowledge about the risk of sexually transmitted infections was lacking which had an impact on the risk of exposure.

The results of this study are not in line with the results of research by Masni (2016), concerning risk factors for sexually transmitted infections at the Kalumata Health Center, Ternate City which shows that knowledge is not a risk factor for the incidence of sexually transmitted infections, because knowledge has a major contribution in changing one’s behavior to behave both positively and negatively. Sufficient knowledge about sexually
transmitted diseases encourages a person to be more aware of diseases that can be transmitted through sexual activity\textsuperscript{10}.

The results of this study are also in line with the results of Ristiani’s\textsuperscript{11} research on the relationship between the level of knowledge about infectious infections and premarital sex attitudes in 8\textsuperscript{th}-grade students at Muhammadiyah 9 Junior High School, Yogyakarta, which states that there is a significant relationship about the level of knowledge about sexually transmitted infections with premarital sex attitudes in 8\textsuperscript{th}-grade students.

Anyone that sexually active is at risk of contracting an STI. Factors that increase the risk include having sex without a condom, having sex with a changing partner, the behavior of a high-risk sexual partner, and having a history of STIs\textsuperscript{12}.

Risk Factors Attitudes towards the incidence of sexually transmitted infections: The results showed that 13.7\% in the case group had a poor attitude was higher than 9.8\% in the control group with the test results show the value of the odds ratio OR = 1.464; CI\textsubscript{95\%} = 0.432-4.957 which means that attitude is a risk factor for the incidence of sexually transmitted infections.

According to Gerungan\textsuperscript{13}, an attitude is a person’s opinion or view of an object that precedes his action. Attitudes may not be formed before receiving information, seeing, or experiencing an object. Adult age can form a person’s opinion or a wider viewpoint about an object. There are 61\% of respondents who are adults but do not make a positive contribution to healthy behavior.

The results of this study are not consistent with the results of research by Gani\textsuperscript{14} about the relationship of knowledge, attitudes, and behavior towards the incidents of Sexually Transmitted Infections in housewives at Bukittinggi, West Sumatra province that showed attitude is not a risk factor for the incidence of sexually transmitted infections (OR = 0.99).

Attitudes often reflect a person’s personality because they are inseparable from the person who supports them. Therefore, by looking at the attitude of a certain object, more or fewer people can know that person’s personality. So attitude is a personal statement\textsuperscript{15-23}.

In general, respondents have a good attitude in preventing sexually transmitted infections, including the statement that using condoms is a safe way to prevent STI transmission, having more than 1 sexual partner can be at risk of contracting STIs, anal sex is very risky of contracting STIs, sucking or putting genitals into the mouth (Oral sex) can be very risky of contracting STIs, however, a person’s attitude can change due to the state of the human being that moves to act or act in social activities with certain feelings in response to the object of the situation or conditions in the surrounding environment\textsuperscript{6}.

Abstract

Indonesia is ranked 5th in the world and 3rd in Southeast Asia with the highest number of stunted children under five. West Papua Province in 2018 is included in 18 provinces with a high prevalence of around 30%-<40%. Stunting is one of the nutritional problems that occur from the pre-conception period, and will continue until pregnancy which can affect the baby being born. One of the efforts that can be done by giving rebon shrimp, its content which is rich in micronutrients can be an alternative food choice for improving blood biochemistry of pregnant women. The purpose of this study is to analyze the differences in blood biochemical levels of pregnant women (serum protein, serum albumin and hemoglobin levels) before and after consuming the supplementary feeding of Koya Powder made from Rebon Shrimp. This study used a quasi-experimental method with a group design post-test control approach. The total sample size is 15 respondents per group, using the incidental technique. The intervention group was given koya powder as much as 100 grams/day for 7 days, while the control was given education on nutritious foods and eating according to the daily pattern. The research was conducted in the work area of the West Sorong Health Center and Malawili Public Health Center, data collection was carried out from 31 August 2020 to 06 October 2020, using an observation sheet. Data analysis used the Mann-Whitney test, if the data were not normally distributed, use the free sample t2 test. The results of the study were significant differences between the control group and the intervention group with a P value of 0.000 <0.05. Conclusion “There is an Effect of Consumption of Supplementary Feeding Koya Powder Made from Rebon Shrimp (Mysis Relicta) on Changes in Serum Protein, Serum Albumin and Hemoglobin Levels for Pregnant Women as Risk Factors for Stunting.”

Keywords: Rebon Shrimp, Blood Biochemical, Stunting and West Papua.

Introduction

Based on data from the World Health Organization (WHO), South East Asia Regional (SEAR), Indonesia is in the third highest position with an average of around 36.4% of children under five with stunting in 2005-2017. Riskesdas,¹ For this reason, referring to the RPJMN (National Medium-Term Development Plan) target in 2019, it is expected that the number of babies under two years of stunting in Indonesia can reach a figure below 28%. Based on data from Riskesdas (Basic Health Research) in 2013, around 37.2% (9 million) of children under five were stunted, so that Indonesia was ranked 5th in the world.²

The latest Riskesdas in 2018 shows a decrease in the prevalence of children under five with very short and short criteria by 30.8%, although there has been a decrease in cases but has not reached the expected target Riskesdas.¹ West Papua Province in 2018 is included in 18 provinces with a high prevalence of around 30%-<40% of cases are short and very short with indicators of height according to age (Height/Age), where the very short category is TB/U <-3SD and the short category Height/Age ≥-3SD to <-2SD. Priority for subscribing to stunting intervention is focused on 3 loci, namely Sorong City, South Sorong Regency and Tambraw.²
Stunting is one of the nutritional problems experienced by children under five today, the results of an analysis of 217 national Demographic and Health surveys from 67 countries with ≥2 surveys between 1993 and 2014, showed the average prevalence of stunting in 1993 was 53.7% in low-income countries and 48.2% in middle-income countries. Stunting occurs from the pre-conception period, the condition is lack of nutrition and anemia is one of the triggers. This condition will get worse when entering conception because of insufficient nutritional intake to meet needs. Mothers with infection and/or chronic disease directly contribute to micronutrient deficiencies that inhibit nutrient absorption. During pregnancy, increased nutritional intake is required, micronutrient deficiency which less exacerbates this period. Evidence suggests that repeated pregnancies with short intervals between pregnancies contribute to the micronutrient status of pregnant women. Micronutrient deficiency is associated with a number of adverse outcomes for both mother and baby. The impact of lack of nutrition during pregnancy will affect the level of intelligence, and are more susceptible to disease. Efforts to prevent and reduce stunting by addressing these factors use a life-cycle approach. WHO recommends iron folic acid supplementation of 30-60 mg of elemental iron and 400 μg of folic acid per day. Rebon shrimp is included in the type of shrimp, according to the Ministry of Health in 2005: 9 quoted in Syarif et al., that every 100 grams of dried rebon shrimp contains 295 cal calories, 62.4 g protein, 2.3 g fat, 1.8 grams of carbohydrates, 1209 mg of calcium, 1225 mg of phosphorus, 6.3 mg of iron, 210mg of vitamin A, 0.14mg of vitamin B1, 20.7g of water.

The high number of cases of linear disorders in infants and the importance of addressing this problem, the researchers want to explore the potential of Papua’s marine resources, to be used as an alternative food choice through research “Supplementary Feeding Development of Koya Powder Based on Rebon Shrimp (Mysis Relicta) Towards Changes In Blood Biochemistry Of Pregnant Women As Risk Factor Of Linier Growth Disturbance (Stunting)” with the hope that the results of this study can be useful for the Papuan people, to raise local food wisdom.

Materials and Method

This study used a quasi experimental design, with a pretest-posttest control group design. Before and after the intervention, a pregnant woman’s blood biochemistry will be examined (Serum Protein, serum albumin and hemoglobin). This research has passed the ethics test by the Ethics Team of the Health Polytechnic of the Ministry of Health in Sorong and has obtained a research permit. The sample in this study were 30 pregnant women, using the Cluster Random Sampling technique. Samples were divided into 2 groups with the same number, the intervention group was given koya powder as much as 100 grams/day for 7 days and the control group was given health education on nutritious food by consuming a daily diet, for SF tablets still consumed in both groups. Rebon Koya powder is made by the research team with a composition of 20% shrimp crackers and 80% rebon shrimp. The research instrument used an observation sheet to assess changes in serum protein levels which were categorized as Low if <6.40 g/dl and Normal if Normal> 6.40 g/dl. To assess changes in serum albumin levels, it is categorized as Low if <3.4 mg/dl and Normal if> 3.4 mg/dl. Meanwhile, to assess changes in serum hemoglobin levels in the category Low if <10.5 g/dl and Normal if> 10.5 g/dl. Blood Biochemistry before and after intervention in both the intervention and control groups used a paired T test if the data were normally distributed and used the Wilcoxon test if not normally distributed. Meanwhile, to measure differences in Blood Biochemistry before and after intervention between the intervention and control groups using the Mann-whitney test if the data are not normally distributed. If the data are not normally distributed using the free sample t2 test, because the data are not paired.
Results and Discussion

1. Univariate analysis

a. Characteristics of Research Subjects: Respondent characteristics include age, religion, occupation, parity and gestational age. For more details, see the description below:

Table 1 shows that the characteristics of respondents based on age in the intervention and control group were mostly at the age of 20-35 years, in the intervention group as many as 14 respondents (93.3%) while in the control group as many as 13 respondents (86.6%). For the characteristics of respondents based on religion, both the intervention and control groups were mostly Muslim, in the intervention group there were 15 respondents (100%) while the control group was 11 respondents (73.3%).% Housewife. Characteristics of Respondents based on parity in the intervention and control groups mostly in the 2-5 children or multigravida group. The intervention group was 12 respondents (80%), while in the control group there were 10 respondents (66.6%). Characteristics of respondents based on gestational age in the intervention group were mostly in the gestational age group in trimester 2 ranging from 27-40 weeks of gestation as many as 8 respondents (53.3%). Whereas
in the control group, most of them were in the 2nd and 3rd trimesters of pregnancy, each of which were 7 respondents (46.6%).

b. **Like or Organoleptic Test:** To assess the texture, taste, color and aroma between formula A and formula B. More details can be seen in Table 2 below:

<table>
<thead>
<tr>
<th>Type of Treatment</th>
<th>Preferred Level</th>
<th>Category</th>
</tr>
</thead>
<tbody>
<tr>
<td>Formula A</td>
<td></td>
<td></td>
</tr>

</tr>
<tr>
<td>Color</td>
<td>2</td>
<td>Dislike</td>
</tr>
<tr>
<td>Aroma</td>
<td>2</td>
<td>Dislike</td>
</tr>
</tbody>
</table>

In the preference test of 10 panelists, it shows that the respondent prefers the texture of Formula A, for the taste the Respondents really like formulation A. As for the color and aroma of the Respondents like formulation A. Thus, the formula used for this study is Formula A.

c. **Compliance Test:** To measure Respondents’ compliance to consume Koya Shrimp Rebon Powder per day. More details can be seen in table 3 below:

<table>
<thead>
<tr>
<th>No.</th>
<th>Compliance Level</th>
<th>Frequency (n)</th>
<th>Percentage (%)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Low (25gr/day)</td>
<td>0</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>Medium(50gr/day)</td>
<td>1</td>
<td>6.6</td>
</tr>
<tr>

<td>High(100 gr/day)</td>
<td>14</td>
<td>93.3</td>
</tr>
<tr>
<td></td>
<td>Total</td>
<td>15</td>
<td>100%</td>
</tr>
</tbody>
</table>

Based on Table 3 regarding the compliance of Respondents consuming Koya Powder for 1 week with a frequency of 25 x 4/day (Total 100 gr/day), it shows that as many as 14 respondents (93.3%) have a high level of compliance while 1 respondent (6.6%) have a moderate level of adherence, this is because the mother has entered the final week of preparation for delivery so that the desire to eat has decreased.

d. **Blood Biochemical Levels of Pregnant Women Before And After Intervention:** Measuring the average blood biochemistry includes Serum Protein, Serum Albumin and Hemoglobin before and after the intervention for 7 days. More details can be seen in table 4 below:

<table>
<thead>
<tr>

<td>3.580±0.3075</td>
</tr>
</tbody>
</table>

Table 4 above shows that the mean results of changes in the blood biochemical content of pregnant women in the control group were smaller than the intervention group. After that, the univariate test will be carried out with the Paired Samples Test. The normality test will be carried out first, which aims to determine how the distribution of data is needed and determine the data that has been collected is normally distributed or taken from the normal population. The normality test was carried out using the Shapiro-Wilk method because the sample data in each group was less than 50 samples. If p> 0.05 is obtained, the data is normally distributed. The results of the normality test can be seen in Table 5 below:
From table 5 above, it is found that some data are normally distributed and not. After the normality test, the Paired Samples Test will be carried out on the HB sample of koya powder, koya protein powder and control albumin. The Paired Samples Test is a two-time difference test for data that is normally distributed and is used to see changes in giving Supplementary Feeding of koya powder before and after being treated. For the other sample, the Wilcoxon test was carried out because the data distribution was not normally distributed. If $p < 0.05$ then there is a significant difference.

The results of the Paired Samples Test and Wilcoxon test in Table 6 above, for the whole sample experienced a significant difference, only control albumin is not. To prove the difference in the effectiveness of Supplementary Feeding of koya powder on changes in blood biochemistry of pregnant women, a bivariate test was carried out using the Independent Samples Test. Data normality testing is required to meet the requirements of the Independent Samples Test.

2. **Bivariate Analysis**: To see the relationship between the dependent variable and the independent variable. So to measure the differences in blood biochemistry of pregnant women, before and after intervention between the intervention and control groups used the Mann-Whitney test, if the data were not normally distributed. If the data are not normally distributed using the free sample $t_2$ test.
Table 7. Bivariate Normality Test Results Using Kolmogorov Smirnov Z

</table>

From Table 7 above, it is found that the data are not normally distributed. After that, the homogeneity test was carried out with the Levene test to see whether the data variance was homogeneous or not. The results of the homogeneity test of the data variance are not homogeneous. The data are not normally distributed and are not homogeneous so that the Independent Sample Test cannot be done. The results of the homogeneity and normality test meet the requirements of the Mann Whitnney test.

It is found that the data variance is not homogeneous, which means that all the requirements are met. After that, the Mann Whitnney test is carried out with the results in Table 9, the results show that there is a significant difference. The conclusion of the null hypothesis is rejected thus “There is an Effect of Consuming Supplementary Feeding of Koya Powder Made from Rebon Shrimp. (Mysis Relicta) Towards Changes in Serum Protein, Serum Albumin, and Hemoglobin Levels for Pregnant Women as Risk Factors for Stunting.

Discussion

Characteristics in the age group of respondents, both the intervention and control groups, are mostly at the age of 20-35 years, this is a safe gestational age and delivery because at this age the mother is physically and mentally ready to face pregnancy and childbirth besides that the risk of anemia is very low. A study conducted by Zahidatul 8 shows that pregnant women aged <20 years have a 2,250 times greater risk of anemia and >35 years of age have a risk of experiencing anemia 5.885 times greater than those of 20-35 years. However, this is not in line with the data obtained by researchers where there are still respondents who have low hemoglobin levels <10.5 g/dl, even though the percentage is below 50%.

Respondents in both groups are 100% unemployed, meaning that mothers carry out their daily obligations as housewives, the group of mothers who do not work is a group that is prone to suffering from anemia, where the data shows that mothers who do not work have a 1.990 greater chance of experiencing anemia compared to working pregnant women. Mothers who do not work have to do hard work during pregnancy to meet their needs. In addition, this group tends to have a lower socioeconomic status so that nutritional needs are not fulfilled.

Parity in the intervention and control groups mostly at parity of 2-5 children, the number of children greatly affects the nutritional status of children under five. Toddlers from families with a large number of household members are 1.34 times more likely to experience stunting compared to toddlers from families with sufficient household members. Mothers who had many children under five had a 3.25 times greater risk of stunting than respondents who had mothers with little parity lack of time in sharing attention to children, the limited food consumed by children is a trigger factor.

There is a significant difference between mothers who were given rebon shrimp koya powder and mothers who were only given education to eat according to their daily diet. Giving rebon shrimp koya powder can meet 70 KKal, with a composition of 41 mg of Calcium (Ca), 265 mg of protein, 21.4 mg of Fe, 0.06 mg of Vitamin B1 and 21.6 grams of water. Protein content in the body functions as a means of transporting iron. Consumption of foods high in protein can increase hemoglobin levels. This is in line with research conducted in Sorong Regency, 2019, showing that women of childbearing age who consume shellfish biscuits can significantly increase their hemoglobin levels because shellfish are rich in protein.

While the content of Calcium (Ca) affects genetic programs that determine height. If calcium intake is reduced it will cause low blood calcium levels and can interfere with the genetic high process. Calcium (Ca), phosphorus (Pi), and Magnesium (Mg) are the main minerals in fetal bone mineralization. Low levels of calcium in maternal serum can cause low serum Ca levels in the fetus.

Serum albumin levels are essential during pregnancy for good delivery outcomes, Department of Obstetrics
Pregnant women who are deficient in zinc can cause gestational hypertension, defects in fetal nerves, premature rupture of membranes, low birth weight, poor neurodevelopmental behavior, cognitive impairment, intrauterine growth retardation, impaired glucose tolerance, congenital malformations, stillbirth, premature labor, postpartum hemorrhage, prolonged labor, inadequate uterine contractions, abnormalities in gene replication, delayed immune system development leading to increased neonatal morbidity and mortality. Serum albumin acts as an antioxidant in the body, low albumin levels in pregnant women are closely associated with the incidence of gestational diabetes. Decreased albumin levels are due to malnutrition.

Maternal nutritional status during pregnancy greatly affects the risk factors for stunting in children. Hardening of the bones begins approximately in the sixth week of embryonic development and continues until the end of pregnancy. However, an insufficient supply of nutrients in pregnant women impairs fetal growth. The results showed that maternal nutritional status during pregnancy was significantly associated with stunting in children (p-value: 0.000). The OR value is 13,222, which means that children born to mothers with insufficient nutritional supply during pregnancy are 13,222 times more likely to suffer from stunting than children born to mothers with good nutrition supplies.

Linear growth failure is the most common form of malnutrition globally. With an estimated 165 million children under 5 years of age affected, stunting has been identified as a top public health priority, and there are ambitious targets to reduce stunting prevalence by 40% between 2010 and 2025. We view this condition as a ‘stunting syndrome’ in which several pathological changes characterized by decreased linear growth in early life are associated with increased morbidity and mortality, decreased physical capacity, neurological and economic development and an increased risk of metabolic disease into adulthood. tend to have neglected offspring, creating an intergenerational cycle of poverty and depletion of human resources that is difficult to break.

Deficiency of micronutrients is one of the triggers for stunting in addition to non-optimal breastfeeding and complementary feeding practices, as well as recurrent infections. In the antenatal period Fetal growth is regulated by a complex interaction of maternal nutritional status, endocrine and metabolic signals, and placental development. For this reason, prenatal micronutrients and provision of balanced energy and protein for mothers can reduce the incidence of stunting by 9% and 31%. Daily iron supplementation during pregnancy reduces low birth weight by 20%.

Stunting reflects poor nutrition and frequent infections can lead to poor cognitive, motor and socio-economic development. Globally, one fifth of pregnant women develop iron deficiency anemia during pregnancy. A meta-analysis showed that anemia during the first or second trimester increases the risk of prematurity and low birth weight. The WHO recommends 60 mg of iron daily during pregnancy, however, a randomized controlled trial in Bangladesh showed that supplementing iron with multiplemicronutrient intake had a slightly more effect on children’s body length at birth, first, third and sixth month. Thus, the addition of micronutrients with iron tablets to pregnant women will have a more positive impact on linear disturbances in babies born.

**Conclusion**

1. The mean serum protein level before consuming the Supplementary Feeding of Rebon Shrimp-based Koya Powder in the Intervention Group was 5,867 ± 0.5948 and after it was 6,493 ± 0.8388. The mean serum albumin levels before consuming the Supplementary Feeding of Rebon-based Koya Powder in the Intervention Group were 3.527 ± 0.4183 and after 3.753 ± 0.4642. The mean hemoglobin level before consuming the Supplementary Feeding of Rebon-Shrimp Based Koya Powder in the Intervention Group were 3.527 ± 0.4183 and after 3.753 ± 0.4642. The mean hemoglobin level before consuming the Supplementary Feeding of Rebon-based Koya Shrimp in the Intervention Group was 10,453 ± 1,8189 and after 11,107 ± 1,7015.

2. The mean serum protein level before the intervention in the control group was 7,113 ± 1,1904 and after
that was 6,427 ± 0.9677. The mean serum albumin level before intervention in the control group was 3.580 ± 0.3075 and after 3.600 ± 0.4175. The mean hemoglobin level before the intervention in the control group was 11,513 ± 1.1575 and after it was 11,073 ± 1.1094.

3. There were significant differences in serum protein levels before and after Consuming Supplementary Feeding of Rebon Shrimp-Based Koya Powder in the intervention group with a significant value of P 0.003 <0.05. There were significant differences in serum albumin levels before and after consuming the Supplementary Feeding of Rebon-based Koya Shrimp in the Intervention Group with a significant value of P 0.003 <0.05. There is a significant difference in hemoglobin levels before and after consuming the Supplementary Feeding of Rebon Shrimp-based Koya Powder in the intervention group with a significant value of P 0.002 <0.05

4. There was a significant difference in serum protein levels before and after the intervention in the control group with a significant value of P 0.003 <0.05. There was no significant difference in serum albumin levels before and after intervention in the control group with a significant value of P 0.767 >0.05. There is a significant difference in hemoglobin levels before and after the intervention in the control group with a significant value of P 0.002 <0.05

5. There was a significant difference between the Control and Intervention Groups with a significant value of P 0.000 <0.05

Abstract

Leprosy is an infectious disease which is a national public health problem, because several regions in Indonesia have a high prevalence rate. There were 17,012 new cases of leprosy in Indonesia in 2010, consisting of 13,734 cases of Multi Basiler and 3,278 cases of PausiBasiler with a Newly Case Detection Rate (NCDR) of 7.22 per 100,000 population. The number was recorded as many as 20,329 cases with a prevalence of 0.86 per 10,000 population.

In Indonesia, there are 12 provinces that still have leprosy rates above one person per 10,000 population, including the Province of Nangro Aceh Darussalam (1.51), South Kalimantan (1.07), East Java (1.67), North Sulawesi (2.57), Central Sulawesi (1.17), South Sulawesi (2.02), Southeast Sulawesi (1.21), Gorontalo (3.62), NTT (1.17), North Maluku (9.51), Maluku (3.47), and Papua (4.62).

This study aims to see the risk factors for leprosy in children aged 5-14 years in Sorong City, West Papua Province. This type of research is a case control study and the population is children 5-14 years old in Sorong City with a sample of 54 respondents. The research data were analyzed using SPSS 16. Data analysis used the Chi-Square test.

The results showed that the socioeconomic level p (0.000) < sig (0.05) and (OR) = 13.600 (> 1 = risk risk) history of home contact p (0.000) < sig (0.05) and the odd ratio value (OR) = 35,714 (> 1 = risk risk) associated with the incidence of leprosy in children aged 5-14 years in Sorong City, while education p (0.569)> sig (0.05), parent’s occupation p (0.766)> sig (0, 05), personal hygiene p (0.136)> sig (0.05) is not a risk factor for the incidence of leprosy in children in Sorong City.

It is recommended that parents increase knowledge about leprosy transmission by seeking information from both health workers and the mass media, as well as the public who can actively participate in supporting government programs and efforts to prevent leprosy.

Keywords: Risk Factors, Leprosy in Children, West Papua.

Introduction

Leprosy or also known as leprosy is a chronic disease caused by Mycobacterium leprae. This disease is still a health problem in some developing countries.

Leprosy is a chronic disease that attacks nerves edges, skin and other body tissues and can cause permanent disability. Leprosy is a chronic disease that attacks nerves edges, skin and other body tissues and can cause permanent disability.

According to the World Health Organizations (WHO), leprosy is classified into 2, namely: type PB (Pausibacillary) and type MB (multi bacillary). As of March 2013, there were 189,018 cases recorded, and the number of new cases in 2012 was 232,857 cases. There were 17,012 new cases of leprosy in Indonesia in 2010,
consisting of 13,734 cases of Multi Basiler and 3,278 cases of PausiBasiler with a Newly Case Detection Rate (NCDR) of 7.22 per 100,000 population. The number of registered cases was 20,329 cases with a prevalence of 0.86 per 10,000 population.4.

There are 12 provinces in Indonesia that still have leprosy rates above one person per 10,000 population. These provinces are NAD (1.51), South Kalimantan (1.07), East Java (1.67), North Sulawesi (2.57), Central Sulawesi (1.17), South Sulawesi (2.02), Southeast Sulawesi (1.21), Gorontalo (3.62), NTT (1.17), North Maluku (9.51), Maluku (3.47), and Papua (4.62) 2.

The indicators used in leprosy are the proportion of MB leprosy and the proportion of children with leprosy (less than 14 years) among new sufferers, which shows the main source and level of transmission in the community.

Provinces with the highest proportion of MB leprosy in 2015 were Bengkulu, Central Kalimantan (100%), Lampung (94.34%) and Gorontalo (91.03%). Meanwhile, the proportion of children leprosy in the same period is around 10% - 12%. Provinces with the highest proportion of leprosy in children are West Papua (30.82), Papua (23.62%), and North Maluku (19.49%) 6.

The proportion of children aged less than 14 years who suffer from leprosy is one of the indicators of the success of the leprosy eradication program, where this figure can be used to see the current state of transmission and estimate the need for medicine. Based on these problems, researchers are interested in knowing the risk factors associated with the incidence of leprosy in children aged 5-14 years in Sorong City, West Papua Province.

**Subjects and Method**

**Types of Research:** The type of research used is an analytical study with a case control study approach. To determine the estimation of the size of the risk factors for disease incidence, it is determined using the Odds ratio (OR) value.

**Research Sites:** This research was conducted in the City of Sorong, West Papua in October - November 2017.

**Sample:** From the study population selected as the sample of this study with the following inclusion and exclusion criteria15,16.

**Research Results**

1. **Overview of the Research Location:** Sorong City is an integral part of the province of West Papua which consists of 8 districts and 1 city. The city of Sorong is located below the equator, between 1310-51 east longitude and 00-54 south latitude. The city of Sorong has an area of 1,105 km2 with geographic boundaries as follows:
   a. The west is bordered by the Dampir Strait, Raja Ampat Regency
   b. In the north, it is bordered by Makbon District, Sorong Regency and Sagawin Strait, Raja Ampat Regency
   c. In the east, it is bordered by Makbon District, Sorong Regency and
   d. In the south, it is bordered by Aimas District and Salawati District, Sorong Regency

Which administratively is divided into 6 districts and 31 sub-districts 2011 data on the condition of health workers in the city of Sorong for labor84 Doctors and 168 Paramedics (nurses, pharmacists, midwives, nutritionists, and others). Sorong City Health Facilities and Infrastructure for Government Hospitals 1 and Private Hospitals 5, Puskesmas 6, Puskesmas Assist 29, and Medical Centers 5.1

**Univariate Analysis:** Univariate analysis is analyzing the data to be tested, namely each independent variable and dependent variable then distributed into a frequency distribution table. The specific data are as follows:

1. Frequency distribution of respondents based on gender (table 4.1). Based on these data, it is known that of the 54 respondents the most were male, namely 35 people (64.8%) while women were 19 people (35.2%).
2. Frequency distribution based on the age of the respondents (table 4.2). Based on table 4.2, it can be seen that the frequency distribution of respondents is known that of the 54 respondents, the maximum age was 10-14 years, namely 34 people (63.0%), while the ages of 5-9 years were 20 people (37.0%).
3. Distribution of respondents based on the level of education of parents (table 4.3).
Based on table 4.3, it can be seen that the frequency distribution of respondents based on the education of the parents of 54 respondents is mostly elementary, junior high school, namely 35 people (64.8%), while SMA, PT is 19 people (35.2%).

4. Distribution of respondents based on the Socio-Economic Status of People (table 4.4) Based on the economy of the parents of 54 respondents, the most were <UMP Sorong, namely 34 people (63.0%) while> UMP Sorong was 20 people (37.0%).

5. Distribution of respondents based on parents’ occupation (table 4.5) Based on the work of parents, it is known that of the 54 respondents, at most> 8 hours a day, namely 38 people (70.4%) while <8 hours a day, namely 16 people (29.6%).

6. Distribution of respondents based on Personal Hygiene (table 4.6) Based on personal hygiene, from 54 respondents the most bad was 38 people (70.4%) while good ones were 16 people (29.6%).

7. Distribution of respondents based on household contacts (table 4.7) Based on table 4.7, it can be seen that the frequency distribution of respondents is known that of the 54 respondents at most there were household contacts, 32 people (59.3%) while there were no household contacts, namely 22 people (40.7%).

8. Distribution of respondents based on the incidence of cases (table 4.8) Based on table 4.8, it is known that the frequency distribution of respondents based on the incidence of leprosy from 54 case group respondents is 27 people (50.0%) while the control group is 27 people (50.0%).

**Bivariate analysis:** Bivariate analysis was carried out to determine the relationship between each independent and dependent variable to see the relationship between the independent variable and the dependent variable.

1. **Sex relationship with the incidence of leprosy in Sorong City, West Papua:** Chi-square test results obtained p value (1.000)> sig (0.05) so that Ho is accepted. This means that it can be known, but because the value of the odds ratio (OR) = 1.176 (> 1 = risk), this means that male respondents have 1,176 times the risk of getting leprosy compared to female respondents.

</tbody>
</table>

2. **Relationship between Age and the Incidence of Leprosy in Children:** The results of the chi-square test obtained p value (0.788)> sig (0.05) so that Ho was accepted. This means that it can be seen that there is no relationship between age and the incidence of leprosy. The odds ratio (OR) = 1.375 (> 1 = risky), this means that respondents aged 5-9 years have a 1.375 times risk of getting leprosy compared to respondents aged 10-14 years.

<table>

3. The relationship between the socioeconomic level of parents and the incidence of leprosy: Chi-square test results obtained p value (0.000) < sig (0.05) so that Ho is rejected. This means that it can be seen that there is a relationship between the economy of the parents and the incidence of leprosy. The odds ratio (OR) = 13.600 (> 1 = risky), this means that respondents with the economic status of the parents < UMP Sorong have a risk of 13.600 times for getting leprosy compared to respondents with the economic status of parents ≥ UMP Sorong.

4. The relationship between education of the respondents’ parents and the incidence of leprosy: Chi-square test results obtained p value (0.569) > sig (0.05) so that Ho is accepted. This means that it can be seen that there is no relationship between parental education and the incidence of leprosy. Odd ratio (OR) = 1.633 (> 1 = risky), this means that respondents with elementary, junior high school parents’ education have a 1.633 times risk of getting leprosy compared to respondents with high school parent education, PT.

5. The relationship between personal hygiene of respondents and the incidence of leprosy: The results of the chi-square test obtained p value (0.136) > sig (0.05) so that Ho was accepted. This means that it can be seen that there is no relationship between personal hygiene and the incidence of leprosy. Odd ratio (OR) = 3.025 (> 1 = risky), this means that respondents with poor personal hygiene have 3.025 times the risk of getting leprosy compared to respondents with good personal hygiene.

6. Home contact relationship with leprosy: Chi-square test results obtained p value (0.000) < sig (0.05) so that Ho is rejected. This means that it can be seen that there is a relationship between contact history and the incidence of leprosy. The odd ratio (OR) value = 35,714 (> 1 = risky), this means that respondents with a history of household contacts have a 35,714 times risk of getting leprosy compared to respondents with no history of household contacts.

Discussion

1. The relationship between sex and the incidence of leprosy: Chi-square test results obtained p value (1.000) > sig (0.05) so that Ho is accepted. This means that it can be known, but because the value of the odds ratio (OR) = 1.176 (> 1 = risk), this means that male respondents have 1.176 times the risk of getting leprosy compared to female respondents.

Sex differences in the incidence of leprosy cannot be ascertained, basically leprosy can affect everyone, but men are more affected than women, with a ratio of 2:1, although there are some areas that show more female sufferers. The results of this study are in accordance with the opinion of Marwali Harahap which states that leprosy can attack everyone. Men are more affected than women with a ratio of 2:1.

2. The relationship between the age of the respondents and the incidence of leprosy: The results of the chi-square test obtained p value (0.788) > sig (0.05) so that Ho was accepted. This means that it can be seen that there is no relationship between age and the incidence of leprosy. The odds ratio (OR) = 1.375 (> 1 = risky), this means that respondents aged 5-9 years have a 1.375 times risk of getting leprosy compared to respondents aged 10-14 years.

The incidence of a disease is often related to age. Chronic diseases such as leprosy are known to occur at all ages, ranging from infants to old age (3 weeks to
adults over 70 years). However, most of them are at a young and productive age.

The results of this study are in accordance with the results of research by Maria Christiana\textsuperscript{18} in Jepara Regency which states that there is no relationship between age at risk and the incidence of leprosy.

**The relationship between education and leprosy:**
Chi-square test results obtained p value (0.569)> sig (0.05) so that Ho is accepted. This means that it can be seen that there is no relationship between parental education and the incidence of leprosy. The odd ratio (OR) = 1.633 (> 1 = risky), this means that respondents with primary and junior high school parents have a risk of getting leprosy 1.633 times compared to respondents with high school parent education, PT.

3. **The socio-economic relationship between parents and the incidence of leprosy:**
Chi-square test results obtained p value (0.000) < sig (0.05) so that Ho is rejected. This means that it can be seen that there is a relationship between the economy of the parents and the incidence of leprosy. Odd ratio (OR) = 13.600 (> 1 = risky), this means that respondents with economic status of parents < UMP Sorong have a risk of 13.600 times for getting leprosy compared to respondents with economic status of parents ≥ UMP Sorong.

The results of the research in Makassar City, it is known that the majority of leprosy sufferers are from low economic groups. The weak socioeconomic condition can be a factor that worsens the development of leprosy. Economic status is a significant risk factor for the incidence of leprosy. Respondents with low economic status have a 41,889 times greater risk of suffering from leprosy than respondents with high economic status. The results of this study are in line with research in Tegal and Christiana Districts in Jepara, showing that economic status is statistically significant with the incidence of leprosy.

Economic factors also influence the needs of life, including food and health needs. If the need for healthy food is not met, it can weaken the immune system, so that it is easy to catch a disease if it gets infected. A person does not take advantage of existing health services, perhaps because there is not enough money to buy medicine, pay for transport and so on, this is in accordance with the opinion which states that leprosy occurs in someone, not easy so there is no need to be afraid. This depends on several factors, including socioeconomic conditions\textsuperscript{19-23}.

4. **The relationship between parents’ work and leprosy:**
The results of the chi-square test obtained p value (0.766) > sig (0.05) so that Ho was accepted. This means that it can be seen that there is no relationship between the work of parents and the incidence of leprosy. Odd ratio (OR) = 0.700 (<1 = protective), this means that the work of parents is not too risky with the incidence of leprosy.

</tbody>
</table>

The statistical test shows that there is a relationship between the type of work and the incidence of leprosy.

This is in line with the research which states that patients with heavy work (66.7%) are more vulnerable than patients with light work (33.8%). Work can be used to analyze any possible risk of developing disease.

5. **The relationship between personal hygiene and the incidence of leprosy:**
The results of the chi-square test obtained p value (0.136) > sig (0.05) so that Ho was accepted. This means that it can be seen that there is no relationship between personal hygiene and the incidence of leprosy. Odd ratio (OR) = 3.025 (>1 = risky), this means that respondents with bad personal hygiene have 3.025 times the risk of getting leprosy compared to respondents with good personal hygiene.
The results of research by Indriani, et al. in the work area of the Kunduran Health Center, Blora, show that there is a relationship between personal hygiene and the incidence of leprosy. It is concluded that respondents who have poor personal hygiene are not necessarily a risk factor for leprosy. Respondents who had bad personal hygiene had a 5,333 times greater risk of getting leprosy than respondents who had good personal hygiene. This shows personal hygiene risk factors associated with leprosy. The results of the research by NisaAmira, et al. show that there is a relationship between body and hair hygiene and the incidence of leprosy in children in Pasuruan in 2014-2015.

The risk of people with a history of household contacts for contracting leprosy is 15,127 times greater than those with no history of household contacts and this is significant. Contact history is a history of a person who has had contact with a person with leprosy, either at home or not at home. The source of leprosy transmission is whole leprosy originating from leprosy sufferers, so leprosy transmission is easier if there is direct contact with leprosy sufferers.

Based on the results of the statistical test, the OR obtained was 15,127 at 95% CI 4,572 - 50,056, meaning that the risk of people with a history of household contacts to contract leprosy was 15,127 times greater than those with no history of household contacts and was significant.

### Research Limitations:

**Limitations in this study include:**
1. Researchers only use 1: 1 small control due to limited costs, time, and energy in data collection
2. Some respondents can only be met at certain hours, so the researcher adjusts the visiting time

**Weaknesses of Research:** In the variable length of contact, only research was conducted on the respondent’s family member who was diagnosed with leprosy. This does not rule out the possibility that the neighbors around the respondents who are also diagnosed with leprosy, especially the multibacillary type who have not received treatment, can become a source of disease transmission.
a. There were some respondents who were embarrassed when they met the officers because this disease was still perceived in the community as a curse disease so that an emotional approach was needed.

**Conclusion**

Based on data analysis from the results of research that has been done in Sorong City, it can be concluded that

1. Parents’ socio-economic factors and a history of household contact are risk factors associated with the incidence of leprosy in children aged 5-14 years in the city of Sorong, West Papua Province.

2. Factors of gender, age, education of respondents, personal hyphenation, work of parents, are not risk factors associated with the incidence of leprosy in children aged 5-14 years in the city of Sorong, West Papua Province.

**Suggestion:**

1. Based on the results of this study, there are several suggestions that researchers can convey, namely: Sorong City Health Office In preventing the occurrence of leprosy both in Sorong City, it is hoped that there will be good cooperation between health agencies, especially in increasing the efforts of the Leprosy Eradication Program.

2. The Community: The results of this study are expected to be used as knowledge about the risk factors for the incidence of leprosy so that people are more aware of the risk factors for the disease, so that it is hoped that they can follow up and participate in efforts to prevent and control leprosy.

3. To further researchers: This research still has many shortcomings, it is hoped that further researchers should add research variables, such as health services, attitudes.

Effectiveness of the Hatam Language Booklet on Family Knowledge and Attitudes About TB on Children in Warmare District, Manokwari Regency

Ivonne Junita Fabanjo1, Yayuk Nuryanti1, Anwar Mallongi2

1Lecturers of Poltekkes Kemenkes Sorong, 2Professor of Environmental Health Department, Faculty of Public Health, Hasanuddin University, Makassar

Abstract

Lack of public understanding regarding the symptoms of tuberculosis(TB) and its relevance to the risk of getting TB, makes TB cases difficult to detect in Indonesia. Increasing knowledge about TB is an important component of a TB control strategy. Patient and family knowledge will improve prevention behavior and medication adherence. One way to increase knowledge is through promotion or health education. The purpose of this study was to determine the effectiveness of the Hatam language booklet on family knowledge and attitudes about TB in children in Warmare District, Manokwari Regency, West Papua Province. This study used a Quasi Experiment design with Pre-Post test without control group involving 50 families with toddlers who live in Warmare district. Data were collected using a knowledge and attitude questionnaire given before and after education using the Hatam language booklet. Data analysis used the Wilcoxon test. Result, There is a significant difference which indicates that the mean score of knowledge and attitudes before and after the implementation of the Hatam Language Education Booklet has increased by 39.80 and family attitudes have increased by 6.98, the p-value is 0.000 (p <0.05). in conclusion, Health education using booklets and a cultural approach effectively increase public knowledge and attitudes

Keywords: Language Booklet, Family Knowledge, Attitudes About TB.

Introduction

Tuberculosis (TB) is a contagious disease that is transmitted through the air and is one of the top ten causes of death12. The five countries that have the biggest burden of tuberculosis are India, Indonesia, China, the Philippines and Pakistan and there are also challenges that must be faced and become a concern, namely the increasing cases of MDR-TB, TB-HIV, TB with DM, TB in children and other vulnerable communities3.

WHO defines High Burden Countries (HBC) for TB based on three indicators, namely Tuberculosis, Tuberculosis with HIV, TB/MDR. There are 48 countries on the list. One country can be included in one of the lists or all three, Indonesia together with 13 countries, are included in the HBC Indicator for the three categories, which means that Indonesia is experiencing major problems and challenges in facing the TB problem6.

In 2016 an estimated 67 million children with Latent TB, and 70 - 80% suffer from pulmonary TB, and the rest is extrapulmonary TB. Based on the WHO roadmap report to stop TB in children and adolescents in 2018 shows that an estimated 1 million children are infected with TB every year and 233,000 deaths of children aged 0-14 years in 2017, 80% of deaths occur in children under 5 years, 96% do not get treatment services4 and 25,000 children will develop into Multi Drug Resistant TB every year10.

In Indonesia, the proportion of TB cases in children who are notified based on the 2018 Indonesian health profile is 10.08%, one of the TB problems in children in Indonesia is diagnosis, which has been implemented since 2005 as the TB scoring system as a diagnostic approach, which is a problem not all health facilities have Tuberculin Test and Thorax Photo facilities, these two indicators are contained in the scoring system, which cause underdiagnosis of TB in children, another problem is the increasing number of drug-resistant TB cases in adults which is a source of transmission for children 6,3.
Research conducted by Faradis and Indarjo on the implementation of Permenkes number 67 of 2016 policy for tuberculosis control shows that of the 4 indicators in policy implementation and there are 2 indicators that have not been optimally implemented, namely policy resources that have not been fully met and a lack of community support in TB control. Increasing knowledge about TB is an important component of a TB control strategy. Patient and family knowledge will improve prevention behavior and medication adherence. One way to increase knowledge is through promotion or health education. Health education can be delivered in various health media, both electronic and non-electronic, one of the media that is often used because it is interesting and simple is made in the form of a pocket book or booklet.

Based on data from the Eradication and Prevention of Infectious Diseases, West Papua Province, the total number of TB cases treated and reported in 2018 was 2180 cases and especially in Manokwari district itself, amounting to 798 cases of which Warmare District is an area of Manokwari Regency.

Materials and Method

The research design used a Quasi Experiment with Pre-Post test without control Group which looked for the effectiveness or influence between variables, namely the Effectiveness of Hatam Language Booklets on Family Knowledge and Attitudes about TB in Children in Warmare District, Manokwari Regency, where knowledge and attitudes were measured before and after education was given. This research was conducted from October to November. Respondents were given a pre-test questionnaire to assess knowledge of pulmonary tuberculosis. Then the intervention was carried out to provide education using hatam language booklet which was also given to the respondent and after being given the intervention, a measurement was carried out to determine the respondent’s knowledge and attitude. The number of respondents involved in the study amounted to 50 people. Before the data analysis was carried out, the data normality test was carried out with the data normality test that will be used in this study is the SaphiroWilk test because the sample size was 50 respondents and the results of the data normality test showed p value <0.05 so it can be concluded that the data distribution was not normal. differences in knowledge and attitudes before and after the intervention using the Wilcoxon Test.

Results

This study involved 50 respondents who are families who have children under five and there are family members who suffer from tuberculosis.

a. Respondent Characteristics

</tbody>
</table>

The mean score of knowledge before and after the implementation of the Hatam Language Education Booklet has increased by 39.80 and family attitudes have increased by 6.98. The results of further analysis obtained the p-value of 0.000, which means that there is a significant difference in the average score of family knowledge and attitudes before and after being given the Hatam language education booklet.

Discussion

Characteristics of respondents in this study include age, gender, occupation and education. Respondents in this study were families who have toddlers and one of their family members was diagnosed with positive pulmonary tuberculosis with an age between 20 to 55 years, all respondents were women and most of them did not have occupation, the respondents had the most education level with basic education level and the lowest with the lowest level of education. middle education.

Differences in knowledge and attitudes of families before and after the application of the Education Booklet. Knowledge

Based on the results of the statistical test, it shows that there is a significant increase in the mean score of knowledge before and after education. One of the efforts to deal with pulmonary tuberculosis is health promotion to increase public knowledge using various method, health education through the media, because the media makes it easier to receive health messages for the public or people with pulmonary tuberculosis.

This research is in accordance with other research conducted on the island of Madura by using a pictorial pocket book in Madura language which shows an increase in knowledge for patients with pulmonary tuberculosis and supervisors taking medication. Another study was also carried out in nine cities in India by Hudart et al which assessed how knowledge about tuberculosis and preventive behavior during Tuberculosis treatment, the results of the study were that knowledge, education, and equality of language used increase knowledge and adherence to preventive behavior. infection.

In general, knowledge and attitudes regarding Tuberculosis vary across countries from an understanding
of the causes of infection to the belief that it is the evil eye, and from a supportive viewpoint of stigma against the disease and patients. Adequate knowledge and positive attitudes about tuberculosis patients greatly contribute to improving health service seeking behavior. Knowledge, individual attitudes of the family and society depend on the actualized patterns of the family, the level of individual maturity and development, the knowledge obtained, the health and culture of the local community. Researchers argue that by taking a cultural approach by providing education and information about pulmonary tuberculosis in children can increase knowledge and positive attitudes and medication adherence to patients.

**Attitudes:** Based on the results of the statistical test, it shows that there is a significant increase in the mean score of attitudes before and after education. Attitude is a mental and neural condition, which is obtained from experiences that direct and dynamically influence individual responses to all related objects and situations, attitudes have cognitive, affective, and conative components. In Ethiopia shows the importance of health education interventions to increase knowledge and awareness and positive attitudes to prevent and control tuberculosis. The positive or negative attitude of society towards Tuberculosis is shaped by educational, knowledge and social status. According to the researchers’ assumptions, a positive attitude is formed from good knowledge and to be able to use method or ways to provide education is important to increase knowledge and attitudes about Tuberculosis.

**Conclusion**

1. Respondents in this study were families who have children under five and family members diagnosed with tuberculosis with an average age of 37.42, the lowest was 20 years and the highest was 50 years. Respondents have the highest level of education with basic education level and the lowest with secondary education, all respondents are female and most of them do not work.

2. The family knowledge and attitudes score was lower before the implementation of the Hatam language book when compared to after the implementation of Education

Abstract

Purpose: This study aims to determine the political commitment of the Enrekang District Government in overcoming the problem of stunting during the COVID-19 period.

Method: This study uses a qualitative research method with a type of case study research. This research was conducted in Enrekang District in May - July 2020. The informants in this study were 13 people who were selected by purposive sampling technique. Data collection was carried out by in-depth interviews, document review, and observation.

Results: The results of this study indicate that the COVID-19 pandemic has an impact on the political commitment of the Enrekang local government in handling stunting. The enactment of Large Scale Social Restriction (LSSR) and refocusing on the budget caused several programs to experience budget cuts. On the other hand, the provision of latrines for sanitation and hygiene absorbs the largest amount of funds.

Conclusions: The COVID-19 pandemic has an impact on the political commitment to handling stunting due to the enactment of Large Scale Social Restriction (LSSR) and budget refocusing.

Keywords: Political commitment, stunting, COVID-19, enrekang district.

Introduction

The problem of stunting is no less important than Covid-19. Stunting is when a child has a low height for their age, usually due to malnutrition, repeated infections, and/or poor social stimulation. The World Health Organization categorizes children who are stunted as those whose height is lower than average for their age, and at least two standard deviations below the WHO’s Child Growth Standards Median.¹ In addition to affecting the golden age of growth, the impact of stunting is expected to continue into adulthood. Currently, globally there are still 149 million children under the age of 5 who suffer from stunting.² In Indonesia, more than 2 million children suffer from malnutrition and more than 7 million children in under 5 years of age are stunted.³ This condition requires political commitment from the central and local governments to show seriousness in food and nutrition interventions in their policy agendas. Lack of political commitment has been identified as the main reason for the low priority received by food and nutrition interventions.⁴

As the COVID-19 coronavirus pandemic begins to spread across the world, many countries including Indonesia have restricted movement as a way to slow the spread of the virus and give their health systems...
more time to prepare for the influx of patients. Indonesia chooses Large-Scale Social Restrictions (LSSR) to prevent transmission of COVID-19. However, countermeasures for COVID-19 such as self-isolation, and social distancing can lead to poor management of key risk factors such as unhealthy diet and physical activity, and limited access to preventive care in primary care settings.

Also, economic instability, limited travel, and access to health care services delay vaccination schedules, and the closure of educational facilities further exacerbates the poor health conditions for children, especially in low and middle income countries. The main sectors that are at risk of collapse or reduced efficiency after COVID-19 include food systems, income and social protection, services health care for women and children, as well as services and access to clean water and sanitation. Moreover, the refocusing of the budget, including programs to reduce stunting, led to a reduction in the budget for various stunting management activities in stunting-prone areas. This could have an impact on the performance of officers and cadres in dealing with stunting.

This study uses qualitative research on political commitment in handling stunting during the COVID-19 epidemic.

This study aims to determine the political commitment of the Enrekang District Government in overcoming the problem of stunting during the COVID-19 period.

Study design: A qualitative methodology was used to explore the political commitment of local governments in handling stunting before and during the Covid-19 pandemic. The design is flexible and approves of the exploration and understanding of meanings that some individuals or groups of people perceive as stemming from social or humanitarian problems.

Instrument Development: The development of an instrument based on the main literature review on political commitment and a national strategy for reducing stunting in Indonesia (NTAPR), then developed a semi-structured interview guide. This guide focuses on the components of political commitment to policies and programs, the size of the budget, and operational/implementation commitments for stunting in Enrekang District. These guidelines were subjected to validation and reliability assessments before data collection. Cumulative validation is used as a cross-reference method whereby researchers use accessible literature to match findings. Based on the nature of the data and the availability of resources, this study followed a cumulative validation process, in which the cross-reference method was combined between the available literature and findings. The reliability of the study was guaranteed by keeping records of the face-to-face interviews of the research informants. This guide was piloted in a local government agency, then modified as needed before being used for research.

Study setting: The research was conducted in the rural area of Enrekang Regency, South Sulawesi Province, Indonesia. Enrekang District is the highest stunting area in South Sulawesi province with around 43.7% in 2019 and is in the category of 100 priority districts/cities for stunting in Indonesia.

Informants and inclusion criteria: The research informants were selected based on the purposive sampling technique. The criteria for informants in the study were people or officials within the scope of the Enrekang District government who had the authority and were directly involved in making policies related to the handling of stunting problems, and those who were directly involved in implementing stunting handling activities. A total of 13 informants were selected, namely 3 key informants, 2 expert informants, and 8 other informants ($n = 13$).

Sampling, data collection, and processing: Informants were selected using a purposive sampling method, based on presumptions about the required sample characteristics. Each interview lasts 30 to 45 minutes. Research questions were raised and informants were given the freedom to express additional views and comments. All interviews were audio-recorded and the principal investigator took additional field notes. The accuracy and consistency of the interviews were verified by listening to the recordings. The first author analyzes the transcript line by line, which is read repeatedly and then analyzed thematically for its content. Research co-authors verified the themes and content that emerged.

Results

The political commitment of the Regional Government of Enrekang District to handling the stunting program before and after Covid-19, based on the results of this study includes three dimensions, namely institutional commitment (policies and programs),
budget commitment, and operational/implementation commitment, as described below.

1. Institutional Commitment:

a. Conditions before COVID-19: Stunting activities have been adopted into the Regional Medium Term Development Plan (RMTDP) according to the vision and mission of the elected regents and deputy regents for the 2018-2023 period, as recognized by the following key informants:

“... from the vision and mission of the elected Regent and Deputy, it has been adopted into the RMTDP where the issue of stunting is a priority for Enrekang Regency ... because it has become an indicator in the RMTDP ... starting in 2018 ... because the issue of stunting at that time has become a national issue”, Deputy Regent of Enrekang) - KI-1

In addition to specific stunting activities, stunting-related activities have also been adopted into regional development planning documents, this is because stunting reduction is a cross-sectoral activity, as explained by the following informants:

“... Stunting activities have been adopted into the 5-year development planning document... in the form of cross-sectoral activities... stunting prevention has become a priority in Enrekang Regency. ... ”(RH, 34 Years, Chairman of Commission III DPRD Enrekang) - KI-2

“... stunting issues are the main performance indicator for Enrekang District ... stunting is also a national program ... and Enrekang is designated as a stunting locus ...” (RD, 48 years old, Secretary of Regional Development Agency) - KI-3

Stunting activities and indicators have also been adopted into the Strategic Plan, including the Health Office and the Food Security Service, as shown in the following interview:

“... in the Health Office strategic plan there are already special activities for stunting ...” ... in the form of maternal and child health, malnutrition, immunization, exclusive breastfeeding, health promotion, clean water and sanitation ... “(ST, 53 Years, Head of Health Service) - KI-4

“... in the 2018-2023 official strategic plan, food security has adopted activities that support the acceleration of stunting reduction ... as a performance indicator of the prevalence of food consumption sufficiency and the proportion of the population with a minimum calorie intake below 1,400 kcal/capita/day ... ”, (SY, 55 Years, Head of Food Security Service) - KI-5

Enforcement of Large-Scale Social Restrictions (LSSR) such as school and work vacations; restrictions on activities in public places or facilities; restrictions on transportation modes, have an impact on handling stunting during the COVID-19 pandemic due to self-isolation, and social distancing. This has resulted in inadequate health services. For example, the Integrated Service Post and Community Health Center services, as explained by the following expert informant (EI).

“... considering that Posyandu is no longer operating and health workers at the Puskesmas are not spared the impact of COVID-19. This situation causes the monitoring of children’s development and development activities to stop early in life”. (EI-1; EI-2)

Economically, PSBB has an impact on job losses and reduced income, which causes a decrease in people’s purchasing power for nutritious food, and increases in poverty. Review the following expert informants.

“On the production side, transportation, storage and sale of food are also disrupted. As a result, nutrition problems in vulnerable groups such as pregnant women and toddlers will increase along with the difficulty of their access to nutritious food.” (EI-2)

“Pregnant women and children under five will experience problems in health and nutrition services, which are essentially stopped by limited access due to the focus of services for Covid-19” (EI-3)

2. Budget Commitment: Refocusing (reallocation and cutting) of the budget of the Enrekang District Government can affect stunting management activities, especially during the COVID-19 pandemic.

a. Reallocation of specific activities for stunting due to Covid-19: Based on the Regulation of the Regent of Enrekang Number 26 of 2020 concerning the Elaboration of Amendments to the District Regional Revenue and Expenditure Budget (RREB). In 2020, data on changes to the budget for special stunting activities are obtained in 4 Regional Apparatus Organizations (RAO) as seen in Table 1,
Table 1. Reallocation of Specific Activities Budget for Stunting due to COVID-19

</tbody>
</table>

There were 18 supporting activities for stunting, 12 activities experienced a reduction in funds, 5 activities did not change the budget, the remaining 1 activity actually increased the budget, namely the provision of latrines, as explained by the following informant.
“... out of 18 activities supporting stunting, 12 of them experienced a budget decline of IDR 457 billion (2.4%). There are 5 activities whose budgets are fixed.

There is 1 activity that has experienced a significant increase in the budget, namely the community sanitation program (provision of latrines) at the Housing, Settlement and Spatial Planning Agency from IDR 2.3 trillion to Rp. 3.2 trillion, an increase of IDR 840 thousand (35.9%). (NM, 41 Years, Head of BPKAD) – KI– 6)

c. Operational Commitment/Activity Implementation: Stunting policies and programs (before and after COVID-19) can be seen in Annex 1 Table 3. Based on the results of in-depth interviews with several informants, it was stated that the COVID-19 pandemic required adjustment of activities based on health protocols in the form of physical distancing.

“....Several cross-sectoral activities, such as stunting deliberations, coaching and mentoring, including monitoring in the locus village, were still implemented but limited the number of participants. Even the training of stunting holders in the district was abolished due to budget reduction” (I-10; --------)

Planning before and after COVID-19 took place, several stunting management program activities did not change but participants were limited according to health protocols. In addition, there was a reduction in incentives for Community Empowerment Cadres (CEC) as a result of refocusing the APBD so that it was estimated that they could reduce their performance. Training for stunting program holders at the district and health center levels was apparently omitted.

Discussion

The political commitment of the local government of Enrekang District in handling stunting can be discussed in three dimensions including institutional commitment, budget commitment, and operational/implementation commitment of stunting before and during the COVID-19 pandemic.

Institutional Commitment: Institutional commitment is a rhetorical commitment converted into a substantive policy infrastructure including institutions responsible for coordinating action, adoption of enabling legislation, policies and policy instruments commensurate with the severity of the problem and the commitment of mid-level bureaucrats who are responsible for coordinating action.11

The COVID-19 pandemic that has hit the world including Indonesia has had an impact on the handling of stunting in high-risk areas such as Enrekang District where the stunting rate reached 47.5% in 2019.15

The enactment of Large-Scale Social Restrictions (LSSR) which close schools and workplaces, restrictions on social activities and public facilities, restrictions on transportation modes, and even the movement of people from one city to another. This has an impact on decreasing family income, disruption of food stocks, barriers to access to health services.17-18 Increases the risk of all forms of malnutrition, even maternal and child mortality.19 Without adequate intervention, it will interfere with early life nutrition and have the potential to disrupt children’s growth and development and have a lifetime impact on the formation of basic human capital.20 Reduced political commitment has been identified as the main reason for the low priority received by government food and nutrition interventions relative to the high disease burden caused by malnutrition.11

The Village Ministry has taken steps to break the chain of spreading the Coronavirus into the village by holding the Village Cash Workforce Program (VCWP). Workers who are involved in the program will not place too much emphasis on workers’ abilities or skills.

The VCWP program will target workers who come from poor, unemployed, and underemployed families, as well as other members of marginalized communities.

Then, wages for workers will be given daily and in implementing VCWP, they must prioritize health protocols such as physical distancing and others.

Many programs have expanded their targets since the COVID-19 crisis hit. The Sembako Program that was given to 15.2 million people has now received 20 million recipients. The value also increased, from 150 thousand rupiahs to 200 thousand rupiahs.

Besides, the Family Hope Program (FHP), Direct Cash Assistance (DCAT), Pre-Employment Cards, discounted electricity rates, and credit payment relief for the informal sector was launched. The same is done in Ethiopia for food insecurity in the form of the Productive Safety Net Program aimed at providing emergency food assistance to 15 million people who are vulnerable to
food insecurity and are considered important for the narrative of reducing stunting in the country.21

Meanwhile, the Unconditional Cash Transfer (UCT) amount was around $ 42 USD per month for 3 months per beneficiary family. The same was done in Peru22 and the Kyrgyz Republic23, using a successful financial incentive-based model as a means of providing a social safety net to reach marginalized and vulnerable populations.

**Budget Commitment**: The budget commitment in dealing with nutrition problems is public expenditure, for example the percentage of the government budget that is spent on nutrition/food issues.10 Budgetary commitment is an allocation of resources allocated to a specific problem relative to a certain benchmark.11

The impact of COVID-19 has forced the Indonesian government to refocus the health budget, including priority programs for handling stunting in the regions to prevent the spread of COVID-19. The results of this study indicate that the budget refocusing for specific stunting activities in Enrekang District (Appendix 1 Table-1) has an average reduction of 47.8%. Likewise, the budget for stunting support activities in Enrekang District (Attachment 1: Table 2) was reduced by 2.4% for 12 types of activities from 18 activities. In addition, there are 5 activities that do not change the budget which is more tangible as a Special Allocation Fund (SAF) such as the National Health Insurance (NHI), purchasing medical equipment, childbirth insurance, and community-based total sanitation.

But interestingly, from refocusing the stunting support budget, there was a drastic increase in the community sanitation program for latrine provision by 35.9% from IDR 2.3 trillion (US $ 161,207) to IDR 3.2 trillion (US $ 219,161). This illustration shows that refocusing the stunting support budget in Enrekang District is a reallocation of the focus of the community sanitation program for the provision of latrines. Based on the results of in-depth interviews, it was revealed that sanitation is one of the main triggers that contribute to increased stunting.

Yet according to Shekar M, et al. related to the increase in the annual cost scale for the period 2016-2025 which was carried out in 37 countries with a high prevalence of stunting, including Indonesia. The research focuses on a package of specific nutritional interventions that have been shown to be effective. The results of the study indicate that the 10-year budget needed to increase specific nutrition interventions is 49.5 billion dollars, to achieve this target current funding must increase from 2.6 billion to 7.4 billion on average per year. Reaching stunting targets is feasible but will require a large and coordinated investment in a supportive environment.24

**Operational/implementation commitment**: The results of the study revealed that monitoring of nutritional status by Community Empowerment Cadres (CEC) in villages affected by Covid-19 was due to a reduction in the regional government budget, in which the incentives for CEC, especially in remote and difficult to reach villages such as Enrekang District, the role of CEC is very effective in the community health education system as carried out by Ethiopian health extension officers (HEWs)21 exhibit models that are successful in mobilizing community health workers (CHWs; who receive basic and commodity training) to deliver vaccines, nutritional supplements, health and nutrition education, and even reproductive, maternal and newborn care.

What is interesting about the reallocation of the budget for stunting support activities (Appendix 1: Table 2) shows that the Enrekang Regional Government’s attention to the provision of latrines to meet adequate sanitation and hygiene is very important for the agenda for overcoming COVID-19 and other positive health impacts. Beal T et.al, reviewing the determinants of stunting in children in Indonesia, revealed that children from households with poor latrines and untreated drinking water were at higher risk of stunting.26 The commitment of the district government of Enrekang is in line with experiences in several other countries in creating a healthy environment by reducing open defecation and encouraging hygienic practices and has been linked to reducing stunting in Senegal25 and Ethiopia21 focusing on change. the behavior to create a village free of open defecation. These programs spark community desire for collective change by encouraging innovation and context-specific solutions while fostering a sense of community ownership. Community-Led Total Sanitation (CLTS) programs in sample countries such as Nepal have had an important impact on reducing stunting in childhood.

Reducing the budget for the development of promotional media and health education during the COVID-19 pandemic in Enrekang District, when schools and workplaces are closed, can hinder the
Community’s Clean and Healthy Behavior (CCHB) program, and reduce stunting, and prevent the spread of COVID-19. It is better to involve women’s groups and other health communities to communicate the best health practices in rural communities. Several countries, for example in reducing stunting, have demonstrated the potential use and impact of this mechanism on stunting reduction. Learning from their experience with Ebola, the CHW Senegal program has proven to be an effective mechanism for communicating health best practices to the public. The FCHV program in Nepal and the HEW in Ethiopia also have a very successful component of health and nutrition counseling. The Republic of Kyrgyzstan uses women’s support groups in the community as a means of keeping up-to-date with the health situation and sharing knowledge, and adaptable model for accelerating stunting reduction.

The results of in-depth interviews with experts and UNICEF estimates show that in the absence of timely action, the number of children who experience wasting or acute malnutrition under 5 years of age could increase globally by around 15 percent this year due to COVID-19. It is in this context that political commitment Regional and central governments need to rearrange strategies and priorities in handling stunting during the COVID-19 pandemic based on data.

**Conclusion**

The COVID-19 pandemic has an impact on the political commitment to handling stunting due to the enactment of Large Scale Social Restriction (LSSR) and budget refocusing. The low political commitment of the Local Government of Enrekang Regency can be seen from the reduction of incentives for monitoring the nutritional status of Community Empowerment Cadres (CEC), and reducing the budget for developing media for promotion and health education, which have an impact on the weak performance of cadres and health workers. In a situation of COVID-19 village cadres can do double duty to reduce the spread of COVID-19.

On the other hand, the reallocation of the accumulated stunting support budget on the provision of latrines shows a high political commitment to fulfill sanitation and hygiene to support stunting reduction.

**Acknowledgment:** We highly say thank you to the local government of Enrekang Regency who have given a permission to conduct this research.

Abstract

Bio-medical wastes are produced during the analysis of a patient, during healing process or vaccination to all animals while performing research and induced into humans by the fabrication or checking of biological samples, as per the guidelines in Schedule I, of the BMW rules, 2016 (AIIMS, 2020). The health care workers should be provided with proper guidance for the safe disposal of biomedical wastes. Especially rag workers are more involved in cleaning residential areas where hospitals are nearby. The awareness of mediwastes should be publicized more to the people in order to prevent from serious health hazards. The sources of mediwaste are elaborated in this review and flowcharts make the readers to easily gain knowledge of the sources and details about the category. There is various treatment method practiced in India but still residential clinics and hospitals should strictly abide by the rules and guidelines of World Health Organization (WHO). The precautionary measures and safe disposal of wastes are mentioned in this review focusing and creating awareness to the public.

Keywords: Health care system, biomedical waste, public awareness, treatment plans.

Introduction

Hospital systems play a vital role in producing medical waste. As per guidelines of WHO, states about precautionary measures for the biomedical waste to be disposed in a careful way for a healthy environment. Health care workers should possess an adequate knowledge for safe disposal of the waste. The hazardous and toxic waste materials produced from the hospitals which lead to spread of infections by improper disposal method. The government of India repeatedly believes in waste management by emphasizing the quote Reduce, Recycle and Reuse[1]. The medical waste should be treated initially in an ecofriendly manner rather than handling till the end point[2].

The microbes present in the waste products are easily penetrated inside an individual and causes harms in healthy bodies. The microbes may be a virus, bacteria; fungus, parasitic or even a tested animal waste can cause serious life threatening effects in humans. The safety level should be a serious concern especially in hospital workers and the cleaners which directly or indirectly affects the public[3].

Industrial waste are globally serious concern and been in media as water been contaminated, air is toxic and so many health concerns are in keen report and to the knowledge of public who mostly raises their voices for
industrial wastes but comparatively rather than industrial waste, medical wastes are more prevalent within the residential area and public was not aware of the toxicity and hazards caused by these wastes. Contamination of underground water by medical waste causes diarrhea, cholera, plague, hepatitis and so on[4].

The real challenge of biomedical waste causes immediate health effect compared with the industrial wastes. So, to overcome the effects World Health Organisation (WHO) has published the “Blue Book” in 2014 for the safe disposal of BioMedical waste[2]. Thus our research review focuses on the sources, types and categories, treatment and precautionary measures of the biomedical wastes which are causing hazards to the residential areas affecting the public health.

Sources of Biomedical Waste: Biomedical wastes possess both solid and liquid waste present in local bodies are categorized into primary, secondary and tertiary sources. The primary sources are given in figure 1. The secondary sources are local residential clinics, Ambulance services, close contact with patients, cosmetic clinics, paramedicals. The tertiary are household wastes, home care treatments, Education centers, funeral houses, Transports etc[5].

![Fig. 1: Primary sources of biomedical wastes](image)

Types of Biomedical wastes: The biomedical wastes are categorized into two types as harmful and harmless wastes. The harmless wastes are eco-friendly in nature and can be degraded in short span of time whereas the harmful wastes are classified based on the guidelines of WHO. These wastes are caused by microorganisms are referred as pathogenic wastes, human tissues and organs are categorized as Anatomical waste, mutagenic and carcinogenic chemical wastes such as alkaloids are cytotoxic wastes, heavy metal disinfectants are pharmaceutical wastes, blood and other fluid excretions are liquid wastes, radioactive wastes are radionuclide’s which possess genotoxic effect and used for imaging purposes. Prickly objects are also referred in common as sharps such as needles, broken glassware, glass vials, surgical knifes, capillary blood sample tubes for example blood sugar lancets etc[6].
**Categories of Biomedical waste based on color:** Hospitals can be found with different color of dustbins; now even Chennai corporation vehicles are fitted with different color dustbins. The color indicates in hospitals are yellow, red, blue and black or white. The yellow color wastes indicate for human tissues, organs, placentas at the time of delivery, animal wastes, chemical wastes. Red color indicates for contaminated recyclable waste e.g. Infectious Blood sample bags. Blue color indicates sharp objects like needles, tamper proof containers, punctures, leak proof etc and black or white color indicates for pharmaceutical wastes such as tablets, cardboard boxes.\(^7\)
Overview of Biomedical waste treatment method:

The waste products from these sources are efficiently treated by performing various method. They are

1. **Autoclaving**: Autoclaving is a steam sterilization method in which the infectious pathogens like bacteria, virus, fungi, spores are present in materials like forceps, blades, glassware’s are sterilized at 121°C for 20 minutes which kills harmful pathogens present in that material.

2. **Microwave**: This method is also similar to autoclave uses electromagnetic rays to produce heat and disinfect the materials. The advantage of using microwave in hospital is absence of liquid discharge and considerable volume reduces[10].

3. **Hydroclave**: This method is similar to autoclave but the difference is the vapor that is present inside the jacket and not into the vessel where the biomedical wastes are sterilized and therefore the vapor does not have a direct contact with waste. This facilitates the apparatus to retain the steam inside the boiler[9].

4. **Incineration**: Incineration is one mode of treatment method where high-temperature is produced due to arid corrosion process in which organic and explosive wastes are reduced to form inorganic, in explosive matter. Incineration technology is more useful where medical wastes cannot follow 3R’s (Reduce, Reuse and Recycle)[8].

5. **Pyrolysis**: It is a thermal method in which the biomedical wastes are burnt completely in the absence of oxygen at 800 °F. As a result of decomposition by thermal method the wastes are completely burnt and the result is to produce gases and charcoal.

6. **Encapsulation**: Encapsulation is the process in which the biomedical wastes are coated with inert materials like High-density polyethylene (HDPE) and polybutadiene as these chemicals are stable, stick to the waste, and resist biodegradation[11].

7. **Chemical Disinfectants**: The wastes to be shredded and small pieces of wastes are in direct contact with chemical agents such as mercuric chloride (HgCl₂), sodium hypochlorite (NaOCl), chlorine dioxide (ClO₂), peracetic acid (CH₃CO₃H), glutaraldehyde (C₅H₈O₂), quaternary ammonium compounds and disinfect the hazardous wastes[12].

Precautionary measures[13]:

1. Employees working on biomedical wastes should strictly wear gloves, goggles and masks.
2. Waste materials should be placed in appropriate bins with labels.
3. Treatment method should be strictly followed depending upon the category of biomedical wastes.
4. Segregated materials should be cleaned without any damage and spillages.
5. Sanitizers with 70% alcohol should be in hand to all biomedical waste workers.
6. Prickly objects should be handled with great care by wearing gloves without piercing the objects.
7. Broken materials like glasses, vials are to be cleaned with brooms and tongs.
8. Place contaminated PPE in closable, leak proof bags or containers for disposal or decontamination.
9. Wash hands frequently with soap and water.
10. Take bath after exposing to hazardous materials and get frequent medical attention.

Conclusion

Our review focuses on the manmade biomedical waste and its treatment plan are major demanding issues in the country. The rules & guidelines by Govt. of India should be more strictly followed as a matter of concern. To develop a healthy and environment safe practice each and every citizen should abide the rules and rag workers should be given adequate knowledge and awareness to keep the environment greener. The residents should also have interest in maintaining the hospitals and other laboratories for the safe disposal of biomedical wastes.

Abstract

The severe acute respiratory syndrome coronavirus 2 from the family of Coronaviridae is causing coronavirus disease. This is a zoonotic disease and identified first in the Hubei Province of China. In early 2020, this disease was announced as a global pandemic. The pandemic hit the nations undiscriminating their economic and development status. Tamil Nadu, a state of India is one of the most affected in the country. In spite of various precautionary measures in controlling the pandemic, the state recorded active cases of 18,881 as of 13th June 2020. With no defined treatment to cure the disease till date, the healthcare workers along with the collective support of various departments of the state are handling the situation with an aim to end the epidemic. Almost all the sectors such as finance, business, education, etc. were affected by the pandemic. This article discusses the current countermeasures for the infection, the impact on the state and suggests a few strategies to control the spread.

Keywords: SARS-CoV-2, COVID-19, Pandemic, Tamil Nadu, Epidemic, Strategies, Lockdown.

Introduction

The severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) is a new strain from the family of Coronaviridae which mainly targets the respiratory system of humans causing coronavirus disease (COVID-19). It was first discovered at the end of the year 2019 when a group of patients were admitted with reports of pneumonia, in the hospitals of Hubei Province of China. This disease is a zoonotic disease which means it is transmissible from animals to humans. This is more similar to earlier reported diseases like Severe Acute Respiratory Syndrome (SARS) and Middle East Respiratory Syndrome (MERS). Since it is genetically similar to SARS, it is name named as SARS-CoV-2 on 11th February 2020 by the International Committee on Taxonomy of Viruses (ICTV). The common symptoms of COVID-19 include fever, cough, sputum production, tiredness, anosmia and breathing difficulties[2,5,17]. In serious cases, this can cause pneumonia, kidney failure and even death. The symptoms of the disease appear after 5.2 days of the incubation period[2]. Patients with mild symptoms recover after a week, whereas patients with severe symptom cases due to alveolar damage caused by virus experience progressive respiratory failure leading to death. However, factors such as the patient’s age and immune system have a large impact of China. This disease is a zoonotic disease which means it is transmissible from animals to humans. This is more similar to earlier reported diseases like Severe Acute Respiratory Syndrome (SARS) and Middle East Respiratory Syndrome (MERS). Since it is genetically similar to SARS, it is name named as SARS-CoV-2 on 11th February 2020 by the International Committee on Taxonomy of Viruses (ICTV). The common symptoms of COVID-19 include fever, cough, sputum production, tiredness, anosmia and breathing difficulties[2,5,17]. In serious cases, this can cause pneumonia, kidney failure and even death. The symptoms of the disease appear after 5.2 days of the incubation period[2]. Patients with mild symptoms recover after a week, whereas patients with severe symptom cases due to alveolar damage caused by virus experience progressive respiratory failure leading to death. However, factors such as the patient’s age and immune system have a large impact
in recovering from the disease. In case studies, deaths are recorded in middle age and elderly patients with pre-existing diseases. COVID-19 disease has shown an unremitting capacity to infect the population of the world [3]. When the disease outbreak reached almost all the nations within a few weeks with the reported cases of 53,401, WHO declared the disease as a global pandemic on 11th March 2020. As on 13th June 2020, globally there are about 7.8 million COVID-19 active cases causing more than 4 lakhs deaths and 4 million recoveries. The pandemic hit the nations undiscriminating their economic and development status. Industrialized countries like the USA, Italy are not exceptions but the most affected.

The developing country like India is no exception for this global health emergency. The first COVID-19 positive case in India was identified on 30th January 2020 in the state of Kerala. As on June, 13th India ranks 4th worldwide and 1st in Asia for having the largest number of COVID-19 positive patients with active cases of 150,101 out of 55,07,182 samples tested [31]. Tamil Nadu is one of the most affected states in India. In Tamil Nadu, the first case of COVID-19 positive was identified on the 7th of March 2020. As on June 14, according to the Health and Family Welfare Department of the Government of Tamil Nadu, the state has identified 42,687 positive cases out of 691,817 persons tested. Tamil Nadu is at 3rd place in having the largest number of active cases (18,881) and 2nd place in the number of patients recovered (23,409) from the disease. Maharashtra and Delhi are having a greater number of active cases than Tamil Nadu [7]. Of the 38 districts of the state, the state capital Chennai is the most affected with active cases of 30,444 comprising 71% and 316 deaths of the infected patients as on 13th June 2020 [16].

**Control Measures:** COVID-19 is an influenza-like disease that is highly contagious. There is no definite treatment to date available for the treatment of COVID-19. Only supportive therapies available for COVID-19 are antibiotics for infection, mechanical ventilation system, administration of analgesic and antipyretic and maintenance of hydration. Some of the studies claimed that interferon-alpha and ribavirin to be showing synergistic effect in early stages and some studies suggested mycophenolic acid as monotherapy [19]. World Health Organization recommended extracorporeal membrane oxygenation (ECMO) to patients with refractory hypoxemia, treatment with convalescent plasma and immunoglobulin G delivered to the critical condition patients. Remdesivir has been reported to treat the first US case of COVID-19 successfully [13,14]. In order to prevent the transmission, WHO announced various infection prevention and control (IPC) strategies such as to wash the hands frequently using alcohol-based solutions, avoid the touching of nose, eyes, mouth, wearing of face masks, social distancing, use of disinfectants, etc [30]. This was seconded by the government of the state and public awareness through print and electronic media was made.

To decrease the impacts caused by the novel coronavirus and to reduce its transmission, state government along with the central government took various precautionary measures and various activities to control the disease spread. The Indian government has allotted 510 crore rupees to the state of Tamil Nadu to fight against the spread of disease. Earlier in February, Tamil Nadu has allocated 5.7% of its total expenditure on health in the state budget 2020-2021 This accounts for about 17,000 crores rupees which is greater than the average expenditure of 29 states of India. From the announcement of COVID-19 to be a disaster till June 4, the state government has allotted about 4,333 crore rupees. The planning in the state like most other states and nations was subjugated by measures to stop the spread of the virus. Since the identified cases had a travel history of infected nations, restriction on airports and temperature screening of the passengers was made. State government reports that more than 2.2 lakhs people have been screened at the airports. The passenger screening was extended to railway stations, bus stations and many public gathering buildings. And those showing symptoms were treated in hospitals. Humanoid robots are used in hospitals for servicing the infected patients. Followed by COVID-19 diagnosis screening and compulsory quarantine of people coming into the state was advised.

On March 23, the day after the number of positive cases increased to 9, the Government of Tamil Nadu announced state-level lockdown for March 24-31 followed by the announcement of a nation-wide lockdown of 21 days on the next day by the Government of India. This was welcomed by most of the people of the state. Lockdown led to complete closures of the borders, restriction in the inter and intra-state movement, a shutdown of all private and government organizations, public gatherings, etc. To ensure the availability of the essentials to the public, travel between states and inside the sates was exempted for some essential commodities. E-passes were made mandatory for travel within the
state to deliver the essentials and for some emergency situations. At the community level, the government started screening of persons who had come to the state from various infected nations. In order to prevent the community-spread, the state started sanitizing the streets and roads using disinfectant powders and sprays, which was later reported to be an inefficient method by WHO. The government took various quick responses and initiatives, such as preparedness by following the Standard Operating Procedure (SOP) in government hospitals - case definitions, laboratory protocols, case transport guidelines, preventive measures, hospital and ambulance disinfection protocols and case management. All the health care professionals treating or screening the COVID-19 cases were advised to use personal protective equipment (PPE) with masks. Considering the requirement more healthcare workers and experts were appointed on a temporary basis to serve during the pandemic. While critical screening of people with symptoms was going on, a sudden increase in the number of asymptomatic cases reduced the effectiveness of the previously conducted screening. More than 80% of the reported COVID-19 positive cases in the state are asymptomatic. Indian Council of Medical Research (ICMR) reported that airport screening, quarantine measures help to delay epidemic to a maximum of three days [1]. And also suggested the need to test for symptomatic people with no travel history. So, the state government began to test all the peoples with severe pneumonia [23]. For daily updates, a dashboard has been created officially which displays the district-wise number of tests conducted, active cases, recovered cases and deaths

After facing criticism for having tested a very low number of persons, the testing for the disease scaled-up over the time from totally 498 persons tested till 24th March to over 16,000 persons tested per day with 72 approved testing centers all over the state as of 12th June. The persons who had direct contact with the positive cases were also screened, isolated and given treatment. The case identification was made available and accessible with the implementation of ICMR’s lab-based surveillance. To identify the infections, protocols suggested by WHO, ICMR is being followed. The most recommended method of diagnosis is nasopharyngeal and oropharyngeal swab. SARS-CoV-2 RNA is detected 63% in nasal swabs compared to oropharyngeal swab (32%) [26]. For diagnosing the COVID-19 in patients many of the assays are uses such as Rapid antigen lateral flow assay, Serological method, random amplification deep sequencing method, Real-Time PCR assay (RTPCR), loop-mediated isothermal amplification, multiplex isothermal amplification followed by microarray detection, and CRISPR (clustered regularly interspaced short palindromic repeats)-based assays. The RT PCR assay is recommended for molecular testing of coronavirus. It minimizes the false-positive result associated with the amplification of product contamination [28, 29]. Till date, the state has 123 government hospitals and 169 private hospitals to treat SARS-CoV-2 infected patients. So far, the state has procured about 14 lakhs testing kits for diagnosis purposes. Based on the categories of symptoms and asymptomatic conditions, the patients are admitted one of the 3 categories of health facilities all over the state. The state has 167 centers under Category I - COVID Care Center (CCC), 105 centers under Category II - Dedicated COVID Health Center (DCHC) and 69 centers under Category III - Dedicated COVID Hospital (DCH).

All the above-said measures were taken only for limiting the rate of transmission and to decrease the epidemic peak. With these measures, as on 12th June 2020, Tamil Nadu is having 2nd largest recovery rate and keeping the fatality rate comparatively less (367 deaths) than many other states and even many other countries. Apart from the control measures, the state has even taken relief measures to the people who are directly or indirectly affected by the pandemic. Monthly financial assistance to about 4 million jobless workers of various sectors, migrant workers and poor is being provided since March. To ensure food safety, the availability of food material supplies at free of cost at state-run “fair price shops” of Tamil Nadu Civil Supplies Corporation and Amma canteens. The relief measures also include the extension of dates for paying various dues. In order to recover the economic losses expert team with former Governor of Reserve Bank of India, Prof. Rangarajan as head has been formed by the state government. On the other side healthcare agencies and research laboratories are working on in developing possible new treatments and vaccines to cure the disease.

Honorable Chief Minister of the state, Dr. K. Palaniswamy penned a letter to the public extending his moral support has stated the stand of the state in various crisis situations like drought, tsunami, various cyclones and floods that hit Tamil Nadu and reminded about how quick the state was back to the normal in all those situations along with the support of the public.
Impact of COVID-19 and Lockdown: The state is stumped due to the effects of the COVID-19 pandemic. Although the government at all possible ways is trying at its best in fighting the pandemic, there remains a series of issues making the situation a more complicated one. Most serious issues include people hiding their travel history, escaping of many COVID-19 positive cases from hospitals, and infected persons trying to dodge mandatory home quarantine which causes the indefinite spread of disease mostly in asymptomatic cases [6].

The state health minister in a press-meet expressed his frustration about the public not following the precautionary measures such as wearing masks in public places. These delays the state’s efforts in controlling the spread of the disease thereby leading to community transmission. Although all the control measures are being taken for the purpose of control and prevention of disease, there are various other impacts too. COVID-19 pandemic situation has its impact on different people differently based on their regional, economic, social status, etc. The sudden announcement of the pandemic lockdown has severely affected all the sectors due to an unorganized workforce. The announcement of the lockdown should have been prepared much better.

In the urge of addressing the pandemic, we have failed to concentrate on other linked problems. Since many hospitals and healthcare units stopped admitting outpatients with other complaints and decreased the inpatient counts, people have to suffer a lot in meeting their health emergencies other than the pandemic. In addition to that, the lack of transport services and fear of infection has locked the people in their homes. In a state where the birth rate is 15.0 per thousand [9], this situation has affected the pregnant women, postpartum women and neonatal. Since the COVID-19 disease affects the people with underlying health conditions, those suffering from chronic diseases, lacking immunizations and whose other medical needs were not addressed may have detrimental health conditions leading them to become an easy host for SARS-CoV-2. Another important issue is the relaxation of the lockdown at the time of increasing cases. However, this can be linked with an increase in the number of tests. Since the numbers are continuing to increase, it is not a good idea to give relaxations in the lockdown protocols. This relaxation can make the condition even worse in the immediate future causing a huge impact.

The measures to reduce the spread of infection has affected economic activities. This has had and having impact on the micro, small and medium enterprises (MSMEs). MSMEs contribute to about one-third of the nation’s GDP, with Tamil Nadu being the one among the large contributors which hosts employment of people from all over the nation in various sectors. The closure of production units, firms and various businesses has resulted in the loss of jobs and financial insecurity, in which the most affected are the daily wagers and migrant workers. This has affected a huge number of populations adversely. It is unfortunate that the first death of migrant workers in the country due to the COVID-19 pandemic lockdown happened in the Theni district of Tamil Nadu who struck in the forest fire while walking through a forest. From the Economic Survey 2016-2017 based on Cohort Migration Metric, it is evident that the state has the largest migrant population of about 1 million migrants in 20-29 age during 2001-2011. During 1991-2001 the same was just 26,000 [8]. This count shows how much migrant workers would have been affected. Furthermore, it is understood that how much the economy is affected due to the effects of COVID-19 and its control measures. The actual impact on the economy cannot be estimated until the global pandemic comes to an end.

During the pandemic, one of the most affected sectors is the education sector. Most of the educational institutes closed even before the announcement of the lockdown. The closure of schools and higher education institutes with the cancellation of examinations has raised a question of doubt about the capability of the students. Though many of the institutions in the state are making a revolutionary changeover from face-to-face teaching to providing online teaching to the students, not all the students are able to access this facility. This is due to various reasons, such as the non-availability of electronic devices with everyone, two students from a single home can’t share a single computer or gadget, the lack of network, etc. Moreover, this change has caused an increasing burden on the teachers who have to spend extra time in learning about how to use the online teaching portal and is also causing mental distress while handling the students virtually. Not just teachers, students are also facing various difficulties and negative physical and mental effects due to over usage of computers or any other devices. Meanwhile, Violence against women is reported to be increasing during this situation. Shalu Nigam, 2020 has reported various incidents of violence against women in Tamil Nadu [22]. Under the Domestic Violence Act 2005, the state has appointed protection officers to move and rescue women who are suffering from domestic violence.
Future Strategies: As the virus is highly contagious and because of the deficiency of herd immunity, with the current growth rate, various mathematical models have predicted the spread of disease in the state. Dr. G. Srinivas using a mathematical model has predicted that state may witness about 1.3 Lakhs COVID-19 cases with 769 deaths by the end of June. He has also said that about 1.5 lakhs people in the state capital will be infected by mid of July and the infection may reach the peak by the second week of October. Hence there is an urgent need for support from both government and public to reduce the spread and “flatten the curve”. Learning from the past and from other countries which are successful in handling the pandemic and prevent the spread, we can consider various possible strategies to help the state recover from this. The authors suggest a concentration on the following strategies to cope up with the situation.

1. Lockdown Extension: Although the extension of lockdown in the past has caused various detrimental effects on daily life, economy, mental and the physical wellbeing of the individuals, it is not the right time to lift the lockdown, especially in the worst affected districts such as Chennai, Chengalpattu, Thiruvallur, Kancheepuram, Thiruvannamalai and Cuddalore. Considering the fact that there is a sharp rise in the number of positive cases, instead of relaxation of the lockdown it is indeed necessary to implement strict lockdown in these districts with additional support from the government to serve the essential needs of the public. Lockdowns implemented so far has effectively supported the transmission of disease. Another strict lockdown will definitely have its impact on limiting the spread and stop the transmission moving to the next level. On implementing strict lockdown in the worst affected regions, sanitized mobile vans to provide daily essentials to the public can be established. This will help in reducing the panic situation among the public, thereby limiting the chances of transmission and administrative officers can have more concentration in eliminating the pandemic. When the decrease in the trend of the cases is witnessed, the lockdown can be relaxed step-by-step.

2. Increased Testing: During the extended strict lockdown, testing for SARS-CoV-2 can be geared up and a large number of populations can be tested, helping in identification, isolation and treatment. Adopting different method for rapid diagnosis of the disease can help in identifying the infected. Many counties affected by COVID-19 pandemic has started conducting large-scale serosurveys to measure the concrete number of COVID-19 cases. Kumar et al. 2020 has suggested a national sero-surveillance protocol to track infection transmission [18]. The state can conduct this survey at least in the most affected districts with required modifications. Sapkal et al, 2020 has developed an indigenous IgG ELISA to detect anti-SARS-CoV-2 IgG. This method has been proved to be sensitive as well as specific for the detection[24]. This may be helpful in conducting epidemiological surveys. Different strategies for rapid identification such as the use of rapid tests, lateral flow immunoassays and ELISA based tests, drive-through testing, school-based testing are being used in countries like Finland, France, USA, Germany Scotland, etc. [4,10,11,12,20,21,25,27]. The neighboring states like Andhra Pradesh, Kerala has largely increased mobile testing centers and walk-in mobile kiosks to sample testing. A handful of approaches for surveillance and contact-racing will help the government to choose the most possible between the options.

3. Medical Facilities: The rapid climb in the amount of COVID-19 infections has led to inadequate primary healthcare followed by an undocumented increase of mortalities due to illness other than SARS-CoV-2 infection. The state has to ensure the functioning of hospitals in treating various other health complications such as heart disease, nephrology related problems, diabetes, etc. Since the urban population of the state has access to alternate measures for healthcare needs such telemedicine, tele pharmacy, etc. it is very important to ensure the availability and accessibility of the basic healthcare facilities in the rural regions and the adequacy should be keenly monitored. The immune response of the people with an immune deficiency should be boosted up by available drugs.

4. Travel Monitoring: Usually, all the modes of transports will be overfilled with the crowd. In such a situation, if the public transport is resumed, the situation will get even worse leading to a community spread and failure in controlling the epidemic. It is good to halt public transport until there is a decline in the daily number of cases identified in the state. In order to provide the transport facility, the concept of more number of frequently sanitized vehicles with less number of passengers can be continued.
5. **Business and Economic Revival**: In addition to economic grants announced by the Government of India, the state has to announce sector-wise grants which benefit all the affected. The organizations and companies which are paying their employees even during the shutdown should not be neglected. Special grants and aids should be provided to all the business sectors to recover from the loss and economic deficit. In doing so, the state can experience a good comeback from the crisis in the long run.

6. **Migrants and Poors**: The outflow of the migrants and inflow of people from other districts and states should be monitored. Monitoring the flow will help in keeping the epidemic trend to the lowest possible. In addition to relief funds announced so far, policy decisions can be taken keeping the poor in mind.

7. **Education Policies**: As the prevalence of pandemic is not definite and complete disease-free situation is not predictable, education of the students should not be affected. Most of the institutions in the state are providing e-learning facility to the students where students are benefitted by the online teaching platforms and resources. However, it is necessary to ensure safe online platforms ensuring the mental well-being of the teachers and students. Guidelines can be formulated in reframing the syllabi to continue delivering quality education during and after the pandemic.

8. **Domestic Violence**: This pandemic crisis has created a place to renew the thoughts and already existing gender inequalities ideas. The Secretary-General of the United Nations has urged the nations to give priority and support for the arrangement of warning systems for those suffering from family violence [15]. In addition to the previous measures taken by the state government in this regard, the government can also start allocating funds to prevent the domestic violence occurring in COVID-19 pandemic situation. And it is essential to take strict actions against the accused to curb the domestic violence.

9. **Public Support**: In spite of the measures taken by the government in fighting and eliminating COVID-19, this will not be possible without the support from the public. By understanding this crisis situation, it is necessary that people follow all the government advisories, protective measures with patience to control the spread of the disease.

10. **Adapt for the Future**: It is important to remember the last pandemic, the Spanish flu which horrified the world in 1918 with its effects and aftermath. The Spanish flu lasted for about 2 years. So, this pandemic has had a great impact on the normalcy of the nations, and also more impact is expected in the future. However, with the advancements of the 21st century in various fields of science medical and healthcare facilities, the human race will come out of this tragic situation with more strength and enthusiasm. But it is important to devise a way by which we are going to achieve that. In this crisis situation, people has also understood how much nature and the environment has been exploited and from these lessons we must correct ourselves, with adaptiveness and step forward for a better future.

**Conclusion**

The SARS-CoV-2 infection is threatening the world nations with its deadly COVID-19 disease. With no particular treatment method, the healthcare workers are indefinitely working towards the service of the people. Whereas the researchers are tirelessly experimenting on finding a cure or vaccine for the disease. Tamil Nadu is one of the most affected states in India. Even though the number of positive cases is increasing day-by-day, with the relentless and collective efforts of all the departments of the state, COVID-19 has not yet reached the community spread level. With a population of more than 7 crore people, the state is running very empathically with all its efficiency and past experience in managing the crisis situations. With the experience of the past, and effective numerable control measures along with relief measures, the impact has been decreased and situation is still under control. It is important to continue the efforts to improve the situation and come out of this crisis. The involvement and commitment of the public are very much needed for this cause.

Abstract

Purpose: Musculoskeletal pain have been an issue of concern for Oral and Maxillofacial surgeons for a long time now. The aim of this study is to find the prevalence of musculoskeletal disorders among oral and maxillofacial surgeons. Method: A cross sectional Analytic study was implemented. The association of musculoskeletal pain and posture, loupes and demographic characteristics where explored. Chi-square analyses were used to compare the different participant responses and the variables and multiple logistic regression was used to determine the significant relationship. Result: Out of a total of 100 Maxillofacial Surgeons 96% and 45% reported to always preferably stand during OT procedures and extractions. Lower back, neck and shoulder were the main regions that pain was reported. Surgeons who opted to sit during extractions experienced pain in elbow (P=0.009). Lower back and neck pain was found to be more common among surgeons who does not use loupes which may be due to the tensed flexion activity of the muscle. Conclusion: Majority of the subjects had pain in the lower back and no statistical association was found out between age and the incidence of pain. It was also found that majority of the subjects who refrained from using loupes had experienced pain at multiple sites.

Keywords: Musculoskeletal pain; prevalence; surgeons; work related.

Introduction

Musculoskeletal disorders are a group of injuries caused by repetition, overexertion, and bodily movement such as chronic neck flexion and repetitive forceful tasks. Doctors are the exposed to a wide variety of occupational diseases among which musculoskeletal pain is one of them. Dentists particularly oral and maxillofacial surgeons are most prone to musculoskeletal pain often due their abnormal posture during working, narrow visual field of the oral cavity and working with a limited scope of movement. Musculoskeletal pain reflects on a number of conditions, such as neck pain, backpain, shoulder pain, pain of limbs, carpal tunnel syndrome, myofacial dysfunction syndrome, atypical facial pain etc. Literature shows that lower back pain was the most common presentation among surgeons who operated in the standing posture.

While some forms of musculoskeletal pain are light, transitory, asymptomatic or even undiagnosed, others may be severe, irreversible and incapacitating. These severe and persistent pain, functional restrictions, and disability associated with musculoskeletal disorders

can affect the daily activities, quality of life, ability to earn a living and independence of those affected thus leading early retirement. Fortunately, it is found that good ergonomic practices can drastically reduce these musculoskeletal pain symptoms. Hence, a study based on Nordic questionnaire was conducted among oral and maxillofacial surgeons to determine the prevalence of musculoskeletal disorders among them.

**AIM**

To find the prevalence of musculoskeletal disorders among oral and maxillofacial surgeons.

**Objectives:**

1. To find the association among demographic features, postural preferences and pain
2. To find the distribution and prevalence of musculoskeletal disorders

**Materials and Method**

This cross-sectional and analytical questionnaire study was carried out in the Department of Oral and Maxillofacial surgery, Meenakshi Ammal Dental College, Maduravayol, Chennai. This study was approved by the Institutional Ethical Committee and Review Board of MAHER University. The subjects included practising oral and maxillofacial surgeons.

**Sample Size:** A total of 100 practising oral and maxillofacial surgeons were included in the study

**Inclusion Criteria:**

1. Practising oral and maxillofacial surgeons only

**Exclusion Criteria:**

1. Physically challenged professionals
2. Pregnant women doctors
3. Any pre-existing health conditions.
4. Degenerative, inflammatory rheumatic diseases and diseases of the central nervous system.
5. Previous history of Musculoskeletal pain before joining dentistry

**Preparation and Distribution of Questionnaire:**

A questionnaire was prepared and distributed to oral and maxillofacial surgeons in with a letter of explanation. Respondents were advised that return of the completed questionnaire constituted informed consent.

Musculoskeletal symptoms were investigated using a self-administered, purpose-designed questionnaire prepared online using Google Forms. Questions were based on the standardized Nordic Musculoskeletal Questionnaire (NMQ), which was used to record work-related musculoskeletal symptoms in working populations. Kuorinka et al and his team developed the NMQ with the support of the Nordic Council of Ministers. This simple, generalized and internationally validated questionnaire was used to detect symptoms in the neck, back, shoulders and extremities. Respondents were asked whether they had ever experienced work-related pain or discomfort.

**Demographic Characteristics:** The complete questionnaire was distributed among oral and maxillofacial surgeons through the social media application, WhatsApp.

The questions asked were categorized into 3 sections – demographic characteristics (Fig 1), surgeon’s behaviour (Fig 2) and pain (Fig 3), as given in the proforma. The surgeon’s behaviour included the use of loupes and postural preferences by the surgeon during procedures – extraction, impaction, implant, operation theater (OT).
Surgeons Behaviour:

**Figure 1: Proforma section 1**

**Figure 2: Proforma section 2**
Demographic characteristics included information on age, sex, marital status, body weight, exercise, years of practice, type of working sector, number of patients per day, dental assistance, usage of direct and indirect vision.

Age in years was categorized as 30s, 40s etc. the subjects were asked to check the answer as “Yes” or “No” with regard to their exercise activity. The duration of the clinical practice of the subjects was categorized into 5 or fewer, 6-10 years, 11-20 years, 20-30 years, and more. The type of working sector was divided onto private, institutional and combined.

Data under the surgeon’s behaviour included the use of loupes and postural preferences during procedures like extraction, impaction, implant surgery and in operation theater.

Postural preferences was analysed as “always stand” for those who stand all the time, “always sit” for those who always sit for the procedures and “sometimes sit” for those who sit in between procedures for better access and vision. Use of loupes as classified as “I use loupes”, “I do not use loupes”, “I sometimes use loupes”. Pain was assessed in different regions of the body by a single yes or no question.
Data analysis: The data was collected using Google Forms, a secure web-based data collection application by google. Chi-square analyses were used to compare the different participant responses and the variables and multiple logistic regression was used to determine the significant relationship. The analysis was completed using Statistical Package for the Social Sciences software (SPSS version 16, IBM).

Results

Pain: All 100 participants have reported to have pain at different sites. The participants who responded, reported neck pain (56%), shoulder pain (48%), upper back pain (48%), elbow pain (12%), wrist or hand pain (32%), lower back pain (62%), hip or thigh pain (8%), knee pain (15%) and angle or feet pain (21%). Out of all the sites, the individuals who had pain in lower back was the most predominant (Table 1).

Pain and posture: Most of the practitioners reported to always stand during extraction. Surgeons who opted to sit during extractions experienced pain in elbow (P=0.009). Majority of the practitioners reported lower back pain following all 4 procedures. It was reported that practitioners preferred to always sit during implants and impaction. Majority of them who “always sat “experienced lower back pain the most. It was also noted that surgeons who reported “always sit” for implant procedures experienced more wrist and hand pain (P=0.037). Lower back pain was reported by a significant number of surgeons choose to always stand during OT procedures (Table 2).

Pain and demographic characteristics: There was a statistical association found between pain and years of practice. 14% of the participants, with years of practice 5 or fewer reported pain in the angle and feet. (P=0.027) which tends to decrease with experience. A marked significance was also found between type of working sector and pain where 7% practitioners working in both institution and private sectors experienced more elbow pain(P=0.018). Most of the practitioners used direct vision for treatment and has reported to experience pain in all sites but a significance was noted in wrist and hand pain (P=0.007). It was found that practitioners between body weight of 61-80 kgs show significant value (P=0.058) (Table 3)

Pain and loupes: Most of the surgeons who responded opted not to use loupes during procedures. It was reported that loupes were mainly used during implant procedures by surgeons. 60% of the practitioners who did not use loupes reported to have experienced lower back pain during impaction. Statistically shoulder pain (P=0.056) and hips and thigh pain (P=0.023) showed evident significance in case of implant placement. It can be observed that pain in the lower back was the most evident in majority of surgeons in during all 4 procedures. (Table 4).

Discussion
Musculoskeletal pain is one of the most important and common occupational health hazards in the working population today. Dentistry among the various occupations, is the most common to develop musculoskeletal pain in which oral and maxillofacial surgeons are the most prone. This may be due to their narrow visual field in oral cavity, working with minimal scope of movement, minimal lighting, which puts them in high risk of neck, shoulder and lower back pain. A polish study reported that the most musculoskeletal problems among dentists was in the lumbar thoracic region [5]. The present study was conducted to find the prevalence of musculoskeletal pain among oral and maxillofacial surgeons by preparing an online questionnaire based on Nordic questionnaire as this appears to be an accepted method of measuring the prevalence of musculoskeletal complaints. The provided self-reported information given by the oral and maxillofacial surgeons can be of clinical relevance for assessment of the occupational health hazard among this profession [1-3].

The most prevalent regions that reported to have pain is the back, shoulder and neck. However, the reported prevalence for these regions varied greatly between each studies. A noteworthy difference in the range of results was also seen [4,10-12]. Finsen et al study among dentists showed that prolonged neck flexion and upper arm abduction were found, as well as high static muscle activity levels (sphenius and trapezius muscles) thereby reporting neck and shoulder pain [9]. A study conducted by Khalid AlWazzan KA concluded that out of 111 candidates who reported pain most them neck and back pain was the most prevalent [7].

Many other possible risk factors have been identified in literature that shows no correlation with any kind of prevalence. Akesson et al in his study stated that the clinical work of dentists and dental hygienists is visually demanding, with a high work zone and unsupported forearms, using repetitive motions with fine tuned actions and using vibrating instruments [6]. Clinical work involving these characteristics are the basis for static neck position, extended neck flexion and poor posture that are also associated with musculoskeletal complaints. A study of Marklin RW concluded that in the working postures of dentists and dental hygienists, both professions spent 86% of their working time with a neck flexed at least 30° and 53% and 50% of their work time respectively and with a trunk flexion of at least 30° was also noted [8]. In our study, a significant number of the respondents reported pain in lower back, neck and shoulder.

Most of the participants reported that they always stand during operation theater procedures (96%) and extraction (45%). Surgeons who always sat during extraction procedures experienced more of elbow pain. There no significance between age and pain. It was noted that surgeons, working in both institutional and private sectors combined experienced more elbow pain which was statistically significant. In spite of working with dental assistance, surgeons experience mainly lower back pain. Many studies done have shown back pain reported the most [4]. Similarly, a study was conducted among dental hygienists reported to have back pain [13].
This may be due to the improper posture positions of the surgeon during procedures.

Most of the surgeons do not use loupes while doing procedures but these practitioners reported to experience pain loupes predominantly in the lower back and neck region. This may be due to the tensed flexion activity of the muscle. Surgeons have report pain even after using loupes. Those who used loupes might be using it for better magnification of the surgical site and was reported to be used more during Implant surgeries. another significant finding is that practitioners who did not use loupes experienced more shoulder and thigh pain during implant procedures.

After analysing the data, it was recognized that further questioning would be needed to determine certain other associations. More follow up questions can be asked on whether the pain had subsided if practitioner had changed the working posture to determine the surgical postural preference and correlate them to musculoskeletal pain.

**Conclusion**

From our study, we conclude that the majority of the subjects had pain in the lower back and no statistical association was found out between age and the incidence of pain. It was also found that majority of the subjects who refrained from using loupes had experienced pain at multiple sites.

DNA Extraction from Archived Paraffin Embedded Tissues: A Comparative Study Using Three Different Extraction Methods—Extraction of DNA from Paraffin Embedded Tissues

Shruthi Suresh¹, Kavitha B.², Sivapathasundharam B.³

¹Former Post Graduate Student, Department of Oral Pathology and Microbiology, Meenakshi Ammal Dental College and Hospital, Chennai, Tamil Nadu, India, ²Professor, Department of Oral Pathology and Microbiology, Meenakshi Ammal Dental College and Hospital, Chennai, ³Professor and Head, Department of Oral Pathology and Microbiology, Meenakshi Ammal Dental College and Hospital, Chennai, Tamil Nadu, India

Abstract

Objective: Formalin fixed paraffin embedded (FFPE) tissue is a valuable source of nucleic acids required for various molecular studies. The purpose of the present study was to extract Deoxyribonucleic acid (DNA) from archival retrieved FFPE oral squamous cell carcinoma tissues using three different extraction methods (salting out, commercial kit and microwave method) and to compare the yield of DNA extracted by these methods.

Method and Material: 30 oral squamous cell carcinoma paraffin embedded tissue blocks were categorized into three groups based on the duration of storage as Group A(<2 years), B(2-4 years) and C(4-6 years). The tissue sections made from these blocks were subjected to three DNA extraction methods and the DNA yield was measured using a spectrophotometer. The extracted DNA was checked by successful amplification of p53 gene using Polymerase Chain Reaction followed by gel electrophoresis. The values of DNA yield and purity were statistically analysed and the level of significance was set at \( P \leq 0.05 \).

Results: The DNA yield was above 3µg in all the three extraction methods. On multiple comparison, the mean DNA yield was statistically significant (\( P \) value<0.05) among the three methods in Group A. Also, the DNA yield was found to be higher in salting out method though successful amplification was obtained from the extracted DNA in other extraction method as well.

Conclusions: DNA was successfully extracted from all the tissue samples using all the three methods. Salting out method yielded the maximum amount of DNA compared to the other method and shall be a good cost effective alternative.

Keywords: DNA; Paraffin embedding; Polymerase Chain reaction; Oral squamous cell carcinoma.

Introduction

There are about a trillion cells in the human body containing the vital source for life, the Deoxyribonucleic acid (DNA) in their nucleus. Isolation of genomic DNA is the key step for numerous applications and molecular studies ranging from basic research to routine diagnostic and therapeutic decision-making.¹ The extracted DNA is used to study alterations in the DNA sequence which is responsible for development and progression of various pathologic conditions. A wide variety of techniques have been employed to extract DNA from different sources such as body fluids, cell cultures, animal tissues (fresh, frozen or fixed) and microorganisms.² The archived Formalin Fixed Paraffin embedded (FFPE) tissues are
an excellent source for recovery and analysis of nucleic acids which has become an important tool for cancer research over the last decade. Fixation techniques, formation of protein cross links, storage condition and duration makes DNA extraction from FFPE tissues challenging. Hence the need arises to choose the best method of DNA extraction to obtain maximum yield of the purest form of DNA and that which can be amplified. The present study was aimed to extract DNA from archival retrieved paraffin embedded oral squamous cell carcinoma (OSCC) tissue blocks using Salting out method, Commercial kit method and Microwave method and to estimate and compare the extracted DNA quantitatively and qualitatively in all the three method using spectrophotometer and gel electrophoresis respectively. The assessment of successful DNA extraction from the three method was done by PCR amplification of p53 gene. 

**Materials and Method:**

A total of 30 archival retrieved tissue blocks previously confirmed histopathologically as oral squamous cell carcinoma were chosen for this *in-vitro* study. Ethical clearance for the study was obtained from the Institutional Review Board. The tissue blocks were categorized into three groups based on the duration of storage as Group A (10 blocks stored for duration of <2years), Group B (10 blocks stored for duration of 2-4 years) and Group C (10 blocks stored for duration of 4-6 years). Ten sections of 10μm thickness were cut from each paraffin embedded tissue block. The sections were collected in a 2mL micro centrifuge tube (Tarsons, Kolkata, India). The same numbers of sections were collected from each case, in three different tubes.

**Deparaffinisation:** 1 ml preheated xylene was added to each micro centrifuge tube containing the sample. The tubes were incubated at 56ºC for 10 minutes in a water bath for dissolution of paraffin and were centrifuged (REMI, Mumbai, India) at 10300 rpm for 5 minutes. The supernatant was decanted without disturbing the pellet. A new change of preheated xylene was added. The steps were repeated until the paraffin was completely removed.

**Tissue Digestion:** The pellet was washed in 100% ethanol (500μl) to remove any residual xylene. The cells in the tissue pellet were lysed using a homogenizer and then centrifuged at 10300 rpm for 5 minutes. The pellet was washed in 95% ethanol (500μl) followed by 70% ethanol (500μl). The homogenization and centrifugation steps were repeated before and after the ethanol washes. 200-400μl of 250μg/μl Proteinase K (MP Biomedicals, USA) containing digestion buffer was added to break the peptide bonds of proteins. The tissues were digested by incubating them at 55-60ºC for 3-5 days in an orbital shaking incubator (REMI, India). 250μg/μl proteinase k (working concentration) was replaced daily. Proteinase K was inactivated after adequate tissue digestion by heating at 95ºC for 10 minutes as they might interfere with further analytical procedures.

**Salting Out Method:** 200μl of Ammonium acetate (3.5M) solution was added to precipitate proteins as they are less soluble in high salt concentration. The tubes were vortexed using a cyclomixer (REMI, Mumbai, India) for 20 seconds and were incubated on ice for 5 minutes followed by centrifugation at 14300 rpm for 3 minutes. The supernatant containing DNA was transferred to another tube. 600μl of Isopropanol was added to the supernatant in order to precipitate DNA. The samples were centrifuged at 16300rpm for 5 minutes. The DNA pellet was washed in 70 % ethanol (500μl) to remove any residual salt attached to the DNA. The tubes were centrifuged at 16300rpm for 2 minutes. The supernatant was discarded and the remaining ethanol was allowed to evaporate. DNA was dissolved in 30-50μl of TE (Tris EDTA) solution. Extracted DNA was stored at 4º C.

**Commercial Kit Method:** The commercial QIAamp DNA Mini Kit (Qiagen, Gmbh, Germany) was used according to the manufacturer’s protocol. The dewaxed tissues were digested with 180μl ATL (Animal Tissue Lysis) buffer and homogenized. Tissue lysis was carried by incubating the tubes at 56ºC for 1-3 hrs with Proteinase K (20μl) until complete tissue lysis. Buffer AL (200μl) was added. Pulse vortexing for 15seconds was done and incubated at 70ºC for 10 minutes. 200 μl Ethanol (96-100%) was added and vortexed. The solution was transferred into a spin column, centrifuged for one minute at 8000rpm, and washed with AW1 and AW2 buffers. DNA was eluted by 1 minute incubation at room temperature with 50μl elution buffer AE and was collected by centrifugation at 8000 rpm for 1 minute. The DNA was stored after eluting in Buffer AE by placing it at -20ºC.

**Microwave Method:** 200μl of digestion buffer (1M NaCl; 1M Tris -HCl, pH8; 0.5M EDTA, pH 8; 10% Sodium Dodecyl Sulphate) was added to the tissue sections and was subjected to high power microwave
irradiation for 1.5 minutes for deparaffinisation. This technique was xylene free. Irradiation time was split into 15 segments to prevent over boiling. Centrifugation for 10 minutes at room temperature was done. The paraffin wax ring formed above the buffer was removed. Tissue pellet was digested in 200μl digestion buffer containing 200μl/ml Proteinase K at 56°C overnight. Centrifugation at room temperature at 8000 rpm for 5 minutes was done. Supernatant containing DNA was collected in a separate tube. It was boiled for 10 minutes at 95°C to denature proteinase and proteins. DNA present in the supernatant was precipitated using the salting out method. [5]

**Evaluation Of Extracted DNA:** Yield of DNA and electrophoretic pattern: For each extraction method, the DNA purity was calculated using the A260/A280 ratio with a spectrophotometer (Eppendorf Bio Spectrometer). DNA yield was calculated using A260. [6]

**Polymerase chain reaction:** The DNA isolated using the three method was used for amplification of a 196bp fragment of p53 gene. Quantitative RT-PCR was performed with the Stratagene MX3000P (Agilent technology). The double standard DNA-binding dye SYBRGreenI(KAPA SYBRFAST qPCR Kit)and primers for p53 (Forward: 5’-CTTGCCACAGGTCTCCCC-3’ and Reverse: 5’-GCCACTTGCCACCCCTGCACA-3’) were used. Amplification conditions were 30 seconds at 95°C, 30 secs at 60°C and 30 secs at 75°C for 35 cycles.

The amplified PCR products were visualised using a gel electrophoresis with standard 2.0% agarose gel containing ethidium bromide stain under ultraviolet light. The optical densities of the electrophoretic bands were determined using Quantity One software. [6]

**Statistical Analysis:** The values of DNA yield and purity obtained using the three DNA extraction method for the three sample groups (Group A, B and C) were statistically analysed using the software Statistical Package for Social Sciences (SPSS), IBM Corp., Version 16. The level of significance was calculated by ANOVA test and Tukey test (for multiple comparison). Probability value (p value) less than 0.05 was considered statistically significant.

**Results**

All the three DNA extraction method provided a yield of DNA above 3µg which was considered to be good and were of adequate amount to perform PCR reaction. (Table 1) On multiple comparison of mean DNA yield obtained from the three different method, the difference in the DNA yield was statistically significant among all the three method (p value<0.05) in group A and the difference in the DNA yield between kit method and microwave oven method was not statistically significant (p value >0.05) in Groups B and C. (Table 2) The average purity of DNA obtained using the three method were within the range of 1.7 to 2.0. There was no statistical difference in the average purity among the three method (p value >0.05). (Table 1) On multiple comparison of mean DNA purity obtained from the three different groups using the kit method, the difference in DNA purity was statistically significant only between Groups A and C. (Table 3) However, a comparison of DNA quantity among the groups was not possible as standardization of the tissue samples by weight was not done.

DNA extracted from the three method in all three groups was assessed for amplification of 196 bp fragment of p53 gene by real time PCR. All the samples of extracted DNA from the three method belonging to Group A, B and C showed successful amplification.

The amplified PCR products were analysed by electrophoresis on 2.0% agarose gel with ethidium bromide staining viewed under UV light. A band was noted at the level of 196 bp in comparison with the DNA ladder indicating successful amplification. However, variation in the intensity of the bands was noticed. The intensity of bands in gel electrophoresis is proportional to the amount of amplifiable DNA. (Figure 1) In the present study, the kit method showed no statistical difference in the mean optical density units among the three groups. (Table 4) The salting out and microwave method showed a statistical difference in Groups A and B and also in Groups A and C. (Table 5).

**Discussion**

The nature of genetic alterations occurring in the cells may be responsible for the clinical behaviour of tumours. Hence, examination of DNA from various tumours is necessary to correlate alterations in the genetic setup clinically and histologically and also to study various biomarkers that can be used in prognosis and targeted therapies or personalised medicine for tumours. Since extraction of DNA from fresh samples of similar tumours at a time may be practically difficult, many attempts have been made to extract DNA from stored formalin fixed paraffin embedded tissues that were previously prepared for routine histopathological examination. The present study was one such attempt to check the possibility of genomic DNA extraction from archival retrieved paraffin embedded tissue blocks. There are many physical and chemical factors (incubation time, temperature and materials used for extraction process, etc.) that affect the extraction of DNA from these tissues which subsequently affects further analytical procedures. Therefore it is essential to choose a suitable method from a wide range of protocols for efficient genomic DNA extraction with sufficient yield and purity. It should ideally be simple, reliable and cost effective.[7]

In the present study, the average yield of DNA from all the three study groups using the three extraction method was greater than 3 μg. According to W. Tang et al, 2009, DNA yield of 1 to 3 μg from three 5μm sections was considered typically good.9 Rivero et al, 2006 and Mirmomeni et al, 2010 obtained significant DNA yield of more than 3 μg using kit method (11-14μg and 7.5-69μg) and salting out method (8-31μg and 6.5-93μg) from FFPE tissues respectively.[4,6]

In Groups A, B and C, maximum DNA yield (μg) was obtained using the salting out method followed by the kit and microwave oven method. Salting out method compared to other method yielded maximum DNA in all the three groups. Kit and microwave method of DNA extraction yielded similar amount of DNA in Groups B and C whereas in Group A, kit method yielded more DNA compared to the microwave method. In the present study, least DNA yield was observed in samples extracted using the microwave oven extraction method (12.37 μg, 9.09 μg and 7.46 μg). This was contrary to Sato et al (2001), who observed mean DNA yield of 76μg in microwave method compared to other method.[9] This reduction in DNA yield using microwave extraction in the present study could have resulted due to an extra purification step that was performed to eliminate the reagent SDS (Sodium Dodecyl Sulphate) which is a potent inhibitor of PCR as proposed by Gelfand et al.[10] As per Sato et al, 2001, better DNA yield in his study using the microwave oven method might be due to lesser DNA loss attributed to less number of changes from the micro centrifuge tubes.[9]

In the present study, Salting out method showed significantly higher yield in comparison with the microwave and commercial kit method. Isola J et al, 1994 found that prolonged incubation time improved total DNA yield greatly compared to shorter incubation periods. This is applicable to the present study, as salting out method had a prolonged incubation time (3 days) compared to the kit (3 hours) and microwave method (overnight).[11]

The values of DNA purity obtained in the present study were within the range of 1.7 to 2.0 which was suggestive of ‘clean DNA’ according to Mirmomeni et al, 2010 who had obtained DNA of purity in a range of 1.66 to 1.97.[6] DNA of acceptable purity was obtained in all the three method which was in contrast to the study by Watanabe et al, 2017, where the kit method provided DNA of better purity when compared to the other method.[12]

The assessment of successful DNA extraction using the three method from the three sample groups was confirmed by a PCR amplification of 196 bp fragment of p53 gene. The genomic DNA obtained from all the samples were efficiently amplified. The intensity of the bands formed after gel electrophoresis of the PCR products denote that the amplifiable DNA was higher in the samples extracted using the kit method although the yield was maximum in the salting out method. This is in accordance with Gilbert et al, 2007, who observed that the total DNA content does not essentially represent
the quantity of DNA that is amplifiable by PCR. Also, the increased nucleic acid – protein cross link reversal properties of the components in the kit extraction buffers when compared to the conventional buffers yield higher levels of PCR amplifiable DNA by kit method.[13]

Studies by Shi et al, 2004 and Sato et al, 2005 suggested that reduction in the DNA manipulations can be done in order to improve the efficiency of PCR by avoiding few steps used in the regular extraction protocol. However, the purity of the DNA obtained may be compromised. [14,9] Though the kit method had minimal DNA manipulation, DNA of acceptable purity was obtained in the salting out and microwave method also.

The comparison of mean optical densities of the PCR products suggested that the amount of DNA that can be successfully amplified reduced progressively with longer duration of storage of the FFPE samples. This was in accordance with a study by Liborio et al, 2005, who observed a linear decrease in the number of successful amplifications with an increase in storage duration from FFPE tissues stored over a period of up to 40 years. This was due to the presence of high concentration of small DNA fragments which compete with the template DNA leading to very low or absence of amplification.[7]

**Conclusion**

In the present study, though the DNA yield was compared among the three different method within the groups, we were unable to compare DNA yield among the three different study groups as the standardisation of samples by weight was not done. Salting out method yielded the maximum amount of DNA compared to the other method in all the three groups. The purity of the extracted DNA was similar by all the three method in all the three groups and within the established range of clean DNA. The amount of amplifiable DNA fragments were found to be reduced with an increase in the storage time. Though commercial kit is a rapid method for DNA extraction, it is expensive. As an alternative, other method like salting out method can be tried for DNA extraction from paraffin embedded tissue samples as it is less expensive. Improved technical measures to enhance the amount of amplifiable DNA from salting out and microwave oven method are necessary.

Smile Designing Using DSD: A Case Report

G. Lambodaran¹, M. Jaisudhaa², Sathya Shankar³, S. Vigneswaran¹, S. Lakshmi⁴, H. Annapoorni¹

¹Associate Professor, ²Post Graduate Student, ³Assistant Professor, ⁴Professor, Department of Prosthodontics, Meenakshi Ammal Dental College & Hospital, Chennai

Abstract

A Captivating Smile Showing an even row of natural gleaming white teeth is a major factor in achieving that elusive dominant characteristic known as Personality – Dr. Charles Pincus. An aesthetic smile has always been an attractive element and it plays a significant role in overall psychology and confidence level of an individual. In Current day dental practice with increasing patient’s aesthetic expectations, smile designing has evolved leaps and bounds in the past decade with the advent of new materials and technical improvement as well. One such recently evolved technique is the application of software in creating smiles using Digital smile Design Software. This case report enlightens about one such smile make over using Digital Smile Design Software.

Keywords: Smile Designing, Digital Smile Design, Lithium disilicate veneers.

Introduction

Confidence is an important aspect of one’s personality and a confident smile makes the picture complete[1]. In modern day dental practice the amount of pupil seeking dental treatment for aesthetic purpose has significantly increased. The various factors that might affect the smile are Missing teeth, Discoloration, malformed teeth, malaligned teeth, reverse smile line, excessive gum exposure of gums, improper occlusal plane[2] ultimately leading to an unpleasant and unsatisfied smile which might have a huge impact on a person’s confidence level. Fortunately, modern day dentistry provides a formidable solution for these clinical situations by means of customized smile makeover treatment plans.

The art of smile make over is dictated by the clinical situation with some clinical situation requiring a very minimal procedures while some other may demand a more comprehensive approach to achieve the desired result. An experienced, skilled dental practitioner will be able to provide the most conservative, less invasive procedures that, in combination, will yield the best possible results. With this objective, the treatment planning during smile make over aims for better predictability and support for the planned treatment. With the emergence of digital tools such as DSD software the former becomes more practically feasible. Digital Smile Design is a multiuse conceptual tool that offers the clinician a new avenue when combined with the 3D printing technique, facilitating and improving the communication among dentist, technician, and patient.[3,4] The combination of DSD and 3D printed model⁵ allows for improved esthetic manipulation, providing a better predictability to support the treatment plan. This case report enlightens about one such case report where a digital smile design software is used for a smile makeover procedure.

Case report: A male patient of age 27 years reported to Department of Prosthodontics, Menakshi Ammal Dental college with the chief complaint of spacing present in the upper front tooth region. On Clinical examination patient had midline diastema, malformed lateral incisors leading to an unsatisfied smile (Figure 1).
Diagnostic Impression and study models were made and after initial evaluation it was decided to design a smile make over procedure using DSD software and the restorative material of choice was Lithium di silicate laminate veneers (emax empress). The patient was explained about the DSD procedure and the treatment plan was framed accordingly. The work flow involved in DSD treatment are:

**Step-1: Extra Oral and Intra Oral Photograph:** The First step in the DSD protocol is the making of extra oral and intra oral photographs in different angles as shown in the (Fig.2) which is the most important step in digital smile designing.

**Step-2: Smile analysis:** Digital face bow analysis is done to evaluate the midline, cant in occlusal plane and smile analysis was done to evaluate the length, contour, size, shape of the teeth. On analysis it was found that the length of central and lateral incisors were short of the reference plane and also the mesiodistal width of the lateral incisors were less and hence that proportion has to be altered to attain a more esthetically pleasing smile.

**Step-3: Smile Simulation:** New Smile simulation was designed by increasing the length of central and lateral incisors and also the mesiodistal width of the lateral incisors.
Step 4: Digital model: The new simulated smile from the photograph is then transferred to the digital model.

Step 5: Fabrication of 3D printed model: A 3D printed model is then fabricated using the digital data which will facilitate in making the template for test drive.

Step 6: Test drive: A template was fabricated using Addition silicone impression material and test drive was done using Bis Acrylic composite resin and the patient was satisfied with the test drive and it was decided to restore both the central and lateral incisors (12, 11, 21, 22) with laminate veneers then the clinical procedures were performed.
Step-7: **Tooth preparation**: Teeth Preparation of 0.5 mm was done in the incisors for laminate veneers.

![Figure 8 Teeth preparation](image1)

Step-8: **Retraction & impression**

![Figure 9: Impression](image2)

Step 9: **Fabrication of E Max crown**: CAD CAM milled lithium disilicate (e Max) Veneers were fabricated based on the new digitalized smile design.

![Figure 10. Veneer fabrication](image3)

Step 10: **Veneer cementation**: The prepared teeth were initially etched with 37% phosphoric acid and the intaglio surface of the veneers were etched with 9% hydrofluoric acid for enhancing micro mechanical retention. Then the Cemenatation was done using dual Cure Resin cement.

![Figure 11. Etching of teeth surface](image4)
Discussion

Digital smile designing aids us in designing better smiles, effective treatment plan, increased perceived value and greater acceptance from patient. Patients usually have apprehension regarding the end result of smile design treatment. In these cases DSD is a boon and aids in motivation and education through the display of end result even before the start of treatment [5]. It acts as a technical tool used to design and modify the patient’s smile digitally and help them to visualize it beforehand by creating and presenting a digital mockup of their new smile design. It helps in visual communication and
involvement of patients in their own smile designing, thus ensuring predictable treatment outcome and increasing patient acceptance of treatment which in turn gives a higher level of confidence. [6,7,8]

In the present case report, a male patient walked into clinic with the complaint of midline diastema and malformed lateral incisors. The patient was explained about the DSD and the patient gave consent to the digital smile designing protocol due to the above advantages. The designing was performed in the exocad software and the major advantage was the 3D printed model, which gave a greater reliability to patient on the dentist and it was also useful for the test drive before the preparation and for temporisation.

The DSD was done after the essential photographs and the diagnostic impressions were made. These photographs were then fed into the software were the virtual facebow analysis was done which includes the analysis of occlusal plane, cant of the occlusal plane and midline. This was then followed by smile analysis were the tooth size, shape, contour, colour and smile line was assessed and the appropriate alterations required were done. In this case, the length of the central incisors were increased and the width and length of the lateral incisors were increased. This was simulated and the 3D model was printed with resin. Eventually, tooth preparation followed by impression making, ceraming procedures, etching protocol for tooth and veneers and finally the cementation was done. Lithium di silicate was preferred because of its excellent esthetic properties. [9]

Excellence can never be achieved by chance, but using a consistent systematic approach for diagnosis, communication, treatment planning and eventually execution yields a perfect result and satisfaction to the dentist and patient. Thus DSD is one such protocol aiding us in providing perfect and esthetic smile.

Conclusion

Digital smile design software not only serves as an aesthetic template but also, make the treatment phases more predictable for both patient and clinician, as the final design can be Visualised on the computer and be used by the patient during the Test drive Procedure. The Precise and proper application of DSD will enable us to create ideal and satisfying smile thereby enhancing the predictability of success in Smile Designing.

Abstract

Background: Mobile health (mhealth) intervention has been proved to be effective in weight loss, diabetes control and tobacco cessation. Objective: To assess the effectiveness of mhealth intervention to reduce consumption of cariogenic diet. Design and setting: Randomized controlled trial in field setting. Materials and method: Forty two adolescents who were in the “Watch-out” zone of sweet score were recruited for the study. The subjects were randomly allotted into the test group (n=21) and the control group (n=21). A three day diet diary was recorded from all study subjects and the average sweet score was assessed at baseline and at post intervention. The subjects in the control group received standard one to one dietary instructions tailored to the needs of the subjects only once at the start of the study. Subjects in the test group received tailored dietary instructions once daily through mobile application (Whatsapp). Intra-group comparison was made using Wilcoxon signed rank test and inter-group comparison was made using Mann Whitney U test. P value <0.05 was considered statistically significant. Results: The sweet score for the control group at baseline was 20.9±6.06 while the post test score was 13.16±4.37 and the difference was statistically significant (p=0.002). The sweet score for the test group at baseline was 18.02±4.03 while the post test score was 14.5±7.74 and the difference was statistically significant (p=0.03). However, there was no statistically significant difference in sweet score between the two groups at the end of the trail. Conclusion: mhealth intervention is effective in reducing sweet score among adolescents.

Keywords: Mobile application, dietary instructions, cariogenic diet, sweet score.

Introduction

Non communicable diseases (NCDs) are the rising public health problem in the developing countries contributing to high morbidity and mortality rate. It is collectively responsible for almost 70% of all deaths worldwide. Low- and middle-income countries account for 3/4th of deaths due to NCD which includes nearly 80% of all premature deaths [¹]. Four major risk factors namely tobacco use, physical inactivity, the harmful use of alcohol and unhealthy diet have been attributed for the rise in NCDs across the world. Increased consumption of food containing highly refined sugar is an important behavioral change which is implicated as a common risk factor for many NCDs like obesity, diabetes and dental caries. Hence, interventions targeting unhealthy diet containing high levels of refined sugar can help prevent these diseases/conditions.

Dental caries is the most common chronic condition of both childhood and adulthood affecting more than 2.4 billion adults and 621 million children worldwide [²]. It is the 10th most common disease affecting children.

Untreated dental caries may cause sensitivity, pain, absenteeism from school and workplace, ultimately affecting the oral health related quality of life. Among 291 diseases investigated for causing disability, untreated dental caries was placed at 80th position [3].

Initiation and progression of dental caries can be prevented by limiting the exposure to cariogenic diet. Diet counselling and dietary instructions are hence advocated as a mainstay in the primary prevention of dental caries. Conventionally, diet instructions in diet counselling is delivered by trained personnel on a one on one basis through which consensus is reached between the counsellor and the subject on required dietary modifications to control dental caries. Despite being an effective tool for caries prevention, it is quite challenging to bring about dietary modification as it requires high level of motivation, and periodic reinforcement [4]. Hence, newer method of delivering dietary instruction which reinforce and motivate subjects on a regular basis might have higher success rate in bringing about the desired change in diet. One such recent technology to deliver health information is through mobile applications using smartphones, popularly referred to as mobile health interventions (mHealth intervention) [5].

Mobile health interventions have been proved to be effective in various health promotion programs involving, tobacco cessation, weight reduction and diabetes control[6-8]. Although many smartphone apps related to diet and nutrition are available, relatively few have been tested for their effectiveness in promoting health. There is an actual paucity in literature regarding the effectiveness of mobile technology based dietary instruction to reduce the intake of diet rich in highly refined sugar. Hence, a randomized controlled trial was conducted to evaluate the effectiveness of mobile technology based dietary instructions and to compare its effectiveness with standard one to one dietary instructions on reducing cariogenic diet rich in highly refined sugar among healthy adolescents in Chennai. The research hypothesis was that dietary instructions delivered through mobile application are as effective as dietary instruction by standard one to one method.

**Materials and Method**

A double blinded randomized controlled field trial employing concurrent parallel design was conducted among 18 years old apparently healthy college going adolescents. This trial conforms to the recommendations of CONSORT statement 2010 [9]. Prior to the start of the study, a detailed protocol was prepared which was scrutinized and ethical clearance was obtained from the Institutional Review Board bearing the reference number MADC/IRB-XIII/2017/287. No changes were made in the methodology after obtaining the ethical clearance.

A multiphase random sampling technique was employed to recruit the study subjects from a randomly selected Arts and Science College in Chennai city. In stage I, all students in the college (n = 946) were screened to identify subjects who have three or more carious lesions in their oral cavity using mouth mirror and dental explorer based on WHO criteria 2013 [10]. A total of 124 subjects had more than three active carious lesions. In phase II, the identified 124 subjects were asked to submit their 24 hour diet chart to assess their Sweet score based on Nizel and Papas criteria [11]. Subjects whose sweet score was ≥ 15 (Watch out zone) were identified. In stage III, 61 subjects in the Watch-out zone of sweet score were identified and were considered eligible for the dietary intervention. The study subjects were recruited between August and October 2018. The subjects were explained about the purpose of the study and informed voluntary written consent was obtained prior to the start of the study. Subjects who were active in using Whatsapp mobile application were eligible for the study. Subjects who have special dietary requirements were excluded from the study.

The sample size for the study was calculated by fixing alpha error at 5% and beta error at 20%. Expecting a difference of five units in the sweet score between the two groups, the sample size was estimated to be 15 subjects in each group. Expecting a drop rate of 30%, the sample size was increased to 21 subjects in each group. Forty two subjects were randomly selected from the list of 61 eligible subjects by simple random sampling using lottery method for the trial and randomized into the test group and the control group. A random allocation sequence was generated using the online randomization software (www.randomizer.org) using 1:1 ratio. The sequence was generated by an independent personnel not involved in the study (NJE). Based on the sequence, opaque envelopes were prepared, serially numbered and used for the allotting the subjects to the test group and the control group with 21 subjects in each group. The investigator who assessed the diet diary and the statistician who analysed the data were blinded to the intervention.
Baseline data on sweet score of the subjects was assessed by recording a diet chart. The subjects were given a three day diet diary and were instructed to enter details of all food items consumed, its quantity in household measurement, details regarding sugar added, and timing of intake. The primary outcome measure was the average sweet score which was calculated for each individual by summing up the sweet score for each day and dividing it by three. The sweet score for each food item containing sugar was allotted based on the Nizel and Papas criteria [11]. The diet diaries collected from the study subjects were coded to ensure blinding and was assessed by two authors (AKS and SS). The dietary instructions for each subject were tailored according to their needs based on the recommendations given by Nizel and Papas.

Subjects in the test group were sent dietary instructions which were tailored to their needs, on a daily basis through mobile application (Whatsapp). They were also sent motivational picture messages and were encouraged to clear their doubts about the dietary changes through messaging using the same application. Daily reminders like “Are you following the dietary instructions?” were also sent to the subjects in the test group. Subjects in the control group received standard one to one dietary instructions once at the beginning of the trial. The data as well as the one on one diet instructions for the control group were conducted at the college premises during the working hours. The subjects were given choices to have hot or cold beverages without sugar or if they found it difficult to have beverages without adding sugar they were asked to reduce the frequency of consuming the beverage or at least try to taper the number of times of beverage consumption. They were also instructed to avoid candies, carbonated drinks, ice-creams and biscuits and include snacks like popcorn, peanuts and sandwiches in their diet. At the end of 4 weeks, subjects in the test group and control group were asked to record a three day diet diary, using which the post intervention sweet score was calculated.

Data analysis was done per protocol. The data was entered in Microsoft Excel and analysed using SPSS version 19. Descriptive tables were made expressing quantitative variables in terms of mean and standard deviation. Normality of the data was assessed using Shapiro-Wilk test and was found to be non-normally distributed. Differences that existed between the intervention and control groups were tested for statistical significance using Mann-Whitney U test. Wilcoxon sign-rank test was used to compare difference between baseline and post-intervention sweet score in both control as well as the test group. P value < 0.05 was considered to be statistically significant.

Results

A total of 42 subjects were randomly divided into test group and control group with 21 subjects in each group. Among the 21 subjects who received the assigned intervention in each group, totally 12 subjects were eliminated from data analysis either due to loss to follow up or due to incomplete data as shown in Figure 1. Thus the data obtained from 15 subjects were available in each for final data analysis. The mean age of the study subjects was 18±0.49 years and 80% (n=24) were females. The mean number of caries teeth of the study subjects was 3.83±0.28 and there was no significant difference between the test group and the control group. The mean sweet score in the control group was 20.9±6.06 at the baseline which reduced to 13.16±4.37 at the end of four weeks and this difference was statistically significant (p=0.002). In the test group the mean sweet score was 18.02±4.03 at baseline which reduced to 14.5±7.74 and this difference was statistically significant (p=0.03). Table 2 shows that the difference in
the mean percentage reduction in sweet score between the test group and the control group was not statistically significant. Among the 15 subjects in the control group who were in the Watch out zone at baseline, two subjects moved to the Excellent zone and three subjects moved to the Good zone of sweet score as per Nizel and Papas criteria. Similarly, among 15 subjects in the test group, four subjects moved to the Excellent zone and one subject moved to the Good zone of sweet score as per Nizel and Papas criteria.

Among the 15 subjects in the control group who were in the Watch out zone at baseline, two subjects moved to the Excellent zone and three subjects moved to the Good zone of sweet score as per Nizel and Papas criteria. Discussion

The aim of the present study was to assess the effectiveness of mobile technology using Whatsapp to reduce the sweet score among adolescents. The results of this randomized controlled preventive trial showed that daily reminders sent to subjects’ mobile phone through Whatsapp mobile application was effective in reducing the Sweet score based on Nizel and Pappas criteria. mHealth interventions are consumer centered and assist the health care providers in delivering health education as well as patient management [12,13]. India, being the second highest mobile phone users in the world, the study result are of practical importance[14].

Adolescents were included in this trial as they have the ability to make informed decision and can process health information in an effective manner. By the time an individual reaches adolescence, he/she can exercise his preference over the diet and can opt for healthy dietary practices. Further in this study, adolescents were selected as they have access to smart phones and can comprehend the health information sent through Whatsapp.

Past dental caries is considered to be the best predictor of future dental caries [15,16]. Hence, subjects with at least three carious lesions were recruited in the present study as they can be considered high risk population for future dental caries and hence require diet counseling. Further, the subjects’ need for diet counseling was verified by collecting a one day diet chart. Only those who were in the Watch out zone of sweet score were recruited for the study. Multiphase random sampling method was employed in the study to facilitate the identification of eligible subjects in the study.

Whatsapp was preferred over short messaging services since the former had the facility to know whether the daily reminders have been sent and subsequently seen by the recipient. In Whatsapp mobile application, if a message has been sent successfully a single grey tick appears besides the message, and it turns to double grey ticks if the message has been successfully delivered to the recipient. The double grey ticks later turns blue once the recipient has seen the message. This in built check mechanism in Whatsapp helped the investigators to follow if the subjects read the daily reminders. Whatsapp was preferred over other messaging applications because it was a freely downloadable application which was highly popular among adolescents.

However, the results should be interpreted by keeping the limitations of the study in mind. Though the study was conducted for a short duration of four weeks, literature shows that many dietary intervention trials were conducted for such a duration. Although the study saw a high loss to follow up, we believe that the power of the study would not be affected as such a situation was anticipated and the sample size was adjusted accordingly at the start of the study. For the same reason, drop out analysis was also not carried out. There is also a possibility of hawthorne effect as well as social desirability bias might have crept into the study. Both the method of diet instruction namely the standard one on one counseling as well as the dietary instructions delivered through mobile application were effective in bringing about a significant reduction in the sweet score. This study was the first attempt to use mobile application to deliver dietary instructions to reduce the sweet score and hence direct comparison of the study results with previous literature could not be performed. The results of this study can be as the study followed rigorous methodology to select the study subjects in a random manner and the size of the sample was adequate despite the drop out Dietary instructions delivered through mobile application can be used in those instances where there are constraints of time and access to health professionals. This method can be considered cost effective method for delivering health information to a wide population given the high usage of smart phones among adolescents. The present study assessed the
short term effectiveness of the intervention in reducing the sweet score of adolescents. However, the long term impact of mobile application based intervention needs to be assessed in future.

**Conclusion**

It can be concluded that dietary instructions delivered through mobile application is effective in reducing the sweet score.

¹Postgraduate student, Dept of Orthodontics and Dentofacial Orthopaedics, Meenakshi Ammal Dental College, Mugalivakkam, Porur, Chennai- 600125, ²Reader, Dept of Orthodontics and Dentofacial Orthopaedics, Meenakshi Ammal Dental College, Chennai, ³Head of the Department, Dept of Orthodontics and Dentofacial Orthopaedics, Meenakshi Ammal Dental College, Chennai

Abstract

Angle’s class II division 1 malocclusion, being the most commonly occurring type of malocclusion, is challenging to treat especially when there is an underlying skeletal discrepancy. Various fixed functional appliances have been developed over the years by different authors for correction of skeletal class II malocclusion due to retrognathic mandible. Among the fixed functional appliances available for class II correction, Advansync2 (Ormco Co, Glendora, Calif) also known as molar to molar appliance has been used effectively in the recent past. It is a fixed tooth-born functional appliance with an advantage of allowing concurrent use of fixed orthodontic therapy. This facilitates reduction of the overall treatment duration. Two case reports of patients treated using the Advansync2 class II corrector has been presented along with the skeletal and dentoalveolar changes observed during the treatment. The effects observed were similar to most fixed functional appliances however the treatment duration was considerably reduced in all the cases.

Keywords: Class II, Advansync2, fixed functional appliance, cephalometrics.

Introduction:

Angle’s class II malocclusion is one of the most common problems affecting one third of the population and it has been a challenge for all the orthodontists owing to its difficulty in predicting its aetiology and its variable nature of representation[1]. In Indian population, orthodontists face a lot of class II div 1 cases mostly characterized by anteroposterior dental discrepancy which becomes severe when combined with an underlying skeletal disharmony. Although class II malocclusions can be associated with mandibular deficiency or maxillary protrusion or combination, a prevalence of 14.6% among 10 – 13 years is found for mandibular retrusion[2].

The treatment modality should consider factors such as aetiology, age of the patient, severity of malocclusion, growth status, patient compliance etc. for the proper selection of the appliance[2,3]. In growing population, Class II elastics or removable functional appliance are usually advocated for class II malocclusion. However, patient compliance becomes a major concern to employ these treatment modalities.

Fixed functional appliances were developed to bring the mandible forward regardless of patient compliance. Use of fixed functional appliance is an effective way to treat Class II malocclusion in post adolescent patients where the growth is mostly completed, thus dentoalveolar changes takes place predominantly rather than skeletal changes[4]. The Herbst appliance developed by H.Pancherz has been used routinely for nearly 40 years[5]. Over the years there have been many design variations developed by different authors in order to
increase the efficiency and reduce the patient discomfort during appliance wear.

AdvanSync2 is a fixed tooth borne functional appliance developed by Terry Dischinger in 2008. It facilitates functional therapy along with fixed mechanotherapy to reduce the treatment duration and also to improve compliance of the patient[6]. It supposedly gives greater skeletal change when compared to other similar fixed functional appliances.

Case 1:

Diagnosis and treatment plan:

A 15 year old female patient reported with a chief complaint of forwardly placed upper front teeth. She did not have any associated medical history and no associated habits. On extra-oral examination, she had a mesocephalic head type, mesomorphic body type with mesoprosopic facial pattern and an aesthetic built. Her profile examination revealed convex profile, posterior divergence, average nasolabial angle and average clinical FMA with a positive VTO (Figure 1A). On intra-oral examination, she had a bilateral class II molar and class II canine relationship with an increased overjet of 8mm and an overbite of 5mm. She had a tapered maxillary arch and ovoid mandibular arch with imbrications in lower anteriors. She had a decreased intercanine, interpremolar and intermolar width in the maxillary and mandibular arch (Figure 1B).

Cephalometric analysis revealed that the patient was in CVMI stage 3 which indicates that 25% - 65% of the growth was remaining (Figure 2A). According to Moyers
classification of skeletal malocclusion, the patient had a horizontal type F (mandibular retrognathism) pattern; Salzmann classification of skeletal class 2 division 1 and stage 8 of Fishman's classification (Figure 2B). She had anorthognathic maxilla and retrognathic mandible, with average mandibular plane angle and a decreased lower anterior facial height.

Pre-treatment orthopantomogram (OPG) revealed that the patient had full permanent dentition with no missing or supernumerary teeth (Figure 2C).

Based on the above findings, the patient was diagnosed with Angle’s class II div 1 malocclusion on a class II skeletal base with orthognathic maxilla and retrognathic mandible on an average mandibular plane angle with proclined upper and lower incisors with an increased overjet of 8 mm.

**Treatment Progress:** The advansync2 appliance was assembled initially (Figure 3) and activated for 3 mm thrice during the therapy. A full orthodontic appliance of 0.022 slot MBT system was bonded in the upper arch and the lower arch. Aligning and levelling was done sequentially with 0.016 NiTi and 16x22 NiTi. At the end of the fixed functional therapy, bilateral class I molar and class I canine was obtained (Figure 4). The archwires were in 17X25 NiTi at the end of the functional therapy.
Treatment Results: An overall increase in the maxillary inter-canine, inter-premolar and inter-molar widths of about 4mm was achieved at the end of the treatment. The post treatment photographs indicate that the patient had obtained a very pleasing smile with an ideal class I molar and class I canine relationship with an ideal overjet and overbite (Figure 5). The radiographs imply that an ideal crown and root inclinations and angulations have been obtained along with functional occlusion (Figure 6). The total duration of the treatment was 18 months. Beggs wrap around retainer was delivered for the upper arch and a bonded lingual retainer was fixed in the lower arch.
Case 2:

**Diagnosis and treatment plan:** A 12 year old male patient reported to the Department of Orthodontics and Dentofacial Orthopaedics with a chief complaint of forwardly placed upper front teeth. No history of medical illness or trauma was elicited from the patient. There was no association of any temporo-mandibular joint disorders and no associated habits. On extra-oral examination the patient exhibited hypodivergent growth pattern with mesocephalic head type, mesomorphic body type and mesoprosopic facial form. Upon examination of his profile, he had a convex profile with posterior divergence with average nasolabial angle on a low clinical FMA. He exhibited a positive VTO (Figure 7A).

On intra-oral examination, he had a bilateral end-on molar relationship with bilateral end-on canine relationship. He had an increased overjet of 10mm with increased overbite of 4mm. He had a tapered upper arch which was asymmetrical with spacing in relation to 12,13,14,22,23. He had a decreased inter-canine width with average inter-premolar and inter-molar width in the maxillary dental arch. His mandibular arch was
ovoid in shape with anterior crowding and decreased inter-canine, inter-premolar and inter-molar width (Figure 7B). On cephalometric analysis, the patient was in CVMI stage 3 which reveals that 25-65% of the growth was remaining (Figure 8A). According to Moyers classification of skeletal malocclusion, the patient had a horizontal type F (mandibular retrognathism) pattern and Salzmann classification of skeletal class 2 division 1. The patient was in stage 7 of fishman's classification (Figure 8B). The patient had orthognathic maxilla and retrognathic mandible with proclined upper and lower incisors. His lower anterior facial height was decreased. The upper posterior, lower anterior and lower posterior dentoalveolar height were also found to be reduced.

Figure 8: Pre-treatment radiographs A) Lateral cephalogram B) Hand wrist C) OPG

Pre-treatment orthopantomogram (OPG) revealed that the patient had full permanent dentition with no missing or supernumerary teeth (Figure 8C).

Based on the above findings, the patient was diagnosed as Angle’s class II Division 1 dentoalveolar malocclusion on a class II skeletal base attributing to an orthognathic maxilla and retrognathic mandible on a low mandibular plane angle with deep bite, rotated 16, 26, spacing in upper anteriors with crowding in lower anteriors, proclined upper and lower anteriors with increased overjet.

Treatment Progress: A full orthodontic appliance of 0.022 slot MBT system was bonded first in the upper arch and later in the lower arch. Aligning and levelling was done sequentially with 0.016 NiTi and 16x22 NiTi. After the completion of levelling and aligning, advansync2 appliance was assembled (Figure 9). The advansync2 appliance was activated for 3 mm thrice during the therapy. At the end of the fixed functional therapy, bilateral class I molar and class I canine was obtained (Figure 10 & 11). The archwires were in 19X25 NiTi at the end of the functional therapy.

Figure 9: Advansync2 Fixation
Treatment Results: The total duration of the treatment was 15 months. Post treatment photographs depicts the amount of intra oral and extra-oral changes obtained at the end of the treatment (Figure 12). The patient had obtained a pleasing smile and an esthetic soft tissue profile. The post treatment radiographs implies that an ideal inclination and angulation of the crown and root of all teeth have been obtained (Figure 13). There was an overall increase of about 3mm in the maxillary inter-canine, inter-premolar and inter-molar widths suggesting arch expansion. Beggs wrap around retainer was delivered for the upper arch and a bonded lingual retainer was fixed in the lower arch.
Discussion

Different treatment modalities have been developed for the treatment of class II malocclusions such as selective extractions, orthopaedic treatment using head gear or functional appliances, removable and fixed – inter or intra arch appliances and orthognathic surgeries. When the functional appliances are used during active growth periods (before or during puberty), they are intended to induce maximum skeletal growth. However, the amount of skeletal or dental change which will be obtained is difficult to quantify as it depends on various intrinsic and extrinsic factors.

Pangrazio et al stated that removable or fixed functional appliance bring about sagittal and vertical skeletal changes in the jaw positions resulting in orthopaedic and orthodontic changes[7]. Skeletal discrepancy correction during growth period can be achieved using removable as well as fixed functional appliance.

The AdvanSync2 appliance is a fixed functional appliance wherein there is no necessity to align and level the arches prior to the placement of the advansync2 appliance, so capitalizing on residual growth is possible, with favourable decrease in the treatment duration. It
is activated in increments until an edge to edge incisor relationship is attained as suggested by Dischinger[8]. The appliance can be removed after the overcorrection of sagittal discrepancy. As given by Jayachandran et al, Advan sync allowed for the simultaneous use of conventional edgewise appliance (0.022 x 0.028inch slots) [2]. It enhances the mandibular growth by constantly posturing the mandible forward upon closure through the telescoping mechanism.

The molar-to-molar attachment brings about intrusion of the molars and also mild proclination of the lower incisors. However, the amount of lower incisor proclination is lesser when compared to other fixed functional appliances where the attachment is fixed to the mandibular anterior segment thereby resulting in greater proclination of the lower anteriors. The direction of the forces generated by the advansync2 appliance includes sagittal, intrusive, and expansive vectors. The sagittal force vector has produced distal movement of the upper molars and also exerted an anterior force to the mandibular dentition and the mandible. Additionally, an intrusive force of the maxillary posterior region and mandibular anterior region was also evidenced. The push force generated by the appliance also leads to 2-3mm of expansion of the maxillary dental arch. This can be evidenced by the increase in the maxillary inter-canine, inter-premolar and the inter-molar widths in both our patients wherein there was an overall arch expansion of 3-4mm.

According to Ruf and Pancherz, Advan sync has produced significant mandibular growth changes in post pubertal patients, past their peak height velocities[9]. This can be evidenced by the post treatment cephalometric findings in both the patients. Al jewair et al stated that Advansync2 has a head gear like effect on maxillary molars and prevents their mesial movement which brings about class I molar relationship[6]. It also restraints the growth of maxilla which is beneficial in maxillary prognathic cases. This can be evidenced by the decrease in the 6 to ptv measurements on comparison of the pre-treatment and post-treatment cephalograms. Maxillary growth restriction with combination of mandibular molar mesialization and mild lower incisor proclination (IMPA-108°; 99°) with increase in FMA angle (25°; 28°) and lower anterior facial height (ANS-Gn – 58°; 62°) have also been evidenced [Table 1 and Table 2].

In cases having residual growth, alignment of the arches using stainless steel or TMA wire with incorporation of labial root torque prior to appliance placement will be beneficial and hence this has been done in case 2 to minimise the lower incisor proclination. Gandedkar and Celikoglu et al, suggested that lower incisor proclination, which is a drawback of advansync2 appliance can be corrected by fixed appliance with labial root torque, cinch backs and heavy stabilizing wires with miniscrew anchorage[10,11]. By employing labial root torque, reduced proclination of the lower anteriors had been encountered in our second case.

Dislodgement of the bands from the molars was encountered. The bulkiness of the molar bands was a disadvantage which could not resist the occlusal forces resulting in dislodgement. Hence, re-cementation of the bands had to be employed. Maxillary and mandibular molars were intruded due to the occlusal forces and the molar-to-molar attachment. This can be evidenced in the post functional cephalogram wherein there was a decrease in the FMA and lower anterior facial height. This had to be counteracted by extruding the molars during the finishing and settling stages. Some amount of spacing had also occurred in the maxillary arch during the treatment which could be attributed to the arch expansion. This was however controlled using stabilising wires and cinch backs.

According to Bock et al 2015, there was a good dentoskeletal stability for Class II correction using Herbst appliance[12]. According to Wigal et al, overcorrection using herbst appliance during early mixed dentition resulted in a significant reduction in overjet and correction of the molar relationship and also the correction was maintained after the fixed appliance therapy[13]. This was attributed to continuous restraint of the maxillary growth and the dentoalveolar adaptations. Since the advansync2 appliance is a miniaturised modification of the original Herbst appliance, the treatment stability can be expected to be the same.

Conclusion
The advansync2 appliance is an effective class II corrector producing an overall arch expansion of about 3-4mm in the maxillary dental arch. The FMA and the lower anterior facial height had reduced postfunctionally (case 1 - 23° and case 2 – 21°). However, due to the post functional extrusion of the molars, there was an increase in the FMA and the lower anterior facial height (case 1 – 28° and case 2 – 25°) at the end of the treatment. Use of fixed appliances with cinch backs and heavy stabilising
wires prior to appliance fixation had reduced the lower incisor proclination. This case series highlights the use of the Advansync2 appliance as an efficient fixed functional appliance producing clinically significant restriction of the maxillary arch (case 1 -3° and case 2 - 4° reduction in ANB) confirming a short term orthopedic effect on the maxilla. The total treatment duration was shortened to 15-18 months with simultaneous fixed appliance therapy.

Soft Tissue Expanders for Ridge Augmentation: A Review

C. Burnice Nalina Kumari¹, Shalini Arumugam¹, S. Ashok Kumar¹, R. Vijayalakshmi¹

¹Department of Periodontology and Implantology, Faculty of Dentistry, Meenakshi Academy of Higher Education and Research, Chennai, Tamilnadu, India

Abstract

Aesthetics in dentistry is one of the great concern for dental professionals as well as patients for maintenance of oral health. Missing tooth is the common esthetic problems in the patients which can be due to various periodontal or endodontic reasons. There are different treatment options available for replacing the missing tooth and the best alternative treatment is replacement using dental implants. Very often, placement of dental implants gets compromised when there is insufficient ridge or ridge defect. So when there is a ridge defect we need to definitely augment the ridge for the successful placement of dental implants. This article gives a short review about the tissue expanders used for ridge augmentation and their clinical efficiency of achieving a proper ridge morphology.

Keywords: Ridge Augmentation, Soft tissue Expanders, Implant.

Introduction

Missing tooth has become the common esthetic problem. Dental implant placement is one of the best treatment modalities. When there is ridge defect the placement of dental implant gets highly compromised. The correction of soft and hard tissue deficiency in such cases is a challenge for the clinician. Ongoing advances in periodontal surgeries permits the clinicians to reconstruct the insufficient soft tissue in alveolar edges with more unsurprising ways than already potential strategies. The deficiency of soft tissue in the alveolar ridge has been a challenge for the clinicians to achieve a proper augmentation outcome for patients with missing tooth.[1,2,3,4,5] This article is an overview of tissue expanders in a predictable augmentation of defective alveolar ridges.

Ridge Defects:

Alveolar ridge defects are classified into three types. They are:

1. Horizontal
2. Vertical
3. Combination

Different method to treat ridge defects have certain disadvantages such as flap transfer, color mismatch owing to different surgical site and loss of grafted bone. There is a new advanced alternative method namely soft tissue expander that holds an effective method to treat soft tissue deficiency.[6] The tissue expanders reduce morbidity of the donor site.

Horizontal ridge augmentation method:

1. Autogenous bone grafting
2. Allogogenous bone grafting
3. Ridge split technique

Vertical ridge augmentation method:

1. Guided bone regeneration (GBR)
2. Autologous local bone augmentation
3. Graft derived bone blocks
Soft tissue expanders for alveolar augmentation:

**History:** The tissue expansion method was first introduced by NEUMANN and it was used on the skin for ear reconstruction.[7] About 20 years later this tissue expansion method was developed by Austad and Rose in 1982; later Randovan et al developed self inflating tissue expanders. The self inflating tissue expanders require longer time to expand which is about to 8 to 14 weeks.[8]

**Forms of soft tissue expanders:** The tissue expanders exist in two forms; they are cylinder and cupola.

- In the straight edentulous region, the cylinder shaped tissue expander is normally used.
- And then in the curved frontal edentulous region, when one or more teeth is missing the cupola form of tissue expander is used.[10]

**Classification of soft tissue expanders:** Soft tissue expanders are of various types:

**Commercially available forms of tissue expanders:**[14]

1. Standard tissue expander
2. Custom-built expander
3. Differential expander
4. Anatomical expander

These tissue expanders are used in general medicine for various purposes like reconstruction of breast after mastectomy, ear and nose reconstruction surgeries, scar revision surgery, development of skin flap, skin pathology such as burns, vascular deformity, severe irregular scars and post-infection defects.

**Tissue expanders in dentistry:** In modern dentistry, various soft tissue expanders are being used in dentistry since 1990’s. The various commercially available expanders are as follows:

1. Osmed self-inflating tissue expander (Osmed GmbH, Germany):

   Mechanism: It is roofed by a perforated silicone shell to ensure the flow of body fluid. Continuous swelling of the expander occurs under a controlled condition.

   Special feature: The gradual increase in size and volume of the expander stimulates the growth of additional soft tissues.

2. Mentor tissue expander (Mentor Worldwide LLC, Minneapolis):

   **Mechanism:**
   - Dacron-reinforced base allows directional expansion by providing a solid platform.
   - Low risk of side-wall leakage due to its bottom-loading design.
   - Presence of remote injection dome.

   Special Features: Used in reconstruction of facial features like lips, nose and eyelids. Various shapes are available: round, rectangular, elliptical and crescent-shaped.

3. CUITM Brand Tissue Expander (Allergan, California)

   **Mechanism:**
   - Consists of a silicone elastomer envelope, a remote injection dome and a patented fill valve, which allows high rate of inter-operative inflation.
   - It is gradually inflated by injecting sterile saline solution at intervals until the required volume and size is obtained.

   **Special Features:** Temporarily used for the development of skin flap and reconstruction of a defect to provide adequate coverage of prosthesis.

**Osmed Self Inflating Tissue Expander:** Osmed self inflating tissue expander was introduced by Osmed in the year 1999. This expander was used as a new option for tissue expansion in dentistry. This osmotic expander is of second generation and it was first investigated in-vitro to determine the mechanical and swelling properties. Osmotic self inflating tissue expander is expanded because of absorption of body fluids and it is made up of solid material such as methyl methacrylate or vinyl pyrrolidone, hydrogel; these materials absorb the surrounding tissue fluid and it will increase in size over a period of 6-8weeks.[15,16]

**Method of Usage:** The osmotic self inflating tissue expander should be coated with silicone shell which has multiple perforations which allows the influx in tissue fluids. The speed of rate of influx in volume increases over time and it gets controlled by the number of perforations.[17] But the first generation of balloon expanders were not coated by silicone; these expanders get swollen slowly and continuously and the injection dependent peaks need to be avoided.
These expanders are available in various sizes of 0.24, 0.25, 0.7, 1.3 or 2.1ml. Surgical template should be used prior to the placement of the expander.\textsuperscript{[18]}

Initial incision performed, submucosal pouch prepared using scalpel and scissors without elevating the periosteum. Using surgical template expander, the size of the pouch should be controlled. The expander has to be placed into the submucosal pouch using bone fixation screw. The surgical area will be sutured with two-layered sutures using a fine monofilament suture material. Antibiotics (amoxicillin 750mg) should be administered one hour before surgery and prescribed for 7 days. The analgesics (ibuprofen 400mg) should also be given for 7 days. Patient has to come for a weekly follow-up and advised to use 0.2% chlorhexidine mouthwash for 2 weeks. After 6-8 weeks of expansion, soft tissue expansion will be achieved for ridge augmentation.\textsuperscript{[19]}

Mechanism: It is roofed by a perforated silicone shell to ensure the flow of body fluid. There is continuous swelling of the expander occur under a controlled condition.

**Advantages of soft tissue expanders:**

- Soft tissue expander is a simple surgical procedure; there is minimal infection and complication.\textsuperscript{[9]}
- Delayed action is there whereby swelling commences after a predetermined period of time.\textsuperscript{[10]}
- A precisely controlled expansion rate.
- Short surgical procedure, thus reducing post-operative pain.\textsuperscript{[11,12]}
- Low cost of surgery.

**Disadvantages of soft tissue expanders:**

- It can over expand,
- Possibility of infection, serum formation and tissue necrosis.
- Silicone bag may get perforated.
- Hypoxia may occur due to quick expansion.\textsuperscript{[12]}
- Vascularization of tissue is poor in the implantation site.\textsuperscript{[13]}

**Discussion**

“Creep” and mechanical and biological “stretch” are responsible for tissue expansion. This surgical tissue expander was historically invented by Neumann in 1957. It is scientifically proven from clinical studies that vertical ridge augmentation can be done using the principles of tissue expansion.

A second era osmotic expander was first examined in-vitro to decide mechanical and growing properties. The natural biologic properties of different soft tissue expansion, for example, skin or mucous layer, it responds to mechanical powers by tissue development bringing about cell proliferation.\textsuperscript{[20]} The hydrogel at expanders core is the result for mechanical properties of swelling and other parameters. Osmed self inflating tissue expanders, most normally utilized in dentistry was adequate to give a sufficient measure of soft tissue for ridge morphology. The requirement for external filling of body fluids is eliminated, which gives the low frequency of irresistible complexities by increasing the size by ingestion of body fluids.

In case reports, another expander used in specific is the intra-oral utilization of inflatable silicone balloon expander for bone graft surgeries. These expanders will be filled once in seven days by using injection and saline in subcutaneous infusion port until blanching appears in overlying tissues. Therefore this method is extremely technique sensitive and requires more surgical skills.

Also the supraperiosteal placement of hydrogel will prevent the significant resorption in the underlying bone which is seen with the subperiosteal expanders. And then the submucosal pouch is easily prepared. The swelling time is 60 days for hydrogels which is four times the silicone balloon and thus, this gives a prolonged discomfort to the patient. Also, slow and constant development will bring about protected and viable age of soft tissue with the osmotic expander.

The two significant histological changes happen during expansion are as follows: One is the fibrous capsule formation optional to an inordinate statement of collagen framework around implanted devices. A subsequent function happens at the bone surface, which fills in as a counter-bearing territory for the expansile pressure applied by expanders. Fibrous capsule formation is a complicated multifactorial process. Fibrous capsule formation is a muddled multifactorial cycle where the capsule severity has a positive direct relationship with the level of nearby inflammatory responses.\textsuperscript{[21]}

The vertical ridge augmentation in return will effectively prove the success rate for prosthetic rehabilitation of missing teeth and gives a high patient satisfaction.
Conclusion

Soft tissue expander is a simple surgical procedure which gives minimal complications and the incidence rate is low in graft exposition after augmentation surgery. Soft tissue expander using the osmotic tissue expander has more advantages over inflatable silicone balloons for vertical ridge augmentation. The tissue expander seems to be a more effective method in developing minimal amount of tissue after a surgical procedure. The soft tissue expander provides better and adequate tissue coverage and aesthetics. The use of soft tissue expander has started gaining more attention towards the surgical procedures, hence it has more advantages which can overcome the problem such as loss of bone graft and disclosure of bone graft. Based on the numerous responses from patients for esthetics, form and function, the tissue expander is expected to play an important part in intra-oral reconstruction in the future.

Keratoameloblastoma of Oral Cavity: Report of Two Cases

Manoj Prabhakar¹, Sivapathasundharam B.², Logeswari J.³, Manikandhan R.⁴

¹Assistant Professor, ²Professor and Head, ³Associate Professor, Department of Oral Pathology, Meenakshi Academy of Higher Education and Research, Faculty of Dentistry, Meenakshi Ammal Dental College, Chennai-600095, ⁴Professor, Department of Oral and Maxillofacial Surgery, Meenakshi Academy of Higher Education and Research, Faculty of Dentistry, Meenakshi Ammal Dental College, Chennai-600095

Abstract

Keratoameloblastoma is a rare variant and histologically heterogenous group of ameloblastomas, which have areas of ameloblastic epithelium and extensive keratin formation. Other subtypes of ameloblastoma which exhibit keratinisation in their parenchyma include acanthomatous ameloblastoma, and papilliferous keratoameloblastoma. Previously it was thought to be a variant of acanthomatous ameloblastoma with focal areas of keratinisation. Extensive keratin deposition in the connective tissue isolates keratoameloblastoma as a separate entity from acanthomatous ameloblastoma. The tumour presents itself as a destructive and an enlarging mass, mostly involving the posterior region of the mandible, with men being more commonly affected in the ratio of 3:1. This case report presents two cases of keratoameloblastoma, one in the posterior mandible and the other in the anterior maxillary region.

Keywords: Keratoameloblastoma, maxilla, mandible, oral cavity.

Introduction

Odontogenic tumours are the most common tumours of the head and neck region that occupy around 3%–9% of all biopsied specimens, and may arise from or associated with odontogenic apparatus, their derivatives or their remnants.[¹] Among the odontogenic tumours, ameloblastoma is considered to be the most common lesion next toodontoma in Asian population.[²]

Ameloblastoma is a true neoplasm of enamel organ type tissue, which is cytologically benign but clinically aggressive and destructive in its course. It is the most common odontogenic tumor of the jaw bones with various histologic sub-types; follicular and plexiform types being the basic histologic presentation.

Other histomorphic variations include acanthomatous, granular, basal cell, desmoplastic and hemangiomatous. Except the last two, the histological variation occurs in the epithelial component. Desmoplastic ameloblastoma does not exhibit the usual peripheral palisading and central stellate reticulum type cells in the epithelial islands. In contrast the epithelial islands appear compressed with the connective tissue stroma made up of hypocellular dense collagenous fibrous tissue with hyalinisation. Further, the distinct site of occurrence and radiographic appearance of this variant made it to be considered as a separate clinical type in World Health Organization (WHO) classification for odontogenic Tumour, in 2005, however it has been re-included as a histological subtype in 2017 classification.[³] In hemagiomatoustype the alteration is present only in the stroma by the presence of large, endothelial lined blood filled spaces. Amidst these variations, few of the subtypes exhibit keratinisation in their parenchyma, which include acanthomatous ameloblastoma, keratoameloblastoma and papilliferous keratoameloblastoma.[²,⁴]

Keratoameloblastoma is a term, which is used to describe a histologically heterogenous group of ameloblastomas, which have areas of ameloblastic
epithelium and extensive keratin formation.[4] Pindborg in 1970 described the tumour islands with papilliferous projections and keratinizing cysts as papilliferous keratoameloblastoma and the same type of tumour without papilliferous appearance was described by Altini as keratoameloblastoma. WHO in 1992, later considered this variant as acanthomatous ameloblastoma with areas of keratinisation.[4,5] Extensive keratin deposition in the connective tissue isolates keratoameloblastoma as a separate entity from acanthomatous ameloblastoma. Both keratoameloblastoma and papilliferous keratoameloblastoma are considered as extremely rare tumours with distinct histological features.[3]

Here we present two such cases of ameloblastoma with extensive keratinisation. Diagnosing these keratinising lesions and differentiating it from other keratin producing intraosseous neoplasms is a confrontable task and so are discussed in the light of this case report.

Case 1: A 74-year-old female patient reported with the complaint of swelling on her right lower jaw region for past 3 months; which was slow growing and was increasing in its size gradually over the period. The medical and familial history of the patient was non-contributory and there were no associated deleterious habits. Clinical examination revealed gross facial asymmetry with the swelling on right side of the body of mandible extending from the commissure of lip till the angle region. [Fig.1] The surface of the swelling appeared smooth with no evidence of sinus or discharge extra-orally. The lymph nodes were not palpable and the swelling was not associated with pain or paresthesia. Intra orally, the lesion was smooth, extending from the edentulous area of 45 to 48 region, with no surface ulceration. Orthopantamograph revealed a multilocular radiolucent lesion occupying the right body of the mandible, extending from 45 to 48 region. CBCT showed bi-cortical expansion of the right side mandible and erosion on the lingual and inferior surfaces. [Fig.2A, B&C] Fine needle aspiration was performed and no cystic fluid obtained from the swelling. Based on the history, clinical and radiographical features, a provisional diagnosis of benign odontogenic tumour was made with the differential diagnosis of ossifying fibroma. Incisional biopsy was performed and the specimen was sent for histopathological examination.

Fig.1: Swelling on right side of the body of mandible

Fig.2A: OPG revealing multilocular radiolucent lesion occupying the right body of the mandible. 2B & 2C: CBCT showing bi-cortical expansion of the right side mandible
Grossing showed three greyish white soft tissue specimen, which were firm in consistency. Histopathological examination of the H&E stained sections revealed an encapsulated lesion with dense connective tissue stroma. Numerous proliferating odontogenic islands in the form of follicular and plexiform pattern were noted. Most of these epithelial islands show extensive keratin occupying the entire follicle. Few islands showed straggling extension into the connective tissue giving a stretched-out appearance of the follicles at the extremities. [Fig.3A]

![Fig. 3A: Keratin filled follicles with stretched-out appearance at the extremities. 3B: Areas of metaplastic bone formation representing osteoplasia](image)

There were also areas of keratin in the connective tissue extruded from the epithelial islands. These keratin were arranged in a lamellar pattern, giving a ‘pacinian-like stack of lamellated parakeratin’ appearance. Few areas of keratin filled cystic spaces were also evident. The connective tissue was fibrous with a very minimal inflammatory component. Areas of metaplastic bone formation were also evident representing osteoplasia. [Fig.3B] Based on these histologic features, a final diagnosis of keratoameloblastoma was made.

Segmental resection of right side of the body mandible was performed and the entire tumour was removed in toto. A bone clearance of 8mm was given both the sides to prevent recurrence. Only a reconstruction titanium plate (2.5mm) was placed as a reconstructive option as the patient had medical co-morbidities as contraindication for major bone flap reconstruction. A six month review showed no relapse and patient was kept on review for future reconstruction. [Fig.4A&B]

![Fig.4A: Segmental resection of right side of the body mandible. 4B: Placement of reconstruction titanium plate](image)
The excised specimen had a gritty texture when cut during grossing. Histological features of the excised specimen were in confirmatory with the previous diagnosis of keratomeloblastoma.

**Case 2:** A 42-year-old male patient reported with a complaint of slowly expanding painless swelling on the right upper front tooth region. The size of swelling increased gradually to attain the size of $4 \times 4 \text{ cm}^2$ within three months. Intra orally the swelling has expansion more towards the buccal side in relation to 11 to 15 region, extending up to the buccal vestibule, whereas the palatal expansion was very minimal. The swelling was hard on palpation with ill-defined margins. Radiograph revealed mixed radioopacities and radiolucencies with loculations. Together with clinical and radiological features, a provisional diagnosis of benign odontogenic tumour was made. Incisional biopsy was performed and the specimen was sent for histopathological examination.

![Fig.5A Ameloblastic island containing central stellate reticulum like cells 5B: Squamous cells replacing the central stellate reticulum like cells](image1)

![Fig.6: Extrusion of keratin outside the island, resembling shredded carrots](image2)

![Fig.7: ‘Pacinian- like stack of lamellatedparakeratin’ appearance](image3)
Microscopic examination of H and E stained sections revealed strands of odontogenic epithelium interspersed in the connective tissue stroma in the form of small islands and cords. The peripheral cells of the epithelial islands are made up of hyperchromatic, palisading columnar cells with reversal of nuclear polarity. Stellate reticulum like cells are present in the center of these islands. [Fig.5A] In few islands, the central stellate reticulum like cells are replaced by squamous cells. [Fig.5B] The connective tissue stroma was moderately vascular with thick irregularly arranged collagen fibres exhibiting desmoplasia. Further focal areas showed multiple large and small cystic spaces, lined by low columnar to flat cells, with central squamoid island containing eosinophilic, acellular discrete strands/bands of keratin. [Fig.6] Extrusion of keratin outside the island, resembling shredded carrots or lamellar pattern, giving a ‘pacinian- like stack of lamellatedparakeratin’ appearance was striking. [Fig.7] All the above histological findings suggested the diagnosis of keratoameloblastoma. Radical excision of the tumour was done and the histopathological examination of the excised specimen revealed features similar to the preoperative specimen and confirmatory to that of the preoperative histological diagnosis.

Discussion

Ameloblastoma is a highly polymorphic benign neoplasm of odontogenic origin, with its few variant undergoing different forms of metaplasia. This kind of metaplastic change can be attributed to the multipotentiality of the odontogenic epithelium. Robinson defined ameloblastoma as unicentric, nonfunctional, intermittent in growth, anatomically benign and clinically persistent. Its benign nature, grotesque size, locally invasive behaviour, and common occurrence make the lesion distinct from other odontogenic tumours.

Pindborg in 1970 first proposed the term Keratoameloblastoma (KA) and later WHO (1992) defined KA as an ameloblastoma with extensive keratinisation. However, WHO in 2005 classification for odontogenic tumours has not mentioned this term but considered this lesion as a variant of acanthomatousameloablastoma with focal keratinisation. The reason for keratoameloblastoma, failed to get placed in the WHO classification of odontogenic tumors, could be due to the lack of adequate number of case reports and no different biological behaviour from conventional ameloblastomas. Pindborg also noted few cystic areas with some papilliferous appearance of odontogenic islands and named it as papilliferouskeratoameloblastoma (PKA). Some authors consider PKA as a sub-type of KA; however, both are considered as rare variants of ameloblastoma.

There are about 19 cases of KA, which have been reported till date in the English literature. In general, KA, shows similar demographic distribution like conventional ameloblastoma in terms of age, sex and site. The age group ranges from 26 to 76 years with 44 years as a mean age, with men being more commonly affected in the ratio of 3:1.

The tumour presents itself as a destructive and an enlarging mass, mostly involving the posterior region of the mandible including body and ramus, followed by posterior maxilla, anterior mandible and maxilla being the least. All the cases reported in the literature are intra-osseous with a very few report on its peripheral variant. Radiographically, it presents as a radiolucent lesion with marginal erosion and perforation of the cortical plates as is seen in the present case.

The varied histomorphology of KA, makes the lesion unique and enabled to categorise it histologically into four subtypes by Whitt, namely:

(i) Papilliferous histology: odontogenic epithelium shows papillary projections into the cystic spaces

(ii) Simple histology: odontogenic follicles are filled with parakeratin or ortho-keratin and lined by ameloblast-like cells showing reversal of polarity

(iii) Simple histology with KCOT(Kerato Cystic Odontogenic Tumour)-like features: shows similar features of simple type, in addition it contains features of conventional KCOT (however, in 2017 WHO Classification it was reverted back to cyst category).

(iv) Complex histology: consists of epithelial follicles packed with parakeratin or orthokeratin, extrusion of keratin masses into connective tissue stroma in the form of “Pacinian-like stacks” with or without foreign body reaction.

Histopathological features in both the cases reveal a complex histology as there were numerous odontogenic epithelial islands arranged in the form of follicles, lined by hyperchromatic, palisading columnar cells with reversal of nuclear polarity, with the presence of
stellate reticulum like cells in the center of these islands. Extensive keratin formation were noticed in most of the islands. The stroma appears highly collagenous, exhibiting marked desmoplasia. Areas of extruded keratin into the connective tissue were also seen, giving a ‘pacinian- like stack of lamellatedparakeratin’ appearance. Focal areas of large and small cystic spaces lined by low columnar cells with multiple clusters of mucous cells were also noticed. Few of the islands were not characteristically lined by odontogenic epithelial cells showing reversal of polarity validating the fact that few cases reported in the literature lack convincing histological evidence of typical ameloblastoma.

Metaplastic bone formation, termed as osteoplasia, was also noticed within the collagenized fibrous connective tissue stroma. A number of immunohistochemical (IHC) markers used for ameloblastoma, include CK 5/6, CK 13, CK 14 and CK 19. Each of these markers’ expression vary according to stages of tooth germ development and subtypes of the tumour. Usually, CK13 is expressed in the stellate reticulum- like cells; CK 14 in the peripheral cells and CK 19 in all the cells of solid/multicystic and unicysticameloblastomas including acanthomatous and granular variant. This kind of expression does not hold the same for few variants like desmoplastic and peripheral ameloblastoma. Contrary to this view, the pattern of IHC expression was altered in the present case that the epithelial cells were not expressed by CK 14 and CK 19 markers. This negative expression suggests that origin of this tumour could even be in a very primitive stage of ameloblasts and need not be essentially in a later stage for its development. Molecular markers related to enamel proteins and transcription factors can be used to express these odontogenic epithelial cells in such scenario.

Keratinisation in amelolastoma can be attributed to any of the following. It can evolve as a squamous metaplastic change in the central stellate reticulum–like cells in the ameloblastic follicles, as in acanthomatous variant; or can arisen from keratinising ameloblastoma; or due to ameloblastomatous transformation in the pre-exiting KCOT. The present case does not exhibit KCOT like areas, and so, the cause for keratinisation can be due to acanthomatousameloblastoma or de novo. However, straggling extension of the epithelial islands at the extremities, blending with the highly fibrous connective tissue, along with few areas of osteoplasia, triggers a thought of KA as a sequela or the later stage of desmoplastic ameloblastoma or a hybrid variant.

Differentiating KA from other keratin producing intraosseous neoplasms (KPIOns) is a requisite at this juncture for a fitting diagnosis. The most debatable acanthomatousameloblastoma can be distinguished from KA by the presence of keratin within the follicles in acanthomatousameloblastoma, whereas, there will be extrusion of keratin into connective tissue stroma in KA. Absence of stromal keratinisation, classic tall columnar cells with reversal of nuclear polarityand stellate reticulum like cells draws out solid variant of keratocystic odontogenic tumor (SKCOT) from the spectrum of diagnosing KA. Primary intraosseous carcinoma (PIOC) is also a keratinising malignant neoplasm of jaw bones. Absence of connection with the oral mucosa and presence of varying dysplastic features distinguishes PIOC from KA.

Treatment modality include wider excision and segmental resection of the affected bone combined with post-treatment follow-up. Aggressive surgical resection along with 10 mm clearance may be necessary to prevent recurrence and reconstruction need diligent planning as the affected patients are usually of an older age. Recurrence is noted in a very minimal number of cases. The biological behaviour and prognosis of this lesion compared to other histological variants of ameloblastoma cannot be ascertained due to the limited number of cases and meagre follow-up.

Keratoameloblastoma is a rare variant of conventional ameloblastoma and its biological behaviour is poorly understood. Having only a handful of cases in the literature, it requires strenuous learning for the pathologists to know its origin, course and recurrence. These kind of subtypes adds significance for academic interest but a knowledge of how these subtypes influence the nature of the tumor is a must requisite.

Anthropometric Measurement Changes in Orthodontic and Orthognathic Surgery Patients in Dravidian Population: A Photographic Retrospective Study

Hemanth Karalapti¹, Ratna Parameswaran², Nagachandran Kandasamy³, Devaki Vijaylakshmi⁴

¹Senior Lecturer, Department of Orthodontics and Orthopeadics, Madha Dental College, Chennai, Tamilnadu, India, ²Professor, Department of Orthodontics and Orthopeadics, Meenakshi Ammal Dental College, Chennai, Tamilnadu, India, ³Professor, Department of Orthodontics and Orthopeadics, Madha Dental College, Chennai, Tamilnadu, India, ⁴Professor and Head of the Department, Department of Orthodontics and Orthopeadics, Meenakshi Ammal Dental College, Chennai, Tamilnadu, India

Abstract

Introduction: To evaluate the anthropometric and divine proportion measurements using pre and post-treatment photographs in patients subjected to only orthodontic treatment and orthodontics with orthognathic surgery.

Materials and Method: The sample size was calculated with a power value of 95% which yielded a sample size of 126 patients. The pre and post photographs of these patients were divided into two groups namely Group I where patients treated only with orthodontics (64 patients) and Group II where patients were treated by both orthodontics and orthognathic surgery (52 patients). The Standard Anthropometric facial proportions and divine proportion measurements were used to digitally assess the pre and post-treatment facial changes using Ilexis FACAD software (Version 3.8.00). These photographs were standardized with the help of interpupillary line measurement which was done on both digital photographs and clinically and correlated.

Results: Group I showed statistical significance (P<0.005) with upper lip length, lower lip length, upper lip, and lower lip vermillion changes whereas Group II subjects showed statistical significance in Skeletal vertical changes. The lower facial height, lower lip length was significant in Class II orthognathic patients whereas the upper facial height, alar basal width, and mouth width showed significant differences (P<0.005) in Class III orthognathic patients.

Conclusion: Significant changes were noticed in both groups when pre and post-treatment values were compared, but orthognathic subjects comparatively showed higher significance values in vertical parameters which were near to the ideal anthropometric values and divine proportion ratios.

Keywords: Anthropometrics, Photographic analysis, divine proportions and Orthognathicsurgery.

Introduction

Facial beauty and physical Esthetics has a strong emphasis on modern social society and individual well-being. The 18th-century philosopher Alexander Baumgarten, who established esthetics as a distinct field of philosophy, coined the term, which is derived from the Greek word for sensory perception (aisthesis) [¹]. Aesthetics play a major role in day to day life of the people for overall social and personal happiness. Even though tastes, fashion, and standards of beauty change from time to time, there appears to be certain facial proportions and relationships that provide a basis for the diagnosis and planning for improvement of facial form.

Many authors over the years tried quantifying facial beauty and physical attractiveness, among which Ricketts\(^2\) gave “golden proportions” through a mathematical proportion of Fibonacci series and Farkas\(^3\) introduced “Anthropometric measurements” based on the extensive technical study of face and head measurements in accordance to age, sex, and ethnic origin. And these indices are referred to quantify and qualify the term overall aesthetics of the face.

In today’s society esthetics play an overwhelming role in a variety of media. The facial standards of esthetics bring the perception of beauty and social acceptance \(^4\). In recent times, patients seek treatment with the most common motive being the enhancement of facial beauty through orthodontic and orthognathic procedures.

The present study aimed to compute the facial esthetics using two-dimensional photographs through anthropometric measurements and divine proportions in patients who underwent orthodontic treatment only compared with patients who underwent Orthodontic and Orthognathic surgical treatment. This comparison adds insight to the present literature based on the dramatic changes that can be achieved through Orthodontic and Orthognathic treatment modalities respectively.

The study also aimed to perceive whether the post orthodontic or post orthognathic facial measurements obtained, were near to the ideal anthropometric measurements and divine proportions. The null hypothesis states that there are no changes in the anthropometric measurements when patients are subjected to orthodontic or orthognathic surgery protocols.

**Materials and Method**

This prospective study was conducted by evaluating records of patients who underwent Orthodontic treatment only and Orthodontic combined with Orthognathic treatment in the Department of Orthodontics and Dentofacial Orthopaedics at our center.

The inclusion criteria for the Orthodontic treatment group (Group I) were patients with dentoalveolar Class I bimaxillary protrusion, dentoalveolar Class II division 1 with an overjet of less than 7 mm, dentoalveolar Class II division 2, and dentoalveolar Class III with an edge to edge incisal relationship. The Orthognathic surgical Group (Group II) comprised of patients who presented with Skeletal Class II division 1 (Sub-group A) with overjet greater than 7 mm (ANB≥6°) and Skeletal Class III (Sub-group B) with ANB≤-1°.

Patients with gross facial asymmetry, craniofacial deformity, systemic illness, improper records, cleft lip and cleft palate, and patients who required re-treatment and those under treatment progress were excluded from the study.

Based on the power factor of about 95% the sample size calculated was 128 patients.

The Pre and Post-treatment Frontal view photographs of 116 Patients were collected from the archives in our center over a period of 15 years, of which 64 were in group I (Orthodontics only) and 52 were in group II (Orthodontics and Orthognathic surgery) as only 52 patients records were retrievable. The sample size was kept to 116 patients as we narrowed it to only the Dravidian population who underwent orthodontic treatment and orthodontic combined with orthognathic surgery exclusively in our center. The subjects who underwent orthodontic therapy were randomly selected relative to the other group. The patient’s age ranged from 13 to 35 years (Mean -25.1yrs). Pre-treatment and Post-treatment photographs were obtained using a Digital camera (Nikon D3200, Japan) fitted with a Ring Flash (Nissin MF18) onto a tripod stand with the object to operator’s distance measuring to 5 feet 8 and a standardized zoom of 105 mm. The sample allocation was done on a randomized method in individual groups.

A Digital Photographic album was created for both the groups and each album consisted of Pre and Post-treatment photographs which were paired and were placed in a random sequence and assessed for change in proportions.

The images were imported into the computerized software (FACAD AB-2014 software, Version 3.8.0.0, Sweden) by a single operator. The standardization and calibration of the photographs were done by correlating the digitized inter-pupillary measurement from the photographs with the clinical measurement of inter-pupillary width in patients. The inter-pupillary distance was used as a stable facial reference as it is not subjected to any change after the age of 11 years for girls and 15 years for boys.\(^7\) The Inter-pupillary width was calculated, from the mid-point of the pupil of each eye or mid-point of each orbit on either side.\(^9\)

Twenty-seven parameters of the Anthropometric
proportion5 were used for the analysis (Table I, Table II, Table III) since the software which was employed for this study could digitize parameters that were in the 2D frontal view. Using the analysis, 116 patient’s pre and post-treatment facial proportional changes were measured and evaluated.

**Statistical Analysis:** The results are statistically analysed and tabulated using SPSS software (produced by SPSS Inc software house in Delaware and incorporated into IBM in 2010, United States of America). The unpaired student ‘t’ test was used to compare the data between the groups and the paired student t-test was used within the groups.

**Results**

The Tables (Tables I and II) demonstrates the mean, standard deviation, and mean differences, as well as the comparison of the variables between pre and post-treatment values of both Orthodontic and Orthognathic groups of patients. The Anthropometric measurements of pre-treatment values when compared to post-treatment values demonstrated significant differences in almost all parameters of the craniofacial region.

The parameters concerning the mouth width, upper and lower lip lengths, upper and lower vermillion heights, mandible ratio, mandible face height ratios showed statistical significance in the orthodontic group (p ≤0.005).

The measurements concerning facial height, lower face height, upper and lower lip lengths, lower lip vermillion, mandible to face height ratio showed statistical significance (p ≤0.005) in Class II skeletal patients (Group II A).

In Class III skeletal patients (Group II B) the parameters concerning facial height, upper facial height, lower lip length, upper and lower lip vermillion, facial index, mandible width- facial height ratio, mandible-lower facial height ratio, and chin-mandible face index showed statistical significance (p ≤0.005).

Regarding divine proportions, the parameters that showed statistical significance are alae width-mouth width ratio and upper lip length to lower lip length ratio in Group I.

In the Orthognathic subgroup (Group II A), forehead to eye and eye to menton ratio, upper lip length, and lower lip length ratios showed statistical significance (p ≤0.005) whereas in the Orthognathic subgroup (Group II B) all the vertical divine proportions showed statistical significance (p ≤0.005) as shown in Table 2.

Discussion

The present study aimed to observe the changes in anthropometric measurements post orthodontic and post orthognathic surgery in the Dravidian population. This study also attempted to discuss the proportion achieved after the treatment was nearest to the ratio of indices of golden (divine) proportion (0.62)\(^2\). Considering this, the changes that were observed in the orthodontic, as well as an orthognathic group, resulted in both ratio and percentage format where the value of ratios are represented by a mathematical assumption of 0.6:1. According to rickets et al, the ratio of 0.6:1 symbolizes the golden proportion which the standard for an aesthetically attractive profile. The maximum changes in the anthropometric parameter were observed in an orthodontic group, statistical significance was upper lip length, lower lip length, upper vermillion show, lower vermillion which was in concordance with a study done by Benedito V. Freitas et al\(^{17}\).

In the orthodontic group, divine proportion ratio\(^2\) changes are evident in alae width and mouth width caused due to the reduction in proclination of the anterior teeth which bring the value closer to the divine proportion ratio (0.6). The other parameter that showed
significant alteration is the ratio of the upper lip to lower lip length. This change was attributed to the proclination and bite correction which in turn increases the lip length thus bringing it closer to the value of pi or golden proportion. According to Jovana Milutinović, lower facial parameters were approaching the set of divine proportions which is per this study.

In the present study when the Class II orthognathic group was considered, the changes in the chin and convexity were improved due to surgery. The other noticeable changes observed were an increase in total facial height, Lower Face height, upper lip length, lower lip length, and lower vermillion show. These changes were attributed to the advancement of the mandible in a downward and forward direction achieved by Bilateral Sagittal Split Osteotomy (BSSO) which led to a better facial profile and bringing these parameters closer to the ideal value of anthropometric measurements. Whereas, the increase in upper lip length is attributed to a reduction in proclination of the upper anterior teeth. which is in accordance with Silvia Augusta Braga Reis et al who stated that facial profile convexity and chin prominence are the most important factors which influence facial attractiveness.

In Class II orthognathic patients, the changes in divine proportions were evident in the eye to menton which is a vertical parameter brought about by the BSSO procedure. This is because the mandible is displaced forward owing to the increase in lower face vertical height thus changing the ratio of the eye to menton and forehead to eye achieving a divine proportion. These changes that are observed in the orthognathic group are also in concurrence with the study reported by Siamak Hemmatpour. Also the upper lip length and lower lip length ratios were altered due to an increase in lower face height by mandibular advancement that caused a stretch in the soft tissue drape of the lower face thus establishing golden proportion ratio of 0.6:1.

In class III orthognathic patients, the changes in Anthropometric measurements were evident in total facial height, upper face height, lower lip length, upper vermillion show, lower vermillion show. These apparent changes were attributed to the downward and forward movement of the Maxilla through Lefort I osteotomy in combination with an upward and backward displacement of the Mandible due to Mandibular set back (BSSO). The combination or single jaw surgery may vary based on the malocclusion and deformities of the individual’s deficiencies where the facial heights are altered. This profile improvement gives the patient a good facial appearance and also brings the linear and angular measurements of the patient’s facial landmarks closer to that of Anthropometric measurements.

The Indices and ratios in Class III orthognathic patients revealed changes in Facial index, Mandibular width face height, Mandibular lower facial height, Chin Mandible face index. Post-surgical facial height alteration influences all the above-mentioned indices. According to Raymond Edler Orthognathic surgery showed dramatic changes in the soft tissue profile and also anthropometric measurements and indices showed good repeatability in terms of clinical assessment, photography, and digitization to compare these changes that are acquired through orthognathic surgical treatment modalities.

Divine proportions in Class III orthognathic patients revealed evident changes in the parameters such as forehead to eye and eye to menton. These changes are due to the facial height changes caused by the Maxillary and Mandibular surgery (combination or non- combinations) thus achieving a golden proportion in vertical parameters. Secondly, forehead to nose and nose to menton showed changes due to Maxillary advancement (Lefort I osteotomy) which brought about facial changes closer to the golden proportion. The third parameter which was altered was mouth to eye and mouth to menton, owing to the alteration of the facial height. Finally, the ratio of the upper lip to lower lip length was altered due to changes observed in lower face height due to mandibular set back causing an alteration in the soft tissue drape. According to Baker BW et al orthognathic and orthodontic treatment results in an improvement of overall esthetics of patients and also the proportions were equally likely to move away from or toward the divine proportion.

Though significant changes were noticed in both the groups, orthognathic patients revealed higher significance due to the changes in skeletal parameters thereby altering soft tissue drape resulting in values nearer to ideal anthropometric norms.

However, the study would have elicited more accurate results if 3D software was used. The future scope of the study would be assessing the anthropometric values and divine proportions by involving corrections in patients with craniofacial deformity and asymmetry.
Conclusion

1. Both orthodontic and orthognathic patients showed evident facial changes in vertical proportions post-treatment.

2. Orthodontic patients exhibited significant changes concerning mouth width ratios due to the retraction of the anterior teeth.

3. Orthognathic patients unveiled more significant vertical facial changes owing to the alteration of the skeletal bases deriving proportions nigh anthropometric & facial indices.

Tooth Eruption: A Review

Sathya Priya R. 1, Kavitha B.2, Sivapathasundharam B.3

1Post Graduate Student, 2Professor, 3Professor and Head of the Department, Department of Oral Pathology, Meenakshi Ammal Dental College, Meenakshi Academy of Higher Education and Research, Chennai, India

Abstract

Tooth eruption, is a developmental process which occurs in a 3–dimension, and various factors are considered to play a major role during tooth eruption. Numerous theories are put forward to explain this process in a different perspective. A better elucidation and understanding of this entire process is essential to identify the cause behind any deviations in eruption from the normal and in treating the same.

Keywords: Tooth eruption, root formation, pulp growth, bone remodelling, Vascular Pressure.

Introduction

The term, “Eruption” takes its origin from a latin word “Erumpere”. The definition of eruption is “the axial (or) occlusal movement of the tooth from its position of development in the jaws to its functional position in the occlusal plane”.[1] The phenomenon of tooth eruption is considered to be physiological, the timing of which depends on numerous factors. The initiation of tooth development and its eruption in the appropriate time becomes essential for the maintenance of a proper and healthy dentition.2 In the present paper, the initiation of tooth formation, various stages of the tooth development, root formation and sequence of eruption are discussed.

Initiation of tooth development: The initiation of tooth development is thought to be induced by the neural crest cells, which arise from the embryonic ectodermal layer.[1] In the tentative position of the jaws, a horse shoe shaped Primary epithelial band forms corresponding to the future dental arches. This gives out two subdivisions–Dental Lamina, from which the tooth bud forms and the Vestibular Lamina from which the vestibule develops.[5] Successional lamina arises lingually from the dental lamina, from which the permanent dentition arises, which are the successors of the deciduous teeth. The dental lamina disappears later but few remnants remain, called as the “Cell rests of Serres”.1 Vestibular lamina is the one which rapidly enlarges and degenerates thereby forming the future vestibule. With initiation, proliferative activity gets intensified at certain points of dental lamina which in turn results in the various stages of tooth development. The formative cells which arises as a result of proliferation is said to give the blueprint for future tooth by morpho differentiation.

Stages: Indicating the morphologic changes, the stages of the tooth development process includes, Bud, Cap, Early and Advanced Bell stages (Fig: 1). In the bud stage, each dental lamina differentiates at 10 different points to give rise to the ovoid or round swellings from the basement membrane, corresponding to the future dental positions. The swellings of the dental lamina resembles to bud microscopically. Since certain cells of the tooth bud form the enamel, it constitutes the enamel organ. Condensed ectomesenchyme subjacent to enamel organ constitutes dental papilla. Dental sac constitutes the condensed ectomesenchyme surrounding the tooth bud and dental papilla.

Cap stage of tooth development forms as a result of proliferation of tooth bud and an invagination in it. The peripheral cuboidal cells form the outer enamel epithelium and in contrast to this, the inner enamel epithelium is composed of tall columnar cells lining the
concaivity. In addition to these layers, there are central stellate cells which synthesize and secrete the hydrophilic glycosaminoglycans, and forms a layer called the Stellate Reticulum.\[1\] Enamel knot is a structure which is formed by the condensation of the central most cells of the enamel organ and studies reveal that, enamel knot acts as a signalling centre, playing essential role in determining tooth shape.\[1\]

In bell stage, the epithelial cap deepens and resembles the shape of a bell with outer enamel epithelium bordering enamel organ and inner enamel epithelium bordering dental papilla. It is divided into early and advanced bell stage. The point where outer and inner epithelium meets is called the cervical loop. In the cervical loop, cell division continues until crown formation is complete and epithelial component of root arises from here. Stratum intermedium forms between inner enamel epithelium and stellate reticulum.\[5\] During this stage, ameloblasts arise from inner enamel epithelium, odontoblasts differentiate from dental papilla, forming predentin and dentin layer (dentinogenesis), followed by enamel formation (amelogenesis). This process of deposition of dental hard tissues is referred to as apposition.

**Root formation:** Once the enamel and dentin reach the future CEJ, the root formation begins. The Hertwigs Epithelial Root Sheath (HERS) (Fig: 2), which plays an essential role in radicular dentin formation and in molding the root shape, forms by the proliferation of cervical loop and encloses the basal portion of the dental pulp. With the odontoblastic differentiation, the root dentin forms following crown dentin. With the odontoblastic differentiation, the HERS loses it structural continuity and detaches from the root. The remnants of HERS remain as discrete clusters which are referred to as the epithelial cell rests of Malassez.\[1\]

The root formation is followed by the formation of periodontal ligament and alveolar bone. Periodontal ligament, a highly vascular specialized connective tissue covers the tooth root and is present between cementum and alveolar bone. During the process of formation of Periodontal ligament, the cervical loop of the tooth bud is formed by the proliferation of inner and outer enamel epithelium in a continuous manner. The mesenchymal cells of dental follicle proper and perifollicular mesenchyme are the two different populations of the dental follicle cells. These cells are randomly oriented between the alveolar bone and hertwigs epithelial root sheath. Comparing these two populations of cells, the perifollicular mesenchymal cells which have an euchromatic nucleus, very little cytoplasm, rough endoplasmic reticulum with short cisternae, mitochondria, free ribosomes and an inactive golgi area are more widely separated. With the continuation in the root formation process, the cells in the perifollicular area becomes elongated due to gain in polarity. As a result of this, active synthesis and deposition of collagen fibrils and glycoproteins happens. The synthesized collagen fibres get embedded in the cementum. The alveolar bone, a part of maxilla and mandible, forms gradually with development and eruption of teeth. This forms and supports the tooth socket and diminishes in height with tooth loss.\[1\]

**Tooth movement:** The complex physiological tooth movement starts with the development of tooth and continues even after eruption, hence categorized into pre-eruptive, eruptive and post-eruptive movements. Pre-eruptive tooth movement begins from the time of initiation of tooth formation to the time of initiation of root formation.\[5\] The tooth movement occurs in association with the growth of the jaws. The pre-eruptive movement places the teeth in a definitive position in the jaw thereby enabling eruptive movement.\[5\] Pre-eruptive tooth movements occur intraosseously and requires remodelling of the bony crypt wall which happens by the selective deposition and removal of the bone.\[6\]

The eruptive phase of tooth movement starts from the root formation till the tooth reaches the occlusal plane. The tooth moves from its developmental position to the occlusal level. The principal direction of movement is either axial or occlusal. After the emergence, the tooth crown keeps moving occlusally until it comes in contact with its antagonist in the occlusal plane. During this process, the tooth crown begins to get exposed gradually with an apical shift of the dentogingival junction. For the intraosseous eruptive tooth movements, two things have to happen – the resorption of overlying tissue to provide an eruptive path and a force for the tooth to move vertically. The blood vessels decrease in number and is also accompanied by the degeneration of nerve fibers and the connective tissue overlying the tooth germ. This leads to the formation of an eruption pathway, which appears as an inverted triangular area of altered tissue.\[6\]

The post eruptive tooth movements happen, once the tooth reaches its functional position in the oral cavity. These tooth movements maintain the position of
the erupted tooth while the jaw continues to grow and compensates for the occlusal and proximal wear. These movements compensate the proximal and occlusal wear and continue throughout the life time.\(^6\) Tooth wear occurs even at the contact points between the teeth. In order to compensate it a proximal drift takes place. Histologically this drift is a selective deposition and resorption of bone on the socket walls by osteoblasts and osteoclasts respectively. Post eruptive tooth movements are divided into 3 categories namely, movements which helps in accommodating the jaw growth, movements which compensate the occlusal wear, to compensate for continued occlusal wear, movements which aids in accommodating the wear of tooth that occurs interproximally.\(^5\)

**Eruption:** Based on the type of tooth and the time of eruption, human dentition is categorized into Primary (Deciduous) dentition (Fig: 4A), Mixed dentition (Fig: 4B) and Secondary (Permanent) dentition (Fig: 4C). Primary dentition comprises of 20 teeth and erupts between 6 months and 2.5 years. They start exfoliating between 6 years to 11 years. Permanent dentition erupts between 6 – 7 years and 18 – 21 years of age. Since both the primary and permanent dentition is present in the age group between 6 – 12 years, this phase is termed as mixed dentition phase.

**Theories:** The mechanism which brings about the movement of tooth is still debatable, as it is thought to be a combination of various factors. Various theories have been proposed in order to brief out the process of eruption.\(^{12}\) The various theories of tooth eruption include:

**Root Formation Theory:** Formation of root causes an increase in root length and hence this is considered to be the essential cause for tooth eruption, as root growth produces a force sufficient for bone resorption. This concludes that, although a force is produced by root growth, this force cannot be translated into eruptive tooth movement unless there exist some structure that withstands the force at the base of the tooth.\(^5\) However the facts that went on as a drawback was that even rootless teeth was able to erupt. Some teeth erupt to a greater distance than the total root length; and the certain teeth erupt after root formation is completed or when the tissue essential for root formation is removed.\(^{14}\)

**Pulp Growth Theory:** As the root formation continues, the thickness of the radicular dentin increases resulting in the decrease in size of pulp cavity. The pulp growth theory states that the growth or constriction of the pulp generates a force which is propulsive in nature by the growth of dentin, pulp and the hydraulic effects happening within the pulpal vasculature. The drawback of this theory is that the eruption happens even in pulpectomized tooth.\(^6\)

**Vascular Pressure Theory:** Also known as “Blood thrust theory” or “Hydrostatic pressure theory”, it is considered to overlap with the pulp growth theory. It is believed that the tooth movement synchronises with the arterial pressure, thereby the local volume changes produce a limited tooth movement. It also states that the eruptive force is provided by the pressure exerted by the blood vessels within the tooth. This is against the fact that pulpless tooth erupt. Also studies state that the removal of root and local vasculature does not impede the eruption of tooth, which again becomes debatable.\(^{14}\)

**Bone Remodelling Theory:** This theory tends to play a prime role in tooth movement. Bony remodelling of the jaws has been linked to the tooth eruption, in that, in the pre-eruptive phase of tooth movement, the growth pattern of maxilla or mandible moves the teeth by the process of selective deposition and resorption of bone. Whether the bony remodelling around the teeth causes the teeth to erupt or is the effect of the tooth movement is not clearly known, but both the circumstances apply.\(^5\) Studies also indicate that the control resides within the bone lining cells, the osteoblasts. However it is also stated that a conclusion cannot be drawn out unless there also happens coincidental bone deposition in the base of the crypt, the prevention of which can pose a challenge to the eruption of tooth.\(^{14}\)

**Periodontal Ligament Traction Theory:** The formation and renewal of periodontal ligament is considered to be an essential factor in tooth eruption due to the traction power of the fibroblasts. A strong deal of evidence says that the eruptive forces exist in the dental follicle – periodontal ligament complex.\(^{14}\) Shrinkage of collagen fibers exhibits a force that plays a very important role in tooth eruption. If the tooth has to erupt, there should be a space in the eruption path, a lift or pressure from the apical region and required adaptability in the periodontal ligament.\(^{16}\) Bone resorption and deposition involved which plays a major role in the movement of the tooth, is considered to be one of the critical surface phenomenon between the soft tissue and the bony interface, which are present surrounding the developing
tooth. Later it is confirmed that the periodontal ligament fibroblast orientation significantly increased during eruption. However, studies state that, the force required for the normal physiological movement of the tooth is not exerted by the fibroblasts. Still, the lack of occlusal movement or mesial drift of ankylosed tooth and implants, which lack the intervening periodontal ligamentis yet to be explained.[14]

**Neuromuscular Theory:** Also known as the unification theory of tooth eruption it is primarily based on the neuromuscular forces which takes its origin from the contraction if the musculature present in the orofacial region. This theory states that the combined forces exhibited by the orofacial muscles, which primarily are controlled by central nervous system, play an essential role in the active movements of a tooth. This combination of forces are converted into energies of various forms such as electrical, electrochemical and biomechanical energies, which becomes essential for the stimulation of cellular and molecular activities taking place within and around the dental follicle and enamel organ. These changes happens inorder to prepare a pathway as well as to bring out other cellular functions required for a developing tooth to erupt.[15]

**Dental Follicle Theory:** This theory postulates that the dental follicle has the potency to induce, resorption of bone above the developing crown and bone apposition below it. This in turn brings about an eruptive pathway. [6]Experimental removal of dental follicle results in eruption failure. Various molecular studies reveal that the eruption is regulated by inductive signals between the dental follicle, reduced enamel epithelium, stellate reticulum and alveolar bone. It is also stated that the osteoclastogenesis or the bone resorption is regulated by the coronal aspect of the dental follicle whereas the process of bone formation or osteogenesis is regulated by the basal aspect of the dental follicle.[14]

**Molecular Events in Tooth Eruption:** The eruption of tooth is considered as a programmed and localized event. Various factors essential for tooth eruption are EGF, TGF, CSF, c-fos, NFκB, MCP, VEGF, RANKL, OPG etc. Determination of the molecules essential for tooth eruption, started with the isolation of Epidermal Growth Factor(EGF). EGF injection into the rodents accelerated the eruption of incisors. In rats both EGF and Epidermal Growth Factor Receptor (EGFR), immunolocalize to the dental follicle(DF), and get expressed in the early postnatal period.[8]

Transforming Growth Factor - α(TGF-α), has shown to accelerate the incisor eruption in mice. Rodents lacking TGF-α also erupt on schedule, showing that EGF alone can initiate the process. Osteopetrotic rodents usually have unerupted teeth and lack functional Colony Stimulating Factor-1(CSF-1). In such cases, injection of CSF-1 restores the process. This is because CSF-1 brings about and increase in the TRAP-positive mononuclear cells count, present in the dental follicle along with increase in the number of osteoclasts in the alveolar bone. Other genes which potentially enhance eruption are transcription factor genes c-fos and Nuclear factor kappa B(NFκB). c-fos is required for the process of fusion of mononuclear cells and osteoclasts and the role of NFκB is osteoclastic differentiation.[9]

Studies using RT-PCR showed that CSF-1 and MCP-1(Monocyte Chemotactic Protein-1) are expressed maximally in the dental follicles at day 3, and are usually chemotactic for the mononuclear cells.[10]CSF-1 is necessary for the osteoclast formation from monocytes. MCP-1 is considered to be the well-known chemokine for monocytes.[9] For eruption to occur, the mononuclear cells must fuse to form osteoclasts, for creating an eruption pathway byosteoclastogenesis. The essential molecules which promotes this are CSF-1 and Receptor Activator of Nuclear Factor-kappa B Ligand (RANKL), whereas osteoprotegrin (OPG), inhibits this. Vascular Endothelial Growth Factor (VEGF) has the ability to replace CSF-1 and upregulate the RANK expression on the osteoclast precursors.[10]

RANKL, a membrane bound protein, and a member belonging to the TNF (Tumor Necrosis Factor) ligand family, induce the formation and activation of from its precursor. OPG, found to prevent the differentiation of osteoclasts, also acts as a receptor for RANKL.[10] The expression of RANKL is upregulated by the by TNF-α, IL-1α and TGF-β. The OPG expression is enhanced by BMP-2(Bone Morphogenetic Protein-2), which enhances OPG secretion from dental follicle cells.[11] Currently, intense research has begun for transcription factors, the “master regulators” of osteoblastic differentiation. One such factor is Osf2(Osteoblast Specific Transcription Factor 2).[9]

**Factors affecting tooth eruption:** Various factors influence the tooth eruption and become a part of the disturbances occurring in it. The important local factors influencing tooth eruption are: Supernumerary teeth(Fig:3A), crowding(Fig:3B), arch length deficiency,
odontogenic cysts and tumors, dentigerous cysts, enamel pearls(Fig:3F), gingival hyperplasia (Fig:3D), premature loss of primary tooth, ankylosis (Fig:3E), thumb sucking, tongue thrusting (Fig:3C), eruption cysts, eruption sequestra and fibrous developmental malformations.[20]

Genetic factors play a prime role. Certain genetic disorders affect tooth eruption either by delaying or by a complete failure of tooth eruption.[3] Gender also plays an essential role with the permanent teeth erupting earlier in girls which is mainly due to the earlier onset of maturation.[3] Though very few studies have emphasized on the nutritional influence, it is proved that chronic malnutrition can lead to delayed eruption. Lack of nutritional supply alters bone mineralization leading to disturbances in bone formation. Eruption of permanent teeth is important as it also stimulates the jaw growth. Experimental evidences also suggest that preterm children have delayed eruption.[16]

Various studies have found that children who belong to the higher socioeconomic status show earlier eruption. [17] Studies also state a positive correlation between the height and weight of the body with teeth emergence, with the taller and heavier children showing an early dental growth.[18] Endocrinal disturbances, which affects the entire body also affects the dentition. The hormonal conditions such as hypothyroidism, hypopituitarism, parathyroidism and pseudohypoparathyroidism usually exhibit delayed permanent teeth eruption. In contrast, turner’s syndrome exhibits an accelerated development.[19]

The other systemic conditions influencing tooth eruption includes: Down’s Syndrome, Cleidocranial dysostosis, hypothyroidism, hypopituitarism achondroplastic dwarfism, Vitamin D resistant rickets, long term chemotherapy, ichthyosis, oral cleft, renal failure, exposure to hypobaria, radiation damage, celiac disease, anemia, dysostosclerosis, cerebral palsy, HIV infection, heavy metal intoxication etc.[3,20]

**Conclusion**

Tooth eruption is not an overnight event. The development of the dentition is characterized by phases of temporary discrepancies between the tooth size and jaw growth. The developing tooth does not move in a single direction, but in three dimensions and a gradual increase in the size of the tooth occurs within the alveolar bone before active eruption. It has been revealed that, the mechanism of tooth eruption is a complete, essentially time specific, biological interaction that occurs due to the coordination of multiple tissue elements in order to create the eruptive movement of tooth. Hence, awareness of the fundamental aspects, and thorough knowledge about tooth eruption and various events associated with it are necessary to understand the discrepancies in tooth eruption.

Nanotechnology in Periodontics: An Overview

R. Vijayalakshmi1, T. Ramakrishnan2, Sruthi Srinivasan3, Burnice Nalina Kumari4

1Associate Professor, Dept of Periodontology, Meenakshi Ammal Dental College, Maduravoyal, Chennai – 600095, 2Principal & Professor, Department of Periodontics, Meenakshi Ammal Dental College, Maduravoyal, Chennai–600095, 3Post Graduate student Department of Periodontics, Meenakshi Ammal Dental College, Maduravoyal, Chennai–600095, 4Assistant Professor, Department of Periodontics, Meenakshi Ammal Dental College, Maduravoyal, Chennai–600095

Abstract

Nanotechnology is a booming field during recent years in medicine and dentistry. Application of nanotechnology in Periodontics is referred to as nanoperiodontics. Nanoscale materials show superior quality and outcome than traditional materials used in almost all areas including diagnosis, prevention, treatment, drug delivery and in dental implant coatings. This article will overview the history, classification, synthesis, applications, toxicity and future of nanoperiodontics.

Keywords: Nanotechnology, Nanoperiodontics, Category and Synthesis of Nanomaterials, Applications of Nano particles.

Introduction

Nanotechnology is a flourishing field in Periodontics. Their contribution in Periodontics is increasing gradually due to expanding research. Nanomaterials exhibit size less than 100nm in atleast one dimension. Nanoperiodontics involves the analysis of matter at subatomic and microscopic level, which has progressed in the field of Periodontics. Nanoperiodontics will perpetuate periodontal health by relating nanomaterials and biotechnology, including tissue engineering and dental nanorobotics. Though it is at a preliminary stage, it has ample impact in clinical and commercially available substances. Moreover, it is shown to have assured role in periodontal health care in near future.

History: The use of nanoparticles began as early as 9th century for creating glittering pots in Mesopotamia. It was Richard. P. Feyman a noble laureate who gave the concept of nanotechnology. In 1974, Norio Taniguchi devised the term ‘nanotechnology’, then Professor Kerie. E. Drexler used the term nanotechnology separately and also gave the first guidelines in the field of nanotechnology. Nanotechnology came into application after the discovery of scanning tunnelling microscope by noble prize winners Binnig and Rohrer in 1986. In the wake of book by Drexler, Peterson and Pergamil in 1991 highlighting the facts on nanorobots and assemblers, the term Nanomedicine was introduced by R.A. Freitus in 2000. To enhance the research in this field “National Nanotechnology Initiative” was developed in 2000 by Michael Roco. During 2005 and 2010, various innovations in the field of 3D robotics, networking and active nanoproducts production were done and from 2011, the generation of subatomic nanotechnology has been in use.

Category of Nanomaterials:

![Figure 1: Category of nanoparticles](image1)

**Properties of Nanomaterials:** Properties of nanomaterials were first put forward by Michael Farady in 1857 during preparation of gold nanoparticles. Nanoparticles because of their surface area, dimensions and quantum effects exhibit enhanced rigidity, pelucidity, increased abrasion, stability, fire resistance and gas penetrability. Besides they also exhibit some unique features including ocular, electromagnetic characteristic different from one’s own discrete molecule or bulk molecule. Another remarkable property of nanomaterials is their self-assembling capacity, i.e. they form copious arrangements in the absence of third party.

**Synthesis of Nanomaterials:** Top down approach involves devasting procedures in which the large materials are converted into smaller ones and these are further manipulated to form nanoparticles. Bottom up approach involves uniting atomic level substrate through ionization of energy from various sources based on which they are classified as shown in Figure 2. In green synthesis, the herbaceutical products are used to synthesize nanoparticles, these nanoparticles are eco-friendly moreover the green synthesised nanoparticles are shown to exhibit enhanced properties. Biomimetic approach is the one in which microorganisms including fungus, bacteria or virus are used to manufacture nanoparticles; this method is in its initial stage and further research is needed to show its effectiveness.[1]

![Figure 2: Manufacturing techniques](image2)
Applications of Nanoparticles in Periodontics: 
Nanoscale particle application in medicine and dentistry during the last decade has grown enormously. The applications of nanoscale particles in Periodontics can be broadly discussed under the topics namely prevention, detection and treatment.

Prevention: Antibacterial Agents: Nanoparticle derived antimicrobial agents are seen to have superior effect due to their large surface area. Various agents that can exhibit antimicrobial effects includes silica, silver, copper and zirconia. Commercially available nanotechnology-based disinfectant, Eco-True containing silver salts are employed for disinfecting instruments and surgical areas.

Personal Protective Equipment (PPE): PPE and masks incorporated with nanoparticles having antibacterial effect are shown to exhibit enhanced protection.

Surface Coatings: Nanomaterial coatings used in paints, medical instruments and other highly contagious surface can be employed to control the spread of COVID-19.

Oral Hygiene Maintenance: The mouthwash and dentifrices containing nanoparticles are shown to aid in oral hygiene maintenance. The mouthwash incorporated with nanorobots and selenium nanoparticles controls halitosis through the destruction of volatile sulphur compound producing bacteria. Dentifrices incorporated with nanorobots are employed to destroy the pathogenic flora while preserving around 500 oral commensals; but these are under study.

Detection: Nanotechnology based diagnostic kits exhibit increased efficacy compared to their original counterpart, besides they are easily portable and highly sensitive and specific.

Nanotubes: These are employed for detecting and locating altered disease-causing genes. Under this category comes the quantum dots that radiate bright light on stimuli and are used for cancer diagnosis.

Nanobelts: Are similar to nanotubes in their application except that they are cost effective and technique insensitive compared to nanotubes.

Lab on chip Method: These device merge numerous devices on single chip and they are employed in Periodontics for detection of IL-1β, CRP, MMP-8 and TNF-α from whole saliva with minimum amount of sample.

Nanoplasmic Sensors: With the emergence of COVID-19 pandemic the need for rapid detection kits are increasing. This sensor rapidly detects live viruses using their corresponding antibodies.

Treatment:

Local Anaesthesia [LA]: Onboardnano computer-controlled micron sized dental nanorobots with colloidal suspension of functional analgesic molecules are employed. They are placed on gingiva and reach the dental pulp through gingival sulcus and dentin and they stay behind until the procedure is complete. Again, on command they reach the gingiva through the same way after restoring all sensations. They are painless and are said to have rapid onset of action in comparison to traditional LA.

Dentinal Hypersensitivity: Dental nanorobots occlude specific dentinal tubules instantly. Besides they also render durable results. Nanohydroxyapatite containing toothpastes are also shown to give promising results.[2]

Dental Longevity and maquillage: They can be enhanced with the use of nano sapphire or diamond particle layers on upper enamel layer.

Host Immunomodulation Therapy: Cafferata et al stated the multitasking efficiency of nanocarriers for treating periodontal disease.[3] In this study, he highlighted the immunomodulatory effects of host modulating agents delivered through nanotechnology-based system. They were shown to decrease the level of proinflammatory and bone resorbing T-cell namely Th-1, Th-22 and Th-17. They also increase the differentiation of TH-2 and Treg cells.

Bone Grafts: Nanoscale based grafts are seen to have superior outcome, because of their small dimensions that mimic the natural bone particles. They can be successfully used for the treatment of intrabony defects[4], socket preservation[5] and sinus augmentation procedures[6].

Nanomembranes: KS Hong et al have used silk fibroin nanomembrane (Nanoguide) in guided bone regeneration and declared them to exhibit superior bone formation in comparison to biomesh.[7]
**Nanoneedles:** Needles containing nanosized silver particles have been developed. They are usually painless and technique insensitive.

**Nanotweezers:** These are under development and will make cell surgery possible in mere future.

**Tissue Engineering:** Nonbiologic self-assembling system production by nanotechnology has made tissue engineering through nanoparticles possible. Polymer based scaffold for cell seeding, growth factor delivery and tissue engineering via the nanoparticles embedded in site of tissue damage can also be constructed. Though tissue engineering through the use of nanoscale perspectives is spellbinding, their use in clinical scenarios still remains fictious.

**Subgingival Irrigation:** Hayakumo et al has described the use of ozone nanobubble water produced by nanobubble technology in subgingival irrigation. The results of their study demonstrated that it can be used as an adjunct to periodontal therapy because of their enhanced antibacterial activity.

**Laser and nanoparticles:** Laser irradiation on nanotitaniumparticles coated surface are shown to increase collagen production. Using this principle, gingival depigmentation and other periodontal procedures can be carried out. Sadony and Abozaidillucidated that nanoparticles along with diode laser has the potential to decontaminate dentin surface.

**Chronic periodontitis:** Kadam et al hypothesized that adjunctive use of silver nanoparticle gel with scaling and root planinghas superior effect in comparison to tetracycline gel in management of chronic periodontitis. Nanoporesolving lipid mediators because of their increased ability to penetrate into periodontitis affected tissue may be an effective method to manage chronic periodontitis.

**Biofilm management:** Biofilms incorporate wide array of microorganisms that results in increased antimicrobial resistance and pathogenicity. Till today, effective technique for biofilm management has not been devised. Nanoscale materials including zinc oxide, titanium dioxide, copper oxide, carbon nanotubes, chitosan, gold and quaternary ammonium compounds are shown to exhibit antibiofilm activity through the disruption of bacterial cell membrane by generating reactive oxygen species.

**Nanoantibiotics:** These are the antibiotics that are delivered through nanocarriers with specialized antibiotic coating on their surface. They manifest broad spectrum of activity and decrease the probability of secondary infections. Gold nanoparticles are described to have increased adhesiveness to antibiotics. Besides nanoscale particles and antibiotics demonstrate positive interactions.

**Wound Healing:** Improved wound healing with the use of nanomaterials has been reported in many studies. Polymer and lipid-based materials revealed excellent antimicrobial and antiinflammatory property with enhanced wound healing capacity. Carbon based particles showed good wound healing and angiogenesis, besides the metal-based nanoparticles showed scarless healing.

**Local Drug Delivery:** Drug delivery using nanotechnology has been formulated as they have increased biocompatibility, targeted release, decreased antimicrobial resistance, long duration of action and less toxicity. Various drug delivery agents include liposomes, micelles, dentrimers, polymers, nanorattels, nanowires and niosomes. Nanoencapsulation technique is a recent technique developed by SWRI for delivering antibiotics and vaccines. Besides nanocomposite hydrogel-based delivery system through the use of triclosan, chitosan and biodegradable nanoparticles are also productive delivery vehicle.

**Nanoscale particles in dental implantology:** Chemical and mechanical modifications dental implants are said to have better osseointegration. Various nanoscale mechanical modifications include creation of nanoareas like nanogrooves, nanopillars and etc. Chemical coatings include coating with nanoparticles of diamond, hydroxyapatite, graphene, titanium oxide and metalloceramic based nanomatters. Nanohydroxyapatite coated implants are commercially available as None Tite BIOMET 3i and have around 50% of nanohydroxyapatite.

**Self assembling implants:** C.X. Li et al investigated the effectiveness of nano structured self-assembling dental implants in type-II diabetes patients and stated that they exhibited decreased marginal bone loss and better osseointegration than the conventional dental implants used.
Periimplantitis: Clot stability can be increased by using nanohydroxyapatite on citric acid conditioned surface. Elangovan et al in their study demonstrated enhanced fibroblast proliferation with the use of platelet derived growth factor-BB delivered using calcium phosphate nanoparticle.[28]

Toxicity of Nanoscale Particles: Increased surface area although seems to be beneficial they can cause increased toxicity by enhancing the duration of action, aquaphobic drug solubility and also their ability to cross blood brain barrier. Because of their small size, the host immune system reaction to the nanoparticle cannot be detected. Other drawbacks include difficulty in concomitant bulk synthesis, haemolytic activity towards host cell, cost ineffective, social and ethical challenges. Biocompatibility of traditional nanoparticles is unsure, since the nanoparticles in gas exhausts from vehicles and industries are shown to elevate respiratory and cardiovascular morbidity & mortality and to overcome these green nanoparticles were introduced; but still, they are synthesized in crude form and is also difficult to find which among the component is active constituent.

Future of Nanoperioodontics: Method for synthesizing high calibrated nanoparticles in bulk will be developed in near future. Most of the nanoparticles-based studies in Periodontics are in-vitro, the productive outcome of in-vivo studies is to be demonstrated. Materials with enhanced antibacterial effect, self-repairing property and compatible drug carriers are to be developed. The self-assembling antimicrobial peptides are under study and may be used for the treatment of periodontal diseases. Numerous untreatable diseases may be treated using nanotechnology. Nanotechnology based diagnosis and treatment of COVID-19 pandemic is the present focus of research and will be made possible in near future.

Conclusion
This is the era of nanotechnology since there is a gradual increase in research and applications of nanotechnology in numerous fields. This review has described in detail the history, classification, manufacture and application in Periodontics of nanoscale particles. Although the field of nanoperiodontics is fascinating, data on long term in-vivo effect of nanoscale particles are essential for clinical application.

Congenital Granular Cell Epulis: A Rare Entity

Pradeep Devadoss¹, K. Thanvir Mohamed Niazi², Keerthana Gajarajan¹, R. Prakash³

¹Department of Oral and Maxillofacial Surgery, Faculty of Dentistry, Meenakshi Academy of Higher Education and Research, Chennai, Tamilnadu, India, ²Prof and Head, Department of Oral and Maxillofacial Surgery, Principal, CSI College of Dental Sciences and Research, Madurai, ³MSR Tooth Clinic, Madurai

Abstract

Congenital granular cell epulis (CGCE) is a rare soft tissue lesion seen exclusively in the neonates which is benign in nature. The common site of occurrence is the maxillary or mandibular alveolar ridge. The clinical significance of this tumor is its location which hampers with breast feeding, posing a potential airway complication and parental apprehension. In this literature we report a case of a one day old baby who reported with feeding difficulty, diagnosis of the lesion and the surgical management of the same.

Keywords: New born, Pregnancy tumor, Congenital Epulis.

Introduction

Congenital granular cell epulis (CGCE) is a rare soft tissue lesion seen in the neonates which is benign in nature. The common site of occurrence is the maxillary or mandibular alveolar ridge[1,2]. It was first described by Neumann in the year 1871 and it is also called as Neumann’s tumor. The etiology is unknown. Clinically the lesion presents as a solitary mass or as multiple lesions. Large or multiple lesions can cause airway obstruction as well as difficulty in post-natal feeding[3]. The lesion appears either as a sessile or pedunculated mass of varying sizes, smooth surfaced, pink to reddish in color and firm in consistency. Congenital epulis does not increase in size after birth. Spontaneous regression has been reported in few cases[4].

The lesion is benign in nature with no recurrence. The treatment modalities is surgical excision of the mass by conventional method or by using CO2 laser[5]. Histiogenesis is not certain, several theories of Origination of the lesion has been postulated namely odontogenic, fibroblastic, hystiocytic, myoblastic and neurogenic. This case report describes the management of a 1 day old neonate with congenital granular cell epulis in the anterior maxillary alveolar ridge.

Case Report: A one day old female neonate reported to us with a complaint of swelling in the upper right front tooth region which was noticed at birth. The swelling was protruding out of the oral cavity (Fig: 1). The major concern for the mother was that the swelling hampered breast feeding. The infant was otherwise healthy weighed about 3.3 kgs. The pregnancy was normal and delivery was normal at full term. Family history was non-contributory.

e-mail: drpradeep.omfs@madch.edu.in
On clinical examination, a pedunculated mass arising from the right maxillary alveolar ridge of size 1.5x1 cm. The color appeared the same as the oral mucosa. On palpation, the swelling was firm in consistency and smooth attached by a thin pedicle to the alveolar ridge. It interfered with the normal closure of the mouth with no airway compromise. The clinical diagnosis was made as congenital epulis. The general physical examination of the child was normal. Surgical excision was planned and performed using electrocautery to provide hemostasis under general anesthesia. (fig:2) Recovery was uneventful with no intra-operative and post-operative complications. The child was assessed after a week and seemed to be thriving and gaining weight. The specimen (fig:3) was fixed in 10% formalin and processed for histopathological examination.

Microscopic examination revealed circumscribed lesion lined by stratified squamous keratinized epithelium with cluster of cells with a central nuclei and eosinophilic cytoplasm. Histopathologically it was confirmed as congenital granular cell epulis.

**Discussion**

CGCE is a rare benign lesion seen in the neonates. CGCE has a female predilection with an 8:1 female to male infants ratio and more commonly is seen in the maxillary alveolar ridge, as seen in our case [6]. Majority of the case presents as a solitary pedunculated mass or as multiple tumours [7,8]. Large lesions causes interference with feeding and airway obstruction. Usually the diagnosis is made at birth. Prenatal diagnosis can be made with an ultrasonography and MRI by the 36th week of gestation which would further be helpful in planning the treatment in prior [9].

The clinical presentation of the tumor is always smooth surfaced, sessile or pedunculated, the color of the lesion is same as that of the oral mucosa. It is firm in consistency and non-tender. Differential diagnosis can be given as fibroma, hemangioma, granuloma, schwannoma, myoblastoma [10]. Prenatal MRI of oral cavity would give a better picture to differentiate from other lesions [11,12].

The surgical intervention includes immediate surgical excision by conventional method or by the use CO₂ laser [5]. Immediate intervention is required as the lesion may interfere with feeding as seen in our case and large lesions would cause airway obstruction. Literature shows surgical excision of the lesion does not hamper the bone growth or teeth eruption [11,12].

In our case the surgical excision of the mass was done under general anaesthesia with nil intra-operative difficulties. The neonate was comfortable with feeding from the next day. Patient was followed up and the healing was satisfactory.

Histopathological features includes circumscribed mass comprised of nests of polygonal or spindle cells with abundant eosinophilic cytoplasm with eccentric nuclei. Lined by stratified squamous epithelium with absence of rete ridges [13,14].

In our case the lesion was present in the anterior maxillary region of size 1.5 * 1 cm which was pedunculated, smooth surfaced clinically correlating with the features of Congenital granular cell epulis. The main concern in our case was that the lesion interfered with feeding. So immediate surgical intervention was done. Prenatal diagnosis was not made with Ultrasonography or MRI. The diagnosis was confirmed histopathologically.

**Conclusion**

Congenital granular cell epulis is a rare entity. The tumor is mostly misdiagnosed as it is a rare occurrence.
Our case report is to emphasize the importance in diagnosing the lesion and treating it accordingly. The clinician should also consider congenital/benign/malignant/lymphatic malformations as differential diagnosis. A multidisciplinary approach with the team of the pediatric surgeon, oral maxillofacial surgeon, anesthetist and oral pathologist is required to arrive at the correct diagnosis and perform an immediate surgical intervention. Prognosis appears to be good.

Ethics in Adult Orthodontics

Kaushik P.¹, Lokamithra R.², Arani Nandakumar³

¹Assistant Professor, Department of Orthodontics and Dentofacial Orthopaedics, Meenakshi Ammal Dental College and Hospital, Meenakshi Academy of Higher Education and Research, Chennai, ²Post Graduate student, Department of Orthodontics and Dentofacial Orthopaedics, Meenakshi Ammal Dental College and Hospital, Meenakshi Academy of Higher Education and Research, Chennai, ³Professor, Department of Orthodontics and Dentofacial Orthopaedics, Meenakshi Ammal Dental College and Hospital, Meenakshi Academy of Higher Education and Research, Chennai

Abstract

Ethics is the understanding and the ability to differentiate right from wrong in human behavior. Dental ethics denotes moral duties and obligations of a dental practitioner towards their patients, fellow colleagues, and the society at large. An ethical practice among dentists ensure good patient care in concurrence with their treatment needs. Ethical principles and codes introduced by regulatory bodies benefit the patient, avoid harm, and respect patient’s preferences. Ethical dilemmas are faced by orthodontists during orthodontic interventions, even though important human values may be at stake during the course of treatment. The code of ethics in dentistry warrants an orthodontist to act in the best interest of their patients regardless of their financial status, even putting themselves at jeopardy if need be. This article thus focuses on the morals and ethics that should be abided by an orthodontist in order to deliver the best possible care to their patients.

Keywords: Ethics, Orthodontics, Dental practice, Ethical practice, Dentistry.

Introduction

The etymology of the term “Ethics” is from the Greek word “Ethikos” which means character or conduct. It is defined as the systematic examination of human behavior. Any decision or action taken to resolve a dilemma should be completely thought through before its initiation.[1]

Both medical and dental specialties consist of various ethical principles and values which are strictly followed and respected for many years now. Like any other dental procedure, orthodontic interventions deal with ethical dilemmas and hence should be subjected to specific ethical inquiries. Although, it is not every day that an orthodontist faces life or death situation in their practice, however, they deal with important human values which are at stake during the course of orthodontic treatment. Some of these include, pain prevention and management, preservation and restoration of oral function for normal speech and mastication, preservation and restoration of patient’s physical appearance, and enhancing a sense of control and responsibility over their health.[2] Apart from treating adult patients, orthodontists also manage a large number of pediatric patients and may encounter ethical issues in that regards it is within the purview of the orthodontist to provide the best treatment option for the child, help in surrogate/guardian decision making, and enable access to care.

This review article thus highlights the ethical dilemmas faced by an orthodontist in their day to day clinical practice and provides an insight into the effective management measures in accordance with the regulations.
**Ethical Principles:** Ethical problems usually arise when there is an uncertainty or conflicting moral obligations.[3] The orthodontist should be aware of the ethical principles present for clinical decision making in their practice. The aim of these codes is to enhance a sense of ethical responsibility in order to ensure the highest level of professional and ethical consciousness to maintain a standard of decision making and conduct.[4] The major principles include:[5]

1. To do no harm (non-maleficence)
2. To do good (beneficence)
3. Respect for persons
4. Justice
5. Veracity or truthfulness
6. Confidentiality

**Ethics in Clinical Practice:**

**Inform Before Perform:** Once the patient has decided to undergo orthodontic treatment, details of the proposed treatment plan from the start to end until retention phase must be explained to them. The information should be conveyed in a lucid easily understandable language without much usage of complicated dental terms. This can be done using hand held models, patient casts or even showing improvement in profile and frontal views after orthodontic treatment using latest digital software. This essential step before the start of active treatment is useful in encouraging and motivating patients towards the treatment, thus gaining their trust towards the orthodontist.

**Right to choose:** Decisions regarding orthodontic treatment are not entirely decided by the orthodontist. They are required to respect the moral and legal authority of the patients and incase of pediatric patients, the parents.[6] Various treatment options, if any, should be informed and clearly explained to the patients prior to the treatment. The health care professionals should respect the patients right and give them the freedom to decide upon their treatment. Patients must be given full authority in the decision making process and must not be forced to make a decision that is favored by the orthodontist.

**Benefit/Risk ratio:** The treating orthodontist must first understand the treatment needs of the patient in depth to have a clear view of the type of intervention required for them. Any orthodontic treatment which is considered ideal and beneficial for the patient, may have certain risks and limitations associated with it. Alternative treatment plans options with lesser risks, if any, should be put forth for the patients to decide, which will benefit their oral function, appearance, and quality of life, rather than not doing any treatment. Orthodontists have a moral obligation to support patients’ interests and to do no harm.[7]

**Course of treatment duration:** Total time taken for completion of orthodontic treatment depends on the severity of malocclusion.[8] Patients should be informed about the treatment duration prior to start of treatment as the time taken for completion of extraction cases is more than non-extraction cases. Estimated treatment time predicted by an orthodontist can be delayed due to secondary factors like irregular or missed appointments and/or broken appliance or debonded brackets. In case of increase in treatment duration due to the secondary factors the orthodontist should differentiate between their responsibility and that of patients, thereby encourage them to be more regular and responsible towards their treatment.[9]

**Retention Phase:** Before removal of orthodontic appliance, the case should be finished in good occlusion without premature occlusal contacts to ensure long term stability. Post active treatment, retainers should be given with instructions on their timely wear to prevent relapse. Importance of retainers in maintaining the corrected malocclusion should be informed prior to the start of treatment and should be emphasized on the duration of wear post active treatment. Patient cooperation in wearing retainers is vital for maintaining the achieved results.[10]

**Informed consent form:** In today’s era of dental practice, patients are the consumers while the doctors are the service care providers. Naturally, legal doctrine of informed consent is plays a pivotal role in everyday practice which has instilled fear in most dental health care professionals. According to the guidelines laid down by the American Association of Orthodontists, an informed consentought to include details such as treatment results and duration, presence and level of discomfort, risk of relapse, extractions and orthognathic surgery, possibilities of decalcification and dental caries, root resorption; periodontal diseases; risk of temporomandibular disorders, status of impacted and ankylosed teeth, allergies and usage of temporary anchorage devices in treatment.[11] The orthodontist
should attach documents of acknowledgement, a consent form and an authorization letter for the usage of patient information and their treatment records in case of future publication.[11]

**Medicolegal Concerns:** It is the medicolegal responsibility of the orthodontist to take radiographs and photographs of the patient before the start of the treatment, after getting a clear consent from them. These records are useful for screening any pathologies or anomalies, planning treatment mechanics for achieving best results, comparison of treatment results achieved and to get a second opinion if needed. Patients records must be filled and maintained in good condition even after orthodontic treatment. Using patients records, especially extraoral photographs for publication and research should be done only after patients’ written approval.[11,12]

In case of referral of the patient to another orthodontist the copy of the patient’s record must be saved. A detailed history if the patient, treatment plan and the progress of the treatment so far has to be transferred to the referral orthodontist. This must be done to ensure that no difficulties are faced both by the orthodontist and the patient in finishing the treatment. A clear and detailed consent should also be enclosed form both the parties.

Similarly, if the patient wants to discontinue the treatment due to personal reasons, orthodontist should explain the ill effects of incomplete treatment in case of extraction, and chances of relapse. Patients written consent should be obtained before removal of the appliance.[7,13]

**Sterilization Protocols:** Strict sterilization protocol must be meticulously followed must be strictly followed in the dental office. Clean sterile instruments, orthodontic attachments and wires should be used for each and every patient. The Operating orthodontist should wear personal protection equipments and maintain a sterile working environment.[14]

**Discussion**

Ethics is a subject of necessity which is considered in all aspects of life either consciously or unconsciously.¹ Health care professionals possess training and expertise which the patients lack, making the treating orthodontist responsible for the decision making in regards to the treatment offered to the patient.[15]

It was suggested by Johnson in 1946 that a philosophical approach to ethics is in fact better than the dualistic approach which will allow the dental professional to pursue an ethical practice following a more eclectic approach.¹⁶ Ethical problems arise from conflicts between orthodontist’s obligation to deliver best care to the patient and the need to respect their decisions. These are based on the underlying ethical principles of beneficence, and respect for autonomy of patients.[8] Orthodontists should clearly outline the indicated treatment plan, the benefits and burden of the procedure as well as the consequence of no treatment. Information shared in an open fashion, should enable the patients and parents, in case of pediatric patients, to freely participate and make decisions.

Studies have shown that dental practitioners do not strictly follow an ethical clinical practice.[¹⁷–¹⁹] Hence, regulatory bodies such as state dental councils and orthodontic societies should form ethical committees to actively monitor and guide the orthodontists to perform a healthy practice abiding by the codes of ethics.[12]

**Conclusion**

In the present scenario of dental practice, Ethics is of immense significance that gives an important dimension to patient care. Professionalism dictates profession as a correction to commercialism and is built on prioritizing professional ethics over personal interests or business.

The codes of ethics require an orthodontist to act in the best interest of patients regardless of their financial status.[8] Abiding by these basic ethical codes will not only give simple moral justification in their duty as an orthodontist but also will protect them legally as a professional in providing the best healthcare to the community.

Abstract

The ongoing virus impact in the whole world is COVID19 infection has led to unprecedented crisis paving to outrage of the world citizens. The highly contagious virus started its spread from the China during the month of late November 2019 and spread to all over the world. The COVID-19 pandemic led catastrophe and earlier episodes of similar epidemic SARS outbreaks in China and Middle East interrogate the preparedness in handling such predicament. The major symptomatic manifestations of patients are not so accurate and vary from one person to another and higher frequency of asymptomatic cases often misled diagnosis, unless the CT chest scan findings affirms the disease progress into fatal SARS. Disambiguation over the other viral respiratory illnesses similar to COVID-19 needs to be meticulously handled by emphasize on simultaneous co-detection of multiple viral pathogens. Henceforth, robust diagnostic tools are necessitated to substantiate suspected cases and to screen large population in less time. This review would keenly focus on the challenging prime requisite for accurate laboratory testing of the infection and the potentials of various techniques in investigating the pandemic.

Keywords: Combined ELISA, COVID-19, SARS2, N/S-IgM/IgG rapid card, Viral load.

Introduction

Novel Corona virus 2019 (nCoV) was a rapid spread and was officially identified by the Chinese Doctors and approved by CDC later, WHO declared pandemic emergency over the disease and outbreak rapidly started in the month of January 2020. The 2019 nCoV was confirmed of the transmission from one person to another and the active infection were evidenced outside China ever since the outbreak, therefore warranting the cause for pandemic. As of October 2020 approximately 9,26,544 fatal cases were reported and over 29.2 crore people were infected with the viral pathogen. The government all over the world and as per the guidelines of WHO has stopped the travel to and fro overpandemic and lockdown periods getting extended in different countries leading to distress among the world citizens[1,2].

The nCoV affects the respiratory system that can range from mild to fatal illness. Symptomatic cases shows high body temperature, wheeze, improper and difficulty in breathing, sore throat and diarrhea often undistinguished from other pathogenic pneumonias. According to WHO asymptomatic cases without any
prompt signs and symptoms are the major threat to the healthcare workers by the way of spread [3]. The delayed and/or failure in probing of outbreak investigation would lead to extensive morbidity [4]. Here, our review focus on various means of testing and strategies for early, robust diagnosis in handling the global emergency.

Ancestrally, the CoV family infects many eukaryotes especially mammals and avian species, very few strains of the CoV family are circulating among humans causes acute respiratory infections. Genomic analysis of the virus revealed 89% and 82% of nucleotide similarity with bat represent the virus as SARS-like-CoVZXC21 and human SARS-CoV respectively and 40% amino acid identity matched with the peripheral sub domain of the spike’s present in the virus acts as receptor binding domain [6]. Historically, 2002-2003 major epidemic outbreaks in China due to SARS-CoV originating in bats were reported of significant mortality [3].

COVID-19 manifestations and clinical diagnosis:
ARD associated with the respiratory Syncytial virus, parainfluenza viruses, metapneumovirus, and CoVs, are hugely uncovered. Understanding the SARS-CoV-2 pathogenesis is imperative in drafting guidelines for screening COVID-19 at the earliest. The clinical variety of infection varies from without symptomatic forms to fatal sepsis and multiorgan dysfunction [9]. Fever (88%), dry cough (68%) are mainly the general signs of infection; other non-specific symptoms are also present in the infected person from mild fatigue, to other respiratory viral infections[4]. Radiographic chest examination during the early COVID-19 presents multiple plaques, changes in the lung margins and as infection develops severity it leads to ground-glass opacities, lung consolidation, and cardiac injury depicting the cardinal signs of ARD as reported by WHO. Another Scientist identified that the infection was related with inflammation in brain of humans with the pathogens RNA sense in cerebrospinal fluid (CSF). Following, Poyiadji et al stated a similar case study with immune mechanism where acute necrotizing encephalopathy is a type of post-infection[10].

The sHLH is a respiratory infections caused by hCoVs and its salient feature of sHLH include hypercytokinaemia, cytopenias, hyperferritinaemia, and blood clots leading to vascular inflammation, thromboembolism, hypotensive shock with multiorgan failure [11]. Garcia et al studied several other bodily
dysfunctions were positively combined, with the death rate and inverse proportionate with P/F ratio. The acute cardiac injury in COVID-19 cases is diagnosed with flanking serum levels of cardiac biomarkers or from abnormalities in recorded in ECG. The blood profile of the COVID-19 cases reveals eosinopenia, creatine kinase, procalcitonin, elevated lymphocytes, and elevated markers for inflammation are interleukin-6, erythrocyte sediment rate and others [4, 12]. The concurrent recognition of dual biomarker is protein A resistant against Myxovirus, CRP test identifies host immune response and also facilitates viral and bacterial acute respiratory illnesses differentiation [13]. These auxiliary findings help the physician in evaluating prognosis of COVID-19 cases upon treatment and in epidemiological surveillances.

**Laboratory testing of COVID-19:** According to the WHO recommendations the laboratory requisite should follow up based on the evidence of epidemiological history, clinical manifestations fulfilling criteria for case suspect definition. Unlikely the typical COVID-19 manifestations are misleading, therefore auxiliary screening of immune components and quantification of pathogen nucleic acid by RT-qPCR is empirical [2,9]. The immune response to CoVs follows a production of antibodies IgM and IgG specifically associated with viral respiratory tract infections. In the presence of viral load IgM antibodies vanish at 12th week, while IgG antibody lasts long playing a protective role and specific titer varies during the acute and convalescent phase. The antibodies against the virus are activated after few weeks of infection [14,15]. Simultaneous likely evaluation of prognostic seromarker included complete haemogram, renal function, liver enzymes profile, creatine kinase, lactate dehydrogenase, electrolytes, CRP, myocardial enzymes, cardiac troponin I, Coagulopathy profile like ferritin are valuable in periodical assessment of the severity and recovery from the disease [12].

**Clinical specimens:** WHO and CDC recommend clinical laboratories handling COVID-19 patient samples with the potential to generate aerosols need to practice standard precautions within a Class II Biosafety Cabinet (BSC) facility to prevent transmission in healthcare settings. Use of appropriate personnel protective equipment, precautions for droplet/aerosol generating specimen must be exactly adapted. Laboratories performing live SARS-CoV-2 propagation and/or isolation, handling large volumes of infectious samples should strictly execute in no less than a BSC-3 milieu [16]. Occurrence of high viral infection in upper and lower respiratory tracts have been reported and therefore sampling the respiratory specimens within 5-6 days of the infection pneumonic symptoms facilitates accurate diagnosis [17]. Zhou observed longer duration of viral infection people for up to 37 days, apart from these, infection is also detected from fecal deposits, urine sample and blood, but less effect compared with respiratory specimens [18]. Investigation utilizing open reading frame 1ab gene specific RT-qPCR in quantifying the virus in assessment of shedding pattern in 1070 specimens revealed 93% bronchoalveolar lavage fluid (BALF) were positive, followed by other parameters showed a negative result [19]. In clinical suspects single respiratory specimen does not eliminate the analysis, testing the respiratory tracks are recommended [9].

URT samples are simple method to collect and therefore frequency of testing patients with mild symptoms, and can be easily implemented in resource limited settings [9]. Reportedly, the swabs from oral pharynx region was more accurate than nasal pharynx specimens; however, the pathogens RNA present in Oral specimen was comparatively least than positive Nasal specimens (63%). CDC advise labs to collect the URT-NP swab and OP swab is a least priority, and if collected also the samples should be mixed with the NP swab and transported in viral transport medium [19]. For the most sensitive detection of virus BALF is suggested as the collection of mucus from lower airways but this increases the chance of biosafety risk to healthcare workers.

Viral RNAemia is chiefly warranted in COVID-19 and therefore along with blood sampling- fecal, urine, stool samples investigations are vital in understanding the pathogenesis and route of transmission [20]. Seminal fluid collected from 34 recovering adult Chinese male were tested negative and the expression profile of the enzyme angiotensin-2 and integral membrane enzyme serine protease 2 within the male reproductive gland testicles showed no significant results [17].

**SARS-CoV-2 cultivation:** The techniques involved in viral cultivation are by Cell culture and nucleic acid-based tests to respiratory viral infections. The viral shedding in the URT secretions are ideal for pathogen recovery, however the viral specimens varies with the viral pathogenesis [19]. The bacterial infection in lungs is identified with blood cultures in corona positive patients cases were 6.9% and specific species were also found in
45.8% of corona patients with *Mycoplasma pneumoniae*, *Haemophilus influenzae*, and *Pseudomonas aeruginosa* infections \[21,22\]. Pyrc et al showed that separation and categorization of HCoVs. For several respiratory viruses the epithelial border has been determined via HAE cultures \[23\]. Harcourt et al isolated SARS-CoV-2 from NP and OP specimens by cultivating in Vero cells and evaluated the cytopathic effect using standard plaque assay \[24\]. The presence of virus was also detected in saliva test patients (91.7%) by RT-qPCR and the load was determined to be $3.3 \times 10^6$ copies/ml when cultivated on Vero E6 \[25\].

**Immunodiagnostic method for COVID-19 testing:**

**Rapid screening test:** Rapid COVID-19 testing kits designed based on lateral flow immunoassay are of diagnostic importance in cost-effective screening during acute phase of infection thereby reducing the need for molecular confirmatory tests in large-scale epidemiological surveillance. COVID-19 rapid card tests are detects specific viral antigens E, S, N and/or specific antibodies in the respiratory and serum samples. The immunochromatographic assay was reported to detect antibodies in the patients were 43.6% suspected cases tested negative for viral RNA \[26\]. The comparative sensitivity of three techniques that included IgG/IgM ELISA, colloidal gold-immunochromatographic assay and RT-qPCR in testing COVID-19 revealed no significant differences \[27\]. The combined test method has 88.66% sensitivity and specificity of 90.63%. However, there results were still remain false being dependent on the serum level of antibodies and the phase of immune reaction \[28\].

In a similar comparative investigation on the combinatorial detection of viral strain IgM and IgG using immunochromatographic strip along with RT-qPCR. Pseudopositive results incurred may be due to sharing of similar epitope with the others members of the CoV family, and other viral etiology of common cold. However, these misinterpretations can be averted with the use of antibody probes which are monoclonal in nature, and the other CoVs are not traced to be circulating in the recent times \[29\]. Combination of viral RNA and specific antibody identification by rapid testing, even in early phase of onset. In exceptional cases, the RT-qPCR confirmed COVID-9 patients exhibiting weak, late or absence of antibody responses. The majority of patients develop rapid antibody testing can be validated chiefly in the recovery phase. Several commercial rapid card kits available in the global market are designed feasibly for screening the viral antigens present in the respiratory specimens. Antigen screening kits are useful in evaluating early exposure ahead of onset of clinical symptoms \[30\].

**Enzyme Linked Immunosorbent Assay (ELISA):**

The viral antigen or specific antibody is of prognostic value in quantitative assessment of immune system of the diseased host. The combined viral nucleocapsid protein specific IgM/IgG ELISA showed lesser false-positives with IgG detection compared to single antibody assays \[28\]. In investigating the nucleocapsid and spike based testing for antibodies in identified cases revealed 80.4% and 82.2% positive rates for anti-N and anti-S SARS-CoV-2 antibodies and the increase in cases as the days are prolonged \[30\]. The virus enter into the target cell with the help of glycoprotein present in spike, which dilutes the antibodies upon URT infection; IgA specific ELISA are useful in early screening. Perera et al developed spike protein from the viral strain as a receptor-binding domain IgG/IgM ELISA with sensitivity and specificity comparative to microneutralisation and 90% plaque reduction neutralization tests \[31\]. However, the utility of ELISA in testing of COVID-19 is restricted to sophisticated laboratories as the protocols are heavily laborious and are time consuming.

**Chemiluminescence immunoassay (CLIA):** Luminogen based chemiluminescence assay for the identification of anti-viral nucleocapsid antibody was formed by Lin et al utilizing the recombinant full length nucleocapsid antigens mixed to the tosyl magnetic beads incubated with the test serum and analyzed in an automated chemical immunoluminescence analyzer. In this method 14 persons were reported to be positive cases (21%) but they are negative and this was identified for antibody testing by ELISA and chemiluminescence assays. Cai et al developed magnetic CLIA specific to ORF1a/b, S, and N proteins for detecting the target antibodies against the virus. Compared to the ELISA kit, chemiluminescence assay showed more promising results \[32\].

**Conclusion**

The contagious spread of the virus demands high processing; the clinical laboratory investigation played the major defensive role to seclude victims away from calamitous COVID-19 pandemic. The accuracy of
laboratory reporting are influenced by a number of interrelated factors such as virus shedding, time period of specimen collection, viral load titers, host immune response and age predicts the diagnostic sensitivity of the laboratory testing. Adding to the low level of testing centers and inadequacy of trained professional is worrisome inflating the health care workers and the public spread is postponed due to isolation of the probable missed cases leading to community spread. These challenging variants in the screening and confirmation of SARS-COV-2 infections define the interdisciplinary secular path for coherent laboratory testing to the necessity of standard clinical practices. The coronavirus and other viral infections associated physiological changes (heart rate, SpO2) which are potential indicators can be monitored using wearable sensors (Apple, WHOOP watches) would be of prognostic value. The future directions leading the mankind in handling such pandemic would be the progress in scientific learning on the advanced diagnostic technologies.

A Comprehensive Study on the Efficacy of Copper Antifouling Coat on Biofilm-Forming Organisms in Industrial Cooling Towers

Nandhini S.1, Revathi K.2, Kiran Srinivasan3

1Associate Professor, Department of Microbiology, Ethiraj College for Women, Chennai–600008, Tamil Nadu, India, 2Director of Research, Meenakshi Academy of Higher Education and Research, Chennai–600078, Tamil Nadu, India, 3Research Scholar, Department of Microbiology, Ethiraj College for Women, Chennai–600008, Tamil Nadu, India

Abstract

Cooling water systems serve as an ideal aquatic environment for microorganisms to proliferate and colonize. Biofouling and scaling are two major factors that adversely influence the water-cooling efficacy of industrial cooling towers, as they not only reduce the heat transfer capacity but also enhance corrosion. The present study focuses on the efficacy of copper antifouling coat applied over biofilm-forming organisms in industrial cooling towers, with a special emphasis on the quorum-sensing auto inducers and the EPS structure of organisms capable of forming the biofilm. Study results demonstrated sufficiently that copper coating has strong antifouling properties and the potential to prevent the growth of biofilm-forming organisms in industrial cooling tower systems. N-Acyl Homoserine Lactones is a major component produced by gram-negative biofilm-forming organisms, and the EPS is an important component of all the organisms that form biofilm. The study findings led to the conclusion that use of copper antifouling paint can reduce biofilm formation and its signaling molecules in industrial cooling towers.

Keywords: Copper, Biofilm, Biofouling, Extra Polymeric Substance and N-acyl L-homoserine lactones.

Introduction

Cooling towers find an extensive application in many large commercial buildings and residential units, such as apartment clusters. Especially industrial power generation units and petrochemical industries need a proper cooling system to remove the excess heat typically produced during many operations. In industrial operations or in residential units, cooling tower systems is an area most vulnerable to the growth and colonization of microorganisms [12]. The cooling towers function by the principle of removing heat from the water by the evaporation of a small portion of the water that is recirculated through the cooling unit [4]. Water released from cooling systems can harbor a variety of microorganisms, organic matter, and minerals. The organic matter and mineral composites present in the water provide nutrients for the growth and colonization of microorganisms that later form biofilms that hamper the efficacy of cooling process [9].

Biofilm constitutes a consortium of cells that grow on a surface and are embedded within a thick mucilaginous matrix composed of extracellular polymeric substance [EPS]. Biofouling is considered to pose a detrimental effect in the water recirculation process of cooling tower systems which are constantly exposed to water harboring bacteria as well as nutrients in most of the industrial settings. The formation of biofilms by microorganisms has been reported frequently in industrial cooling towers, and its resistance to disinfectants is another
complication. The signaling molecules N-Acyl Homo-Serine Lactone play a vital role in biofilm formation and in the development of resistance to available disinfectants [3]. Quorum sensing has emerged as a hot topic in recent times, and it is defined as the mechanism by which different species of bacteria communicate with one another. The acyl homoserine lactone [AHL] molecules are the best-studied autoinducers that serve the purpose of primary quorum-sensing signals used by gram-negative bacteria and in the case of gram-positive bacteria, they rely on peptide-based autoinducers and structural EPS [3].

Numerous studies have reported on the efficacy of the application of copper antifouling on the superstructures or surface areas of marine transport systems, including submarines and ships, and have shown enough evidence that the application of paint mixed with copper-based antifoulants can help prevent biofouling and corrosion to a large extent. In this study, the efficacy of antifouling copper coat on biofilm-forming organisms in industrial cooling towers was studied with a special emphasis on quorum-sensing molecules and the EPS.

**Materials and Method**

**Specimen Collection:** Biofilm samples were collected from Thirumalai Chemicals Limited, Vellore, Chennai and also from Ultra Marine and Pigments Ltd, Vellore, Tamil Nadu. Using sterile scalpels, the surface biofilms found in the cooling tower panel were scrapped at four different points of each of these cooling towers and later collected in two sterile containers. The circulating water from the cooling tower was used as a transport medium for sample preservation. Next, samples were stored in thermocol ice packs for maintaining the environmental viability of microorganisms that survived in the conditions of cooling tower and were transported to the lab. Water samples from the cooling towers were also collected in sterile cans for further use in order to study the propagation of microorganisms.

**Test materials:** Galvanized stainless steel coupon and copper-coated stainless steel coupons were used as test and control samples after welding to obtain a dimension of 20x20x0.5mm.

**Experimental Setup:** Copper and stainless steel [SS] coupons were subjected to surface sterilization using 70% ethanol and were incubated as test and control systems, respectively, in both industries for a period of 45 days [6].

**Sample processing and isolation of organism:** A presumptive wet mount for the purpose of microscopic observation was performed to identify algal colonies. Heterotrophic plate count was then performed to qualitatively analyze the bacterial colonies present in the biofilm and in the water samples.
Identification of bacteria: Significant bacterial isolates were identified in accordance with Bergey’s manual that provides data such as colony characteristics, staining reaction, and biochemical properties. For further confirmation, isolates were sent to the lab at NCIM, Pune, to subject them to 16S rRNA sequencing and use the results for further analysis.

Collection of incubated coupons: Copper and SS coupons were collected using sterile ziplock bags filled with cooling tower water after an incubation period of 45 days. Macroscopic observation of patterns of biofilm formation was carried out for all the coupons.

Isolation of biofilm: Mucilaginous biofilms were collected in sterile containers by scraping the respective coupons under sterile conditions.

Extraction of N-acyl homoserine lactone, purification, and quantification: Modified physiochemical extraction and purification was carried out to analyze the samples through FTIR [5]. As much as 200ml of LB Broth was inoculated with 1 ml biofilm suspension for each experimental setup (Sample1-TCL SS, Sample 2-TCL Cu, Sample 3-UMP SS, Sample 4-UMP Cu) and incubated overnight at 35°C (100 rpm). After incubation, culture suspensions were transferred to sterile centrifuge tubes that were labeled as Sample 1-TCL SS, Sample2-TCL Cu, Sample3-UMP SS, Sample4-UMP Cu, respectively. These suspensions were subjected to centrifugation at 15,000 rpm, 4°C for 20 minutes. The supernatant was then filtered using a membrane filtration apparatus with membrane of 0.22-μm pore size. For purification, 200 ml of the filtrate obtained was mixed with 100ml ethyl acetate in 2:1 ratio and was incubated in a shaker for 10 minutes at 100 rpm [16]. Then the mixture was subjected to liquid–liquid extraction using a separating funnel for obtaining two immiscible layers using the FTIR-grade DMSO as solvent. Subsequently, the upper organic layer was collected in sterile containers. The extract was used as AHL sample and was further analyzed through FTIR.

Extraction and Quantification of EPS: Physical method was used for extracting extracellular polymeric substances [2]. Biofilm samples were transferred to sterile centrifuge tubes labeled differently (Sample 1-TCL SS, Sample2-TCL Cu, Sample3-UMP SS, Sample4-UMP Cu) and subjected to centrifugation at 20,000 rpm, 4°C for 20 minutes. The supernatant was then filtered using a membrane filtration apparatus with membrane of 0.22-μm pore size. The filtrate was used as the EPS sample, and quantification was carried out by performing protein and sugar estimation following the Phenol- Sulfuric method and Bradford method, respectively.

Invitro biofilm propagation: Microtitre Plate method was performed for studying the properties of biofilm formation from the obtained samples [11].

Test 1-A mixture of bacterial isolates from the Nutrient Agar plates (TCL-SS and Cu; UMP-SS and Cu) were transferred to sterile LB broth for all the samples.

Test 2-About 2ml of the preserved biofilm sample was transferred to a sterile test tube and further processed.

Propagation of Biofilms: The samples from Test 1 and Test 2 were cultured in an LB medium with overnight incubation. The overnight culture was then diluted 1:100 using fresh medium for biofilm assays. A quantity of 100 μL of dilution was added into each well in a 96-well dish. A total of eight replicates were maintained. The microtiter plate was then subjected to incubation for up to 24 hours at 37°C. After incubation, unattached cells were dumped out of the plate by turning the plate and rinsing thoroughly by gently submerging in a small tub of water. This process was repeated one more time to remove unattached cells, and media components were stained in the next step, thereby significantly lowering the background staining. About 125 μL of 0.1% solution of crystal violet was added into the water of each well of the microtiter plate. The microtiter plate was subjected to incubation at room temperature for 10 to 15 minutes. Then the plate was rinsed 3 to 4 times with water and blotted onto a stack of paper towels to remove excess cells and dye. The microtiter plate was turned upside down and dried for few hours or overnight and later photographed after drying.

Quantification of the Biofilm: A quantity of 125 μL of 30% acetic acid was added to water in each well of the microtiter plate for solubilization of CV. The microtiter plate was kept undisturbed at room temperature for 10 to 15 minutes. Next, 125 μL of solubilized CV was added to a new flat-bottomed microtiter dish, and the absorbance was quantified in a plate reader at 550 nm using 30% acetic acid in water as the blank.

Statistical Analysis: The z score test for the two population proportions was used for determining the significance of difference between the biofilm-forming potentials of Test 1 and Test 2. The test of significance
was set at <.05. Two-tailed hypothesis was selected for this study.

Results

Identification of Biofilm sample: The algal colonies obtained were identified as Nostoc spp, Chlorella spp, Lyngbya spp, and Synechococcus spp. A total of 35 x 10^6 CFU/ml and 40x10^6 CFU/ml was obtained from the samples collected from TCL and UMP, respectively. Three colonies each from TLC and UMP were isolated and further subjected to processing for obtaining pure cultures. Table 1 and 2 show the colony morphology of organisms isolated from the TCL and UMP samples. Fig. 5 to 10 show the colony morphology of microorganisms from the TCL and UMP samples on a nutrient agar medium.

Estimation of EPS:

Sugar Estimation by Phenol Sulfuric Method: Sugar content in coupons obtained from TCL industries was estimated to be 4.89/100ml in SS coupons and 3.14/100ml in Cu coupons. A significant decrease was observed in sugar concentration. Sugar content in coupons collected from UMP industries was estimated to be 1.99/100ml in SS coupons and 1.07/100ml in Cu coupons. A very minute decrease was observed in sugar concentration. Fig. 11 is a graphical representation of sugar estimate of TCL (SS, Cu) and UMP (SS, Cu).

Microtitre Biofilm Formation Assay: The adsorption readings at OD sub 550 of cultures from Test 1 and Test 2 after staining the formed biofilm samples with crystal violet helped to identify a substantial difference between the isolates of SS and Cu coupons collected from TCL and UMP.

The Z score test was carried out for the two population proportions to determine the significance of difference between the biofilm-forming capabilities of Test 1 and Test 2, and results were found to be significant at p < .05 for both the tests.

Discussion

Crude biofilm and water samples were collected from Thirumalai Chemicals Limited (TCL) and Ultra Marine and Pigments Ltd (UMP), Vellore. Preliminary microscopic examination revealed algal colonies such as Nostoc spp, Chlorella spp, Lyngbya spp, and Synechococcus spp. They occur widely in aquatic habitats and form active biofilms due to production of alkaloid compounds and intense pigmentation on surfaces exposed to moisture (Sanmartín et al, 2010).

A homogenized form of biofilm and cooling-tower-water samples was subjected to heterotrophic plate count using LB media for enumeration of bacterial colonies. Three colonies exhibiting maximum characteristic growth from both samples were selected and subjected to gram staining, motility, and biochemical tests (Indole, Methyl Red, Voges Proskauer, Citrate, and TSI) for identification. The process of identification revealed Micrococcus luteus, Burkholderia cepacia, and Bacillus megaterium from TCL, and Bacillus subtilis, Sarcina aurantiaca, and Pseudomonas putida from UMP. Further confirmation of the isolates was done by subjecting the identified organisms to 16SrRNA sequencing.

Micrococcus luteus is a gram-positive as well as gram-variable coccus; it is as a protrophic and nonmotile bacteria residing in water released by industrial systems. In a study [15], the biofilm-forming abilities of the organism in a microtiter plate test was studied. Burkholderia cepacia is an aerobic gram-negative bacillus that occurs in various aquatic environments. It is of low virulence and is a frequent colonizer of fluids. In a study [13], it was reported that even the non-mucoidal stage of the organism is capable of producing biofilms effectively. Bacillus megaterium is considered a gram-positive, endospore-forming, rod-shaped, aerobic, and saprophytic bacteria that produces a variety of enzymes and proteins. Currently, active research is taking place to study this organism’s capacity for biofilm formation after manipulation of its genome for bioremediation. Bacillus subtilis are a gram-positive, aerobic, rod-shaped, and catalase-positive bacterium. In study [10] the extracellular matrix produced by Bacillus subtilis B-1, an environmental strain capable of forming robust floating biofilms, was studied.

Sarcina aurantiaca are gram-positive bacteria that form characteristic packet of cells in both solid and liquid media. They produce a characteristic orange pigmentation [1] studied the diverse genomic profiles
and heterogeneity of the biofilm capabilities of Sarcina aurantiaca and other archaic organisms. Pseudomonas putidaare a rod-shaped, flagellated, gram-negative bacteria that occurs in most of the soil and water habitats. A study [7] revealed the complex water-soluble EPS produced by the organism containing polysaccharides in a larger proportion.

For testing the efficacy of copper antifouling coat on biofilm, a control (Stainless Steel-SS) and test (Copper-Cu) system was installed at the cooling tower panel. We ensured the SS and Cu coupons were subjected to the same water circulation system. This setup was followed for both the industries. Coupons were incubated for 45 days for the completion of primary attachment assay and microcolony formation. The autoinducers [N-Acyl Homoserine Lactones] and the tensile EPS structure are the two major compounds produced during these stages. After the 45-days incubation, the biofilm-laden SS and Cu coupons were subjected to the extraction of quorum-sensing molecules as well as the EPS structure for both TCL and UMP samples. AHL molecules were further analyzed by FTIR.

The SS and Cu AHL extracts from TCL were analyzed for the presence of AHL functional groups, which included the C=O lactone and a N-H amine group. The C=O lactone ring from SS exhibited peak intensity at 53.6007 and 74.6818 at two different frequency ranges. The N-H amine group was at a peak intensity of 92.7753, and for the Cu, it was 28.799; for the lactone rings, 46.5075; and for the N-H group, 65.7366. This occurrence of the N-H amine group was the fingerprint region and confirmed the decrease in AHL activity between the biofilm sample extracted from SS and Cu coupons. Subsequently, the SS and Cu AHL extracts from UMP were analyzed for the presence of AHL functional groups, where the C=O lactone ring from Cu demonstrated peak intensity at 30.2544 and 46.7873 at two different frequency ranges. The N-H amine group occurred at 65.4578. For the SS, it was 38.2943, and it was 56.9419 for the lactone rings while 72.915 for the N-H group. The second peak of the lactone ring exhibited higher intensity in the Cu sample, but the N-H fingerprint region exhibited a decreased peak intensity. These results confirm the decrease in AHL activity between the biofilm samples that were extracted from SS and Cu coupons.

The EPS structure is composed of only two major components-sugars and protein. Total carbohydrate concentration was estimated by the phenol-sulfuric method, and it was found to be 4.89/100ml and 3.14/100ml in SS and Cu coupons, respectively, for the TCL sample, and 1.99/100ml and 1.07/100ml in SS and Cu coupons, respectively, for the UMP sample. Total protein was estimated to be 4.3/100ml and 3.98/100ml in SS and Cu coupons, respectively, for the TCL sample and 2.14/100ml and 1.22/100ml in SS and Cu coupons, respectively, for the UMP sample. A considerable difference of significance was found in the total carbohydrate estimated and a slight difference in protein content as estimated. When the total estimated values of carbohydrate and total protein were added, a significant difference in the concentration of the EPS extract was observed. Microtiter biofilm formation was performed for assessing the biofilm-forming capabilities of bacterial isolates from the TCL and UMP samples, and the method allowed for an invitro propagation of the biofilm sample. The isolated bacterial isolates from SS and Cu coupons were taken as Test 1. Upon propagation, staining with crystal violet, and subsequent calculation of absorbance rate in ELISA plate reader, the total absorbance of the 8 replicates was found to be 8 (SS) and 3 (Cu) for TCL. While it was 7 (SS) and 2 (Cu) for UMP. A homogenized sample of biofilm with the cooling tower water was considered as Test 2. Upon propagation, staining with crystal violet, and subsequent calculation of absorbance rate in ELISA plate reader, the total absorbance of the 8 replicates was found to be 7 (SS) and 3 (Cu) for TCL and it was 6 (SS) and 2 (Cu) for the UMP sample.

A significant decrease in the biofilm-forming potential was observed between the SS and Cu samples for both Test 1 and Test 2. This might be due to the result of reduced activity emphasized by the copper antifouling coat present, in the autoinducer molecules as well as in the EPS structure. Z-score test was used to determine the significance of difference between the biofilm-forming capabilities of both Test 1 and Test 2 samples and the result was significant at p < .05 for both these tests. With the results obtained from the study, it can be concluded that copper coating demonstrated active antifouling efficacy against biofilm-forming organisms isolated from the cooling tower system. Hence, further studies on other autoinducer molecules produced by such organisms should be undertaken with a special focus on the signal molecules–targeted therapy and in quorum-sensing manipulations.
Conclusion

The uncontrollable formation of biofilm in industrial cooling towers has been a major problem for the past few decades. Chlorine and other biochemicals are the most preferred antifouling agents to curtail the growth of sessile organisms. However, current research shows these chemicals do not exhibit adequate efficacy due to the emergence of resistance in the biofilm-forming organisms against such agents. Coating copper as an antifouling agent on the surface of the cooling tower has proved copper to be a potential proactive agent against biofouling. From the findings of study, it was concluded that effective use of copper antifouling paint can significantly reduce biofilm formation and its signaling molecules in industrial cooling towers and has the potential to create newer, more effective alternatives for tackling existing biofilm problems in cooling towers and other similar setups.

Acknowledgment: The authors are thankful to the Principal, Faculty of Microbiology Department, Ethiraj College for Women, Chennai, and Thirumalai Chemicals Ltd and Ultra Marine and Pigments Ltd, Vellore, for providing the necessary facilities and support to carry out this research successfully.

Abstract

Coronavirus disease 2019 (COVID-19) is a life-threatening global health scenario. The WHO (World Health Organization) has announced this disease as global issue. The severity of this disease causes highest death rates from December 2019-October 2020 world wide. There is an urgent need to develop medicines and vaccine to prevent the immune system of human. Medicinal plants and plant based drugs play a major role in preventing by provoking the immune system. This review discusses about the major global issue pandemic coronavirus disease (Covid -19) and the traditional medicines as preventive and curative agent in treating this global health issue.

Keywords: COVID-19, medicinal plants, preventive measures.

Introduction

In the beginning stage the spreading of coronavirus was identified through the blood, sputum sample and the excreta of diseased patients. Coronavirus virion particles measured the length of 80–140 nm protein spikes like projection around the virion layer, were observed through the electron microscope. The arrangement of corona virus is single-stranded RNA with 30 kb in length, gene sequence matched with previously found coronavirus gene sequence. RNA Polymerase is responsible for higher proliferation rate of coronavirus.

Coronavirus is novel virus emerged from the virus causes respiratory issues already present hence its mutation level is unexpectedly high. With structure identification it can be matched and given for sequence similarity by using the bioinformatics tools such as CLUSTALW, BLAST and other sequence similarity tools and with the basic identification tools we can design a drug against the deadly virus. The use of herbal plants to withstand human health is a biggest challenge according to doctors in ayurveda, siddha to find a medicinal plant which are of with many complex molecules those are not easy to derive. The medicinal drugs can be derived from turmeric, ginger, cinnamon, cloves, tulsi, fenugreek and fennel seeds. These are important man-found medicines to cure many complicated health ailments. With the aid of scientists and researchers there is an urgency to find the natural ways to cure this disease. And to make strong anti-COVID-19 herbal medicines from endless plant materials present. Undoubtedly these medicinal plants, aids in reducing the patients suffering from illness through the COVID-19.
Use of Medicinal Plants: Necessity to find the plants which are different in their dosage and the use of plant parts some of the examples are: Thumbai poo (leucas aspera), karpoo ra valli (Coleus amboinicus), Tulsi (Ocimum tenuiflorum), Gentian (Bitter root), Goldenseal, Ginseng Musumusukkai (Ocimum tenuiflorum) [4].

Ginger (Zingiber officinale Rose): Ginger (Zingiber officinale Rosc.) belongs to the family Zingiberaceae. The anti-oxidant and anti-arthritic compounds of ginger and its components utilized in various research oriented tests. Strengthening the body’s defense mechanism by improving the antioxidant property will undoubtedly cure many chronic diseases and disorders. 6-Shogaol obtained from ginger is the important compound aids in relieving the patients from respiratory issues. The alakaloid irritant taste from ginger also aids in clearing respiratory issues thus it is also known to help preventing from COVID-19 [5].

Curcumin (Curcuma Aromatica): Turmeric consists many medicinal properties includes, anti-cancer, antiseptic and antibacterial and anti-fungal which helps in hindering the molecules responsible for the diseases. Its antioxidant activities helps us in cleansing and repairing the digestive disorders. Anti-thrombotic properties of Curcumin may also helps in clearing the mucous in lungs so that relieving the oxygen supply to the entire body [6].

Ashwagandha (Withania Somnifera): The natural product Withaferin A is isolated from Ashwagandha (Withania somnifera) mostly obtained to treat many diseases such as common cold, gynaecological disorders, and even infertility issues. It possess antiviral activity against many viral diseases and also against COVID-19 [7]. Molecular docking studies shows that as per YASARA scoring out of 28 compounds from W. somnifera (Ashwagandha) only the major compounds Withanoside V and Somniferine showed significant binding affinity as compared to native coronavirus. Withanoside V showed highest binding energy of 10.32 kcal/mol [9].

Liquorice (Glycyrrhiza Glabra): The glycyrrhizin is a compound present in licorice plant for covid-19 is not clearly studied. This compound Glycyrrhizin inhibiting the tyrosine kinase enzymatic cellular signalling pathways responsible to develop tumor and induce cancer cell proliferation in uncontrollable manner. A glycone metabolite 18β glycyrrhetinic acid up-regulates the gene expression of the molecules helps in increasing the macrophage s tremendously which engulfs the antigen. Glycyrrhizin helps in increasing the nitrous oxide level capable to destroy viruses. The research carried on this plant shows that glycyrrhizin a natural compound enhances the level of nitrous oxide synthase it induces the high rate of apoptosis in the vero cells in culture medium. HIV-1 patients and patients with chronic hepatitis C virus are treated with the natural compound glycyrrhizin shows the positive recovery graph. However the toxic level of this particular compound is also studied in different ways because the variation in dosage level can lead to unexpectable complications in Covid patients as well as normal sick patients.

Tulsi (Ocimum Sanctum L): In Ayurveda treatment tulsi plant is majorly called as holy plant and holy water for that ability of healing and compounds it possesses and treats major health disease and disorders. Even in the covid period people are advised to take handful of basil leaves and boiled water with basil leaves. health complications. In the Indian medicinal system tulsi leaf extracts are known to cure bronchitis, rheumatic arthritis, and asthma. It is recorded in the research that tulsi plant has the binding property to destroy covid-19 deadly disease [11].

Cinnamon (Cinnamumom Zeylanicum): Cinnamon (Cinnamomum zeylanicum, and Cinnamon cassia) Lauraceae family one of most important tree containing bark with endless medicinal compounds. By considering the medicinal properties of the bark it is used in Indian cooking everyday to cure digestive disorders. Cinnamon primarily contains essential oils and other derivatives, such as cinnamaldehyde, cinnamic acid, and cinnamate which are taken to heal gynaecological disorders and enhancing the immune system by keeping the reproductive organs healthy. People often use it for weight loss procedures by putting it in boiling water and taken orally. It is also used for cosmetic purposes in ancient medicines to cure pimples and clear people with many skin infections. [13].

Baikal Skullcap (Scuttelaria Baicalensis): Baicalin, a major constituent of the plant, Bioactive compounds such as baikalin, wogonoside, are extracted for medicinal purposes from the root of this important medicinal plant S. baikalensis. It has been taken orally to treatment many digestive disorders such as diarrhea, vomiting and gastric problems. It is also known to
treat respiratory problems that’s why it is it has been researched and revealed that it is a potent medicine against coronavirus causing COVID-19. People with insomania and hypertension are advised to take this medicinal drug. This baicalin plays a major role in inhibiting the proliferating the HIV-1 virus[14].

**Tinospora Cordifolia (Giloy, Guduchi):** Giloy or Guduchi, scientific name Tinospora cordifolia is one of the most flexible restoring bushes. This is the simple herb utilized as a part of Ayurvedic medication. It is considered as best rasayana in its strong flexibility. It consists many biologically important phytochemicals including lactones, alkaloids, glycosides, steroids, sesquiterpenoid, diterpenoid, aliphatic compounds, phenolics, polysaccharides and flavonoid which play immunomodulatory activity in human body. It has anti-diabetic, antioxidant, Anti-inflammatory, antiperiodic, antispasmodic, anti-arthritic, anti-allergic, antimicrobial, anti-osteoporotic, anti-toxic, anticancer, anti-HIV, wound healing. Its alkaloid components including tinosporin, tetrahydropalmatine, choline, palmatine and magnoflorine are in high demand, it also has protective role against aflatoxin induced nephrotoxicity. This herb has broad activity plays important role to improve our immune system to fight against infectious diseases. Generally, extract (juice) of Giloycan be taken orally. The following herbal formulation is found to be helpful for preventing and curing COVID-19 disease [15].

**Neem (Melia Azadirachta L.):** Neem has strong bitter taste known to cure many health disorders, taken orally in empty stomach to flush out the toxins and kill worms in the stomach. The juice extract has been used to treat many skin infections. It is well for its anti-plasmodic activity against plasmodium spread by mosquitoes. Neem usage in traditional ways of curing diseases for more than two thousand years. Urinary, respiratory and digestive systems can be treated with the use of neem extracts to detoxify and enhance its functioning capacity. The bitter taste of neem helps in clearing the mucous of lung while having common cold by the way of steaming and taken as preventive medicine for COVID-19[16].

**Conclusion**

Traditional plants has many beneficial properties to explore, conducting extensive research necessary for experimenting and development for the healthy society. The proper use of medicinal plants can heal and help people with many disorders and diseases. The use of modern medicine can be used for emergency cure and its side-effects are also known and sometimes become incurable. Traditional herbal medicines help people in treating skin diseases such as psoriasis, leprosy and digestive disorders such as dysentery, gastric and even many types of cancer. The medicine from such herbal plants are used in many research institutes to treat deadly diseases such as cancer, cardiac arrest, memory loss, anaemia, insomnia. During this COVID scenario all these are used as preventive agent and are followed till date. Many plants possess beneficial antiviral compounds now it is used regularly by people to treat COVID disease. The proper utilization of traditional medicines against COVID-19 Pandemic disease would help people in many ways to safe guard and elevate the immune system.

Effect of Various Sweeteners on Cariogenicity Features of Streptococcus Mutans: In-Vitro Study

Nijesh J.E.¹, Srudhy R.², Preetha Elizabeth Chaly³

¹Associate Professor, ²Postgraduate Student, ³Professor and Head, Dept. of Public Health Dentistry, Meenakshi Ammal Dental College and Hospital, Chennai, India

Abstract

Background: Dental caries is a global pandemic health crisis, that is caused by diet containing refined sugar. Many alternative sugars in the market have been used as a substitute for table sugar. But there is paucity in literature regarding the cariogenicity properties of these.

Aim: To assess the effect of various alternative sweeteners on Streptococcus mutans growth and acidogenicity.

Study Design: Laboratory based In-Vitro Study.

Materials and Method: Ten percentage solutions of refined sugar, brown sugar, jaggery, palm jaggery, palm sugar, honey, Rare Sugar Sweet were used as test products to assess the growth of Streptococcus mutans in terms of the optical density using a spectrophotometer, Colony forming units(CFU) in Mutans-sanguis agar (MSA) and acidogenicity by measuring the pH. Statistical Analysis Used: Non-parametric test of significance with p value <0.05 was performed. Results: S. mutans growth in the honey and D-Psicose were significantly lower than that in the sucrose, while greater than that of xylitol and placebo group (p < 0.05). pH after 48 hours was statistically significant between the groups and dropped below the 5.5 in all the test groups except honey and D-Psicose. Honey had least cariogenicity in terms of growth of S.mutans and acidogenicity. Rare sugar sweet had S.mutans growth and acidogenicity less than sucrose.

Conclusion: Honey had least S. mutans growth and acidogenicity hence, can be regarded as safe alternatives for other commercial sweeteners in the market.

Keywords: D-Psicose, Cariogenicity, Acidogenicity, Optical density, Colony Forming Units.
It seems impractical for the complete restriction of sugar given the human preference for the sweet food item. Instead, cariogenic sugar can be substituted with other sweetening agents that might be less cariogenic.

Honey could be an alternative for sucrose as it is found to be non-cariogenic or less cariogenic. Brown sugar, jaggery, palm jaggery, palm sugar are alternatives to refined sugar that are functional foods and have health benefits. The presence of reducing sugars, significant quantities of minerals and other minor constituents makes ‘alternative sugar’ looks promising.

Xylitol, another alternative, is a naturally occurring non-fermentable five-carbon sugar alcohol, which cannot be converted to acids by oral bacteria, thus it helps to restore a proper alkaline/acid balance in the mouth.

With current advancements in food processing technology, many attempts have been made to find a novel “caries-preventing sweetener” or “anti-cariogenic sweetener”. One such recent product manufactured in Japan is D-psicose. D-Psicose, a Japanese product is a low-calorie sweetener, which claims to controls bacterial growth and acid production (anti-cariogenic), even in combination with existing sweeteners.

There are very few studies published to explore the cariogenic potential of these sweeteners. Hence an in-vitro study was conducted to assess the effect of various alternative sweeteners such as refined sugar, brown sugar, jaggery, palm sugar, palm jaggery, honey and D-Psicose on cariogenicity features of Streptococcus mutans.

Methodology

An in-vitro study was conducted on S. mutans MTCC 890 strain in the Central Research Laboratory, after obtaining the ethical approval. The cariogenic potential of Refined white sugar, Brown sugar, Jaggery, Palm sugar, Palm jaggery (Karupatti), Commercial honey, D-Psicose with sucrose (Rare sugar sweet®, Japan), Sucrose as Positive control (Lab grade) and Xylitol as a negative control (Lab Grade) was assessed.

a. Preparation of Test solutions: Ten percent of each test solution was prepared by mixing 10 grams or 10 mL of the test product in 100mL of distilled water and solutions were then filtered, sterilized through a 45- micron size pore filter and stored at 4°C. This solution was used for the preparation of agar media using Mutans Sanguis Agar.

b. Bacterial growth as a measure of Optical Density: Sterile 96-well microtiter plates were taken and wells were labeled as Tests and controls. In the test wells, 10 microliters of S. mutans from the overnight culture were added along with 290 microliters of MSA-sweeteners. In the control wells, 300 microliters of the MSA-sweetener dilution without bacteria were added. The absorbance of each well read at 540 nm in a spectrophotometer after an incubation period of 48 hours at 37°C. The test was done in triplicate. The final test optical density was calculated by subtracting the optical density of the test minus the optical density of the control of each product used.

\[ \text{OD}_{\text{final}} = (\text{OD}_{\text{test}} - \text{OD}_{\text{control}}) \]

c. Bacterial viability in terms of Colony-forming units (CFU): The effect of sweeteners on S. mutans viability was assessed. Bacterial cultures of all sweeteners from the microplate wells were plated on the MSA agar plate. The number of CFU for each sweetener was measured using an automated colony counter after incubating it for 48 hours at 37°C. The test was done in triplicate.

d. Sweeteners influence on S. mutans acidogenicity: The pH of the test solutions in the micro-titre plate was measured at baseline and the end of 48 hours using a digital pH-meter. The test was done in triplicate. To know the media characters at the end of 48 hours, a separate media solution with a microbe was prepared and kept as control.

Statistical tests: The colony count was transformed into \( \log_{10} \) CFU for analysis. The data were analyzed using SPSS software version 19.0. by a statistician who was blinded to the groups. Non-parametric tests of significance were performed. In all tests, a P-value of <0.05 was considered as the level of statistical significance.

Results

a. Inter-group comparison of optical densities: The ascending order of the optical density of the sweeteners is as follows, xylitol, honey, palm sugar, refined sugar, brown sugar, rare sugar sweet, jaggery, palm jaggery and sucrose. In the post-hoc analysis, the optical density of palm jaggery was higher when compared to other test sweeteners used in this study and this difference was statistically significant (p<0.05). (Table 1)

b. Inter-group comparison of \( \log_{10} \) of Colony Forming Units per mL: The ascending order of the optical density of the sweeteners is as follows, xylitol, honey, rare sugar sweet, jaggery, brown sugar, palm sugar, refined sugar and sucrose. Honey and rare sugar sweet had \( \log_{10} \) CFU/mL when compared to refined sugar, brown sugar, palm sugar, palm jaggery, jaggery and sucrose, while it was higher in both these sweeteners when compared to xylitol. This difference in colony-forming units in honey and rare sugar sweet with other test products was statistically significant (p<0.05) (Table 1).

c. Intra and Inter-group comparison of pH: The pH at baseline was around 7.2 for all the sweeteners, and even though there was a slight difference in pH, this was not statistically significant (p=0.802). The pH of media without sweetener added (Control) was 8.6 at the end of 48 hours, suggesting that the sweeteners were responsible for the change in pH. The pH after 48 hours for various sweeteners were 5.4±0.2 for refined, brown sugar and jaggery, 5.2±0.1 for palm jaggery, palm sugar, 5.9±0.2 for honey, 5.6±0.2 for rare sugar sweet, 5.2±0.2 for sucrose, 6.6±0.1 for xylitol and 6.8±0.1 for placebo. The difference in pH at end of 48 hours between the sweeteners was statistically significant (p=0.003). All the test products except xylitol, honey and rare sugar sweet had a pH less than 5.5, which is regarded as the critical pH for demineralization of enamel.

![Figure 1: Preparation of Test solutions](image1)

![Figure 2: Bacterial growth as a measure of Optical Density using spectrophotometer](image2)
Dental caries is caused by the interaction of the agent, host and substrate. The substrate is particularly refined carbohydrates in the diet. The refined carbohydrates in the diet are easily metabolised by S. mutans into inorganic acids, which causes demineralization, eventually leading to cavitation. The nature of the substrate, the frequency and amount of sugar consumed affects the initiation and progression of dental caries. [12] This has led to an intensive search for an alternative sweetener without cariogenicity. Advancement in food technology and a rise in health consciousness has led to the launch of many new alternative sweeteners.

One such novel alternative is D-Psicose which is marketed as ‘Rare Sugar sweet’ in Japan which is a C-3 epimer of D-fructose, with higher solubility, smooth texture, desirable mouthfeel and has 70% of the sweetness of sucrose with only 0.2 kcal/gm. [13] It has a low glycaemic index and prevents postprandial hyperglycaemia. [14]

In India, many traditional sugars such as brown sugar, jaggery, palm jaggery, palm sugar and honey have been consumed regularly for centuries. Parents substitute these sugars in common food items and drinks for their children’s well-being, as they are regarded as a safer alternative to that of refined sugar. Hence, these sugars were tested for cariogenicity in this study.

Sucrose has been regarded as arch-rival for dental caries hence used in this study as a positive control. [15] Xylitol was used as a negative control as it is an alternative sugar as it is not metabolised by S. mutans to produce acids. [16]

Cariogenicity of food items can be assessed by four parameters viz cariogenic plaque forming ability of the substrate, acid forming potential, clearance time and ingestion time. [17] Since this is an in-vitro study only, the plaque forming ability of the substrate and the acid forming potential was recorded.

Plaque forming ability of the substrate was assessed by measuring the growth of Streptococcus mutans. Triangulation was done between optical density and colony forming units to obtain a good calibrated growth estimate. The acid forming ability was assessed using a calibrated digital pH meter.

In this study, ten percentage of solutions were prepared, for all the test products. This was done to ensure that the results are comparable to the study conducted by Stephen in 1940, where 5.5, which is the critical pH of demineralization of enamel was determined using 10% solutions of glucose/sucrose. [18]

In this study, natural honey, had lower OD as well as CFU when compared to that of the positive control and the pH did not drop below 5.5. This suggests that honey can be a potential alternative to refined sugar. Natural honey contains various amino acids, vitamins, minerals and enzymes along with 95–99% sugar, which is predominantly fructose and glucose. [19] Honey has anti-inflammatory, antibacterial, anti-viral, antifungal, anti-oxidant properties and promotes wound healing, protects from gastrointestinal infections. [20] The topical application of honey caused less fall in pH when compared to sucrose solution among orthodontic patients. [21]
Both refined sugar and other sweeteners except honey which are tested in-vitro might be cariogenic as they contain fermentable carbohydrates. [22] But, the tested alternative sweeteners contain reducing sugars with significant quantities of minerals like Calcium, Copper, Iron, Manganese, Chromium, Magnesium, Potassium, Niacin, Vitamin B6, and other minor constituents, which makes them, nutritionally and functionally different from refined sugar. [23] Besides, the processing of food in the oral cavity depends on its properties and oral physiology. [24] The cariogenic potential of these traditional sugars is a subject of debate and further in-vivo evidence is needed to determine its cariogenicity.

The novel product D-Psicose has bacterial growth less than that of positive control and the pH was above 5.5. Hence might be a potential alternative to refined sugar, for the prevention of dental caries. The study is the first of its kind to assess the cariogenicity features of the tested sweeteners using two key determinants of cariogenicity and triangulation did to assess the S. mutans growth increases the reliability of the results. This is a preliminary In-vitro study, hence the results have to be interpreted with caution. To conclude the cariogenicity of the sweeteners in humans in-vivo studies is required.

CONCLUSION:

Among the tested traditional sugars, honey seemed to have a less cariogenic effect when compared to that of refined sugar. Besides, the novel sweetener D-Psicose as well as the potential for being suggested as an alternative. The other tested traditional sugars though seem as cariogenic as refined sugar, the cariogenicity is still debatable. Hence, further In-vivo studies are necessary to determine the cariogenicity of these sugars in humans by measuring all four parameters for the cariogenicity of food.

Abstract

A respiratory disease caused by the corona virus is SARS-CoV-2 spread from China to all over the world. The pathogen causes serious health hazards to humankind from infectious bats. The symptoms range from mild infection to serious problems and life threatening incidence occur globally. The testing method should be more rapid for correct diagnosis and clinical laboratories play a pivotal role in COVID-19 testing, providing presumptive diagnosis at the earliest and nucleic acid based amplification techniques such as RT-qPCR delivering high fidelity reports. The rapid point-of-care testing is crucial in handling such emergency to enhance large-scale surveillance to aid quarantine of suspicious cases and thereby encasing the contagious spread. The review focuses on RT-qPCR and future method such as LAMP assay and nano based techniques are suggested for efficiency and to overcome the false results.

Keywords: RT-qPCR, Molecular method, LAMP, Corona 19, Respiratory infection.

Introduction

The pandemic situation caused by the virus genetic material is SSRNA which affects the host and the entire respiratory system, causing severe illness and leads to death [¹]. In past years diseases like SARS and MERS [²] showed this pandemic effect, causing death affecting thousands of people compared to this novel corona virus is more pathetic and entire world is affected by this harmful pathogen. The most worrisome is that there is no proper drug and scientists are showing tremendous work in identifying the vaccine and to prevent the disease. World Health Organization (WHO) named this virus as nCOV and later renamed as COVID-19 [³]. International Committee on Taxonomy of Virus (ICTV) later identifying the structural morphology of the virus and is currently called by the name of SARS-CoV-2 [⁴].

The virus belong to coronaviridae family and possesses 4 different genera’s such as α, β, γ and Δ corona virus. The α and β viruses were present in bats and γ and Δ virus present in birds [⁵, ⁶]. The virus has genetic material of single standard RNA, which is about 32kb in length and largest human affecting RNA virus. The study focuses on the molecular techniques which can identify the nCoV more precisely. The aim of this technique is to gain knowledge among researchers in handling the molecular biotechnology as an essential medium.

Molecular techniques in COVID-19 testing:

Real-time RT-qPCR: Human corona virus (hCoVs) possesses minimum 10 open reading frames (ORFs) and the genetic material is similar to SARS-CoV-2. Out of 10 ORF, ORF1a/b has two large polyproteins with 16 proteins which are not in exact structure and forms the enzyme viral replicate transcripts in SARS-CoV as well as MERS-CoV [⁷]. The nucleic acid sequencing based techniques is advantageous over the other diagnostic investigations and are validated as confirmatory testing for COVID-19. The presence of viral SSRNA not only shows the presence of acute disease, since RNA traces decrease from 66.7% before day-7 to 45.5% during the days 15th to 39th days of infection [⁸]. The negative test in patients should be more careful and repeated sample
testing along with Chest imaging is very much helpful in tracking the records of severity of infection [9]. With certainty nucleic acid sequencing techniques is robust yet many difficulties remain such as damages that incur in SARS-CoV-2 target RNA during replicative processes and release of broken pieces of RNA into the bloodstream. These challenges can be overcome for isolation of RNA fragments using CRISPR or in combination with nano-based nucleic acid extraction.

COVID-19 testing by RT-qPCR is performed with labeled probes targeting either of ORF1 gene RNA dependent, N, E & S genes. USA developed an RT-qPCR diagnostic tool for identifying the corona viruses. For a patient to be confirmed positive, 3 reactions, dependent, N, E & S genes. USA developed an RT-qPCR diagnostic tool for identifying the corona viruses. For a patient to be confirmed positive, 3 reactions, focusing the N gene detect the virus and validated for the infection [10]. The Charite testing algorithm for SARS-CoV-2 infection states that test assays detect target genes to be positive in order to progress through the next step. The second step would consist of testing with RT-qPCR targeting the virus specific to RdRp with quality control of Alpha and Beta corona viruses, since other SARS-CoVs are not currently present in humans, the cases that are augmented and patients are true positives for the viral infection. Apart from these CT scan is highly recommended with false negative people. The possibility of false negatives by RT-qPCR tests with the patient’s nucleic acid shows high probability of false result in the early stage of COVID-19 infection patients[9].

The other persons viral RNA can be used as a positive control, the RdRp assay with two probes specific to the viruses and an additional probe that reacts only with novel CoV. By inhibiting the experiments, the probes react alone or in groups, show the same level of identification in each target virus. The assays were highly accurate with 95% detection probability and the copies per reaction have been identified. Similarly the N gene testing assay after ORF1b confirmation is a subgenus of Sarbeco virus [11]. The presence of viral pathogen in respiratory tracts was detected by amplification of the virus, nucleocapsid protein genes fragments for a total of 4880 cases revealed 39.80% positivity for virus nucleocapsid protein and ORF1ab (40.98%) [7]. The performance of QIAstat-Dx respiratory for the virus panel, which uses QIAstat-Dx cartridge permits direct insertion of the 66 NP specimens, was kept in transport medium without additional manipulation with testing activity comparable to that of the WHO suggestions. The RT-qPCR assay has a limitation of 1,000 copies/ml, and no cross-reaction other hCoVs (229E, OC43, NL63 and HKU), other respiratory viruses [13].

Future prospective of COVID-19 testing:

**LAMP Assays:** LAMP activity is based on the techniques of amplification of nucleic acid which is rapid and also amplifies target SARS-CoV-2 DNA with elevated specificity beneath isothermal conditions. Isothermal LAMP amplified a piece of ORF1ab gene; and synthesized a new RNA was equivalent to 10 copies of corona virus [14]. Random-amplification deep-sequencing of the novel CoV by mNGS platform helps in determining its origin, evolutionary history and discrimination among MERS-CoV and SARS-CoV identification. For the investigative purposes, the genetic material performs molecular assay for the human corona virus while some type of CoV deteriorates many primer sets. The respiratory panel consisted of multiple sets of oligo nucleotide detected endemic human corona virus whereas target virus was not detected in these panels. Eleven molecular devices from various manufacturers approved for testing of SARS-CoV-2 revealed variable performances. MGI Tech and Innovita utilized the NGS technique to detect all the species along with SARS-CoV-2 and an isothermal amplification technique coupled with chip detection respectively, while the remaining nine devices utilized real-time technique for amplification and detection [15].

**Film array for respiratory virus pathogens:** The ePlex RespiratoryPathogen Instrument is a comprehensive system requiring no additional accessories and has a testing capacity ranging from 24 to 96 samples tested within 2hrs thus providing flexibility of testing in small spaced laboratories. An added advantage of this system includes the generation of customized information and possible for the two directional interface with information system of the laboratory. In a multicentre study, USA and Canada, evaluating the ePlex panel (GenMark
Diagnostics) facilitated differentiation of four CoV genotypes with simultaneous detection of 19 different viruses. The ePlex offered a highly specific method of identification in microbial respiratory pathogens with 100% reproducibility and facilitates genotypes epidemic surveillance for better treatment strategies\(^{[16]}\).

**Nano-based diagnostic techniques:** The implication of nano materials with potential application into diagnostic tests is a critical tool for rapid screening of cases at-risk populations. A one-step reverse transcription with nanoparticles-based physiochemical detector, i.e. biosensor designed using 2 LAMP primer sets, F1ab and nasal pharynx genes of the virus concurrently identified both targets with sensitivity of 12 number of copies and there is no cross reaction generated from the viral templates\(^{[17]}\). Seo et al developed virus with a particular protein in spike which is coated with the sheets of graphene sheets possessing a detector for the novel virus in clinical samples\(^{[18]}\). The 2D-gold nanochip-based plasmonic nucleic acid biosensor developed by Qui et al facilitated the detection of viral RNA up to 0.22ppm concentration using localized Surface Plasmon Resonance. A micro fluidic ELISA developed by Tan et al reported of quantitative, sensitive detection of the virus specific antibody and antigen in serum within a short period of 15-20 minutes\(^{[17]}\).

**Conclusion**

Health care workers are involved in tremendous efforts in global crisis to stop the spread of COVID-19 with their therapeutic plan as per the guidelines of WHO. Scientists were actively involved in treating the virus and developing new vaccines and therapies. Deeper knowledge and clinical tests are conducted all over the globe and countries join hands to prevent the spread and vaccinations are in trial till date. Thus, our study focuses on the molecular diagnostic tools to identify the virus more accurately to avoid false positive or negative cases to inhibit the pathogenic spread.

Topical Applications of Antioxidants for a Topic Dermatitis

Rajesh R.1, Anbumalar2, Nithya P.3, Jaikumar S.4

1Associate Professor, Department of Dermatology, Meenakshi Medical College Hospital and Research Institute, Enathur, Kanchipuram, Tamilnadu, India, 2Assistant Professor, Department of Dermatology, Meenakshi Medical College Hospital and Research Institute, Enathur, Kanchipuram, Tamilnadu, India, 3,4Associate Professor, Department of Pharmacology, Meenakshi Medical College Hospital and Research Institute, Enathur, Kanchipuram, Tamilnadu, India

Abstract

Atopic dermatitis is a skin disease which majorly affects the children. It can be caused by dust, mites, pets and food allergens. Atopic dermatitis is induced by the allergens and ends up in the elevated level of Immunoglobulin G. People from the developing countries such as New Zealand and U.S are more prone to atopic dermatitis skin disease because of the low level of melanin production in their skin. This can be reduced by the use of natural compounds such as glutathione derived from plants. In this article, the functioning and active molecules of glutathione for atopic dermatitis are discussed.

Keywords: Skin disease, Atopic dermatitis, glutathione, IgG, melanin.

Introduction

Microorganisms play an important role in curing the skin infections like eczema which are caused by the microbes like bacteria, fungus and viruses. Patient with atopic dermatitis is infected with the pathogen Staphylococcus aureus and these kinds of bacteria does not require antibiotic for the treatment. Antibiotics are used for the lesions and oozing leakages in the skin for the patients. Antimicrobial peptide production deficiency in the skin of atopic dermatitis can lead to have a greater risk of getting viral infections such as pox viruses caused by Molluscum contagiosum produced round shaped blisters, pimples on the skin. Typical super infection on the skin is caused by another important virus called herpes virus. Herpes simplex virus causes infection spreads all over the face and in the chest region leads to vesicular eruption. Eczemic conditions in patients are recommended for antiviral treatment [1].

Glutathione: Glutathione consists of thiol, compound having a multifunctional role in plants. Function of glutathione is recognized earlier, is based on the thiol-disulphide interaction with other compounds. It works by how glutathione is reduction and oxidation manner to give a disulphide form that is then recovered by the NADPH-dependent glutathione reductase enzyme to form glutathione. Role of glutathione in animals is established as a defensive mechanism in animals that is because of the enzyme, selenium dependent glutathione peroxidase production which works as a central pillar of animal metabolism. Glutathione works as antioxidant in animals [2].

The analysis of GSH(Glutathione) is gaining great interest in the field of science, many method have been proposed for the production of glutathione. The experiment on liquid chromatography and enzymatic determination are most processed experiments. Capillary electrophoresis is also one of the best method to obtain glutathione, which is simple, fast and reproducible method to obtain and analyze the compound with low cost effective procedure [3].

Superoxide Dismutase: Atopic dermatitis are formed by the association of oxidative stress and others intruders in the development of skin peptides and proteins. This superoxide dismutase is worth in reduction...
of oxidative stress in the development of Atopic dermatitis in children. This is possible through the use of topical antioxidants, such as SOD. It is referred as the primary antioxidant and also as a ubiquitous enzyme, knowns to be the defensive agent anti-oxidant [4]. This enzyme shows catalytic activity induces the reaction in a fast manner helps in renewing the process. Mechanism of action is not common with other active compounds such as vitamin E, glutathione, and carotenoids they are compounds which are believed to be easy exhaustible without the possible renew abilities. This enzyme is capable of converting an enzyme superoxide anion to hydrogen peroxide by distracting the reaction of O$_2$. Hence the ROS production and free radicals are converted by this superoxide dismutase enzyme. A very harmful reactive nitrogen species are also protected by the enzyme superoxide dismutase [4].

**Vitamin C**: It is considered as one of the water soluble in all the Vitamins. Lipophilic are antioxidant A and E. Vitamin E is considered as the bond breaking antioxidants, which helps preventing the skin from oxidative effects and unsaturated lipids present on the membrane of the cell. For skin regeneration, Vitamin C is mostly preferred. It plays an important role in neutralizing free radicals by giving hydrogen ions to free radicals, then the vitamin C changes as ascorbate after the donation process. Vitamin C not only prevents the skin from free radicals induces oxidative stress it also works as Co-factor of glutathione and Vitamin E in the causative agents of stress in the production of proteins for skin protection. One of the most effective scavengers is beta-carotene works well against the alkoxyl and peroxide free radicals [4].

**Vitamin E**: Atopic Dermatitis patients are treated with vitamin E orally and given as transdermal. The random clinical trial has suggested to use vitamin E for the topical application of this skin infection after observing the inflammatory responses. To incorporate such micronutrients nanotechnology approaches are made to make the compounds bioavailable water soluble vitamins. Nano formulations with vitamin E have been utilized for the efficient delivery of skin retention nanotechnological approaches towards this issue are more advantageous. [5]

**Astaxanthin**: These studies are conducted in mice for the antioxidant activity using Astaxanthin, 3,3′-dihydroxy-β-carotene-4,4′-Dione, carotenoid obtained from an algal compound without the Vitamin A. Astaxanthin work efficiently than the β-carotene and α-tocopherol. It has many therapeutic agents and activity such as anti-cancer, anti-tumor and antiviral activity. ROS activity is controlled by astaxanthin and oviduct epithelial cells in bovine also the n-oxidative stress. Additionally, Astaxanthin inhibits the inflammatory mediator production by controlling the signaling pathway of nuclear factor-kB. It prevents the skin from ultraviolet (UV) induced photokeratitis in the topical administration of mice by decreasing the oxidative stress in the eye cornea region [6]. An antioxidant, which inhibits the inflammatory response are Vitamin A, C and E. Antioxidants that are produced during the maternity period are intended to have protection against the child prone to atopic dermatitis leads to asthma [7].

**Melatonin**: Melatons are well known for immunostimulation in allergic reactions. It is also known for its antioxidant and cryoprotective effect in the cell affected by inflammatory actions. Inflammatory diseases lead to the decrease in melatonin secretion and free radical production that worsen and increases the skin infection. The release of Pro-inflammatory mediators and vaso active agents and infiltration of mast cells leads to the skin disorders such as atopic dermatitis. The immunoglobulin E and interleukin-4 in the serum are increased during the atopic condition when the melatonin production is inhibited in the skin. Allergens in the bronchial region indicate the presence of Immunoglobulin E leads to asthma by the inhalation of allergens. It regulates the immune response and shows the smoothness in muscle. This anti-oxidant however, increase the activity of pro-inflammation in asthma tends to bronchial inconvenience. It also works as a sleep inducing agent in asthma patients, but not recommended for intake in regular basis [8]

**Solanum tuberosum L.**: Solanum tuberosum extracts inhibit the lesion formation in atopic dermatitis patients from the study carried out in NC/NGA mice. Skin irritation, itching ear bulging and scratching habits was inhibited by the use of extracts from Solanum plant role is to inhibit the inflammatory responsive cells reaction. Solanum tuberosum treated mice showed reaction against the Ig E serum level [9].

Mast cells and activation of helper cells are found in the patients with atopic dermatitis. It is found to be associated with an increase in Th2 cytokine serum, including interleukin-4, interleukin-5, interleukin-10, and interleukin-13 productions are noticed in patients
with this skin infection. The expression level of interferons is also reported in patients with atopic dermatitis. Antioxidants play a major role in inhibiting the cells with a skin infection and protect the skin from UV-rays. β-hexosaminidase is also recommended in research incorporated to the mice to check the reaction against atopic dermatitis [10].

**Furfuryl Palmitite:** It is an ester based compound obtained when palmitic acid reacts with furfuryl it has remarkable oxygen quenching property. This antioxidant is low reactive in nature, consisting of no ionic charge, which helps in spreading through the dermis layer beneath the skin and damages the cytoplasmic and nuclear composition. These are one of the primary reasons in skin aging and other dermatitis issues and it protects the skin in spreading infection [11].

**Natural Antioxidants:** A Phenolic compound plays a major role in photoaging derived from natural compounds present in plants. It is identified in flavonoids. Flavones, isoflavones, cinnamon compounds these are derived from berries which are rich in antioxidants. These entire compounds play a major role in protecting the skin from oxidative stress, inflammatory response, UV-damage to the cells. All these compounds and skin care regimes play a defensive mechanism in protecting the skin from those damages [12].

**Ethanolic Extract of Juglans regia:** *Juglans regia* plant showed very good scavenging activity and confirmed by the DDPH scavenging assay. These plants will protect the skin from damages [13]. The impact of ROS in biological systems is that the level of body fluids, DNA and lipids are measured by the biomarkers helps in the identification of diseases. DNA oxidative damage and repair are identified by the biomarker Urinary 8-hydroxydeoxyguanosine (8-OHdG). Some of the antioxidants are derived from protein with advanced antioxidant property and glycation products [14].

**Ferulic acid:** The major phenolic compound present in the plants works against the skin infection are ([E]-3-[4-hydroxy-3-methoxy-phenyl] prop-2-enolic acid) in the plant tissues. Biological properties and phenolic compounds protect the skin from atopic dermatitis. Glycosides, tannins, flavones and tannins are present in plants which safe guards the health of human in many ways. Benzoic acid and cinnamic acids are the major phenolic compounds which are responsible for the reduction of free radicals and oxidative stress in the skin [15].

**Conclusion**

Skin infections are higher in children due to many reasons such as close contact; unhygienic approaches such as hand wash and healthy food intake are the major problem in children. Atopic dermatitis is caused by the bacterium and develops as a major intolerable skin infection. This can be controlled by the antioxidants which will reduce the oxidative stress and UV-rays caused damages to the skin. Many antioxidants, phenolic compounds play a greater role in controlling the skin related disorders. The daily intake of these natural compounds and topical administration to the skin prevents from major skin diseases.

Hypertension: A Review

Midhun Kumar G.H.1, Shanmuga Priyan2, Arunachalam P.3, Elavarasan K.4

1Associate Professor, Department of Community Medicine, Meenakshi Medical College Hospital and Research Institute, Enathur, Kanchipuram, Tamilnadu, India, 2Associate Professor, Department of Pharmacology, Meenakshi Medical College Hospital and Research Institute, Enathur, Kanchipuram, Tamilnadu, India, 3Professor & HOD, Department of Cardiology, Meenakshi Medical College Hospital and Research Institute, Enathur, Kanchipuram, Tamilnadu, India, 4Senior Resident, Department of General Medicine, Meenakshi Medical College Hospital and Research Institute, Enathur, Kanchipuram, Tamilnadu, India

Abstract
Throughout the world, as per research about 1.13 billion people are affected by hypertension. The increase in blood pressure which is unable to be handled at a given situation is known as hypertension. People from middle and low income countries are affected due to the hypertension. This is due to the high expectation in living style, job dissatisfaction, and comparison between persons. This phenomenon is becoming a burden throughout the world and it is affecting the younger generation. This leads to decrease in life expectancy and it is a leading cause of deaths around the world. This paper analyses the various reasons for the hypertension and its causes and the obtained results are summarized.

Keywords: Hypertension, risk factor, determinants, occupational stress, DALYs

Introduction
Elevated blood pressure in medical terms is known as Hypertension. It is a serious condition in which the end organ damage is very obvious. Around the world about 1 in 4 among men and 1 in 5 in women affected by hypertension which amounts to about 1.13 billion. Many of those affected are from middle and low income countries. The prevalence of hypertension in India is found to be about 30.7%, according to a study conducted in India. The men in India are found to be more prone to developing the disease when compared to men.[2] In Tamil Nadu the prevalence was reported to be 21.4% and the prevalence was same in both the genders.[3] In a Meta analysis published shows the hypertension to be 27.6% in rural areas of India.[4] It is also leading cause of mortality and global disability-adjusted life years (DALYs). In 2015 it was observed those 10.7 million deaths and 20.9% of all DALYS. It was also estimated that the killer disease is becoming more prevalent in children and adolescents. The prevalence is more in low and middle income countries than those in high income countries and it is the same in European countries.[5] It was also estimated that a reduction in the prevalence of hypertension by 17%, which was attributed to reduction in salt intake would prevent 24.3 thousand deaths by the year 2030. It was also suggested that by reducing the deaths by hypertension can reduce the additional cost of hypertension by 6 to 8 folds.[6] Thus, hypertension is a major disease and a leading cause of DALY and deaths around the world.

Though there are many studies on hypertension, there is not much study done in rural population and in our country. This article is a review work done on hypertension, especially in the rural population of our country. Hence this study will provide an insight into the hypertension status in our country and especially in rural population.
**Material and Method**

Data were taken from Google Scholar and Pubmed by using terms such as hypertension, rural, risk factors from January 2000 to September 2020. Articles which were available as full text and in the English language were selected. All articles related including cross sectional, descriptive, cohort, randomized, non randomized, qualitative and systematic studies were taken. About 30 articles were in total. Based on non availability of full text articles 19 were excluded. So finally 11 were included.

**Result**

**Socio demographic determinants:** In a study conducted among tribal population the prevalence of hypertension was found to be different in different states. It was found to be higher in Orissa (55%) and lowest in Gujarat with prevalence to be around 11%. Among those diagnosed as hypertensives more than half were taking treatment for the condition. According to the same study, elderly people were more at risk of developing hypertension when compared to the younger population. Abdominal and also general obesity were found to be a major risk factor. Age, literacy obesity and physical activity were found to be statistically significant. [7]

In a study conducted among tribal population the prevalence of hypertension was observed to be 27.1% among men and 26.4% among the women. Of those who were found to be hypertensive’s only 10% were previously diagnosed rest were only newly diagnosed rest all were known hypertensive sans more than half (55-68%) were taking. In a study conducted among the rural population, it was found that the prevalence increased with age advancement. Hypertension was found to be more prevalent in people of higher socioeconomic strata. It was also reported that a higher socioeconomic group about 15%-35% of the people were having obesity. About 69% of the men and women have reported low vegetable intake. And about 33% men had dyslipidemia in higher socioeconomic groups. Where else in the lower socioeconomic group only about 13% of them were having obesity. And risk factors for developing any non communicable disease was found to be more in south Indians when compared to North Indians. It was reported that dyslipidemia was seen in 21% of the North Indians when compared to South Indians where the percentage was 33%. It was also reported that only 13% of the North Indian women had obesity where else 24% of the South Indian women were suffering from obesity. [8]

In one another cross sectional study conducted the prevalence of hypertension was found to be 7.24%. It was reported as age advances the prevalence also increases. Like it was 0.41% among 19-28 years whereas, it was 31% among subjects of around 79 years. Age was also statistically significant with hypertension. Among the genders, women 55.2% had hypertension, but in men it was only 44.6% and gender was not statistically significant. About 5.58% who had hypertension had a normal Body Mass Index. But those with increased BMI had higher prevalence of hypertension. It was found that about 5.31% were reported to take extra salt and among those, more than half were found to be hypertensives. [9]

In a study, conducted among rural population the prevalence of hypertension was found to be 14%. The prevalence was more in age group above 35 years. It was also observed that income had no effect on the disease development. It was also reported that 72% of the people who were having hypertension. The different education levels showed a difference in hypertension. About 20.7% of the subjects who had increased level of cholesterol had hypertension. It was also found that cholesterol levels and development of hypertension was found to be statistically significant. [10]

**Psychosocial determinants:** In a study conducted among tribal population the alcohol consumption was associated with disease development. The alcohol and tobacco habits were all statistically significant with the disease development. [7]

In a review article it was reported that 40% of the men and about 4% of the women had the habit of consuming tobacco. It was observed that people in the lower socioeconomic group had been using tobacco more when compared to those in higher socioeconomic group. [8]

In a study conducted among rural population the tobacco intake showed no significance. The alcohol intake had a significant risk of developing the disease. [9] In a review study conducted it was found that occupational stress was linked with hypertension. The various studies taken for explained the relationship between work stress and hypertension. It was also observed that immigrant population had varying hypertension state when compared to the general population. It was concluded that acculturation had an effect on disease development. [11]
**Public health considerations:** Most people due to changes in lifestyle are prone to non communicable diseases such as Hypertension. Though it is a well known disease, but still takes light from the people around the world, especially in developing countries like India that too people in rural population are very highly affected.

Government of India has already brought in programs for screening, treatment and management of complications. But not that it has reached the rural population in many areas of the country. So the general public should be made aware of the risk factors, signs and symptoms, the complications and about the dangers of not taking proper treatment. They should also be made aware that hypertension is curable when diagnosed early we can avoid any further complications.

**Conclusion**

The major risk factors identified were age, socioeconomic status and habits such as alcohol consumption and smoking. It was also identified that hypertension is more among the rural population and also among migrants as these are the areas where the health care becomes difficult to reach due to environmental factors and various other determinants.

Endangerment of Pharmaceutical Waste Disposal in the Environment

Mahendran C. 1, Midhun Kumar G.H. 2, Parimala K. 3, Shanmuga Priyan 4

1Assistant Professor, Department of Community Medicine, Meenakshi Medical College Hospital and Research Institute, Enathur, Kanchipuram, Tamilnadu, India, 2Associate Professor, Department of Community Medicine, Meenakshi Medical College Hospital and Research Institute, Enathur, Kanchipuram, Tamilnadu, India, 3Professor & HOD, Department of Pharmacology, Meenakshi Medical College Hospital and Research Institute, Enathur, Kanchipuram, Tamilnadu, India, 4Associate Professor, Department of Pharmacology, Meenakshi Medical College Hospital and Research Institute, Enathur, Kanchipuram, Tamilnadu, India

Abstract

Disposal of pharmaceutical wastes in the environment leads to many losses and causes damage to the ecosystem. Plants, animals and human beings are put in endangerment due to the medicines and injections disposed in the environment. Toxic chemicals and substances exposed to the public nearby places causes many diseases such as respiratory syndromes and cancers skin infections and genetic disorders. Disposal in marine area pollutes the living atmosphere of aquatic organisms affects the ecosystem in unexpected ways. Considering this, environmental department should take effective precautions to protect and ensure the safety and peaceful living of beings in the environment. In this the article pollutants, toxic chemicals scavenged in the environment by the pharmaceutical industry, which has many adverse effects to the safety and a clean environment are discussed.

Keywords: Pharmaceutical waste, chemical industry, environment, pollution, pollutants.

Introduction

Pharmaceutical wastes are disposed in many forms such as the remained stocks of drugs, used needles, cottons with impurities and the surgical wastes, the expired medical kits and the cytotoxic wastes. All the wastes are considered as toxic to the ecosystem devastating materials. People are unaware of these consequences caused by the wastes from hospitals. Public concern level and voice against the illiterate activities done by pharmaceutical industries also leads to the impure ecosystem. Biggest worrying the bird vultures are affected by the diclofenac medicine, it is used in the treatment of inflammation in the veterinary hospitals. Antibiotic disposal in the environment, bacterial mutations are occurring and contamination strains are becoming resistant to such medicines which are of no use. In Waste water management the livestock feed is mixed with the disposal from pharmaceutical industries that disrupts the lives of the aquatic organisms. Ciprofloxacin, Oxytetracycline, sulfamethoxazole these are the major antibacterial drugs found to be resistant to many bacterial strains present in the pools and ponds of fresh water. Denitrifying and degradation of organic matter are affected the sewage wastes left in the environment. Such exposure to medicines and drugs led to the environment and mutation occurs in the soil born bacteria may cause adverse effects. On the whole high level of precaution must be taken before letting the exhausting materials from hospitals, laboratories and pharmaceutical industries which affects our ecosystem[1].

Biomedical Wastes: Biological waste materials can be a liquid or a solid form disposed from the industries,
hospitals from the treated patients. WHO says the toxic chemicals estimates that only ten percent of the disposals are infectious and 50% are non-infectious and remaining are non-toxic but consists the hazardous materials like methyl chloride and major concern is the toxic chemical transmits the virus and deadly bacteria from the wastes and not managed properly and just disposed as such in the environment. It seriously affects the living of slum people and people living around the rivers and roadside can lead to high range of environmental pollution [2].

Water Pollution: Risks are categorized into three types such as genotoxicity, carcinogenicity and toxicity create negative impact on the society in terms of environment disposal and wastages from industries and develops resistance in the microorganisms. Toxic chemicals inhaled by the organism show different mode of transmission from their natural behavior may be resistance and a species endangerment can happen. Maternal wastes such as hormonal tablets and drugs are toxic when it is exposed in the public environment. Some of the research, conducting institutes and industries letting the hazardous chemicals in the sewage that causes mutation in the organisms developed from the sewage wastes. These phenomena may accelerate the pathogens becoming resistant to the powerful drugs. This issue may cause changes in aquatic living organisms, some of the fish species are dead after the uptake of disposed drugs which also affects their fertility process [3].

Soil Pollution: Mesophilic are the group of organisms living in moderate temperature is involved in the treatment of soil in recent times, which are indirectly affected by the pharmaceutical wastes. Sinking matters, microorganisms which enhance the fertility of the soil and organic matters are demolished when met with pharmaceutical wastes [4]. Major concern is active ingredients present in the environment which doesn’t support the environmental safety. Some of the cost effective mechanisms are developed to find and determine the trace level of contaminants produced by the pharmaceutical wastes which affects the quality of life. The cooling water system and the floor, wash system have been introduced and it is established to control the soil by the pharmaceutical wastes [5].

Aquatic Pollution: The pharmaceutical wastes are dumped in the sea and thrown without the care about the ecosystem and the organisms present in the sea. Discharged particles mixed in the seawater directly affect the organisms; especially it creates abiotic stress in the sea. The major accumulation of toxic chemical affects the tissues of the fish. Some of the parameters include pH, sunlight, temperature should be taken into concern. The level of toxic chemical affecting the atmosphere should be eliminated and discarded from the sea to maintain the temperature level. The particles which are hard to eliminate from the sea affects the ecosystem which should be properly eliminated to safeguard the earth to protect it from natural disasters formed in recent years [6].

Hazardous Wastes: Amoxicillin possesses antibacterial activity and it is present with beta-lactam ring this molecule is known to be cleavable. There are majorly two metabolites present in the compound especially amoxicilloic acid, amoxicillin diketopiperazine-2,5- dine as DIKETO. It has high allergens with high risk when it is disposed in the environment. Several method to determine the presence of this antibiotic is found. This low amount of antibiotic is found in soil, water and in the environment. Liquid chromatography is the technical method and powerful tool to determine the traces of amoxicillin present in the environment. This is the major pollutant and pharmaceutical wastes put into the environment [7].

Chemotherapy Waste: Bulk chemotherapy wastes are let into the environment which is considered as the most hazardous materials. P- and U hazardous materials which are low in limit to detect and destroy. The mostly preferred method is incineration the use of heat to destroy the materials that are toxic and when it’s incorporated into the ecosystem it creates the unimaginable adverse effects due to the biological materials such as used syringes, infected gloves, tubing surgical gloves and aprons used for surgeries and treatment. The routine method of cleaning, preparation and administration of drugs should be taken care properly in the absence of such cleanliness leads to toxic effects in the normal people. There are safeties level should be properly followed by the industries and hospitals [8].

Genotoxic Waste: The carcinogenicity is mostly referred as genotoxic and also referred as mutagens cause’s effects in bacterial strain, aqua livings and also in human. These sorts of materials should be disposed with utmost care and the huge distracting waste material in soil in a cancer hospital and research institutes dealing with cancer. Drugs such as doxorubicin, phenacetin, lomustine and cyclosporin are carcinogenic and get easily accumulated in the soil without proper waste disposal [9].
With the help of contractors and public health volunteers involved in the disposal management, the wastes are disposed. There are certain laws, rules and regulations are maintained in the health department to maintain the safety of the public. While disposing and discarding the drugs in the soil or the clearance of drugs needs specialized companies who have taken care in disposing the waste has to report to the government. They also have special equipments and instruments to clear the waste from industries [10].

Rules and regulations divided into six categories in India. The major categories are BMW (Biomedical waste). All the wastes from hospitals are established and the leap of wastes are generated were discarded on a daily basis. Mostly it was incinerated and deeply buried in the soil and to discard those debris hospitals should get approval regarding this from the corresponding authority. They need to have extra care while disposing the outdated products and expired medicines and drugs because they can interact with bio molecules present in the soil [11].

Determinable effects are created after disposing the hormones, antibiotics and tablets to the environment. By flushing out the substances in ground water, river and in sewage water can create drastic changes in the microorganisms living in all the places. Even though people are careful while living near the slums the waste disposal indirectly affects the health of people by air, drinking water and in the soil. Instead, it directly affects the land, the wastes should be properly packed and disposed to prevent the birds, and animals surrounded in the ecosystem will be protected [12].

HPLC (High performance liquid chromatography) has been found as one of the important qualitative and quantitative measure of drug used worldwide. HPLC is preferred in most pharmaceutical companies for the analytical technique. This technique is used for validation, formulation, production and to ensure the quality of drug these are pre steps taken before releasing the drug to the market. These analytical method can take even few hours or many days to validate the process of drug development [13].

**Bio-active compounds in the pharmaceutical wastes:** Paddy is the most stable grains available for the global population. Paddy waste such as dusk and straw are let simply into the environment considering the no use of it. Annually, the straw and husk from the paddies are taken for the pharmacological potential as it can save the soil fertility and soil quality [14].

Polysaccharides namely hemicellulose that are mainly differing from the several cellulose materials branched and have chain smaller in length. The unique nature of this material has attracted many industries, especially pharmaceutical industries. It is polymerized and used as disposable agents and identified in many natural plants which have highest composition of cellulosic material. Methylcellulose is considered as one of the other beneficial compounds dissolved in the alkaline solution and used further [15].

The hospitals conduct the pharmaceutical waste disposal program called Disposal of used medicine program. This program is conducted to deliver the ideas of disposal and ways involved in the disposal of the expired medicines and products from the hospitals [16].

**Conclusion**

Toxic chemicals and drugs causing severe effects and creates impact on the society by the pharmaceutical industries. People are affected by the poisonous material let by the industries in the environment. The ecosystem is altered with the consequences faced by the organisms living in soil, air and water. The government and public health department volunteers should involve in such matters to insist people about the drastic effects caused by the pharmaceutical wastes. Safety measures and risk assessment should be done before the disposal of drugs, medicines and products before disposal to ensure the safety of the ecosystem.

Phycoremediation of Heavy Metal Removal from Pharmaceutical Industrial Effluents, Kandigai, Kanchipuram District, Tamil Nadu

Prathiba S.,1 Muninathan N.2, Ponnulakshmi R.2, Nalini D.2

1Lecturer, Department of Pharmacology, Meenakshi Ammal Dental College and Hospital, Chennai, India, 2Research Scientist, Central Research Laboratory, Meenakshi Medical College Hospital and Research Institute, Enathur, Kanchipuram, Tamilnadu, India

Abstract

Water pollution occurs due to excessive releases of toxic heavy metals in urban wastewater is increasing the threat to aquatic ecosystems. Treatment of waste water with the algae is termed as Phycoremediation which is a unique, cheap, method to treat the polluted water by a method of natural selection. Therefore, in the present study effluents with an algal species were taken for Phycoremediation using five different concentrations were used for treating pharmaceutical industrial effluents. Our research focused on microalgae Chlorella sp. and Scenedesmus sp. were used to treat the effluent at different concentrations depending upon the tolerance in severe conditions. In addition to this treatment algal consortium was also treated in the same way. These two algal species were taken based on its predominant growth in the effluents collected. The physico-chemical parameters of all treated effluents were recorded in different time intervals, from 1st week to 3rd week respectively. Chlorella and Scenedesmus sp. reduces drastically heavy metals like sulfate, lead, nickel, copper and zinc. According to the present investigation, the highest Phycoremediation was achieved in sulfate, zinc and copper. The results revealed that the above mentioned both algal species were also highly efficient in reducing BOD, COD, TSS and TDS. In addition to this the biochemical and bio pigment analyses were done for these two micro algal species. Therefore, this preliminary study indicates that the use of two microalgal sp. could be used as they are eco-friendly adsorbents in treatment of polluted wastewater.

Keywords: Consortia, Chlorella sp., Phycoremediation, Scenedesmus sp.

Introduction

Heavy metals are exposed chemicals present in waste water, which has higher density than water. Depending upon heaviness, the toxicity caused by these heavy metals is of serious health concern. The metalloids like lead, arsenic zinc when present in least amount doesn’t produce toxicity, but when formulating industries releases tones of heavy metals the ground water gets totally disturbed and the outcome of this is diseases due to contamination. Thus, public health and ecological disturbances affects the population and the environment by these toxic heavy metals.

The major concern causing heavy metal contamination is due to the increased population which acts as a cycle so more demands rises and more people are employed in industrial, domestic and commercial sectors. The toxicity produced by these sectors when directly released into the nearby ponds and pools the health hazard is a common criterion in these exposed areas. The industries which produce heavy toxic metals are mining industry, smelting industry or any metal manufacturing industries, though the metals are required in the body to some extent but larger proportions leads to severe illness. Wastewater with these heavy metals is a serious threat to the environment because of the presence of poisonous nature [6-9]. The heavy metals released from the pharmaceutical industry contain mutagenic and carcinogenic agents [4].

e-mail: prathibamahesh86@gmail.com
To overcome this issue a new technology of Bioremediation was in practice to transform harmful organisms by inhibiting its growth and making the effluent to be good to deliver in the ponds or estuaries. This alga based technology treats the wastewater and absorbs the heavy metals and make the water fit for drinking. Hence this treatment plan was economically feasible and eco-friendly in nature [13]. The nutrient rich wastewater reduces pollutants and helps to maintain the external conditions [7,11].

Thus, our research focus on treating the heavy metal contaminated pharmaceutical waste water using microalgae is more efficiently uses the heavy metals to take up the nutrients and produces a valuable biomass to produce other byproducts [10-12](Park, 2011; Venkata Mohan, 2011, 2015, 2016a). The phycoremediation is very cheap and low growth period to remove heavy toxic metals and possess other applications.

Materials and Method

Sample collection: The wastewater sample was collected from the Pharmaceutical Industry, Kandigai, Kanchipuram district, Tamil Nadu. Algal deposits were collected from the sites and physiochemical parameters were recorded using an YSI Multi parameter.

Identification of algae: The collected algal samples were observed in the microscope and based on the structural morphology and by the expert handling the algae was identified. The selected 2 algal strains were *Chlorella* sp. and *Scenedesmus* sp. These two algae were collected by serial dilution method and spread plate method. The purified culture was grown in Bold Basal Medium and culture was maintained for 21 days to obtain the growth curve.

Analysis of Growth curve: The growth rate of the experiment was kept in optimal conditions of 12:12 (Light: Dark) at a temperature of 28°C. The periodic monitoring of the sample was measured and shows a peak at 680nm. Three samples (*Chlorella* sp., *Scenedesmus* sp. and consortium) were frequently checked to establish a growth curve for a period of 21 days for 5 different concentration and control samples.

Physiochemical and Biochemical tests: The physiochemical parameter is checked for both untreated and treated effluent by using microalgae was estimated (APHA, AWWA, and WEF. 1998). The pigments such as Chlorophyll a, b and â-carotene were estimated by the following method; [5] Jeffrey and Humphrey method, 1975 and [8] MacKinney method, 1941 respectively using different wavelengths by a UV visible spectrophotometer (Hitachi U-2900). Bio-Chemical analysis, such as Carbohydrate (Dubois et al. method 1956) [2], Protein [1] and Lipid [3] were also determined. The absorption of metals by algae was studied using Scanning Electron Microscopy (Golab, 1992).

Results

Physiochemical parameters: The various physico-chemical parameters measured were pH, water temperature, dissolved oxygen, BOD and COD. The water temperature in pharmaceutical industry ranges from 28.0 to 32.0°C. The pH of sampling site ranged between 5.8- 6.7. The value of the dissolved oxygen content of water is 4.1 to 9.52 mg/L. Pharmaceutical industry waste water sample shows COD (1240mg/L) and BOD was observed as (374 mg/L) in the sampling site. Based on the quick adaptation and the high growth rate the microalgae strains were selected. The growth rate was calculated using spectrophotometric readings for 21 days.

Biochemical parameters: The *Chlorella* sp., *Scenedesmus* sp. and consortium showed the extracted sample was subjected to biomass productivity till 21 days of incubation. The estimation of protein content was high in *Scenedesmus* sp. (45.10%) consortium (39%) and least in *Chlorella* sp. (18.65%). The carbohydrate and lipid show a high amount in a consortium of 17.12 μg/ml-1 and 40.49% and both *Chlorella* and *Scenedesmus* sp., shows a similar range of 15.07 and 15.67 μg/ml-1 and 38.10% and 18.89%.

Conclusion

The industries and pharmaceutical manufacturing companies should abide by the rules of FDA to maintain the quality of waste water and these industries should discharge and reuse without releasing the toxicity. Phycoremediation technique is a promising source to treat the waste water without causing any health hazards and also making the environment green and clean. The selected algal strains help in reducing the toxicity and facilitate 3R’s. The use of wastewaters for cultivating microalgae is necessary in order to reduce the cost of microalgae production. Furthermore, countries like India with abundant sunshine are suited well for Phycoremediation as a method of green technology.

Studies on Invitro Analysis of Sargassum Wightii Against Human Simplex Virus (HSV)

Akila1, Anitha C.1, Pratheeba J.2, Sumanth Kumar B.2

1Assistant Professor, Department of Microbiology, Meenakshi Medical College Hospital and Research Institute, Enathur, Kanchipuram, Tamilnadu, India, 2Assistant Professor, Department of Biochemistry, Meenakshi Medical College Hospital and Research Institute, Enathur, Kanchipuram, Tamilnadu, India

Abstract

Introduction: Human simplex viruses are ulcerative diseased found in skin and genital organs depending upon the strain. It affects an individual at least once in a lifetime by direct contact with an infected person. There are two strains of HSV predominantly found are HSV-1 and HSV-2. HSV-1 infects the pharynx and oral region, whereas HSV-2 infects the genital areas of sexual contact.

Materials and Method: The crude extract of *S. wightii* on the proliferation of Vero cells was assessed by the neutral dye uptake method. Various fold of serially diluted solvent crude extracts showed cytotoxic concentration 50 (CC 50) at 750 and 500 μg/mL of ethyl acetate and methanol extract, respectively.

Results: The Antiviral activity of solvent crude extract against HSV-1 showed significant reduction of virus on Vero cells. Among the solvent crude tested, the ethyl acetate showed effective IC 50 against HSV-1 at 300 μg/mL.

Conclusion: The seaweed *S. wightii* is a natural source in treating the pathogen HSV-1 and it clearly indicated that, the marine brown algae *S. wightii* possess strong antiviral activity with slight cytotoxic effect.

Keywords: Sargassum wightii, HSV-1, Antiviral activity, Octyl butyl phthalate, Neutral dye.

Introduction

Marine resources are abundant and most of them are not explored due to its vast environmental conditions and growth patterns. A country like India is diversified with a long coastline of about 7500 km with high amount of seaweed population [1]. The habitat of macroalgae in the marine environment is present along the coastline, embedded with rocks having high nutrients, immersed in the sea water at great depths. Depending upon the nature's pattern seaweed produces numerous active compounds [11] which are very much useful for the mankind. The active ingredients obtained from the seaweed helps the society to have a healthy life against harmful pathogens and enrich the field of Pharmacology in producing new drugs [2].

Herpes simplex virus (HSV) is a communicable virus which transmits from person to person. Our studies focus on HSV-1 which affects the oral and pharyngeal regions of the population. It affects almost all the people irrespective of any age from neonatal to old age people. The structure of HSV-1 consists of ds DNA, Capsid, Capsomeres and tegument and type 1 belongs to α-HSV. Viruses are manifested in epithelial cells and then spreads to the sensory nerves and finally produces cutaneous lesions [3]. The symptoms with HSV-1 patients are mouth sores, tingling, itching and oral sex. Patients with HIV, Cancer, AIDS, transplantation performed, patients, when infected with HSV it may cause serious effect such as inflammation in the brain, eye infection, and even deaths can happen [4].
1 is easily prevented by avoiding direct contact with infected persons, sharing their utensils; avoid kissing or oral sex and frequent hand wash. In newborn infants of about 10,000 births, 10 babies are infected with HSV-1 as per the WHO report. This infection in babies causes nerve problem and even death when passed from mother to fetus\[5\].

The seaweed Sargassum wightii belongs to a Pheophyceae family\[6,12\] and abundantly found in warm and temperate climate\[7\]. In India, it is distributed in Maharashtra, Goa, Kerala and Tamil Nadu. In Tamil Nadu, it is found along the coastline of Kovalam, Rameswaram, Mandabam areas. The macroalgae S.wightii is rich in alginic acid, which is a commercial product. The macroalgae is rich in secondary metabolites and these are helpful in synthesizing pharmaceutical products (Subash et al., 2014). Thus the present work aimed at treating the HSV-1 strain with the macroalgae as a biological method and it is cost effective in nature.

Material and Method

Study area and Extraction process: The seaweeds were collected from Coastal line of Mandapam, Ramanathapuram District, Tamil Nadu, India and was identified as Sargassum wightii by the phycologist expertal committee and sample were washed in tap water followed by distilled water and shade dried at room temperature. The dried sample was powdered using mechanical blender and extracted using mid polar to polar solvents i.e. Ethyl acetate and methanol. The sample was filtered and condensed using rotary evaporator and stored till further use \[8\].

Cells and viruses: Vero E6 cells were cultured and maintained in Eagles Minimum Essential Medium (EMEM) with 10% fetal calf serum (heat inactivated) and antibiotics like penicillin and streptomycin 100 µg/ml kept in incubator at 37°C with optimal conditions like CO₂ and humidity. HSV-1 stocks were proliferated Invero E6 cells and stored at -20°C till further use.

Cytotoxicity Study: Seaweed S.wightii i crude extract was proliferated on Vero E6 cells by the neutral dye uptake method in 96 well plates by the method of Rajabhandari et al., 2009 \[9\].

Antiviral activity of crude extract of S.wightii: Vero E6 cells were seeded in 96 well plates in 100 µl of the EMEM medium by serial dilution technique in four different replicas for a time period of 24h. Once the cells were infected with 30 µl of HSV-1 strain, TCID₅₀ was incubated at 37°C for 3 days i.e. 72h. Control samples were also maintained without viral strain and antibiotic act as positive control. sulforhodamine B assay (SRB) was used to determine the viability of cells by showing absorbance at 540nm and percentage was calculated.

Results and Discussion

The Crude Extract Yield: The Sargassum wightii sample was shade dried and powdered. The powdered sample was extracted and condensed using a Soxhlet apparatus. The percentage of the crude extract yield was 4.7 ± 0.27 in ethyl acetate and 2.6 ± 0.54 in methanol solvent. From the obtained yield in the crude extract sample showed a good amount of yield in ethyl acetate mid polar solvent compared to high polar solvent Methanol.

In-vitro Antiviral Activity of S. wightii Solvent Crude Extracts: Various fold of serially diluted solvent crude extracts results as showed in (Graph 1). Cytotoxic concentration₅₀ (CC₅₀) of the solvent crude showed 750 and 500 mg/ml of ethyl acetate and methanol, respectively. The Antiviral activity of solvent crude extract against HSV-1 showed significant reduction of virus on Vero cells. Among the solvent crude tested, the ethyl acetate showed effective IC₅₀ against HSV-1 at 300 µg/ml, while methanol extract showed at 500 µg/ml (Graph 2).

The reduction of HSV in the tested samples is due to the narrow action against HSV-1 than the Vero cells. Brown macroalgae, is rich in compounds like phlorotannins which have been analyzed to have anti-HIV\[13\] and anti-HSV activity\[10\].
Conclusion

The present study preliminarily focused on a crude ethyl acetate extract of *Sargassum wightii* is a suitable macro algae for the production of new drugs against HSV-1 due to the presence of the secondary metabolites[14,15]. Further studies are purified of the crude extract and Invivo studies can be performed to identify the extract drug for HSV-1.

Abstract
Arthritis is a persistent autoimmune ailment occurs more in females than in male above the age of 40. It initially affects the lining of synovial joint and the secretion of low synovial fluid also can lead to rheumatoid arthritis. It primarily affects the patient's health swelling in joint, redness and level decreases eventually. Diagnosis at an early stage of rheumatoid arthritis is the key to prevent from severe injuries in joint and other bone related diseases. There is also several plant based anti-inflammatory compound which involves in decreasing the pathogenesis of the ailment. There are several diseases related to rheumatoid arthritis, it includes pulmonary granuloma, vesicle damages and other symptoms are expected to occur early if unnoticed. This article discusses the risk factors, damages to joint and pharmacological therapies available for the diseases.

Keywords: Arthritis, Pharmacology, synovial joint, pathogenesis, anti-inflammatory.

Introduction
Rheumatoid arthritis or synovial hyperplasia is a provocative disease, occurs to damage the properties of joints. T cells, endothelial cells and antigen presenting cells that are majorly involved in the rheumatoid arthritis⁴. An addition to the inflammatory cells participation fibroblasts produced in the synovial membrane play an important part in the complications of RA. These fibroblasts exhibit the constant cellular activation, which is processed routinely in the non-appearance of inflammatory stimuli. In osteoarthritis patients, the synovial fibroblast shows the gene expression of proto oncogenes and its transcriptional factors which helps in the degradation of and it ends up with apoptosis. Here the complications develop as these fibroblasts stick to the cartilage to increasingly destroy the articular structures. The mechanism of RA is that it leads to the constant activation synovial fibroblast development. Dietary intake in a healthy manner contributes to the reduction of RA also having chance to reduce the occurrence of this disease at the young age. Hormonal levels are noticed in the pathogenesis of RA. By observing the above said complications, it is important to find the effective treatment strategies and therapies for rheumatoid arthritis would be essential ⁵.

Therapies for Rheumatoid Arthritis:
Methotrexate: The diagnosis of the disease, Methotrexate is prescribed by the doctors as a first line of defense and it is usually prescribed with 15-20mg of the week and gradually increased up to 25mg per week. It is usually as a combination medicine with

Corresponding Author:

Associate Professor, Department of Community Medicine, Meenakshi Medical College Hospital and Research Institute, Enathur, Kanchipuram, Tamilnadu, India
e-mail: midhunkumargh@mmchri.ac.in
glucocorticoids to compensate the mechanism. The production of this medicine is limited and based on the availability it is combined with other medicines. The combinations mainly result in adverse effects in patients when increasing the rate of administration. Increased level of dosage in patients sometimes leads to failure of methotrexate reaction because of the risk associated with this disease [3]. The long term study on this compound for RA showed highest recovery rate. It is reported in research articles that among the rheumatologists in the U.S methotrexate has a good recovery rate for RA also for other diseases [4].

RITUXIMAB

Rituximab a monoclonal antibody anti-CD20 recognized for the treatment of a rheumatoid arthritis. Bone marrow is located where B-cells are produced and it is an impactful therapy against the disease after the effective treatment with rituximab. The patients who took this compound have been observed in the clinical response later they were implemented with the B-cell treatment. Association of these two therapies helps the patients with longtime maintenance of the patients with RA. The effect of this treatment results in the production of protein and rheumatoid factor helps the patients in recovery of the disease. Patients treated with this therapy before the rituximab shows slow clinical response for RA. Anyhow, half of the patients regain their effect for the treatment with B-cell depletion therapy after the treatment with rituximab. Patients are observed for the risk development. The risks occur due to the dosage level of rituximab and people are prone to infection. The most common adverse effects are the level of IgG concentration associated with the rheumatoid arthritis disease [5].

Anti-TNF Therapies: This TNF therapy was identified in the year 1980’s for the pathogenesis of rheumatoid arthritis in animals and also in human. The evidence from this impact is studies in mice with TNF expressing factors. It revealed that the mice induced with rheumatoid arthritis could be prevented by stopping the production of TNF-alpha factor. There are three drugs mainly inhibiting the TNF are infliximab was tested in RA patients with clinical approval and the next is an Adalimumab antibody against the TNF factor and finally etanercept which was biologically approved to treat RA. Patients were improved after the treatment with these drugs. The TNF factor block was the major challenging in the improvement of treatment with RA [6].

Synovial Fibroblasts: The recovered rheumatoid arthritis patients were incorporated with synovial fibroblasts, which are present in rheumatoid synovium, which are considered as the destructor of causes for rheumatoid arthritis. After the incorporation it releases the increased amount of enzymes that prevent the cells from direct contact with RA cells. The endothelial cells that tend to act as the destroyer of articular cartilage. These are the ways how it recruits the cells to fight the RA with the help of macrophages, and T-cells and the rheumatoid synovium that attracts large amount of inflammatory cells that develops the activation of osteoblasts [7].

Cytokines: The activity level of cytokines is based on the secretion and the target of cell for the destruction. It clearly indicates that the response to inflammatory stimuli is just developed by the production of competing cells that are antagonists. Research studies have reported that the existence of polymorphisms of the TNF, and IL-1ra genes. Particularly the TNF-gene is situated on the chromosome 6 short arm in the HLA region. The abnormal high molecular weight TNF mRNA has been observed in the macrophages of murine and in monocytes of human that are infected with influenza A virus [8].

Eicosanoids and Lymphokines: These two immune agents are known to present in the inflammation process. In this process the lymphocytes and macrophages are activated to produce this agent eicosanoids which have higher efficiency to work against inflammatory cells. These two compounds can modulate the immune responsiveness. Proteases and collagenases which are known to degrade the secretion of cells and bone development which are related to many vascular diseases in the bone related diseases. TGF (Tumor growth factor-beta) produced by synovial tissues and lymphocytes can stop the process of inflammation. Fatty acids are the suppressors of T-cell proliferation. The major interleukins such as 1, 2 and the production of TNF are shown to have benefit in rheumatoid arthritis patients [9]. Rheumatoid arthritis with cognitive issue are related to skills in stress management and other symptoms. It is predicted that the treatment will show a reduction in symptoms and improve both immunological competence and the functioning of bones. The enhanced self-efficient, reduces pain and inflammatory cell proliferation in patients with RA [10].

IL-6: Interleukin-6 is one of the most potential therapeutic target pleiotropic proinflammatory cytokines.
It is produced by various cells, including lymphocytes, monocytes, and fibroblasts. It is involved in the multiple immunological processes of the immune cell activation. These cells are particularly in relevance with Rheumatoid arthritis, interleukin-6 induces osteo cell differentiation and it contributes to joint osteoporosis.[11]

**Celastrol:** The other bioactive component of TwHF, celastrol belongs to celastraceae family it has many anti-arthritic activity. The research studies have revealed that it can suppress that rheumatoid arthritis severity in the AA Lewis rat model. Moreover, it can suppress the proinflammatory cytokines production and balance Thymus cell to regulate the morphology in the targeted organ. Additionally, celastrol compound protects the erosion of bone by targeting certain pathways and the deviating osteoprotegerin level stops the osteoclastic activity which in turn reduces the damage in the bones[12].

**Curcuma longa LINN:** Curcuma is the anti-potent agent which grows in tropical regions, mainly in India and China. The turmeric heated with oil and applied all over the knees. The chemical compounds present in this plant are Sodium-Curcuminate, Curcumin and Methylcurcumin. In our tradition, it is used for healing antiseptic and possesses anti-helminthic activity. It is studied that herbal formulation produced from the turmeric plant works well with the arthritic patients. It is researched to possess anti-inflammatory activity, ant-fungal, anti-protozoal activity and hepatoprotective agents. The oil produced from the plant has high anti-inflammatory activity and anti-arthritic activity[13].

**Inula Helenium:** It is a perennial plant also known as horse heals. Importantly dihydroflavonols elicited from the aerial part of the plant showed anti-inflammatory activity. This compound significantly suppresses the activity in rat peritoneal leukocytes. These flavonoids are the components of viscosa plants reduce the leukotriene production. Elastin is the outer cell protein, has the automatic effect on dissimilar tissues. Hence it is referred as the contributory agent in the reduction of RA[14].

**Pluchea lanceolata:** This plant is one of the important medicinal plant having these anti-inflammatory and analgesic activities for rheumatoid arthritis, sciatica, edema and psoriasis. This involves the synthesis of different secondary metabolites viz., flavonoids and daidzein and the major compound pluchine from this plant contributes in the anti-inflammatory activity. The alcohol extract from pluchea plant showed maximum reduction in formalin induced arthritis in rats. The powder form of the plant is applied for arthritis[15].

**Madimadi:** It is a Korean based medicinal plant, fermented alcohol prepared from the extracts of *Madi madi*. It is found to be the curative agent for long time in the tradition of Korean medicines. It has an inhibition effect on the pro-inflammatory cytokine and dose dependent inhibition against of patients with RA with these interleukin-beta and interleukin-8. It also down regulates the alpha-tumor necrosis factor. It is a recurrent plant with creeper like structure found growing in Taiwan. The main active compound present is called triptolide has anti-inflammatory activity[16].

**Conclusion**

Rheumatoid arthritis occurs mostly in aged patients with many health complications such as swelling of knee, redness and motion reduction in the bones. The synovial fluid synthesis is the major cause of arthritis. It can be cured with many therapeutic agents when treated early with worthy medications. Some of the important plants also contribute to the anti-inflammatory activity, neurological disorders and patients suffering from sciatica. Monoclonal antibodies based therapies are most welcome in people from developing countries with highest medicinal facility. Still medicinal plant based drugs are mostly preferred for the cure because of its log term effects. This paper presented some of the important therapeutic agents both synthetic and traditional medicines for the patients with rheumatoid arthritis complications.

Studies on Phytochemical Analysis and Antimicrobial Activity of Sargassum Wightii

Anitha C.1, Akila1, Muninathan N.2, Nalini D.2

1Assistant Professor, Department of Microbiology, Meenakshi Medical College Hospital and Research Institute, Enathur, Kanchipuram, Tamilnadu, India, 2Research Scientist, Central Research Laboratory, Meenakshi Medical College Hospital and Research Institute, Enathur, Kanchipuram, Tamilnadu, India

Abstract

Introduction: Seaweeds are natural sources rich in active compounds used extensively by cultivating the weeds to cure various ailments. Sargassum wightii is distributed in coastal areas, especially in tropical regions.

Materials and Method: Seaweeds are collected from coastal area of Tamil Nadu and screened for phytochemical analysis by Evans method, total phenol content by Folin-Ciocalteau colorimetric method and antibacterial activity were performed by the well diffusion method.

Results: S.wightii was extracted in the ratio of 1:10 and phytochemical analysis of ethyl acetate extract showed the presence of various secondary metabolites. The S.wightii crude extract was screened for antimicrobial activity and showed good zone of inhibition against human pathogens.

Conclusion: S.wightii is a potent antimicrobial drug as it shows a good zone of inhibition against the harmful pathogens and the secondary compound screening proves the activity. So the S.wightii can be cultivated more and can be used for clinical purpose without any side effects.

Keywords: S.wightii, secondary metabolites, phytochemical analysis, Antimicrobial.

Introduction

The emergence of science in pharmaceutical industry explores the active ingredients from natural resources is the current era of development. In this scenario, seaweed gained the importance, especially against human pathogens and the cultivation has been started by the local people and supply of raw material is about 15 Million MT in one year as per the guidelines of[22]. Sargassum species distributed widely in external conditions where the temperature is humid and semihumid across the world and the characteristic feature of the plant is dark-brown, with approximately 30cm in height. S.wightii has branched leaves, stem like parts and root like holdfasts. This seaweed not only helps the pharmaceutical industry, but also act as supplementary food, fertilizer for plant enrichment and conversion of renewable sources.

Secondary metabolites derived from the innate source are not responsible for growth or reproduction [5] but minor quantities of these materials are very much helpful in producing new drugs in pharma industry, defense mechanism against harmful pathogens [8], hormones, enzymes[14] symbiotic activity[7], in agriculture and interacts with other species.

The bioactive compounds obtained from the seaweeds helps pharma industry as polysaccharide production[4], against bacterial, fungal pathogens[6,10], as a remedy for cancer[12,25] and against viral
The secondary metabolites consist of chemical structures which possess high therapeutic activities. The study from earlier researchers focused on phytochemical analysis, Nutraceuticals and medicinal value from marine macroalgae as food and in the field of research it is widely used in characterizing the medicinal properties\(^\text{19}\).

The current study focused on analyzing the crude extract of *S.wightii* for phytochemical analysis and Antimicrobial activity against the harmful pathogens. The outcome and aim of the research is to attain the knowledge of *S.wightii* and explore to the scientific world. Thus products from the natural sources are always advisable as a means of safer method without any side effect.

**Materials and Method**

**Sample location and extraction:** The sample was collected from the southern region of Tamil Nadu, i.e. Mandapam coastal area and was identified as *Sargassum wightii*. The sample was initially collected with forceps and a sterilized plastic bag and immediately after reaching laboratory sample has to be washed in running water followed by double distilled water and the entire process was left for a few days in shade condition and dried at appropriate temperature inside the room.

The dried sample was powdered and soaked in mid polar solvent ethyl acetate for a period of 3 days. The compounds will be eluted from the sample are mixed with solvent by frequent shaking or kept in shaker at 37°C for a fixed time period. The collected sample was pooled by filtration method and condensed using a rotary evaporator.

**Phytochemical analysis:** Screening of secondary metabolites from the sample *S.wightii* are alkaloids by Mayers reagent method\(^\text{20}\), Tannins, by Ferric chloride method and Flavanoids, by alkaline reagent and shinoda’s magnesium ribbon test\(^\text{9}\), Saponins and Terpenoids\(^\text{18}\) and cardiac glycosides by Keller-Killani method.

**Quantitative analysis of Total Phenol content:** The crude extract of *S.wightii* determines the total phenolics present in the sample by UV spectrophotometer and followed Folin-Ciocalteau calorimetric method\(^\text{17}\). The obtained total phenolic content was measured at 726nm and expressed by GAE in mg/g of dry sample.

**Antimicrobial activity of *S.wightii***: The most common technique to perform Antimicrobial activity is by the well diffusion method of Peela *et al.*, (2005)\(^\text{16}\) using the MHA medium. The test was performed against four bacterial strains and one fungal strain and the test results were observed for inhibition zone.

**Results and Discussion**

**Sample Extraction:** The sample was powdered and extracted with the solvent ethyl acetate in the ratio of 1:10 and sample was condensed using a rotary evaporator. The percentage of the crude extract yield was 5.2%. The solvent ethyl acetate was preferred because it elutes both polar and non polar compounds and the toxicity of the cell is very much low compared to other solvents.

**Crude Extract of *S. wightii* screened for Phytochemical analysis:** The secondary metabolites present in the ethylacetate extract of *S.wightii* is Flavanoids, Terpenoids and Cardiac glycosides and alkaloids, Tannins and saponins are absent in this extract. Flavanoids belong to phenolic group and rich in antioxidant activities\(^\text{2}\) and it helps in healthy circulation by strengthening the capillary wall\(^\text{15}\). Terpenoids are widely useful against various pharmacological activities by inhibiting the synthesis of cholesterol, antimicrobial and also acts as an anticancer agent\(^\text{13}\). Glycosides consists of sugar molecule adhered with non carbohydrate moiety and has sedative property and diuretic\(^\text{21}\).

**Table 1: Phytochemical analysis of crude extracts *S. wightii***

**Determination of total phenol content:** Phenols are a diversified group of natural element obtained from innate sources and distributed widely. The ethyl acetate extract of *S. wightii* were analyzed and showed 18.98 mg of GAE/g dry weight of phenols are present (Graph 1). The phenolic estimation is performed because the macroalgae *S.wightii* has redox property and has a high amount of antioxidants.
Well diffusion method against harmful pathogens: *Sargassum wightii* crude extract obtained from ethyl acetate were tested against four human bacterial pathogens viz., *Staphylococcus aureus*, *Klebsiella pneumoniae*, *Pseudomonas aeruginosa* and *Escherichia coli* and one fungal pathogens *Candida albicans*. Antimicrobial activity of crude extract from *S.wightii* showed good inhibition to all the tested human pathogens (Figure 1). The antimicrobial activity was concentration dependant, when increasing concentration showed increased zone of inhibition. Among the solvents, the ethyl acetate crude extract showed more activity than the methanol extract (Table 2).

The antimicrobial activity was concentration dependant, where increasing the concentration showed increased zone of inhibition. The red and green seaweeds *Gracilaria edulis* and *Enteromorpha flexousa* at 60μg/disc, concentration showed effective antibacterial activity against *Klebsiella aerogenes*. The methanol extract showed highest activity compared with other solvents[1]. In challenge, our results showed maximum zone of inhibition from ethyl acetate extract.

Abstract

In recent years, Obesity has become one of the major health issue affected the children to adult people. Changes in life style, food habits and stress management has been the disease related problems not only for obesity for many health complications. Many of the drugs has been developed in the market to the availability of people. Some of the drugs produced by the pharmaceutical companies shows side effects after using the medicines. The most recently used drugs are Phentermine, Diethylpropion, Phendimetrazine, Benzphetamine, and Mazindol are referred for the obese patients for short term treatment. Sibutraminea, the sympathomimetic are referred as long term medication for the patients with obesity. Many of the drugs are banned from the pharmaceutical industry due to the adverse effects it has on patients health. This paper discusses the major reasons and issues related with obesity. The medications and treatments in available recent times are also discussed.

Keywords: Obesity, risk factors, treatment, BMI, Gynaecological Problems.

Introduction

The world Health Organization has reported this obese issue as “excessive and abnormal fat accumulates develops risks to health” it is usually calculated with the formula of BMI known as Body Mass Index it presents the level of fat accumulated in the body[1]. The available treatment options are set according to the range of body mass index, circumstances and other health problems are taken into record to avoid any future health complications. However for endocrinologists are trying to resolve the major health consequence of developing obesity and type 2 diabetic patients[2]. Research study on obese reports that around 30% of middle age european people are obese and in united states nearly around 3 lakhs people died every year those are obese. Obesity patients are tend to associate with the risk of developing higher mortality rate. The average obese body weight range patients are saved without any risk development. Life style changes, junk food eaters and lack of exercise among the people are the biggest causes of obese people. There are certain technologies available for the people such as anthropometric measurement namely skin-fold thickness, measurement of waist and hip range are used to assess the complications in obese patients associated with type 2 diabetes mellitus also cardiovascular diseases. In 2015-16 THE WHO has announced obesity as epidemic and this has arised worldwide about 1 billion and 600 million people are adults with obese. Public health sector has announced many health insurance schemes for aged people to recover their health[3]. Obese are also tend to develop gastroenterology disorders such as hernia, colon cancer, haemorrhoids so on [4].

Obesity; Risk Factors: The public are not aware of such health complications associated with obesity,
and how it influences people's life in the way of affecting health and economical imbalance in running families these are all the important problems related with the disease. It arise when the energy imbalance in energy utilized and spent in day to day life when the calories are not utilized properly it is converted into fat and gets deposited in the body. The major reasons for change in people behaviour towards health are the availability of nutrition and the less nutritious foods the industries growth all these problems affects the people health directly and ends up in obesity.

**Gynaecological Problems:** Obese women health definitely varies from normal health women. Starting from menstrual issues irregularities and amenorrhea that is long time absence of menstrual cycle. The menstrual issues in women arises because of the hormonal imbalance in the female body. This change is due to the upregulation of androgens and oestrogen levels and increased conversion of androgen to estrogen in female obese patients. Research studies also suggests that the obese women are more prone to endometrial cancer with the highest production rate of oestrogen in the endometrium. Types of cancers arise in obese are breast cancer gall bladder cancer and ovarian cancer. 70% of the obese women are developing polycystic ovarian disease or syndrome commonly known as PCOD or PCOS. During pregnancy this overweight issue leads to hypertension, diabetes and pre-eclampsia and big headed baby development are seen.

**Pulmonary Functioning Issues:** Research reports says that the obesity problem is related with sleeping disorders known as (OSA) OBSTRUCTIVE SLEEP APNEA. The enlargement of neck width range is associated with sleep disorder in obese patients. There are two major reasons to affect health because of the tissue fat has been attached in lumen and secondly the fat tissues blocks the airways and collapses the ranges of air passes through the way. Breathing issue asthma is critical disease even that may develop in the obese patients. There are also evidences provided to prove obese patients are developing asthmatic issues. Seventy % of the patients with asthma are diagnosed from the obese patients. Active mechanism is obese people are related with asthma complaint because of the hyper-responsive airways and decrease in function. The block of inhibitors results in the hyper reaction where the inhibited agents are cytokines, chemokines and adipocyte factor leptin.

**Coronary Heart Disease:** Obesity majorly affects the heart by blocking pathways by fat accumulation and increases the chances of getting cardiovascular disorder. The metabolic rate of obese patients compared with normal healthy patients are low in range leads to many diseases and disorders many heart disease. Hypertension reporting studies reveals that the adipose tissue containing fat are accumulated in high level is indicated by calculating the BMI (Body Mass Index). The blood circulation is reduced and pumping capacity of blood to the heart is reduced by the deposited fat in the arteries leads to severe hart blocks and heart attacks. Nearly millions of people die every year because of obesity related heart problems and attacks. Overweight and lacking in exercise and the fried food items are major reasons for obesity leads to cardiovascular diseases. Daily walking for 40mins can eventually reduce such coronary diseases by burning the excess calories we can reduce the fat accumulation in body.

**Anti-Obesity Medicines:** Many number of drugs are prescribed for obese people for weight reduction. These recent medicines are approved during past years. Some of the pharmaceutical companies still developing medicines for the obesity patients. Drug called topiramate anti-epileptic medicine used for migraine and roflumilast plays role in pulmonary disorders. Bupropion are known to treat depression. Other important drugs for the reducing weight is not the first line treatment but adopted for the obesity treatment. In developed countries phentermine and the drug diethylpropion are distributed largely in 1970. These releases medicinal compounds such as dexfenfluramine and fenfluramine. It is known that these agents had potential to develop hypertension of pulmonary and it was highly put under risk order which works against the weight loss process.

**Diethylpropion:** It is a compound consists of phenylalanine ring compound with small sympathomimetic property and present with stimulants shows effect thanamphetamine. Diethyl had approved by Food drug and administration for obesity treatment in 1959. It has been in use for weight reduction and the studies had been under evaluation for the use of this medicine for long term. Analysis called meta analyses assess the action of this diethylpropion drug for in different individuals and presented in the published report between 1960& 1980. These studies were carried out for at least more than 20 weeks. The obese patients are treated with these drug to ensure weight loss each.
individual has at least lost three kilo of weight without any side effects [9].

**Phentermine:** It is sympathomimetic anorectic medicine belongs to the phenylethelamine class pharmacologically relevant to the amphetamine. The action of this medicine is to work in the stimulation of hypothalamus in the adrenal glands releasing the nor-epinephrine reducing the abdominal fat [10]. To notice it is not established as a first line medicine such as amphetamine in treating the obesity by weight loss. Central nervous system activity and metabolic activity may be involved. FDA has approved this medicine to treat obesity for week based treatment named monotherapy because of this single medicine for weight reduction, physical exercise and calorie reduction in obese patients with highest BMI rate. TILL 2006 this medicine was prescribes as an anti-obese medicine in the U.S country. Some of these formulations had side effects also such as headache, increased heart rate and constipation [11].

**Cathin:** It is one of the anti-diabetic drug derived from the formulations of amphetamine drugs in the pharmaceutical industry for the past years of treatment for obesity patients. It is an alkaloid derived from the leaf of khat plant it is licensed to use in the short period of time for diet improper obesity. Pharmacology formulations of this plant works as an amphetamine drug utilizes which induce the anorexia and sensory simulating, urine retention associated disease. Variation in medicine dosage can increase heart rate and many safety related problems are considered while giving the medicine. Monotherapy of cathin can be prescribed for atleast 20 weeks and reported safe. The use of this medicine is not advised for long time and still cannot be identified even in many clinical trials specially with cardiovascular diseases [12].

Pharmacology is an major part in treating the obesity disease its role in weight loss is uncountable. Considering the major health issue and death rate are the complications taken into consideration by the industries to produce drugs that are available for people with obesity. Taking drugs can reduce the health ailments but real weight loss procedures should be followed by the patient to ensure healthy body The fact is the use of medicines for obesity will work only while you are using the medicines later it wont show its action. So use of medications is only a temporary path and having a healthy life still with exercise and taking nutritious food are the key to success [13].

**Weight Management:** A group of obese patients were analysed for weight loss in research it was separated into 3 groups and after period of six months patients from three different groups were put into weight loss pattern they all showed average range of change in their weight. The average weight loss were seen in different groups. The analysis were brought to secondary stage the patients with obesity are put into these group with mixed number of people from all the groups there was change in weight loss pattern. These patterns are finalized and revealed that these low-energy intake of diet shows the effects in weight loss treatment. Hence it is proved that weight loss is possible with proper diet intake. Reduced calories will burn fat and also stops the accumulation of fat in body of both male and female [14].

**Food Systemic Approach Preventing Obesity:** Attention seeking towards current policies and system for food may create an impact towards public health and things related to diet may reduce the diseases in chronic level. An organizational authority of food system says that the food should be available for all the people that is availability of food, and accessibility of food and affordability to all the people. Reduction in healthy food supply induces the malnutrition in children it also creates many deficiencies in human health. There are efforts taken to reduce the space between the science people and public policy related issues that requires changes in the improvement of food availability and healthy living of people in the risky population [15].

**Dietary Therapy:** Obesity patients can receive charts and patterns for the diet intake from nutritionists according to their weight loss goals and risks in their health. The obese should follow the medications properly for long time and some of the changes should take place in their life style diet intake for the patients. To follow these procedures patients should participate in the health programs conducted by the health institutes. Normally fiber, grains and fruit juice consumption plays a major role in weight reduction. Fruits intake 30% in daily diet can reduce 70% of weight in obese patients recommended by nutritionists. Weight loss process with some nutritious food for a long period of time helps in weight loss also for healthy living of people [16].

**Conclusion**

People have awareness towards a healthy lifestyle and exercises are less nowadays. That should be managed and maintained by people for make a disease free life.
So many health complications are followed in the absence of healthy diet such as cardiovascular diseases, neurological disorders, memory issues, menstrual problems in women and also developing cancers in many obesity patients. All these can be avoided by having a healthy diet and following exercises are key to have healthy life. Alcohol consumption is also one of the major health complications related to obesity. To avoid these complications and to maintain a healthy lifestyle these implications should be followed throughout the weight loss process to lead a disease free healthy lifestyle.

Combinational Therpies and Drugs for Diabetes Mellitus Type I and Type II

Sivasankari S.1, Kumaravel S.2, Govardhanan K.3, Ganesh Kumar4

1Professor, Department of Microbiology, Meenakshi Medical College Hospital and Research Institute, Enathur, Kanchipuram, Tamilnadu, India, 2Professor & HOD, Department of Dermatology, Meenakshi Medical College Hospital and Research Institute, Enathur, Kanchipuram, Tamilnadu, India, 3Professor, Department of General Surgery, Meenakshi Medical College Hospital and Research Institute, Enathur, Kanchipuram, Tamilnadu, India, 4Assistant Professor, Department of Pharmacology, Meenakshi Medical College Hospital and Research Institute, Enathur, Kanchipuram, Tamilnadu, India

Abstract

Diabetes mellitus is a metabolic disorder causes changes in the blood glucose level either it can be elevated or lowered. These are classified into two type insulin dependent and insulin non-dependent. The basic treatment provided for diabetic patients are insulin therapy it has been clinically proven but this is not the only solution to cure diabetes. Metformin is widely used medicine for patients. Glucose lowering therapy is applicable for patients with severe hyperglycemia, hepatic and renal related diseases. The therapeutic applications such as The therapeutic medicines exenatide and to induce the insulin secretion and also liraglutide helps people with insulin. Other therapeutic compounds heals the defects of beta-cells secretion are compensated with the use of stitagliptin to inhibit the dipeptidyl peptidase-4 (DPP-4) enzyme, and increases the the function of Islets cells. This article further discusses about the combinational therapies available for the diabetic patients.

Keywords: Diabetes, therapies, drugs, mellitus.

Introduction

Diabetes mellitus is considered as life-threatening metabolic disorder worldwide. In recent survey around 300 million people got affected with this disease with the diagnosed rate of 8% and 50% undiagnosed [1]. The maximum people with middle income are found to be diabetic related with stress, unhealthy diet with the age group of 45-55 in the population. In the estimation of recent survey by ICMR collaboration with china predicts in the survey an estimation of 99 million people with the case history and the future predicted survey says that in upcoming years 6 million people are tend to get affected. There are few incidence that makes people with diabetic are prone to cardiac related disease in the east Asian countries. There are chances to get diabetic in people with obesity. There are the major health complications in diabetic patients[2]. The drug metformin is utilized as the combinational therapy medicine for type 2 diabetic patients. It was available in Europe and U.S. and approved in the year 1995. The usage of metformin has adverse effects for the patients with increased level of serum creatinine. It should be properly prescribed with mg level in elder patients around 80 yrs of age because of the complications in renal functioning [3]. Attaining the targeted glycaemic level is of utmost importance the initial stage in use of combinational medicines leads to reduction in HbA1c. Combinational therapy for types 2 diabetic is more risky than type 1 because type has more metabolic defects. Hypoglycemic patients cells can have an impactful memory of vascular cells of the

e-mail: sivasankaris@mmchri.ac.in
target organs creating a metabolic memory leads to complications in future. Diabetic people those who are with poor control leads to develop risk factors [4].

Preclinical studies in recent establishment of medicines for diabetes: FDA has approved many drugs of combinational therapy for diabetic patients also to avoid side effects which leads to immunosuppression in patients. The ultimate standardization approach to achieve approval can be developed. Type 1 diabetic patients approval of medicines requires a panel of members with animal models to develop medicines for FDA approval. To ensure even formulations of medicines it is compared with standards and compared with operating procedures it is presented and multiple data has been stored. Such consortium can consist diverse laboratories developing the preclinical models in standardizing the procedures to get the approval from Diabetes combination therapies assessment group. This formation will allow two or three labs work to test the combinational medicines. The protocols from all laboratories will put to standardization so that the therapeutic medicines turn as a GMP material known as good manufacturing practise. The ultimate goal of this initiatives are to provide quality preclinical-data for the novel combinational medicines therapies for type 1 diabetic medicines [5].

Type I Diabetes mellitus Combinational Medicines:

Rapamycin: It is an inhibitor of non-calcineurin used in the prevention of graft rejection after the allogenic transplant. Additionally administering the rapamycin drug prevents the type 1 diabetes in mice. This drug rapamycin drug for humans provided for juvenile for beta cell replacement diabetes research foundation center. The research studies revealed that recipients of renal transplant t-cell depletion by inducing CAMPTH-1H. The clinical protocol in using rapamycin therapy is provided to type 1 diabetic patients before transplantation of islets to reach therapeutic plasma level before infusion of islets that follows rapamycin mono therapy. Rapamycin has an effect on human nTreg function, which supports its clinical immuno suppressant agents for tolerance.

Stem Cell Therapy β-Cell Immunomodulation: BETA-cells for therapy is a major challenge. Limitations of using stem cells represents ultimate potential of stem cells to regenerate the cells and immunomodulation potential. The capacity to renew to turn from differentiate into specialized cells can be a useful for glucose supply and insulin producing cells for transplantation. The mesenchyma cells and hematopoetic cells can aid to retrieve the beta cell destructors and facilitates the regeneration of cells. Hence the cells with these potency can be utilized in beta-cell therapies to reverse hyperglycemic in type 1 diabetic patients. These Stem cells can be produced from various sources obtained to test their potential to restore homeostasis or to enhance the survival in transplant patients. It includes pluripotent stem cells, embryonic stem cellsand bone marrow-mesenchymal cells and adipose tissue-derived cells and the cells that secretes in the ductal epithelium Beta-cell progenitors are found [6].

Peptide Hormone Therapies: Peptide hormone mimics the cells. The peptide (GLP-1) Glucagon-like peptide are widely being used to treat the diabetes and obesity. Pre-clinical data deposited that strongly suggests the benefits of many hormonal peptides, which develops the potential type 1 diabetes treatment. Including the potential regulation of glucose and secretion of insulin, beta cell preservation and increases the insulin sensitivity. The pre-clinical study exposes the GLP-1 therapeutic utilization of insulin in type-1 diabetic patients. It demonstrates the reduction of postprandial glucose excursions, production of decreased glucagon and the delaying of empty the gastric in patients insulin uptake and combination with GLP-1R as compared with insulin therapy. The study demonstrates the controlled glycaemic level in combinational therapy with anti-IL2 antibody [7].

Therapeutic Drugs for Type II Diabetes mellitus:

Type II α-glucosidae inhibitors: Acarbose, miglitol and the voglibose are the currently available medicines for type 2 diabetic patients. These medicines are currently available for anti-diabetic property it possess for the mode of action. Mainly the acarbose has been utilized for more than 10 years in the treatment of diabetic mellitus. These inhibitors take role in reducing the triglycerides but improving their effect on low density and high density lipoprotein levels are inconsistent. This inhibitor sometimes rarely induce the hypoglyciathese do not stimulate the insulin level and do not disturb the weight of patients. Acarbose inhibitor has reduced the risk of cardiac related disease shows progression in patients with glucose intolerance [8].
**Gut Microbiota:** Human gut consist beneficial bacterium, identified as gut microbiota. These microorganisms consists essential functions gut microbiota serves several essential functions in vitamin production such as vitamin k, folic acids to enhance energy production. Research studies have reported that the colonizing bacteria contact happens in birth canal. In this therapy the microbiomes have found in amniotic cavity, amniotic fluid and in umbilical cord.In infants the microbiota composed of materials are completely different from adult people. After three years of birth the microbiota has developed to the maturation stage which is essential throughout the adult stage. The major diseases are prevented by the developments in human body. Studies revealed that animal models and in adults had demonstrates that microbiota improper function can lead to the development of obesity in type 2 diabetic patients.There are chances of fluctuation in the energy level of healthy individuals these inhibits the insulin resistant and and develops dyslipidemia are developed by low anti-bacterial activity [9].

**Thiazolidinediones:** These Troglitazone has been found in the year 1997 in the type 2 diabetes milletus. These are removed from the production companies because it causes liver toxicity. With the use of medicines patients gained weight after taking troglitazone medicine. This medicine sticks with the peroxisome activator proliferation and gamma nuclear receptors affects the gene regulation. This alteration transcription of gene takes place in adipocytes and the primarily concerned genes participate in regulation of fat metabolism. This reduction in fatty acids eventually regulates the production of insulin. This FFA develops the beta cell function by reducing the lipotoxicity. The toxicity leads to cell death in beta cells [10].

**Pioglitazone:** This drug is used as a mono-therapeutic agent combined with metformin (increases anti-hyperglycemia). These compounds such as meglitinide works well in diabetic patients with metabolic disorder associated with type 2 diabetic patients. Low dosage is recommended per day. It shows a relevant mode of action and adverse effects in liver toxicity when compared to rosiglitazone. It can also interact with another medicine that are functioned by enzyme p45 and change the level of serum. Contraceptive drugs used in higher dosage in diabetic female who does not want to get conceived [11].

**Sulfonylureas:** The first and second generation nature of this compound binds with the receptor of sulfonylurea present in the pancreatic beta cells surface and it ultimately leads to the increased range of secreting insulin. These cause changes in potassium channel and depolarization in the membrane of the cell. These calcium channel pave way to an influx in calcium and increases insulin secretion in pancreas. The first generation medicines are with low potency compounds include (diabinase, dymelor, to linase). The second generation medicines easily penetrate through the cell membranes [12].

**Sodium Glucose Cotransporter 2 Inhibitors:** These inhibitor targets the organ kidney to develop the glucose in excreta from urine and eventually decreases hyperglycemic condition. In normal condition, organ reabsorbs the glucose filtered. Hence no glucose is excrete from the urine samples. Glucose re absorption happens at the proximal tube, by the help of glucose protein SGLT2. The expression of this protein seem to be increases in type 2 diabetic patients. Re-absorption capacity is increased by inhibiting the protein for reabsorption of glucose decreases the hyperglycemic condition. This inhibitors can be utilized in different combinations, different types of agents aids in lowering the glucose [13].

**Hybrid chimeric peptides:** The combinations of two peptides are injected to the patients has developed with the molecules hybrid are two peptide molecules and the amino acids linked the peptide molecules to form a single compound. For instance gluacon peptide has been mixed with the gastrin eventually improves the control glycaemic condition in patients and also controls the beta cell mass. It is also linkswith glucagon improves the energy level and leads to weight reduction. Possibility to arrange chimeric peptides with good properties to deliver the desirable effects through the receptors of targeted cells. The acute reaction, immunogenecity and physio chemical challenges are considered in the development of drugs [14].

**Patho-Therapeutic processes:** The action of anti-diabetic medicine is pharmacologically inactive sometimes. In the beginning stage, pharmacologists focus in the sugar level in blood and intake of food and digestive compounds related to glucose. Development of novel drugs for the type 2 diabetes milletus should be diverse and helpful without any complications. Therapeutic medicines are related with coronary diseases and obesity that should be avoided while designing a drug. Experimental studies should develop and enhance
the mode of action of drugs. Accordingly, we should not rely on one or two therapeutic pathways. Generally these medicines are not toxic when compared to high risk synthetic drugs.

**Exenatide:** This drug mimics the incretin protein which has glucose regulating molecules having glucoregulatory activities related to hormonal peptide glucagon. The activity includes the blood glucose-dependency enhances the secretion of insulin. The drug enhances the glucose level for secretion of insulin mediates the binding of exenatide with glucagon with pancreatic cells. The glucagon peptide improves the cell function by using the drug in exenatide by increasing the gene expression involved in secretion of insulin and the augment the beta cell mass. This peptide controls the intake of food and helps in weight loss increases insulin effect in body.

**Conclusion**

These therapeutic drugs are available in recent years considering uncontrollable diabetic cases in India and all over the world. The developed countries life style and lethargic manner in junk food intake are also the reasons for developing diabetic mellitus metabolic disorder. The therapeutic drugs mainly helps to reduce the weight and improves the metabolic rate in diabetic patients. This should be taken into consideration by people to change their idea of having irresponsible changes in life style. The use of combinational therapeutic drugs will eventually help people with type 1 and type 2 diabetic patients for the well being of highest population.

Epithelioid Hemangioendothelioma–Two Rare Case Reports with Review of Literature

J. Logeswari 1, B. Sabarinath1, B. Sivapathasundharam2

1 Associate Professor; 2 Professor and Head, Department of Oral Pathology, Meenakshi Academy of Higher Education and Research, Faculty of Dentistry, Meenakshi Ammal Dental College, Maduravoyal, Chennai–600095, India

Abstract

Epithelioid hemangioendotheliomas (EHE) are decidedly are form of hemangioendotheliomas with biphasic histopathological components. It is known to occur rarely in head and neck region. They are known to have aggressive behaviour with depictable recurrence rate and metastasis. Here we present two cases of epithelioidhemangioendothelioma with review of literature.

Keywords: Hemangioendothelioma, Epithelioid, Vascular Neoplasms, Metastasis, immunoreactivity.

Introduction

Hemangioendotheliomas (HE) are rare proliferative vascular neoplasms, known for its intermediate biological behavior that ranges between benign hemangiomas to malignant angiosarcomas.[1-6] Its clinical behavior and disease course remains unpredictable even amongst its histological types namely epithelioid, kaposi’s and hobnail form (Dabska-retiform). Epithelioidhemangioendotheliomas (EHE) are decidedly are form of hemangioendotheliomas with biphasic histopathological components composed of characteristic short cords and nests of proliferating round to epithelioid endothelial cells as well as spindle shaped endothelial cells. It is known to occur in any soft tissues but primarily in abdomen, liver, lung, extremities and also rarely in head and neck region.[2-6] Epithelioidhemangioendotheliomas are known to have aggressive behavior with exemplified recurrence rate and metastasis, than any other types.[7-9]

The exact nature of intra oral EHE is not clearly established because of its rarity. Till now only thirty four cases of intra oral EHE cases have been reported in English literature, including current two cases.

Case 1: A 35 year old female patient reported to the dental clinic with a chief complaint of red to pink, painless swelling in right lateral border of the anterior tongue (Fig. 1). The swelling was present for past three months which increased gradually to the present size of 3x1 cm². It is a lobulated, ovoid mass with a sessile base. The clinical differential diagnosis of hemangioma, fibroma, and pyogenic granuloma, was considered based on the clinical appearance and incision was performed after routine investigations.

The microscopic examination revealed plenty of tiny blood vessels lined by round to oval and spindled epithelioid cells, exhibiting eosinophilic cytoplasm with vacuolization arranged in short cords and nest (Fig. 2). Mitotic figures were minimal in number. The overlying epithelium was stretched and hyperplastic with surface ulcerations. Based on this diagnosis of EHE was considered. The tumour cells also exhibited immunoreactivity for CD31 confirming the endothelial nature of epithelioid cells and negative expression for cytokeratin and thus EHE was confirmed.
Chest radiograph was taken to rule out metastasis. Complete excision of the lesion was done. Patient reported after three months with no recurrence and complications and failed to report back further.

**Case 2:** A 22 year old male patient reported to a dental office with a complaint of solitary painful, mass in the buccal mucosa for past six months. The swelling was red to grey in colour with surface ulceration in the center of the mass. The swelling developed gradually to the present size of 3x2 cm$^2$. Patient gives frequent history of trauma on mastication otherwise no other symptoms were elucidated in relation to the growth. Family and personal history was unremarkable.

Provisional diagnosis of traumatic fibroma was given. Incision biopsy was performed and tumour mass was submitted for histopathological analysis. Tumour was yellow to grey solid mass with soft to firm consistency. The microscopic examination revealed cords and nests of proliferating spindle cells along with round to oval epithelioid cells with eosinophilic cytoplasm and intracellular vacuolization indispersed within a loose fibrovascular connective tissue stroma with plenty of tiny blood vessels. Few mitotic figures were evident. Overlying peripheral epithelial lining was also evident. Positive immunoreactivity of tumour cells for CD31 confirming the endothelial nature of epithelioid cells and negative expression of cytokeratin was elucidated. Considering the histopathological and immunohistochemical features, diagnosis of EHE was made.

Surgical excision of the tumour was performed and the patient was disease free till follow up examination of 16 months.

**Discussion**

Hemangioendothelioma is rare proliferative vascular neoplasm with intermediate malignant potential$^{[3,9]}$. The variable behavior of the neoplasm, led to its compounded terminologies such as histiocytoidhemiangioma, intravascular bronchioalveolar,malignant hemangioendothelioma, cellular angiomma of infancy, angioendothelioma, angioblastoma and led to the categorization of HE as an intermediate tumors or borderline tumor.$^{[1,2,6,10-12]}$ Though the concept of intermediate or borderline tumours remains complex and ill defined, it was designated to tumours with uncertain behavior. It was described as early as 1899 by Boremann,$^{[4,5,8]}$ and was introduced particularly in vascular tumours by Enzinger and Weiss and latter added to WHO classification in 2002$^{[3,4,6,9]}$. These HE lack consistent clinical and histological behavior with limited number of reported cases, fails to elucidate the exact biological nature of this tumour.

The first case of oral HE occurring at gingival was reported at 1975 by Wisely et al, as “primary malignant hemangioendothelioma”. Later in 1986 Ellis and Kratochvil reported twelve cases. The three histological variables listed under HE are epithelioid, kapossis and hobnail (dabska-retiform). Amongst is histological type, EHE are relatively rare, aggressive member of this group with unpredictable behavior with increased tendency for recurrence and metastases.

A wide range of age group is being affected ranging from first to seventh decade of life with mean age of 34.7 years. Men and women are equally affected except few authors believe slight female predilection in those occurring in extremities.No predisposing factors have been claimed for its occurrence except contraceptives usage in females as mentioned by few authors$^{[10,11,16]}$.

Clinically, lesion appears as a solitary, painful to painless red to grey soft tissue mass with size not greater than 2 cm hinting for benign nature and confuses with more common lesions such as pyogenic granuloma, fibroma, fibroepithelial polyp, peripheral giant cell granuloma and hemangiomas$^{[1,11]}$. Radiographic details are usually non contributory, showing a mild bone resorption. Normally excision is performed considering other common benign lesions as provisional diagnosis.
Histologically, these lesions are characterized by proliferating sheets, cords and islands of eosinophilic round to oval shaped epithelioid cells intermixed with strands of spindle shaped cells around proliferating tiny blood capillaries (Figure 3&4). The morphology of cells is epithelioid in shape, with round to oval nucleus with occasional intracytoplasmic-lumina. The classic intracytoplasmic-lumina (vacuolization) with round to oval vesicular nucleus are the distinct feature of EHE (Figure 5). The lumen is frequently filled with RBCs may account for a primitive vessel formation and also suggests the endothelial origin. Frequently collagenous and myxohyaline areas are reported in tumor stroma[4-6], which was evident in the second case. Few authors attest it could possibly be a sulfated acid mucin from vessel wall [2] and also specifies the endothelial nature of the lesion. Infrequently few areas of calcifications, multinucleated giant cells and mitotic figures are also reported [3,4,6,9]. Angiocentricity is not very well appreciated in oral lesions in contrast to cutaneous lesions, where only less than 9% of oral lesions showed history of pain, ischemia could be the probable reason for pain[1,6]. Advent of cytology in diagnosis of EHE occurring in other extra oral sites were found useful, and showed 85% positivity in reported cases. However its usage in oral lesions as an adjuvant, not yet described.

Immunohistochemistry plays a confirmatory role in rendering diagnosis as well as differentiating it from other histologically similar lesions [4,6,7,9,13]. Look alike lesions includes epithelioid sarcomas, other metastatic carcinomas and vascular lesions like epithelioidhemangiomas, epithelioidangiosarcoma and epithelioid spindle cell hemangioma. Endothelial markers such as CD 31, CD 34, CD 68, Factor VIII were used in previously reported cases to aid in diagnosis of the vascular nature of lesion. While the epithelial markers like cytokeratin, epithelial membrane antigen are frequently found negative and excludes the epithelial origin[1,5,10,17]. It permits us to presume that, these epithelioid cells are altered endothelial cells rather true epithelioid cells. Few case reports with focal cytokeratin positive immunoreactivity[1,10,14] also complicates the diagnosis, however the knowledge of the pathologist along with the adjuvants contributes in differentiating further. The positive immunostaining for CD 31 cytokeratin and negative staining (Figure 6&7) confirmed the diagnosis assisted in removing other differential diagnosis including epithelioid sarcomas and other metastatic carcinomas which are frequent and indigenous to the tissue of origin.

Local recurrence is not uncommon in EHE but intra oral cases accounts relatively lesser frequency, compared to those occurring in other anatomical site. Out of 34 cases, collective sum of earlier reviews and the current review, affirms the raise in propensity of recurrence at the rate of 22.5% in intra oral cases, specially with gingival cases [7,19]. It is not unknown for EHE to metastasis, especially to the regional lymph nodes, at the however distant metastasis is seldom noticed. Despite features like cellular pleomorphism, altered nuclear cytoplasmic ratio, increased number of mitotic figures (more than 3mitosis/50HPF) [6,7,18,19], metaplastic bone formation, areas of necrosis and few authors prefer including the tumour size greater than 3cm diameter, can be considered for predicting the recurrence and metastasis. It requires more clarity, to claim it as a criterion, since much times, lesion also develop metastasis and recurrences from an indolent lesion with bland histopathology. Multicentiricity of EHE is a well appreciated, frequent event in extremities and found have better prognosis than the unifocal ones, whereas, it is exceptionally rare in oral cavity.

Wide excision is a preferred treatment of choice, reflecting the intermediate malignant potential of the tumour but recurrence is commonly associated with inadequate excision. On other hand adjuvant therapies such as radiotherapy and chemotherapy are frequently suggested, for recurrent cases, merely found effective. Mortality rate in relation to oral EHE is not recorded till date that assents us to consider oral lesions are relatively less aggressive compared to those occurring in other areas of body.

Thus oral EHEs are rare intermediate vascular neoplasms, with increased tendency for recurrence and metastasis appears frequently as a sessile benign lesion. Considering the raise in recurrence rate especially with those occurring in gingiva, all lesion with high vascularity should be considered as a common differential diagnosis. Those diagnosed with EHE, should be evaluated for, recurrence and metastasis with long term follow up. In both the cases did not present any atypical features microscopically, chest radiograph were also evaluated, in order to exclude the possibility of metastasis and also insisted on frequent follow up to rule out recurrence.

A Rare Presentation of an Oro-Antral Communication after Trimble’s Modification of Lefort I Osteotomy

J. Godwin Alex Kiruba\(^1\), Manikandhan Ramanathan\(^2\), S. Senthil Nathan\(^3\), J. Godwin Alex Kiruba\(^4\)

\(^1\)Meenakshi Cleft and Craniofacial Centre, MAHER University, Chennai-600095, Tamilnadu, India, \(^2\)Professor, Department of Oral and Maxillofacial Surgery, Meenakshi Ammal Dental College and Hospital, MAHER University, Chennai-600095, Tamilnadu, India, \(^3\)Assistant Professor, Department of Dentistry, Meenakshi Medical College and Hospital, MAHER University, Chennai-600095, Tamilnadu, India, \(^4\)Surgical Fellow, Meenakshi Cleft and Craniofacial Centre, MAHER University, Chennai-600095, Tamilnadu, India

Abstract

Lefort I osteotomies are one of the most commonly performed surgeries in the maxillofacial spectrum. There had been reports of umpteen number of complications after Lefort I osteotomy. The authors present a case of an oro-antral communication after Trimble’s modification of Lefort I osteotomy, which has not been published before in the English literature.

Keywords: “Oro-antral communication, Trimble’s technique, Lefort I osteotomy, Buccal advancement flap, Buccal pad of fat.”

Introduction

Le Fort I osteotomies are routinely employed in the correction of various dentofacial deformities. They are associated with a wide number of complications ranging from an abscess to total unilateral blindness [1]. Occurrence of oro-antral fistulas are a rare complication after Lefort I osteotomies and there has been no report in the English literature documenting the occurrence of an oro-antral fistula after Trimble’s modification of Lefort I osteotomy.

The authors present a case of oro-antral fistula after Trimble’s procedure, with explanation of the probable etiologic factor and its management.

Case Report: A 24-year-old male patient who reported to Meenakshi Ammal Dental College and Hospital was examined and diagnosed with midface hypoplasia, vertical maxillary excess and mandibular prognathism. After pre-surgical orthodontics and cephalometric analysis, it was planned to advance the maxilla by 7mm and impact it by 6mm. Intraoperatively, Trimble’s modification of Lefort I osteotomy was performed to mobilize the maxilla and the necessary movements were accomplished. Adequate closure of the extracted third molar socket was achieved. The patient had an uneventful immediate postoperative recovery.

At the end of the first post-operative week, the patient presented with a complaint of watery leakage from the right nostril, on intake of fluids. Clinical examination revealed a wound dehiscence on the maxillary right third molar region. The authors confirmed the presence of an oro-antral communication of about 5mm on the region adjacent to maxillary tuberosity, where the right third molar was removed (Fig. 1). On the following day, the communication was closed in layers with buccal fat pad and buccal advancement flap (Fig. 2). The patient was followed up for three months and he had a satisfactory healing (Fig. 3).
Discussion

Since the first descriptions of Lefort I osteotomy by Wassmund\cite{2} and Schuchardt\cite{3}, there had been suggestions of several modifications by various authors\cite{4,5}. Trimble et al proposed a modification by advocating the placement of vertical posterior osteotomy cuts through the tuberosity. This technique has considerable advantages over the conventional technique as it is anatomically less hazardous, allows greater segmental mobility and also permits maintenance of a larger vascular pedicle\cite{6}.

Lefort I osteotomies are associated with a varied number of complications. Occurrence of oro-nasal/oro-antral fistulas are rare complications after Lefort I osteotomies. Steel et al reported that oro-nasal fistulas are more common than oro-antral fistulas\cite{7}, specifically in anterior segmental osteotomies and Ho et al recorded an incidence rate of 5% for oro-nasal fistulas\cite{8}. Midline osteotomies are more commonly associated with palatal tears due to the thin palatal mucosa and these are less likely to heal.

Khandelwal et al defines oro-antral fistula as an epithelialized pathological unnatural communication between the oral cavity and maxillary sinus \cite{9}. Initial treatment of oro-antral fistula includes routine sinus management with decongestants, nasal spray, antibiotics and obturation of open fistulas by using a soft “suck down” material for shrinkage or elimination of fistula\cite{10}.

Numerous surgical procedures have been recommended by various authors for the closure of oro-antral fistula. These procedures maybe categorised into local flaps, distant flaps and tissue grafting.

The Rehrman buccal advancement flap is the most common method implemented in the closure of oroantral fistula. After debriding the epithelium, the defect is covered with a buccal mucoperiosteal advancement flap. The shape of the flap is trapezoid, with its base at the buccal sulcus to ensure maintenance of adequate blood supply. The major disadvantage of this technique is that it leads to reduction in the vestibular depth\cite{11}.

The buccal pad of fat (Boule de Bichat) is a simple lobulated mass which is covered by a thin capsule and located inside the masticator spaces. Since Egyedi reported the use of buccal pad of fat in the closure of oro-antral fistula\cite{12}, several authors have utilized them to a good effect\cite{13,14,15}. The advantages of this technique
include ease of harvesting, good epithelialization and a high success rate\cite{9}.

Batra et al have demonstrated a double layer flap closure method wherein, a buccal fat pad flap was advanced to cover the oro-antral fistula, followed by a layer of buccal mucosal advancement flap over it\cite{11}.

To the authors’ knowledge, there is no published evidence of an oro-antral fistula in relation to maxillary third molar socket after Trimble’s technique. The authors feel that despite adequate closure of the extraction site, the advancement at the site of third molar socket might have created more gap between the bone segments, predisposing to a larger communication. The authors performed a two-layer closure with buccal pad of fat and buccal advancement flap, which ensured excellent healing within a span of 2 weeks. The authors advocate that extreme care is necessary while suturing the third molar socket after osteotomies to negate the occurrence of such complications.

¹P.G. Resident, Department of Radiology, Meenakshi Medical College and Research Institute, Enathur, Kanchipuram, Tamilnadu, India, ²Assistant Professor, Department of Radiology, Meenakshi Medical College and Research Institute, Enathur, Kanchipuram, Tamilnadu, India

Abstract

This study aims to evaluate the role of preoperative HRCT temporal bone in the diagnosis of the disease, its extension and complications and plan for surgery. The involved structures and also in knowing prognosis is compared with Intraoperative findings made by the surgeon to know its precision in diagnosis. It also helps in diagnosing intracranial complications of CSOM at an early stage and help to plan surgery. Patients presenting/Suspected to have CSOM who were planned for mastoid exploration surgery in Department of ENT, within a period of 2 years–from February 2019 to September 2020, were taken up for study. The patient will undergo HRCT temporal bone with Aquilon 160 slice CT scanner producing sub millimetric thin axial scans Following areas of interest were looked up in preoperative scans:

- Pneumatization of mastoid
- Tegmen tympani erosion
- Facial canal dehiscence
- Ossicular status
- Extent of disease
- Sinus plate erosion
- Lateral semicircular canal dehiscence
- Disease outside middle ear cleft

Out of total 30 patients of CSOM, 26 (52%) were males. Majority of the patients (70%) were in the age group of 11 to 30 years. Left ear was involved in 40% of the patients. Majority of the patients (80%) presented with chief complaints of otorrhoea. In the present study, External Auditory Canal (EAC) was seen normal in majority of patients (82%) both radio logically and per operatively. HRCT scan was found to be highly sensitive (100%) in diagnosing cholesteatoma. CT scans diagnosed erosion of malleus with 100% sensitivity and specificity and erosion of incus with 91% sensitivity and 100% specificity. HRCT has a very high reliability for diagnosis of erosion of scutum, erosion of ossicles and its disruption, Pneumatization of mastoid, anterior lying sigmoid, extent of cholesteatoma in the middle ear and MAC. The study concludes that HRCT can be recommended not just for symptomatic cases but in all suspected cases in knowing the extent of the disease thereby reducing the morbidity.

Keywords: Cholesteatoma, Chronic suppurative otitis media, HRCT temporal bone, Middle ear, Otitis media, Otorrhoea investigation, HRCT unsafe ear.

Introduction

Chronic otitis media (COM) is the chronic inflammation of the lining formed by mucoperiosteum of the middle ear cleft. Overcrowding, poor socioeconomic status, illiteracy and poor hygiene are all factors, which play an essential role in this disease. The prevalence of COM is around 65 to 330 million people. Over 90% of
the burden is borne by lower socio-economic countries, India was found to have the highest prevalence (around 7.8%).

Chronic otitis media causes persistent foul-smelling ear discharge and leads to conductive hearing loss. The patient can develop intracranial and extracranial complications. Myringoplasty can be performed if there is a dry and inactive perforation for 3 to 6 months.[1]

HRCT Temporal bone is a common modality available in diagnosing and knowing the extent of the disease, and can inform the surgeon of its extent, severity, and associated pathologies. It’s fairly cheap and easily available. HRCT has proved to be better than plain CT and can visualize areas that cannot be visualized by the endoscope.

The purpose of the study is to compare the diagnostic accuracy of HRCT temporal bone in diagnosing CSOM with its severity, extent and associated pathologies in correlation with the intraoperative findings to know the diagnostic efficacy of HRCT. The study is conducted in the department of Radio-diagnosis for over a period of 2 years.[2]

Materials and Method

This present study entitled “Role of HRCT Temporal bone in diagnosis of CSOM in correlation with intraoperative findings” is a prospective study done in Meenakshi Medical College & Research Institute from February 2019 to September 2020. After obtaining approval from the ethical committee this study was done on 30 patients with CSOM. Written informed consent was obtained from patients.

Patients with complaints of pain, foul-smelling ear discharge referred from departments of Otorhinolaryngology to the Department of Radio diagnosis at Meenakshi Medical College Hospital & Research Institute and are scanned by TOSHIBA PRIME Aquilion 160 Slice Computed Tomography machine by the technique described below[3]

Technique:

- Slice thickness: 0.8 mm
- Reconstruction algorithm: high spatial frequency or “sharp” algorithm
- kV(p) 120
- mA less than 80; mAs
- Scan (rotation) time: as short as possible (e.g., 0.8 s)
- Scan mode: Spiral mode
- Contrast – None
- Inspiratory level: Not needed
- Position: Supine
- Acquisition: spaced axial imaging
- Reconstruction: Coronal and sagittal
- Window: Window Width 2000 H and Level at -700 H

The parameters compared with intra operative findings are Pneumatisation of mastoid, extent of disease, tegmen tympani erosion, sinus plate erosion, facial canal dehiscence, lateral semicircular canal dehiscence, Ossicular status, disease outside middle ear cleft.

In the current study, it is found that external auditory canal involvement is detected by HRCT in 26 cases; the intraoperative findings show EAC involvement in 26 cases. The sensitivity and positive predictive value of HRCT in diagnosing EAC involvement is 100%. Specificity – 90% and negative predictive value is also 100% (For prevalence of 33%)

In the current study, it is found that Scutum erosion is detected by HRCT in 12 cases and 18 cases are found to have normal Scutum. The intraoperative findings show Scutum involvement is seen in 10 cases and 20 cases are found to have normal Scutum. The sensitivity of HRCT in diagnosing Scutum involvement is 96%, specificity is 80% with a positive predictive value of 96% (For prevalence of 83%). However, 2 cases (6%) show the false-positive result in HRCT.

</tbody>
</table>

In the current study, Ossicular involvement is detected by CT and are categorized into mild and severe erosions based on number and parts of ossicles involved

In current HRCT study, 11 cases have normal ossicles, 10 cases have mild Ossicular erosions (with the sensitivity of 100% and positive predictive value of 100%) and 9 cases have severe Ossicular erosions. Intraoperatively it is found 12 cases have normal ossicles, 10 cases have mild erosion and 8 cases have severe erosions (with the sensitivity of 100% and positive predictive value of 100%), however, there is one false positive in detecting severe erosion.

In current study it is found that for prevalence of 17%, the sensitivity is 100%, specificity is 100%, PPV is 100% and negative predictive value is 100%. HRCT detected facial canal involvement in 5 cases and 25 cases were found to be normal. Intraoperatively 5 cases had facial canal involvement and 25 cases were found to be normal. HRCT detects facial canal involvement with 100% sensitivity and with 100% positive predictive value.

In current study it is found that for prevalence of 6.7%, the sensitivity is 100%, specificity is 100%, PPV is 100% and negative predictive value is 100%. HRCT detected lateral semicircular canal involvement in 2 cases and 28 cases were found to be normal. Intraoperatively 2 cases had facial canal involvement and 28 cases were found to be normal. HRCT detects lateral semicircular canal involvement with 100% sensitivity and 100% positive predictive value.

Discussion

In this study, a total number of 30 patients were selected randomly. The maximum number of patients were in the 21-30 age group (3rd decade of life) this is in consistence with Gerami et al (2009) [3] claims that average age of CSOM is 35.1 years. There is more variation in children. The gender radio was which is 1:0.6. More than 90 % patients belonged to low socioeconomic status. Lack of hygiene is one of the causes for CSOM. Left side (54 %) is affected more than the right side (46%). From the clinical data obtained from the Department of Otorhinolaryngology, 64 % of patients had AAD and the remaining 36 % had TTD. Mastoid was found to be well pneumatized (normal) in 9% cases, 43% cases had soft tissue density lesion in CT (suggestive active infection) and 48 % patients had sclerosed mastoid with improper pneumatization. In the case of Mastoid air cells, HRCT has 100% sensitivity and specificity was 66.7% which is similar to Gerami H et al (2009) [3]. HRCT is 100% sensitive and 66.7% specific in detecting soft tissue density lesions. However, HRCT is less sensitive in differentiating cholesteatoma from a granulation tissue for which MRI has a better diagnostic role. There is 100 % sensitivity in detecting cholesteatoma in Prussacs space, this is in consistence with Ranga Reddy Siliguri et al (2011) [4] but there is 90% specificity which is slightly higher than the study conducted by Ranga Reddy Siliguri et al (2011) [4]. Bony erosion is diagnosed by HRCT in the presence of cholesteatoma in 100% cases this is in consistence with Jacker et al (1984) [5] who found 98 % in their cases. HRCT detected ossicle erosion in all cases, there is usually some degree of subjective variation when reporting the grade of ossicular erosion, however, irrespectively of grading, cases reported to have any degree ossicular erosion had erosions intraoperatively. This is in consistence with Zhang X et al (2004) [6] and Chee NW et al (2001) [7]. In this study, there was facial canal involvement in 5 cases, with a sensitivity of intraoperatively of 100 % which is similar to the result obtained by Firas Q Alzoubi et al (2008) [8] and Chee NW et al (2001) [7]. RCT for Lateral semicircular canal involvement in 2 cases and 28 were found to have normal lateral semicircular canal with 100% sensitive and 100% specificity. Similar results were found by Firas Q Alzoubi et al. (2008) [8] and Gyanu et al [9]. HRCT was found to be fairly sensitive in detecting Tegmen erosion which agrees with results by Jackler RK (1984) [3] and Gerami H et al. (2009) [3]

Conclusion

HRCT has a very high reliability for diagnosis of erosion of scutum, erosion of ossicles and its disruption, Pneumatization of mastoid, anterior lying sigmoid, extent of cholesteatoma in the middle ear and MAC, It also helps in detecting presence of complications like mastoiditis, abscess, dehiscence of mastoid cortex, erosion of sigmoid plate, facial canal dehiscence, labyrinthine fistula and intracranial complications. COM can at times be life-threatening when it’s associated with intracranial complications that warrant the ENT surgeons to be familiar with standard approaches in surgeries. The use of HRCT and advances in radiological imaging had improved the study of the temporal bone in cases of CSOM in diagnosing the disease, knowing its extent and associations, anatomical and neurological structure involved. Therefore the study
concludes that HRCT can be recommended not just for symptomatic cases but in all suspected cases in knowing the extent of the disease thereby reducing the morbidity.

Diffuse Neurofibroma of Face: A Rare Case Report

Selva Ganesh S.

Assistant Professor, Department of Oral Pathology and Microbiology, Faculty of Dentistry, Meenakshi Academy of Higher Education and Research, Meenakshi Ammal Dental College and Hospital, Chennai, India

Abstract

A case of a 17-year old male who presented with a chief complaint of unesthetic facial appearance due to malformed nose from the time of birth with a history of surgical correction for nasal deformity at the age of 11 years. Microscopy revealed a diagnosis of diffuse neurofibroma with areas showing nerve fibers with wavy nuclei.

Keywords: Unaesthetic face, diffuse neurofibroma, case report.

Introduction

Neurofibromas generally assume three growth patterns: localized, diffuse, or plexiform. Diffuse neurofibroma is not a common variant of neurofibroma, children and young adults being most commonly affected, head and neck being the common sites of involvement. Upon histological examination it appears similar to conventional neurofibromas except for a few unique features. We report a case of a 17-year old male who presented with a chief complaint of unesthetic facial appearance due to malformed nose from the time of birth this case is reported here because of its unique and rare nature.

Case Report: A 17-year-old boy presented with a chief complaint of unesthetic facial appearance with malformed nose from birth along with swelling of right cheek region. The malformation and swelling was initially small and has attained the current size in a gradual manner. Patient has congenital loss of eye which was treated when the patient was 10 years old. From birth the nose had three nostrils. History of surgical correction for nasal deformity at the age of 11 years but no record of previous surgery was available with patient. Post auricular cartilage was taken for nasal reconstruction.

On clinical examination bifid right nostril and presence of left eye prosthesis was seen. Diffuse swelling of right infraorbital region measuring upto 7 × 3 × 5 cm. Swelling was soft in consistency. Scar on right cheek and scar on the midline of nose was noticed (figure 1). The swelling involved only the skin and underlying bone appeared normal upon palpation. No café-au-lait macules, lisch nodules or freckles were seen anywhere in the body.

e-mail: drselva.oralpathology@madch.edu.in

Fig. 1: Diffuse swelling of right infra-orbital region, bifid right nostril and scar on right cheek and scar on the midline of nose.
No abnormalities were detected in OPG and CT except for nasal polyp. An incisional biopsy was planned and during surgery some cystic fluid or pus discharge from perialar region was observed. Provisional diagnosis of neurofibroma was given by the surgeon. The tissue submitted for biopsy was greyish yellow soft tissue specimen measuring about approximately (15x32x35) mm3 (figure 2). The tissue was grossed into three bits, each of the cut surface exhibited solid gray white areas intermixed with gelatinous areas (figure 3).

The microscopic examination revealed a soft tissue section showing loosely arranged fibrocollagenous tissue with areas showing nerve fibers with wavy nuclei and arranged in fasicles in varying sizes and shapes. These nerve fibers were also seen spread in between the muscle fibers in many areas(figure 4). Less cellular hyalized regions made up of thin, wispy and loosely arranged cells separated from each other with few microcystic spaces resembling areas known as Antoni B regions were seen (Figure5). Chronic inflammatory cell infiltrate consisting of lymphocytes, plasma cells and predominantly mast cells were seen with adipocytes and ecstatic vessels. A cystic space lined by epidermis made up of keratinized stratified squamous epithelium in varying thickness with numerous sebaceous glands and other skin adnexal structures like hair follicles and sweat glands were noticed (Figure 6).
Fig. 6H&E section under 4x view showing cystic space lined by epidermis made up of keratinized stratified squamous epithelium in varying thickness with numerous sebaceous glands and other skin adnexal structures

Discussion

A benign peripheral nerve sheath tumor arising from a mixture of Schwann cells and perineural fibroblasts is called neurofibroma. It can be present either as a solitary lesion or can be associated with neurofibromatosis. According to their growth pattern they can be classified into localized, diffuse, or plexiform.

Diffuse neurofibromas are not common but distinctive type of neurofibroma that is recognized as a separate entity from 1997. It mostly involves the skin and the subcutaneous tissues occurring primarily in 10th and 30th decade of life in either sex. They have a slight predilection for trunk, head and neck and the limbs and may become very large as seen in our case. More than 90% of diffuse neurofibromas are isolated lesions and about 10% are associated with neurofibromatosis type 1. Diffuse neurofibromas are poorly circumscribed non-encapsulated tumors and typically involve the subcutaneous tissue down to the level of the fascia. As seen in our case the diffuse variant is usually ill-defined and infiltrate the dermis and connective tissue sparing the skin appendages.

Except for nasal polyp there were no abnormalities seen in our case but generally diffuse neurofibromas erode through the skeletal structures and shows an intracranial extension. These bone deformities can be seen on OPG or computed tomography scans. The characteristic MR pattern of a diffuse neurofibroma is linear or reticular strands of intermediate signal intensity in the subcutaneous fat, which indicates infiltration of the tumor components of neurofibromatous tissue, interposed collagen, and ectatic vessels.

Although benign, these tumors are prone to significant neovascularisation. Troublesome hemorrhage often occurs during the excision of the neurofibromatous tissue which did not happen in the present case. Hypotensive anesthesia has proven to be effective in decreasing intraoperative bleeding. Because the vessels in tumor or skin lesions are abnormal, incisions must be made on normal skin if possible, which provides better bleeding control.

Histologically, it is characterized by a diffuse replacement of the dermis and subcutis by interlacing bundles of spindle-shaped cells with round or fusiform buckled nuclei and eosinophilic cytoplasm within a loose matrix of fine fibrillary collagen, such wavy nuclei of nerve fibers were seen in this case. Though it is infiltrative there is no destruction that will be evident in this histological type instead it envelopes the structures like skin adnexal structures, adipose tissue and muscle fibers. Meissner’s bodies are characteristic feature of diffuse neurofibroma but rarely they can be absent as reported in this case.

Surgical excision of the tumor is planned only when the functional need is compromised but complete removal is rarely achieved because of the extensive nature and multi centricity of the tumor. Radical surgery is reserved for instances of malignant transformations. However, malignant transformation rarely occurs in the diffuse neurofibroma.

Conclusion

Care must be given during examination and diagnosis of solitary diffuse neurofibroma. Depending on the site of involvement preoperative angiogram is preferred to avoid troublesome hemorrhage during excision. A yearly follow-up of the case is recommended as there is possibility of the potential development of neurofibromatosis and recurrence of the lesion though the malignant transformation is rare.

Augmentation of Interdental Papilla with Advanced Platelet Rich Fibrin: A Case Report

C. Burnice Nalina Kumari¹, Shalini Arumugam¹, Vijayalakshmi Rajaram¹

¹Department of Periodontology and Implantology, Faculty of Dentistry, Meenakshi Academy of Higher Education and Research, Chennai, Tamilnadu, India

Abstract

Esthetics in dentistry is of great concern for dental professionals as well as patients for the maintenance of oral health. The key esthetic component is the black triangle which is the presence of lost interdental papilla between the maxillary anterior teeth. The most common problems associated with black’s triangle are phonetics, impaction of food and esthetic problems. Because of patient concern on esthetics, papilla reconstruction techniques is employed to regenerate the lost papillary tissues. Advanced platelet rich fibrin which are rich in platelets and growth factors allows predictable regeneration due to its advanced properties. This case report aims at evaluating the augmentation of interdental papilla along with A-Platelet rich fibrin.

Keywords: Esthetics, black’s triangle, interdental papilla, A-platelet rich fibrin.

Introduction

Dental Esthetics is a great concern for dental professionals and for the patients as well. The presence of interproximal papillae between the maxillary anterior teeth is the key component for an esthetic smile. Hence the loss of interdental papillae or tissues is known as the black triangle. Unaesthetic smile, phonetic problems and impaction of food are the most common difficulties associated with black’s triangle¹¹.

There are various treatment modalities for the reconstruction of the lost interdental papilla. Non-surgical treatment options comprise of repeated curettage, orthodontic treatment and restorative techniques for reconstructing the interdental papilla²³. Surgical techniques aim in the correction the lost interdental papilla which are the repeated interproximal curettage, free epithelialized gingival grafts, developmental of interproximal tissue in the buccal direction, and connective tissue graft⁴.

The various surgical procedures for papilla reconstruction techniques are technique sensitive because of the compromised vascular supply in the interdental space. The periodontal surgical procedures included Beagle’s pedicle graft procedure (Beagle, 1992), Han and Takei’s semilunar technique in 1996, Cortellini et al’s simplified papilla preservation flap (Cortellini, Prato, & Tonetti, 1995). The surgical procedures are successful when it is combined with or without regenerative materials. One among the most popular regenerative material used these days is the platelet concentrates. Advanced platelet rich fibrin when used as the regenerative material with its superior mechanical properties enhances periodontal regeneration in interdental papilla⁵. This shows the case report where A-Platelet rich fibrin was used to augment the interdental papilla inbetween 11 and 12 region.

Clinical Presentation: A systemically healthy 33 year old female patient reported to the Department of Periodontology with a chief complaint of unaesthetic smile in relation to the right upper front tooth region for the past two months. On intra-oral examination, an
isolated Norland’s class 2 interdental papilla loss was present in between 11 and 12 other clinical findings showed the healthy gingiva. The treatment was planned and a written informed consent was obtained from the patient.

Case Management: In the phase 1 therapy the scaling and root planning was done. Patient was reviewed after two weeks prior to the surgical procedure. [Fig 1].

A-PRF was prepared using the following protocol. 5ml of whole venous blood was collected in two sterile vacutainer tubes each and these tubes were centrifuged at 3000 revolutions per minute(rpm) for 10 minutes. Following this, the blood in the tubes settled into the three different layers: the lower-most fraction containing the red blood cells, the middle portion containing the fibrin clot and upper-most layer comprising of the acellular plasma fraction. Hence the platelet rich fibrin was procured by separating the middle layer from the centrifuged blood which was 2mm below the lower dividing line in the sterile tube and the A-PRF was ready to be placed on the surgical site. [Fig 2].

The defect sites was anesthetized using 2% lidocaine along with 1:100,000 epinephrine in relation to 11,12. A semilunar incision of 3-4mm was given with tunnel blade (0.2mm), 2mm coronal to the mucogingival junction and just above the papillary region and a crevicular incision was given over the teeth neighboring the defect and extending from the buccal aspect to the palatal aspect keeping the existing papilla intact and preserved. [Fig 3,4].

A Pouch was created at the apical aspect to the base of interdental papilla of 11 and 12. The preparation of A-PRF was done in accordance to the choukron’s protocol. A-PRF was trimmed to get the desired size and then tucked and placed beneath the recipient site with the help of 5-0 vicryl sutures. [Fig 5]
Periodontal dressing was placed over the surgical area. Patient was advised analgesics and antibiotics for 5 days along with 0.12% chlorhexidine digluconate two times a day for 2 weeks along with other post operation instructions.

The patient was asked to report after 24hrs and assessed for any post operative complications or discomfort. After 2 weeks the patient was recalled, the periodontal dressing was removed and healing was assessed at 3 and 6 months period post-operatively. After 6 months, post-operative photograph has been taken where the patient was satisfied for that esthetic outcome. [Fig 6].

Discussion

Loss of Interdental papilla is one of the troubling dilemmas in dentistry, posing the patients to functional, phonetic and esthetic problems. Various surgical and non-surgical techniques are proposed for the augmentation of the lost interdental papilla. But most of the surgical procedures fail to achieve long term stability because of the minor blood supply to the interdental papilla[6].

Both surgical and non-surgical treatment modalities are used to reconstruct the lost interdental papilla. Surgical techniques aim in the correction the lost interdental papilla which are the repeated interproximal curettage, free epithelialized gingival grafts, developmental of interproximal tissue in the buccal direction, and connective tissue graft[7].

In this study, A-PRF was used for the augmentation of the lost interdental papilla. A-PRF contains growth factors intracellularly which comprises of platelet-derived growth factors, transforming growth factor beta and insulin like growth factor-1[5]. All these factors release slowly from the fibrin matrix and aid in the healing of the surgical site. A-PRF along with other alloplastic materials like putty alloplastic material are used as new innovative minimally invasive method for management of intrabony defects with no post-operative complications that arises with conventional flap surgery. A-PRF has an advantage over connective tissue graft which is easy to procure, better healing of surgical site, no second surgical site required and is less expensive[8].

Thus stable results are achieved with this technique along with A-PRF in our study. There was a complete reconstruction of papilla at 3 months and 6 months and the results were achieved.

The interdental papilla is scalloped and delicate. There is limited access to the interdental papilla, microsurgical instruments and surgical magnification benefits the surgeon by increasing visibility, facilitating access to the interdental papilla and eliminating unnecessary releasing incisions. Use of microsurgical instrumentation allowed the surgeon to elevate the flap atraumatically and avoiding vertical incisions, thus maintaining the blood supply to the surgical area[9,10].

Conclusion

Loss of interdental papilla its augmentation using A-PRF was completely achieved when reviewed at 3 and 6 months postoperatively. Thus the use of A-PRF gives a predictable and successful result in the reconstruction of the lost interdental papilla. The A-PRF membrane placement in the present case report seems to be effective, innovative, and more predictable method in treating isolated lost interdental papilla.

Dengue Fever among Rural Population

B. Lavanya¹, Mary Sophiya², Fabiola M. Dhanaraj³

¹Clinical Instructor, ²Associate Prof., ³Principal, Arulmigu Meenakshi College of Nursing, Meenakshi Academy of Higher Education and Research Institute, India

Abstract

Background: Dengue fever is a viral illness commonly caused by Flavivirus. Dengue becomes the most common public health issue in India because the incidence of dengue fever is high all over the world. In Tamil Nadu, the existence of all the four serotypes of the dengue virus was proved during the several outbreaks of dengue fever earlier and the reported seasonal changes especially Rainfall influencing the several crucial issues of people.

Objectives: Assess the knowledge regarding dengue fever, and associate the level of knowledge with selected demographic variables.

Method: A quantitative approach and a descriptive research design for 100 samples by non-probability convenient sampling technique were used. Results: The results revealed that 10.0% of people were with inadequate knowledge of dengue fever, 58.0% of people have moderately adequate knowledge, and 32.0% of people had adequate knowledge.

Conclusion: Only a moderate level of people has adequate knowledge about dengue fever and seeks prevention.

Keywords: Assess, Knowledge, Dengue Fever, Rural Population.

Introduction

Dengue is caused by a flavivirus, It can be affected by the infected mosquito bites of anyone. Dengue is spread by a female mosquito is called Aedes aegypti which bites during the early morning and evening before dusk. It is more common in wet and warm areas.

Dengue cases increase during the beginning of the rainy season, the common symptoms of dengue is high fever, headache, joint pain, muscle pain, vomiting, and rash, most people with dengue recover within two weeks or sometimes progresses into dengue hemorrhagic fever. Dengue is the most life-threatening condition in the pediatric population and is highly susceptible to complications and deterioration. The fever can occur rapidly and the ability to recognize early warning signs is crucial. Approximately, 50-100 million people are affected by dengue worldwide annually, 1000-20000 people died annually because of dengue.[6,7]

Dengue hemorrhagic fever it’s a serious condition that will cause severe bleeding and a person will be going into the stage of Hypovolemic shock. Commonly infants, pregnant women, and older adults are at risk of developing Dengue hemorrhagic fever[1].

Nevertheless, health is a fundamental human right of all mankind. All over the world, health care settings are striving to expand their health care service to overcome the continuous threat from the emergence and resurgence of vector burn disease[2].

In America, 1, 346,991 dengue cases have been reported between the year January 2019 to March
2020 and 1,530 peoples died in the same year. In India, 69,393 cases were reported in the year 2019 — 2020, and 124 deaths. Finally, in Tamil Nadu, 2,951 patients who had dengue fever have been treated. From this year beginning the number of dengue cases was reported in the highest numbers in Chennai, 3,034 people in Tamil Nadu has been tested positive for dengue of which the highest incidence of 543 cases was reported by Chennai till October 8th, 2019. [3,4]

Among the vector-borne disease, dengue is the major public issue in Tamil Nadu because nowadays cases are slightly increasing. Health care workers are also feeling difficulty in finding the cases during this COVID 19 crisis with symptoms as the cases are overlapping and there is a high risk of the wrong diagnosis. The main aim of the study is to assess the knowledge regarding dengue fever among rural people and their ability in recognizing life-threatening signs and symptoms of dengue [5].

**Methodology**

The quantitative approach was adopted for the study. A descriptive research design was adopted for the study; The study was conducted at Villapakkam among the rural population with 100 samples who fulfilled the inclusion criteria. The study adopted a convenient sampling technique. The demographic variable and modified self-structured tool were used to collect the data for the study. Getting permission and informed consent was obtained. Data were collected, organized, analyzed, and tabulated by descriptive and inferential statistics.

**Results**

The study findings show that the percentage of the knowledge level of dengue fever among 10% of people was inadequate knowledge, 58.0% were the moderately adequate level of knowledge and 32% of them were having an adequate level of knowledge about dengue fever.

The analysis depicted that rural people are having more knowledge scores regarding dengue fever (95.0%) and a minimum score of 11.0% regarding the drugs used to avoid dengue fever. In the association between the level of knowledge score and people with demographic variables, younger males are more knowledgeable scores than the other groups which were statistically significant calculated using the chi-square test. (P=41.0f).
Further, in the association between the level of knowledge score and educational status, it is found that 26.5% of the rural people with high school education have good knowledge, and 64.4% of the rural people hailing from nuclear family has average knowledge regarding dengue fever which was statistically significant. (P=0.05).

**Discussion**

Based on the objectives of the research, the dengue fever knowledge among the rural populations in the community is discussed objective wise. The first objective was to assess the knowledge regarding dengue fever, the result revealed that their knowledge score about dengue fever is good (95.5%) and the minimum
score regarding avoidance of drugs during dengue fever (11.0%). The second objective was to associate the level of knowledge with selected demographic variables, reveals the association between the level of knowledge score and the demographic variables. The younger age groups are having more knowledge (45.9%) and joint family people are having more knowledge scores (41.1%) than others, whereas, 64.4% of the rural people hailing from nuclear families have average knowledge regarding dengue fever which was statistically significant. Age group more than 60 are having poor knowledge. Dengue is a major health burden in India. Annually the number of dengue cases is increasing.

The Government has taken some steps to overcome the COVID 19 crisis. The seasonal epidemic of dengue is started now in Chennai and in some of the areas, there are complaints of the mosquito menace escalating. Therefore, the city corporation has transferred all domestic breeding checkers from COVID 19 duty to vector control work and conducting the fever camps. The government also is creating awareness and taking steps to control breeding. The health care professionals also playing a vital role in taking some precautionary measures to control the spread of dengue making sure that water stagnation is not allowed anywhere.

Emmanuelle Kumaran (2018) conducted a study to assess the knowledge, attitude, and behavior of dengue fever among the rural people in the selected community area the study revealed that the knowledge on dengue fever symptoms, transmission, and prevention method was high. (96.7%) of people were able to identify mosquitoes as being the dengue vector. Most of the people were able to identify the biting time of dengue mosquito’s, although, 17.8% of participants were having knowledge on dengue causing mosquitoes to bite the person at night time. (95.5%) of peoples were have adequate knowledge about least breeding sites of dengue mosquito.

**Conclusion**

Dengue fever is a disease that can take a toll on people if they are not educated. This study has proved that rural people need to be educated to prevent dengue. Serious steps have to be taken by the Government on taking preventive measures programs in the rural areas as the major it y of the population of India is in the rural areas.

Conjoined Twin: Review with a Case Report

Hara Prasad Pattanaik1, Sasmita Parida2, Mrutyunjay Mohapatra3

1Consultant Gynaecologist & Obstetrician, Cuttack, Odisha, 2Prof & HOD, Department O Radio Diagnosis, SCB Medical College, Cuttack, Odisha, 3Consultant Gynaecologist & Obstetrician, Cuttack, Odisha

Abstract

Conjoined twins are suggested to result from aberrant embryogenesis. The two main theories proposed to explain the phenomena are fission and fusion. The incidence rate is 1 in 50,000 births; however, since about 60% of the cases are stillborn, the true incidence is approximated at 1 in 200,000. There is a higher predisposition towards female than male gender with a ratio of 3:1. Conjoined twins are classified based upon the site of attachment. The extent of organ sharing, especially the heart, determines the possibility and prognosis of a separation procedure. Meticulous preoperative evaluation, planning, and preparedness of the team are crucial for a successful separation. Separation of conjoined twins poses several technical, legal, and ethical issues. With the aid of diagnostic imaging techniques, such as ultrasonography (US) and three-dimensional magnetic resonance imaging (3D-MRI), physicians are able to make prenatal diagnoses.

Keywords: Conjoined twins, cephalopagus, Monozygotic, Prenatal diagnosis, Surgical separation

Introduction

This is a 22 years PRIMIGRAVIDA with four months of amenorrhea attended Gynaecology OPD of city hospital, Cuttack for her routine pregnancy check up. She was married for last 6 months and was only taking folic acid after her urine examination revealed beta grav index positive. No history of taking any other medicines. Family history was not suggestive of any multiple pregnancy. On General examination all parameters were normal. All systemic examination was also normal. Obstetric examination revealed 16 weeks size Uterus with external ballotment positive. She was advised to do all blood investigations and USG to confirm the period of gestation as well as to rule out any congenital anomaly1,2.

USG Report Revealed: Conjoined twin with one head (cephalopagus), two bodies joined anteriorly with two pairs of upper limbs and two pairs of lower limbs and single placenta.

Patient was explained fully about the prognosis. She wanted termination of pregnancy. She was admitted to the City Hospital O&G ward and termination was done with Misoprostol (200mg), 2 tabs 6 hourly3.

Discussion

Conjoined twins are identical twins joined in utero. An extremely rare phenomenon, the occurrence is estimated to range from 1 in 49,000 births to 1 in 189,000 births, with a somewhat higher incidence in Southeast Asia, Africa and Brazil. Approximately half are stillborn, and an additional one-third die within 24 hours. Most live births are female, with a ratio of 3:1. Most stillborns are male4,5.

Two contradicting theories exist to explain the origins of conjoined twins. The more generally accepted theory is FISSION, in which the fertilized egg splits partially. The other theory, no longer believed to be the basis of conjoined twinning, is FUSION, in which a fertilized egg completely separates, but stem cells (which search for similar cells) find like-stem cells on the other twin and fuse the twins together. Conjoined twins share a single common chorion, placenta, and amniotic sac, although these characteristics are not exclusive to conjoined twins as there are some monozygotic but non-conjoined twins that also share these structures in utero6,7.

Types of conjoined twins: Conjoined twins are typically classified by the point at which their bodies are joined. The most common types of conjoined twins are:

- **Thoraco-omphalopagus** (28% of cases): Two bodies fused from the upper chest to the lower chest. These twins usually share a heart, and may also share the liver or part of the digestive system.

- **Thoracopagus** (18.5%): Two bodies fused from the upper thorax to lower belly. The heart is always involved in these cases. As of 2015, separation of a genuinely shared heart has not offered survival to two twins; a designated twin may survive if allotted the heart, sacrificing the other twin.

- **Omphalopagus** (10%): Two bodies fused at the lower abdomen. Unlike thoracopagus, the heart is never involved in these cases; however, the twins often share a liver, digestive system, diaphragm and other organs.

- **Parasitic twins** (10%): Twins that are asymmetrically conjoined, resulting in one twin that is small, less formed, and dependent on the larger twin for survival.

- **Craniopagus** (6%): Fused skulls, but separate bodies. These twins can be conjoined at the back of the head, the front of the head, or the side of the head, but not on the face or the base of the skull.

Other less-common types of conjoined twins include:

**Picture 1: Foetus and the placenta.**
• **Cephalopagus**: Two faces on opposite sides of a single, conjoined head; the upper portion of the body is fused while the bottom portions are separate. These twins generally cannot survive due to severe malformations of the brain. Also known as janiceps (after the two-faced god Janus) or syncephalus.

• **Syncephalus**: One head with a single face but four ears, and two bodies.

• **Cephalothoracopagus**: Bodies fused in the head and thorax. In this type of twins, there are two faces facing in opposite directions, or sometimes a single face and an enlarged skull.

• **Xiphopagus**: Two bodies fused in the xiphoid cartilage, which is approximately from the navel to the lower breastbone. These twins almost never share any vital organs, with the exception of the liver. A famous example is Chang and Eng Bunker.

• **Ischiopagus**: Fused lower half of the two bodies, with spines conjoined end-to-end at a 180° angle. These twins have four arms; two, three or four legs; and typically one external set of genitalia and anus.

![Picture 2: Types of Conjunctions](image)
**Picture 3: Siamese Twins**

- **Omphalo-Ischiopagus**: Fused in a similar fashion as ischiopagus twins, but facing each other with a joined abdomen akin to omphalopagus. These twins have four arms, and two, three, or four legs.

- **Parapagus**: Fused side-by-side with a shared pelvis. Twins that are **dithoracic parapagus** are fused at the abdomen and pelvis, but not the thorax. Twins that are **diprosopic parapagus** have one trunk and two faces. Twins that are **diecephalic parapagus** have one trunk and two heads, and have two (dibrachius), three (tribrachius), or four (tetrabrachius) arms.

- **Craniopagus parasiticus**: Like craniopagus, but with a second bodiless head attached to the dominant head.

- **Pygopagus (Iliopagus)**: Two bodies joined at the pelvis.

- **Rachipagus**: Twins joined along the dorsal aspect (back) of their bodies, with fusion of the vertebral arches and the soft tissue from the head to the buttocks.

The most famous pair of conjoined twins was Chang and Eng Bunker (1811–1874), Thai brothers born in Siam, now Thailand. They travelled with P.T. Barnum’s circus for many years and were labeled as the **Siamese Twins**. Chang and Eng were joined by a band of flesh, cartilage, and their fused livers at the torso. In modern times, they could have been easily separated. Due to the brothers’ fame and the rarity of the condition, the term “Siamese twins” came to be used as a synonym for conjoined twins.

### Conclusion

Conjoined twins arise from abnormal embryogenesis. There have been many well-observed cases of conjoined twins throughout history, as well as attempts of separation. While separation is normally opted for, there have also been many examples of unseparated conjoined twins leading fulfilling lives. Conjoined twins are classified based on the attachment site. This, as well as the extent of attachment, determines their prognosis. Due to the near infinite variations in conjoined twins, the outcome is highly case-specific. Prenatal diagnosis is possible using ultrasound, MRI, and CT, and can be performed as early as 12 weeks of gestation. Due to the presence of several congenital anomalies associated with conjoined twins, preoperative, intraoperative, and postoperative management is essential to improve prognosis. Cardiovascular and respiratory failures are the two major risk factors for death of the twins postseparation. There are many ethical challenges associated with treating conjoined twins, such as difficult decisions regarding early termination and determining the individuality of each twin.

Cesarean Section in Low Birth Weight Babies: An Original Research

Hara Prasad Pattanaik1, Mrutyunjay Mohapatra1, Sasmita Parida2

1Consultant Gynecologist & Obstetrician, Cuttack, Odisha,
3Prof & HOD, Department o Radiodiagnosis, SCB Medical college, Cuttack, Odisha

Abstract
The high prevalence of high-risk pregnancies, which can lead to premature delivery, contributes to an increase in the rates of preterm and low-birth weight (LBW) infants, with an increase in the number of cesarean deliveries. This study was done to access maternal variables and their associations with cesarean deliveries of LBW newborns. A retrospective study was conducted by reviewing the medical records of pregnant women who underwent cesarean sections for the delivery of LBW infants (weight, ≥1500 and 35 weeks at delivery, and 50.8% attended less than eight prenatal consultations. Hypertensive syndrome (23.8%) was the main indication for cesarean delivery. Among the newborns, 58.3% had an Apgar score of 7 in the first minute of life, 79.3% had a score of 9 in the fifth minute of life, and 54.3% were females. Conclusions: Several maternal variables such as primiparity, education level, number of prenatal consultations, and presence of maternal hypertensive syndrome had a statistically significant association with the occurrence of cesarean sections for the delivery of LBW infants.

Keywords: High-Risk Pregnancy; Cesarean Section; Low-Birth Weight Newborns; Prenatal Care; Gestational Age; Hypertensive Syndrome.

Introduction
In a developing country like ours the increased incidence of low birth weight babies either due to preterm delivery or IUGR is a major problem so far as perinatal outcome is concerned. The proven contention over the last few years that rise in the rate of caesarean section has dramatically reduced the perinatal mortality and morbidity to a significant extent. Though it is difficult to prove the causal relationship between these two events, the consensus of opinion about recognition of the foetus in utero as a second patient and its right for survival beginning from the time of fertilisation has revolutionized the approach for the appropriate mode of termination when one considers quality maternity and child health services in the present day obstetric practice. Though birth weight is one of the most important considerations regarding the mode of delivery, in broader perspective, the Obstetrician encounters two main Intricate aspects while encountering cases of low birth weight; preterm and growth retarded. Apart from the fact that Improved neonatal care in the present era has revolutionized the management of these groups. Regarding birth weight, the World Health Organization (WHO) defines NBs with low birth weight (LBW) as those with birth weight of <2500g and ≥1500g, regardless of gestational age (GA). Birth weight is the factor that most influences infant survival, and because it represents only one final measurement, anticipating its diagnosis can contribute to decreased morbidity and mortality.

In these High risk pregnancies, still the decision of the gynecologist in regards to the mode of delivery is of vital concern which affects the perinatal outcome to a great extent. Epidemiological studies revealed that LBW is a risk factor for increased neonatal morbidity and mortality and for the later development of obesity, diabetes mellitus, and particularly cardiovascular illnesses.
On the other hand, the management of growth retarded babies in utero is also very delicate as the correct formulation of the route of delivery is an essential prerequisite for subsequent intensive care reflecting in increase in both short term and long term survival. Viewed in these controversial contexts in mind this piece of work has been undertaken in the department of Obstetrics and Gynaecology where various perinatal factors in the low birth weight babies delivered by caesarean section are correlated with a control group of low birth weight babies born via natural is in order to find out the positive value of mode of delivery to an optimum perinatal outcome.

The present study was carried out in the Department of Obstetrics and Gynaecology of S.C.,B. Medical College, Cuttack in Pregnant mothers having low birth weight babies (weighing less than 2500g) were scrutinized from amongst antenatal diagnosis. A sum total of two hundred cases of pregnancies having low birth weight babies undergoing caesarean section served as study series where as hundred cases, having low birth weight babies delivering vaginally which were selected at random, taken as control group. Exclusion criteria in our study include Multifoetal pregnancy and Intra uterine deaths. A detailed history of the patients with special reference to age, parity, socio-economic status, present obstetric and medical complications were taken. An effort was made to ascertain the gestational age with accuracy as far as possible. Thorough intrapartum events were looked into and a meticulous search was made as regards the neonatal outcome with reference to details of morbidity as well as mortality pattern; so as to have a positive correlation with the study as well as control group in order to find out the role of caesarean section in low birth weight babies.

This study was made on the role of caesarean section in 200 cases of low birth weight babies and were compared to 100 vaginal deliveries as control in closely matched birth aspects.

**Results**

The following Observations were made on various weights of cases and controls.

Highest number of low birth weight caesarean sections has occurred in 21-25 years age group. In vaginal delivery cases it was also highest (51%). Highest number of low birth weight deliveries is in low socio-economic status (68% in both). We have taken monthly income of less than Rs.1000.00 as low, Rs.1000-3000/- as middle and more than Rs. 3000.00 per month as upper socio-economic group. 61% of low birth weight caesarean cases were unbooked compared to 47% of low birth weight vaginal deliveries. Conversely only 39% of study were booked compared to 53% of controls.

Both in study and control series highest number of low birth weight deliveries took place in primi (49.5% and 50% respectively). Highest number of deliveries took place in the gestational age group of 37-38 weeks both in study and control series (33% and 28% respectively) followed closely by the gestational age of 35-36 weeks. In the gestational age of 29-34 weeks 19% and 21% deliveries took places in each group respectively (14 in 29-30 weeks 3.5% in 31-32 weeks and 14.5% in 33-34 weeks gestational in study group and 3%, 4% and 14% in control group respectively).

This study shows relevant maternal complications during Pregnancy in both groups. Maternal complications were not detected in 77.5% case in caesarean group and 71% in vaginal delivery group. Pregnancy induced hypertension contributed to 10.5% and 12% respectively in study and control group and antepartum haemorrhage was found in 7% and 8% respectively. Among the maternal indications placenta praevia topped the list (16.5%) with premature rupture of membrane (14.5%), PET/Eclampsia (10.5%) following it. Among foetal indications foetal distress (27%) was the commonest followed by IUGR (3.5%) and breech’ presentation (13%) of cases.

In many cases operation has been done for more than one indication. 79% had spountaneous onset of labour where as 21% cases were induced. 29 cases had normal deliveries, 41 cases had episiotomy. Forceps was applied in 22 cases and 8 cases had Assisted breech delivery. This study shows distribution of cases in different birth weight group of newborn infants. In study group highest number of infants (48.5%) were delivered with birth-weight of 2000-2249 grams. Similarly in vaginal delivery group 37(37%) infants were in same birth weight group. In the study group 50% of infants had no morbidity. In the rest Asphyxia was found in 43% and hypothermia in 31.5% of infants. In the vaginal delivery group 35.3% of babies had no morbidity while 43.7% suffered from asphyxia and 31.7% from hypothermia.
Discussion

The present study comprised of two hundred cases of low birth weight babies delivered by caesarean section while one hundred cases of low birth weight babies born via naturalis served as control.

The cases were selected from amongst the emergency and booked admissions to the department. We excluded the cases having multifetal pregnancy and intrauterine foetal death. Relevant history noted and thorough examination done. Nature of deliveries were studied in these low birth weight cases. On delivery the babies were resuscitated and Apgar score at birth & after 5 minutes were noted. The neonatal mortality and morbidity pattern compared.

Out of a sum total of 918 caesarean sections during the study period there were 200 cases of low birth weight babies, the incidence being 21.8% (Hospital data), the figure close to that reported by Rege et al (1987) (27%).

Analysis of age distribution of cases both in the study as well as control series (Table-I) closely demonstrates an almost similar percentage of cases in each age group, where maximum number of cases are observed between the age range 21-25 years (50% and 51% in study and control respectively). This is a justifiable fact because second and third decade of life is the period of maximum reproductive potential and hence present to the institution more commonly for their confinements. The frequency of occurrence of low birth weight babies is commonly encountered amongst patients belonging to low socio-economic status3-5.

Distribution of cases according to gestational age as reported by Jayant et al (1987) however revealed 31.8% in 37-38 weeks, 26.4% in 39-40 weeks and 19.7% in 35-36 weeks. The association of relevant maternal complication in our series in the form of pregnancy induced hypertension, Antepartum haemorrhage, Diabetes mellitus, cardiac disease and anemia. Our observation closely tallies with esslein et al (1979) who reported a wide ranging associated with Preterm labour (19.1%), PROM (38.1%) mia (19.1%), Abruptio placentae (7.1%) and placental gestation (7.1%)6.7.

The nature of caesarean section in study group reveals relatively small percent of cases where elective caesarean section has been contemplated (8%) in contrast to emergency caesarean. Our finding did not corroborate with those of Pinion in 92% of cases. The different indications for caesarean section in which majority of cases required intervention because of foetal distress (28%). However section was performed in 16.5% for placenta praevia, 10.5% for preeclampsia/eclampsia, 14.5% for PROM 12.5% for breech and 13.5% for IUGR.

Pinion et al in contrast recorded that caesarean section done in 6.5% of cases for foetal distress which shows a significantly reduced figure in comparision to our series. The other indications of their series in nearly similar to that of ours. This could be because of the fact that more number of cases of our series probably had intrauterine growth retardation in contrast to a preponderance of preterm caesarean section in Pinion’s series8.9.

In a study of 91 cases by Jayant et al (1987) the common maternal indication for low birth weight caesarean section were feto-pelvic disproportion 11(12%) cases, previous caesarean section 11 (12%) cases, pre-eclampsia/eclampsia 10 (10.9%) cases, mechanical dystocia 7 (7.6%) cases. Amongst foetal indications, foetal distress accounted for 20.8% of cases, other malpresentations 7.6%, and breech 5.4% of cases. Indications of above series correlates to our study.

Haesslein et al (1979) in a study of 30 cases found that the indication of low birth weight caesarean section was mostly due to breech presentation (36.3%) and pregnancy induced hypertension(33.3%).

In the study by Barret et al (1983) breech (45.6%) severe PET (21.7%), foetal distress (10.8%) and IUGR (8.6%) were the common indications for low birth weight caesarean section. Indications of operations in our study do not correlate to that of Haesslein et al and Barret et al as their studies are mainly on lower birth weight groups than those of ours. In study group, 48.5% had a birth weight of 2000-2249g where as in the same range 37% were found in the control series. In birth weight below 1500g, 3.5% of cases were observed in study in contrast to 74 in control group. The distribution pattern in relation to birth weight follows an almost similar pattern in both the study and control series, the findings being compatible to those of Jayant et al (1987) and Pinion et al (1988).

Correlation of birth weight with gestational age reveals that in birth weight group more than 2000g majority of cases are encountered at a gestational age beyond 35 weeks both the study as well as control group.
Below the gestational age of 30 weeks, 2 cases are seen in the weight range of 1000-1499g while not a single case was recorded in the study group in the same weight group. Out of the cases delivered by caesarean section on babies weighing between 1000-1499g majority (42.8%) are encountered in 31-32 weeks range.

Rege et al (1987) observed in their series that the highest section rate in 1000-2000g weight group was at 37-38 weeks of gestation indicating the preponderance of growth retardation. Overall section rate before 37 weeks were 12% in Pinion et al (1988) and 21.7% in Kafka et al (1969) series.

From our study it could be inferred that the low birth weight babies are in a compromised state at birth and hence an optimum level of neonatal resuscitative measure is mandatory both in the study and control series10.

Our study shows the neonatal morbidity pattern in both study and control group, which reveals that the overall neonatal morbidity is significantly more (64.7%) amongst babies born vaginally in comparison to a morbidity figure of 50% in study series. This shows a probable relationship between morbidity and route of delivery. Asphyxia by far accounted for maximum number of cases both in study and control series (434 and 43.7%).

Analysing The morbidities in different weight groups, it is evident that in 1000-1499g birth weight group all the babies (both groups) had neonatal complications. But the caesarean babies had fared better than the control group percentage wise. 71.4% and 87.5% in study and control series respectively11.

Asphyxia remained as the dominant factor i.e. In 1500-1999gm weight group the caesarean babies had less perinatal sufferings than the control group (percentagewise), majority being attributed to asphyxia (70%, vs 93.7%). In higher birth weight groups of 2000-2249g and 2250-2499g the neonatal morbidities were found in similar proportions in both series. Asphyxia remained as the main complication but the percentage dropped down as birth weight improved (42.2% and 21.2% in study and 48.6% and 21.8% in control groups). Our observation closely corroborates to those of Pinion et al (1988), Rege et al (1987), Haesslein et al (1979) and Shennan et al (1980)12.

**Conclusion**

As regards perinatal mortality in our series it is evident that the overall perinatal mortality is significantly higher in cases born by vaginal route in contrast to those where section has been contemplated (19% and 14.5%). Another important point of concern is that about 36.8% of cases had fresh still birth in comparision to 63.2% of cases having neonatal deaths amongst vaginally delivered babies.

Why Mothers Die: An Original Research in Odisha

Hara Prasad Pattanaik¹, Mrutyunjay Mohapatra¹, Sasmita Parida²

¹Consultant Gynecologist & Obstetrician, Cuttack, Odisha,
²Prof & HOD, Department of Radio diagnosis, SCB Medical college, Cuttack, Odisha

Abstract

Maternal mortality is defined as the death of a woman while pregnant or within 42 days of termination of pregnancy, irrespective of the duration and site of pregnancy, from any cause related to or aggravated by the pregnancy or its management, but not from accidental or incidental causes. Each year in India, roughly 28 million women experience pregnancy and 26 million have a live birth. Of these, an estimated 67,000 maternal deaths and one million newborn deaths occur each year. In addition, millions more women and newborns suffer pregnancy and birth related ill-health. Thus, pregnancy-related mortality and morbidity continues to have a huge impact on the lives of Indian women and their newborns.

Keywords: Maternal mortality ratio, epidemiology, maternal complications.

Introduction

High maternal mortality is a major concern in India, especially in the northern Indian states. The maternal mortality ratio (MMR) is as high as 400 per 100,000 live births in India. The state of Uttar Pradesh, which has the largest population in the country, has the highest MMR at 599 per 100,000 and Rajasthan has the second highest maternal mortality rate at 670 per 100,000 live births. The main medical causes of maternal deaths are hemorrhage, severe anemia, obstructed labor, puerperal sepsis, and others. These preventable causes of mortality are well known and manageable through simple interventions with appropriate clinical and obstetric care. Notwithstanding the knowledge of causes and availability of technology needed to avert maternal deaths, the maternal mortality rate has remained unacceptably high. There has been a secular decline in IMR and CMR until 1996 and thereafter stagnation in IMR. The decline in IMR was on account of the decline in post neo-natal mortality. The future decline is anticipated due to decline in neonatal mortality. The neonatal mortality is primarily consequences of endogenous factors, which are largely governed by the maternal causes and thereby call for the monitoring of maternal mortality ratio in the population. The results of large-scale survey have however shown that there was no decline in MMR over time indicating an urgent public health concern¹,².

In the Third World, every time a woman becomes pregnant, her risk of dying is 200 times greater than the risk run by a woman in the developed world. About 15% of all pregnant women experience complications that can be detected and appropriately managed given proper clinical care. Various reports and surveys have shown that MMR has not declined in India (ICMR, 2003). However, estimates of MMR are not reliable owing to methodologic complexities involved in the community based surveys. The complications of pregnancies and the births are found to be the leading causes of deaths and disability among women of reproductive age. The health problems of mothers and newborns arise as a result of synergistic effects of malnutrition, poverty, illiteracy, unhygienic living conditions, infections and unregulated fertility. Maternal mortality is called direct when it is a complication of the pregnancy, delivery or their management. It is called Indirect when there is a Pregnancy related death in a patient with a pre-existing or newly developed health problem. Maternal Mortality Rate is used as the measure of the quality of a health care system in a community. It is no. of maternal deaths per 100,000 live birth. In India Maternal Mortality Rate was 174 (2011-15) whereas in Odisha it is 222 (2011-2015)³,⁴.

Causes of Death as Per WHO:

Maternal mortality can be attributed to various factors such as: Haemorrhage (26%), Infection(13%), Unsafe abortion (13%), Eclampsia(12%), Obstructed labour (8%), Other direct causes (8%), Indirect causes like Malaria, Anaemia, HIV/AIDS, cardiovascular disease (20%). More than 90% of maternal death occurs in developing countries whereas 45% of post partum death occurs within 24 hours.

Methodology

It is a retrospective study of maternal death from year 2011 to 2016 from the available data in the Cuttack district. Cuttack district -14 block level hospitals. Two Sub-divisional hospital (Banki & Athagarh). 5 FRUs. One Secondary level hospital(DHH). One Tertiary care hospital ( SCB MCH). Total no of Deliveries in five years were 277051 out of which 276106 were live birth. Total Delivery includes deliveries from different districts of the state those who have delivered in cuttack district. It also includes deliveries in Private Institutions and nurshing homes (Table 1).

Maximum no of death occurred in the age group of 20-29 yrs. The analysis of the medical causes of deaths revealed that hemorrhage was responsible for the highest toll. Hemorrhage maximum maternal mortality followed by eclampsia, pregnancy induced hyper tension and other factors. postpartum hemorrhage alone accounted for one fourth of the total maternal deaths. Out of total death Haemorrage accounts for 30%, Sepsis 8%, Eclampsia 11.2%, PIH 9.7%, Pulmonary Embolism 5.2%, Ruptured Uterus 2.2%, Sepsis 0.75%, HELPP Syndrome 2.2%, Ut.Inversion 0.75%, Ectopic pregnancy 0.75% (Table 2).

Discussion

Maternal deaths are a significant cause of death in women in the 15–49 years age group, and they make up a larger proportion of all-cause deaths in the rural areas of poorer states, compared to other regions of India. We found that the distribution of cause specific mortality was the same across poorer and richer states, suggesting that the high burden of maternal death in poorer states
is not due to an excess of one or more causes of direct obstetric deaths.

Lack of quality care in the health facilities was perceived as the factor most contributing to the maternal deaths by family members of deceased women. Proximal factors, which encompassed any pregnancy complication or medical comorbidity, were the strongest predictors of women dying in pregnancy followed by lack of access to the health facility. More importantly, the study showed that the effects of living rurally and being poor could be mitigated by improving access to the health facility. Other risk factors identified were younger or older maternal age, belonging to a scheduled tribe or caste social group, and not being enrolled in a health scheme.

The WHO reported MMR for India in 2010 was 208/100,000 live births compared with 383/100,000 live births calculated in our study population for a similar period (2007–2009). This discrepancy reflects the high burden of maternal mortality in India’s nine socioeconomically disadvantaged states. Moreover, in our study, more than half of the maternal deaths had not been previously recorded. Efforts to create a national electronic database for maternal death surveillance in India began in 2013 but the progress is still limited, mainly due to lack of resources.

The association between proximal factors and maternal death was strengthened after accounting for other factors showing that these complications remain the most important risk factors for maternal death, thus reinforcing the importance of high-quality antenatal care, availability of basic emergency obstetrical care and postnatal care. Nonetheless, in our study population, poor quality of care was reported as the factor most contributing to the maternal death in 55% of the deaths.

In 2005, the Indian government implemented the NRHM to address gaps in maternal healthcare. Improving the access to and quality of care, particularly for rural areas in high focus states, were the main objective of this initiative. Since 2005, India has seen some improvements. Institutional deliveries increased from 39% in 2005 to 79% in 2013. Complete antenatal care coverage increased from 37% to 51% and postnatal care increased from 27% to 36%. However, studies show that the programme has had little or no effect on clinical outcomes. For example, despite the increase in health facility deliveries, there has been no demonstrated decline in maternal mortality.

Studies have repeatedly shown that quality of care is lacking in public health facilities, including non-availability of essential medicines such as uterotonics and antibiotics, and lack of facilities for caesarean section and blood transfusion. Further, government reports on the state of public facilities in these nine states have reported lack of toilet facilities, unreliable electricity and unsatisfactory cleanliness, and lack of basic measures of obstetrical care such as adequate hand hygiene. Moreover, there have been reports of verbal and physical abuse of staff towards patients.

Conforming with the findings of other studies, age and maternal death exhibited a strong U-shaped association in which the youngest (women aged 13–19 years) and the oldest age group (women aged 40–49 years) had the highest risk of dying. India’s National Family Health Survey showed that of women aged 20–49 years, 27% had been married before the age of 15 years and 58% were married before the legal age of marriage of 18 years. In addition, 30% of Indian women had given birth by age 19 years. While age itself is not a modifiable risk factor, childbearing age should be regarded as one. Women should be able to exert control over when they choose to become pregnant. Policies supporting universal access to contraception, family planning counselling, safe abortion and promoting women’s empowerment need continued attention in India.

**Conclusion**

According to this study it is observed that the high level of maternal mortality in India is a critical policy concern. A huge inter-state and intrastate disparities in MMR remain a major concern. It is important to mention that economic performance alone would be insufficient to achieve faster reductions in MMR. In India, these groups largely include women and tribal sub-groups living in unfavourable geographic locations demotivating (inaccessible rural areas and hilly regions). Moreover, states with high MMR also tend to have an unfavourable geography; therefore, economic growth would largely be confined to advantaged locations, and the remotest and tribal areas will remain underserved and have high levels of MMR. Economic growth may help initiate improvements in MMR but, to reduce MMR faster, simultaneous investment is important in strengthening the health system; education and empowering women; and making available qualified human resources in health, good governance, and transportation facilities.
Also, improvement in recording and sharing vital health (and health-related) information is critical to facilitate policymaking and enhance effectiveness of various interventions. India’s developmental narrative should display increased socio-political commitment towards health, one that could place India ahead of other countries.

A Rare Complication of the Non-Union of Maxilla After Lefort I Osteotomy

R. Manikandhan¹, Ratna Parameswaran², Arun M. Krishnan³, Godwin Alex Kiruba⁴, M. Monisha⁵

Abstract

Lefort I osteotomies are routinely performed for correction of dentofacial deformities. There are reports of a wide number of complications after Lefort I osteotomies. Due to the rich vascular supply of maxilla, non-union is a very rare complication. The authors present two cases of non-union of maxilla after Lefort I osteotomy, with a brief discussion on the probable etiologies and their management.

Keywords: Lefort I osteotomy, Non-union of maxilla, Iliac bone graft, Maxillary mobility, Floating Maxilla.

Introduction

Lefort I osteotomy is one of the most widely performed surgeries across the maxillofacial spectrum. In the United States of America, there were about fifteen thousand Le fort I osteotomies performed over the course of 9 years[¹]. Lefort I osteotomies are associated with various intra-operative and post-operative complications[²] which can be further divided into anatomic, septic, neurologic, otologic and vascular categories[³]. Non-union at the osteotomy site is a serious complication, which invariably demands surgical intervention.

In this article, the authors report two cases of this complication after Lefort I osteotomy and review the literature.

Case Reports:

Case 1: A 29-year-old patient reported to Meenakshi Ammal Dental College and Hospital with a complaint of pain and mobility in the maxilla for a time period of about 5 years. She gave a history of being operated thrice in a different hospital within a time span of 2 years. She underwent the first surgery for bimaxillary protrusion in 2011. She had an uneventful immediate post-operative recovery but had reported back to them with a complaint of mobility of the maxilla and underwent two surgeries for the same in 2012. In both the instances, the pre-existing implants were removed, followed by freshening the edges of the non-united bone segments and resecuring them with a newer set of implants.

Clinical examination revealed the presence of mobility of maxilla and tenderness on the maxillary vestibule. Radiographic examination showed that the edge of the osteotomized segment was in close proximity to the infraorbital foramen (Fig. 1). The authors diagnosed her with maxillary non-union and planned for a surgical intervention. Pre-surgical orthodontics was carried out and bite planes were cemented to the mandibular posterior teeth bilaterally (Figs. 2, 3).

Intra-operatively, the authors observed the

e-mail: drgodalba@gmail.com
eburnation of bone edges at the osteotomy site and they completely mobilized the maxillary segment. Autogenous cortico-cancellous iliac bone graft was harvested and sandwiched in between the osteotomized segments. Mandibular subapical osteotomy was also performed and the osteotomized segment was moved downwards. A stable internal fixation was performed in both the jaws (Figs. 4,5).

The patient had a post-operative follow-up of 2 years and the authors observed a satisfactory healing with a stable maxilla and recorded a significant improvement in the vertical dimension.

**Case 2:** A 23-year-old patient who reported to Meenakshi Ammal Dental College and Hospital with malocclusion and facial deformity was examined and diagnosed with vertical maxillary excess. After presurgical orthodontics and cephalometric analysis, it was planned to impact the maxilla. Intra-operatively, the patient underwent Lefort I impaction, after complete mobilization of the maxilla. Internal fixation was performed in the maxilla using indigenous titanium implants.

The patient had an uneventful immediate postoperative recovery. In the third post-operative month, the patient presented with a complaint of pain and discomfort in the maxilla at the Lefort I level with no signs of inflammation or oro-antral communication. On radiographic evaluation, the internal fixation was right in place, and there was no evident maxillary sinus pathology. He was treated with analgesics and anti-inflammatory drugs. In the sixth post-operative month, the patient reported of recurrent pain and mild mobility of the maxillary segment with clicking noise on mastication.

Clinical examination confirmed the mobility of maxilla and an orthopantomogram revealed broken titanium plates at the osteotomy site. He was diagnosed with maxillary non-union and was planned for surgical intervention. Intra-operatively, the authors observed fracture of two plates, loosening of screws and eburnation of the bone edges at the osteotomy site (Fig. 6). The rounded bone margins were freshened, and the vascularity was ensured with adequate bleeding points. Onlay bone grafting was performed with autogenous cortico-cancellous iliac bone graft, which was secured through titanium anchor screws (Fig. 7). The patient had an uneventful post-operative recovery phase with no discomfort. Post-operative radiographs showed good uptake of the bone graft with intact titanium plates and screws.

Discussion

Lefort I osteotomies have been the mainstay for the correction of severaldentofacial deformities like maxillary excess, deficiency, malposition or asymmetry. The first description of a maxillary osteotomy was published by von Langenbeck in 1859. After Rene Lefort’s landmark article in 1901, Wassmund was the first to describe the classic Lefort I osteotomy in 1921. Through the contributions of eminent surgeons like Axhausen, Schuchardt and Obwegeser\[4,5\], the technique of Lefort I osteotomy has evolved with better adaptation between the bone surfaces, improved stability, and lesser rate of complications.

Non-union of maxilla is a serious but a very rare complication after Lefort I osteotomy. The authors retrospectively reviewed the patient data and found that there were about 150 Lefort I osteotomies performed in their unit for the last 10 years. They identified 2 cases of non-union and report an incidence rate of about 3%. Kramer et al\[2\] reported an incidence rate of about 1% while Imholz et al\[6\] reported an incidence rate of about 2.6% in patients who underwent Lefort I osteotomies. Postoperative unstable dental occlusion, infection, osteosynthesis failures, insufficient bone contact are some of the probable etiological factors for non-union\[7\]. Maxillary mobility is the single most important diagnostic feature of non-union. Otterloo et al\[8\] had described this condition as a ‘floating maxilla’. Radiographic investigations are mandatory to confirm the presence of fractured plates, if any. Advancements in imaging techniques like 3D reconstruction of the computed tomography sections aid in formulating a proper treatment plan. Imholz et al reported that the mean delay between osteotomy and the non-union was 15.5 months. The time elapsed from the time of surgery to the occurrence of symptoms varied from 6 to 56 months\[6\].

Maxilla is a membranous bone with a thin cortical structure, variable bone density and with excellent inherent vascularity. It houses the maxillary antrum with thin external walls. Any major movement involving the maxilla might not produce edge to edge bone contact unlike the mandibular movements, thereby increasing the prospect of secondary healing after maxillary osteotomies. In cases of superior repositioning of the maxilla, there is a resulting ‘telescoping effect’, which prevents end to end approximation of the maxillary segments\[9\]. This lack of approximation would create a space that might lead to pseudoarthrosis\[10\] and impair normal bone healing.

In the first case, the patient was treated in a different centre and was operated the first time for vertical maxillary excess and bimaxillary protrusion. Later, she underwent a couple of surgeries for non-union of maxilla, which arose as sequelae to Lefort I impaction. The authors attribute the reasons for non-union to be trauma from occlusion, deep bite, antero-posterior movements of more than 6mm without bone grafting, improper plate fixation, infection and sinus pathologies.

The impetus for the edge of the osteotomized segment to be in close proximity to the infraorbital foramen, could be due to the repetitive freshening of the bony edges and lack of bone grafting.

Bite planes were fabricated and cemented to the mandibular posterior teeth bilaterally to relieve the anterior teeth from occlusal loading. Intraoperatively, in addition to mobilizing the maxilla, an anterior subapical osteotomy was performed in the mandible and the osteotomized segment was moved downwards to alleviate trauma from occlusion. The trauma from occlusion might have produced incessant minor movements that would have been a predisposing factor of non-union.

In the second case, the patient had no remarkable medical history. The radiologic and intraoperative findings indicated that the quality and morphology of the maxilla were normal and the patient reported with maxillary mobility at six months post-operatively.

The authors believe that in this case, the non-union might have been due to the ‘telescoping effect’, as the maxilla was superiorly repositioned. This might have resulted in the bending of titanium plates at acute angles and probably caused stress fractures of the plate. The patient initially experienced dull ache, followed by clicking, as the fractured plate became completely mobile with loosening of the screws.

Non-union in maxilla can be initially managed by restricting the patient to a soft diet, discontinuing or decreasing the strength of elastic traction, fabricating a modified splint to balance occlusion and eliminating para functional habits. Local and systemic measures are being used to treat post-operative infection. Robl et al recommends recreation of the osteotomy with aggressive mobilization, removal of surrounding fibrous tissues and
passive repositioning of the osteotomized segments. They recommend bone grafting and stabilization with rigid fixation to resist segmental displacement\textsuperscript{[11,12]}. Imholz et al stresses on the necessity of a revision surgery with a bone graft and a stronger osteosynthesis\textsuperscript{6}. The authors also recommend strict adherence to these protocols. They suggest the use of good quality titanium plates of 1.5mm size and advocate the clearance of sinus pathologies prior to performing a Lefort I osteotomy. They emphasize the necessity of using a block cortico-cancellous graft for movements of more than 6mm and in cases of cleft maxillary hypoplasia.

Role of Plants in Biomonitoring Vehicular Emissions

Muninathan N.1, Ponnulakshmi R.1, Nalini D.1, Prathiba S.2

1Research Scientist, Central Research Laboratory, Meenakshi Medical College Hospital and Research Institute, Enathur, Kanchipuram, Tamilnadu, India, 2Lecturer, Department of Pharmacology, Meenakshi Ammal Dental College and Hospital, Chennai, India

Abstract

Introduction: Air pollution caused by the pollutants present in the atmosphere which is harmful to the environment and the living population. The plants showed stunted growth, animal’s causes various form of diseases and the pollutants harmfully affect the human beings by causing respiratory problems and the whole environment is totally affected causing depletion of ozone layer and that directly or indirectly affects the living system present in the environment.

Materials and Method: The leaf samples were collected from the Sholinganallur area and authenticated. Later the samples were characterized for morphological characters, pigment analysis, Biochemical parameters and the score of tolerance index of Air pollution was calculated were tabled and graphed as per the standard protocol.

Results: The samples were collected from sholinganallur traffic zonal area and totally 14 leaf samples were gathered from the experimental site and was authenticated. The morphological characters of length and width of leaf samples were calculated and in Biochemical parameters, pH of leaf, Relative water content and ascorbic acid content showed good activity in evergreen shrub. In pigment analysis of chlorophyll, the maximum and minimum amount was found in evergreen shrub Bougainvillea glabra with 68.72mg/g and Tecoma capensis in 14.72mg/g. The APTI value was maximum and minimum in evergreen shrub Tabernaemontana divaricata with 114.66 and Nerium oleander with 48.05.

Conclusion: The plants found in and around the experimental area possess good activity against the air pollution and these plants can be kept at the roadside to prevent and withstand the air pollution in the environment.

Keywords: Evergreen tree/shrub, air pollution, APTI, vehicular emission

Introduction

The global impact in change of atmosphere [1] especially in metropolitan cities are due to rapid industrialization and urbanization process causes serious effects of air pollution on both human and plant communities [2]. Due to industrialization, urbanization and raising human population [3] vehicles play a predominant role in the transport sector. Approximately 60–70% of air pollution is produced from cities across the globe by vehicular emissions which are randomly increasing day by day as means of transportations [4].

There are enormous number of pollutants are released from the vehicles are carbon monoxide, particulates, hydrocarbons, heavy metals, nitric oxide, sulphur dioxide and so on [5,6]. The emission of oxidized carbon monoxide and hydrocarbons from the fuel is a product of incomplete combustion (i.e) lacks the combustion of air leading to insufficient oxygen and will not form an end product of carbon dioxide (CO₂). Ground level Ozone (i.e) smog is formed when hydrocarbons combine with nitrogen oxides and sunlight. The smogs are widely spread and major interactable air pollution. Nitric oxide (NO) like hydrocarbons is predominant source in the formation of ozone and produce acid rain [7]. This harmful chemical has an adverse effect on soil and plants grown in that area [8]. This serious impact on plant health changes the biochemical parameters such as the action
of enzymes, proteins, pigments, ascorbic acid and sugar contents \[9\] rate of photosynthesis, seed germination \[10\].

Leaves are the most receptive part exposed widely to the polluted air causing a change based on its sensitivity \[11\]. On the surface of leaf or on the stomatal pores dust and other particulate matter get adsorbed \[12\] and such exposed plant shows changes internally and then the plant after severe effect shows external changes like chlorosis, necrosis and epinasty \[13\] when exposed to air pollution \[14\]. Thus Air pollution tolerance indices were examined for the selected area and these plants are very much useful in afforestation, reforestation and development of green belt.

**Materials and Method**

**Leaf sample collection:** The samples were collected from the experimental sites from the road sides of Mohamed Sathak College of Arts and Science, Sholinganallur, Chennai, Tamil Nadu, India. The study was carried out and samples were collected before the onset of summer season and the plants were selected based on the change in morphology of leaves due to vehicular pollution.

**Identification of collected samples:** The collected leaf samples were identified based on its morphological characters from the book, Flora of the Presidency of Madras by Gamble, 1847-1925 and the samples were authenticated \[15\].

**Morphological characters of identified plants:** The collected leaf samples were identified for its family, common name through previous literatures and morphological characters like leaf length (cm), leaf width (cm), weight of leaf with dust (mg) and without dust (mg) were estimated.

**Biochemical parameters:** The pH of the leaf was determined by\[16\] Krishna Veni, 2014; \[17\] Prasad and Rao, 1982. Relative water content was determined by Liu and Ding 2008 \[14\] and Sen., 1978 \[18\]. Ascorbic acid content was determined by metaphosphoric acid (5%)-acetic acid (10%) solution. Total chlorophyll content was performed by the method of Arnon (1949) \[8\].

**Air Pollution Tolerance Indices (APTI):** The Air Pollution Tolerance Indices (APTI) were calculated based on Singh and Rao (1983) \[19\].

**Results and Discussion**

**Collection of samples:** The leaves were collected from traffic zones of Sholinganallur around the campus of Mohamed Sathak College of Arts and Science, Chennai where vehicular emission was high during the peak hours where most vehicles travel towards the IT parks. The collected mature leaves were stored in a polythene bag for morphological and biochemical analysis.

**Identification of collected samples:** The collected leaf samples were photographed from the collected sites and authenticated. The list of 14 plants were collected from the experimental site and tabulated (Table 1; Fig 1).

**Table 1: List of leaves collected from the experimental site, Sholinganallur, Chennai**

Categorization of collected leaf samples: The leaf samples from experimental site were collected, identified and authenticated. Based on the literature survey the plants are categorized or grouped into three distinct phase’s namely deciduous tree, Evergreen shrub and Evergreen tree. The entire study was distinguished or compared based on these three categories (Table 2).

Morphological measurements of collected leaf samples: The length of the leaf was high in Plumeria obtusa and leaf width was found to be lower when compared to Caryota urens. Similarly, the weight of the leaf was found to have significant changes when weighed with dust and after cleaning the dust (Table 3). According to the results obtained, the accumulation of dust was more on leaf surface which indicates the polluted environment in the selected site.

Biochemical parameters of the samples:

pH: The leaf extract pH was ranged from acidic condition of 1.19 to slight alkaline condition of 7.82. From the experimental site only one deciduous tree was found with a pH of 6.21 from Plumeria rubra (L.). Evergreen shrubs totally 7 are present in experimental site of which maximum acidic condition was present in Bougainvillea glabra of pH 1.19 and minimum acidic condition was found in Tecoma capensis with a pH of 6.50. Evergreen trees totally 8 are present in experimental site of which maximum acidic condition was present in Muntingia calabura with a pH of 5.30 and slightly alkaline condition was found in Ficus benghalensis with a pH of 7.82 (Table 4; Graph 1). In a study conducted by Bharti et al., 2017, Ficus benghalensis showed pH of 8.2 where the pollutant converts the hexose present in the plant to ascorbic acid.

Graph 1. pH level of the collected leaf samples

**Relative water content:** RWC varied greatly from 13.39% to 80.78%. RWC in deciduous tree was found to have high content of 72.38%. The RWC in evergreen shrub was found to be minimum in *Bougainvillea glabra* with 13.39% and maximum in *Tecoma capensis* with 59.61%. The RWC in evergreen tree was found to be minimum in *Spathodea campanulata* with 16.94% and maximum was found in *Caryota urens* with 80.78% (Table 5; graph 2). Air pollutant increases the RWC in plants under stress which undergoes the changes in physiological functions during Transpiration and facilitates drought conditions leads to early senescence[20].

Estimation of Ascorbic Acid: The Ascorbic acid present was ranged from 12.50mg/g to 27.78mg/g. In deciduous tree *Plumeria rubra* was found to be 16.59 mg/g. In evergreen shrub, the ascorbic acid content was minimum in *Pongamia pinnata* with 12.50mg/g and maximum in *Tecoma capensis* with 27.78mg/g. In evergreen tree, the presence of Ascorbic acid content was minimum in *Sterculia foetida* with 14.80mg/g and maximum in *Spathodea campanulata* with 26.67mg/g (Table 6; Graph 3).

**Estimation of chlorophyll content:** The total chlorophyll content was found to be in range of 14.72mg/g to 68.72mg/g. In deciduous tree *Plumeria rubra* was found to be 27.03mg/g. In evergreen shrub the minimum chlorophyll content was found to be in *Tecoma capensis* in 14.72mg/g where maximum chlorophyll content was found to be in *Bougainvillea glabra* in 68.72mg/g. In evergreen tree the minimum chlorophyll content was found to be in *Spathodea campanulata* in 17.35mg/g and maximum chlorophyll content was found to be in *Sterculia foetida* 63.12mg/g (Table 7; graph 4).

Air Pollution Tolerance Indices (APTI): The value ranged from 48.05 to 114.66 which reveals that the plant present in the experimental sites were all tolerant towards the vehicular emissions but the most tolerant plant was evergreen shrub compared to deciduous an evergreen tree. The deciduous tree showed the value of 62.38 and in evergreen shrub the APTI value was tolerable in all collected leaf samples but minimum in Nerium oleander with 48.05 and maximum in Tabernaemontana divaricata with 114.66. In evergreen tree the APTI value was minimum in Muntingia calabura with 48.47 and maximum value in Caryota urens with 108.97 (Table 8; Graph 5).

Graph 5. APTI of the leaf samples

Conclusion

The results of the present study revealed that vehicular emission in sholinganallur area are prevented by the plants present on the road side with good tolerance rate and among that evergreen shrub and evergreen tree can be planted more to prevent air pollution from these vehicular emission sites. Various biochemical parameters behaved differently in the studied plant species, however, ascorbic acid content was found to be the most crucial factor providing tolerance to the plants against air pollution. So, Tecoma capensis were found to be tolerant, and can be incorporated into a greenbelt design to assist the air pollution management practices.

Call for Papers / Article Submission

Medico-Legal Update invites articles, case reports, newspaper clippings, report medico legal activities to update the knowledge of readers in scientific disciplines such as Forensic Medicine, Forensic Sciences, Environmental Hazards, Toxicology, odontology, Anatomy and law etc.

The following guidelines should be noted:
- The article must be submitted by e-mail only. Hard copy not needed. Send article as attachment in e-mail.
- The article should be accompanied by a declaration from all authors that it is an original work and has not been sent to any other journal for publication.
- As a policy matter, journal encourages articles regarding new concepts and new information.
- Article should have a Title
- Names of authors
- Your Affiliation (designations with college address)
- Abstract
- Key words
- Introduction or back ground
- Material and Methods
- Findings
- Conclusion
- Discussion
- Acknowledgements
- Interest of conflict
- References in Vancouver style.
- Please quote references in text by superscripting
- Word limit 2500-3000 words, MSWORD Format, single file

All articles should be sent to: medicolegalupdate@gmail.com

About The Journal

Print- ISSN: 0971-720X, Electronic- ISSN: 0974-1283, Frequency: Quarterly (4 issues in a year)

*Medico Legal Update* is a journal which brings latest knowledge regarding changing medico legal scenario to its readers. The journal caters to specialties of Forensic Medicine, Forensic Science, D. N. A. fingerprinting, Toxicology, Environmental hazards, Sexual Medicine etc. The journal has been assigned international standard serial number (ISSN) 0971-720X. The journal is registered with Registrar of Newspapers for India vide registration numbers 63757/96 under Press and Registration of Books act, 1927. The journal is also covered by EMBASE (Excerpta Medica Database) from 1997 and by INDEX COPERNICUS, POLAND.

*Medico-Legal Update* is a quarterly peer reviewed journal. The journal has also been assigned E- ISSN 0974-1283 (Electronic version). The first issue of the journal was published in 1996.
